

Package ‘digitalDLSorteR’

October 20, 2021

Type Package

Title Deconvolution of Bulk RNA-Seq Data Based on Deep Learning

Version 0.1.1

Maintainer Diego Mañanes <dmananesc@cnic.es>

Description Deconvolution of bulk RNA-Seq data using context-specific deconvolution models based on Deep Neural Networks using scRNA-Seq data as input. These models are able to make accurate estimates of the cell composition of bulk RNA-Seq samples from the same context using the advances provided by Deep Learning and the meaningful information provided by scRNA-Seq data. See Torroja and Sanchez-Cabo (2019) <[doi:10.3389/fgene.2019.00978](https://doi.org/10.3389/fgene.2019.00978)> for more details.

barErrorPlot	<i>Generate bar error plots</i>
--------------	---------------------------------

Description

Generate bar error plots by cell type (CellType) or by number of different cell types (nCellTypes) on test pseudo-bulk samples.

Usage

```
barErrorPlot(
  object,
  error = "MSE",
  by = "CellType",
  dispersion = "se",
  filter.sc = TRUE,
  title = NULL,
  angle = NULL,
  theme = NULL
)
```

Arguments

object	DigitalDLSorter object with trained.model slot containing metrics in test.deconv.metrics slot.
error	'MAE' or 'MSE'.
by	Variable used to display errors. Available options are: 'nCellTypes', 'CellType'.
dispersion	Standard error ('se') or standard deviation ('sd'). The former is the default.
filter.sc	Boolean indicating whether single-cell profiles are filtered out and only correlation of results associated with bulk samples are displayed (TRUE by default).
title	Title of the plot.
angle	Angle of ticks.
theme	ggplot2 theme.

Value

A ggplot object with the mean and dispersion of the errors

## End(Not run)

```

barPlotCellTypes	<i>Bar plot of deconvoluted cell type proportions in bulk RNA-Seq samples</i>
------------------	---

Description

Bar plot of deconvoluted cell type proportions in bulk RNA-Seq samples.

Usage

```

barPlotCellTypes(
  data,
  colors = NULL,
  simplify = NULL,
  color.line = NA,
  x.label = "Bulk samples",
  rm.x.text = FALSE,
  title = "Results of deconvolution",
  legend.title = "Cell types",
  angle = 90,
  theme = NULL,
  ...
)

## S4 method for signature 'DigitalDLSorter'
barPlotCellTypes(
  data,
  colors = NULL,

```

```

simplify = NULL,
color.line = NA,
x.label = "Bulk samples",
rm.x.text = FALSE,
title = "Results of deconvolution",
legend.title = "Cell types",
angle = 90,
theme = NULL,
name.data = NULL
)

## S4 method for signature 'ANY'
barPlotCellTypes(
  data,
  colors,
  color.line = NA,
  x.label = "Bulk samples",
  rm.x.text = FALSE,
  title = "Results of deconvolution",
  legend.title = "Cell types",
  angle = 90,
  theme = NULL
)

```

Arguments

data	DigitalDLSorter object with <code>deconv.results</code> slot or a data frame/matrix with cell types as columns and samples as rows.
colors	Vector of colors to be used.
simplify	Type of simplification performed during deconvolution. Can be <code>simpli.set</code> or <code>simpli.maj</code> (NULL by default). It is only for DigitalDLSorter objects.
color.line	Color of the border bars.
x.label	Label of x-axis.
rm.x.text	Logical value indicating whether to remove x-axis ticks (name of samples).
title	Title of the plot.
legend.title	Title of the legend plot.
angle	Angle of text ticks.
theme	ggplot2 theme.
...	Other arguments for specific methods.
name.data	If a DigitalDLSorter is given, name of the element that stores the results in the <code>deconv.results</code> slot.

Value

A `ggplot` object with the provided cell proportions represented as a bar plot.

Examples

```
# matrix of simulated proportions (same structure as deconvolution results)
deconvResults <- gtools::rdirichlet(n = 20, alpha = c(1, 1, 1, 0.5, 0.1))
colnames(deconvResults) <- paste("CellType", seq(ncol(deconvResults)))
rownames(deconvResults) <- paste("BulkSample", seq(nrow(deconvResults)))
barPlotCellTypes(deconvResults)

# Using a DigitalDLSorter object
DDL <- DigitalDLSorter(deconv.results = list(Example = deconvResults))
barPlotCellTypes(DDL)
```

blandAltmanLehPlot	<i>Generate Bland-Altman agreement plots between predicted and expected cell type proportions from test data results</i>
--------------------	--

Description

Generate Bland-Altman agreement plots between predicted and expected cell type proportions from test data results. The Bland-Altman agreement plots can be displayed all mixed or split by cell type (CellType) or the number of cell types present in samples (nCellTypes). See the facet.by argument and examples for more information.

Usage

```
blandAltmanLehPlot(
  object,
  colors,
  color.by = "CellType",
  facet.by = NULL,
  log.2 = FALSE,
  filter.sc = TRUE,
  density = TRUE,
  color.density = "darkblue",
  size.point = 0.05,
  alpha.point = 1,
  ncol = NULL,
  nrow = NULL,
  title = NULL,
  theme = NULL,
  ...
)
```

Arguments

object	DigitalDLSorter object with trained.model slot containing metrics in test.deconv.metrics slot.
colors	Vector of colors to be used. Only vectors with a number of colors equal to or greater than the levels of color.by will be accepted. By default a custom color list is used.
color.by	Variable used to color data. Options are nCellTypes and CellType.
facet.by	Variable used to display the data in different panels. If NULL, the plot is not split into different panels. Options are nCellTypes (by number of different cell types) and CellType (by cell type).
log.2	Whether to display the Bland-Altman agreement plot in log2 space (FALSE by default).
filter.sc	Boolean indicating whether single-cell profiles are filtered out and only correlations of results associated with bulk samples are displayed (TRUE by default).
density	Boolean indicating whether density lines must be displayed (TRUE by default).
color.density	Color of density lines if the density argument is TRUE.
size.point	Size of the points (0.1 by default).
alpha.point	Alpha of the points (0.1 by default).
ncol	Number of columns if facet.by is used.
nrow	Number of rows if facet.by is used.
title	Title of the plot.
theme	ggplot2 theme.
...	Additional argument for the facet_wrap function from ggplot2 if facet.by is not NULL.

Value

A ggplot object with Bland-Altman agreement plots between expected and actual proportions.

)

```

```
## End(Not run)
```

bulk.simul	Get and set bulk.simul slot in a DigitalDLSorter object
------------	---

Description

Get and set bulk.simul slot in a [DigitalDLSorter](#) object

Usage

```
bulk.simul(object, type.data = "both")
```

```
bulk.simul(object, type.data = "both") <- value
```

Arguments

object	DigitalDLSorter object.
type.data	Element of the list. Can be 'train', 'test' or 'both' (the last by default).
value	List with two elements, train and test, each one being a SummarizedExperiment object with simulated bulk RNA-Seq samples.

calculateEvalMetrics	Calculate evaluation metrics for bulk RNA-Seq samples from test data
----------------------	--

Description

Calculate evaluation metrics for bulk RNA-seq samples from test data to understand model performance. By default, absolute error (AbsErr), proportional absolute error (ppAbsErr), squared error (SqrErr) and proportional squared error (ppSqrErr) are calculated for each test sample. In addition, each of these metrics is aggregated using their mean values according to three criteria: each cell type (CellType), probability bins in ranges of 0.1 (pBin) and number of different cell types present in the sample nCellTypes. Finally, the process is repeated only considering bulk samples (filtering out single-cell profiles from the evaluation). The evaluation metrics will be available in the test.deconv.metrics slot of the [DigitalDLSorterDNN](#) object (trained.model slot of the [DigitalDLSorter](#) object).

Usage

```
calculateEvalMetrics(object, metrics = c("MAE", "MSE"))
```

Arguments

object	DigitalDLorter object with a trained model in the trained.model slot and the actual cell proportions of pseudo-bulk samples in prob.cell.matrix slot.
metrics	Metrics used to evaluate the model performance. Mean absolute error ("MAE") and mean squared error ("MSE") by default.

Value

A [DigitalDLorter](#) object with the trained.model slot containing a [DigitalDLorterDNN](#) object with the test.deconv.metrics slot. The last contains the metrics calculated.

    on.the.fly = TRUE,
    batch.size = 15,
    num.epochs = 5
  )
  # evaluation using test data
  DDLS <- calculateEvalMetrics(
    object = DDLS
  )

  ## End(Not run)

```

cell.names	<i>Get and set cell.names slot in a ProbMatrixCellTypes object</i>
------------	--

Description

Get and set cell.names slot in a [ProbMatrixCellTypes](#) object

Usage

```

cell.names(object)

cell.names(object) <- value

```

Arguments

object	ProbMatrixCellTypes object.
value	Matrix containing the name of the pseudo-bulk samples to be simulated as rows and the cells to be used to simulate them as columns (n.cell argument)

cell.types	<i>Get and set cell.types slot in a DigitalDLSorterDNN object</i>
------------	---

Description

Get and set cell.types slot in a [DigitalDLSorterDNN](#) object

Usage

```
cell.types(object)

cell.types(object) <- value
```

Arguments

`object` [DigitalDLSorterDNN](#) object.

`value` Vector with cell types considered by the Deep Neural Network model.

<code>corrExpPredPlot</code>	<i>Generate correlation plots between predicted and expected cell type proportions from test data</i>
------------------------------	---

Description

Generate correlation plot between predicted and expected cell type proportions from test data. Correlation plots can be displayed all mixed or split by cell type (`CellType`) or number of cell types present in the samples (`nCellTypes`). See the `facet.by` argument and examples for more information. Moreover, a user-selected correlation value is displayed as an annotation on the plots. See the `corr` argument for details.

Usage

```
corrExpPredPlot(
  object,
  colors,
  facet.by = NULL,
  color.by = "CellType",
  corr = "both",
  filter.sc = TRUE,
  pos.x.label = 0.01,
  pos.y.label = 0.95,
  sep.labels = 0.15,
  size.point = 0.1,
  alpha.point = 1,
  ncol = NULL,
  nrow = NULL,
  title = NULL,
  theme = NULL,
  ...
)
```

Arguments

object	DigitalDLSorter object with trained.model slot containing metrics in the test.deconv.metrics slot of a DigitalDLSorterDNN object.
colors	Vector of colors to be used. Only vectors with a number of colors equal to or greater than the levels of color.by will be accepted. By default, a custom color list is used.
facet.by	Variable used to display data in different panels. If NULL, the plot is not split into different panels. Options are nCellTypes (by number of different cell types) and CellType (by cell type).
color.by	Variable used to color data. Options are nCellTypes and CellType.
corr	Correlation value displayed as an annotation on the plot. Available metrics are Pearson's correlation coefficient ('pearson') and concordance correlation coefficient ('ccc'). The argument can be 'pearson', 'ccc' or 'both' (by default).
filter.sc	Boolean indicating whether single-cell profiles are filtered out and only errors associated with pseudo-bulk samples are displayed (TRUE by default).
pos.x.label	X-axis position of correlation annotations (0.95 by default).
pos.y.label	Y-axis position of correlation annotations (0.1 by default).
sep.labels	Space separating annotations if corr is equal to 'both' (0.15 by default).
size.point	Size of points (0.1 by default).
alpha.point	Alpha of points (0.1 by default).
ncol	Number of columns if facet.by is other than NULL.
nrow	Number of rows if facet.by is different from NULL.
title	Title of the plot.
theme	ggplot2 theme.
...	Additional arguments for the facet_wrap function from ggplot2 if facet.by is not NULL.

Value

A ggplot object with the correlation plots between expected and actual proportions.

deconv.data *Get and set deconv.data slot in a [DigitalDLorter](#) object*

Description

Get and set deconv.data slot in a [DigitalDLorter](#) object

Usage

```

deconv.data(object, name.data = NULL)

deconv.data(object, name.data = NULL) <- value

```

Arguments

object	DigitalDLorter object.
name.data	Name of the data. If NULL (by default), all data contained in the deconv.data slot are returned.
value	List whose names are the reference of the stored data.

deconv.results *Get and set deconv.results slot in a [DigitalDLorter](#) object*

Description

Get and set deconv.results slot in a [DigitalDLorter](#) object

Usage

```

deconv.results(object, name.data = NULL)

deconv.results(object, name.data = NULL) <- value

```

Arguments

object	DigitalDLorter object.
name.data	Name of the data. If NULL (by default), all results contained in the deconv.results slot are returned.
value	List whose names are the reference of the stored results.

deconvDigitalDLorter *Deconvolute bulk RNA-Seq samples using a pre-trained DigitalDL-orter model*

Description

Deconvolute bulk gene expression samples (bulk RNA-Seq) to enumerate and quantify the proportion of cell types present in a bulk sample using Deep Neural Network models. This function is intended for users who want to use pre-trained models integrated in the package. So far, the available models allow to deconvolute the immune infiltration of breast cancer (using data from Chung et al., 2017) and the immune infiltration of colorectal cancer (using data from Li et al., 2017) samples. For the former, two models are available at two different levels of specificity: specific cell types (`breast.chung.specific`) and generic cell types (`breast.chung.generic`). See `breast.chung.generic`, `breast.chung.specific`, and `colorectal.li` documentation from the **digitalDLSorteRdata** package for more details.

Usage

```
deconvDigitalDLorter(
  data,
  model = NULL,
  batch.size = 128,
  normalize = TRUE,
  simplify.set = NULL,
  simplify.majority = NULL,
  verbose = TRUE
)
```

Arguments

<code>data</code>	Matrix or data frame with bulk RNA-Seq samples with genes as rows in SYMBOL notation and samples as columns.
<code>model</code>	Pre-trained DNN model to use to deconvolute data. Up to now, the available models are intended to deconvolute samples from breast cancer (<code>breast.chung.generic</code> and <code>breast.chung.specific</code>) and colorectal cancer (<code>colorectal.li</code>). These pre-trained models are stored in the digitalDLSorteRdata package, so it must be installed together with digitalDLSorteR to use this function.
<code>batch.size</code>	Number of samples loaded into RAM each time during the deconvolution process. If not specified, <code>batch.size</code> will be set to 128.
<code>normalize</code>	Normalize data before deconvolution (TRUE by default).
<code>simplify.set</code>	List specifying which cell types should be compressed into a new label whose name will be the list name item. See examples and vignettes for details.
<code>simplify.majority</code>	List specifying which cell types should be compressed into the cell type with the highest proportion in each sample. Unlike <code>simplify.set</code> , this argument allows to maintain the complexity of the results while compressing the information, as no new labels are created.

verbose Show informative messages during execution.

Details

This function is intended for users who want to use **digitalDLSorter** to deconvolute their bulk RNA-Seq samples using pre-trained models. For users who want to build their own models from other scRNA-Seq datasets, see the [loadSCProfiles](#) and [deconvDigitalDLSorterObj](#) functions.

Value

A data frame with samples (i) as rows and cell types (j) as columns. Each entry represents the predicted proportion of cell type j in sample i .

 deconvDigitalDLSorterObj

Deconvolute bulk gene expression samples (bulk RNA-Seq)

Description

Deconvolute bulk gene expression samples (bulk RNA-Seq). This function requires a `DigitalDLSorter` object with a trained Deep Neural Network model (`trained.model` slot) and the new bulk RNA-Seq samples to be deconvoluted in the `deconv.data` slot. See [?loadDeconvData](#) for more details.

Usage

```
deconvDigitalDLSorterObj(
  object,
  name.data,
  batch.size = 128,
  normalize = TRUE,
  simplify.set = NULL,
  simplify.majority = NULL,
  verbose = TRUE
)
```

Arguments

<code>object</code>	<code>DigitalDLSorter</code> object with <code>trained.data</code> and <code>deconv.data</code> slots.
<code>name.data</code>	Name of the data stored in the <code>DigitalDLSorter</code> object. If not provided, the first data set will be used.
<code>batch.size</code>	Number of samples per gradient update. If not specified, <code>batch.size</code> will default to 128.
<code>normalize</code>	Normalize data before deconvolution (TRUE by default).
<code>simplify.set</code>	List specifying which cell types should be compressed into a new label whose name will be the list item. See examples for details. If provided, results are stored in a list with 'raw' and 'simpli.set' results.
<code>simplify.majority</code>	List specifying which cell types should be compressed into the cell type with the highest proportion in each sample. Unlike <code>simplify.set</code> , it allows to maintain the complexity of the results while compressing the information, as no new labels are created. If provided, the results are stored in a list with 'raw' and 'simpli.majority' results.
<code>verbose</code>	Show informative messages during the execution.

Details

This function is intended for users who have built a deconvolution model using their own single-cell RNA-Seq data. If you want to use a pre-trained model to deconvolute your samples, see [?deconvDigitalDLSorter](#).

Value

`DigitalDLorter` object with `deconv.results` slot. The resulting information is a data frame with samples (i) as rows and cell types (j) as columns. Each entry represents the proportion of j cell type in i sample. If `simplify.set` or/and `simplify.majority` are provided, the `deconv.results` slot will contain a list with raw and simplified results.

digitalDLSorteR

digitalDLSorteR: an R package to deconvolute of bulk RNA-Seq samples from scRNA-Seq data based on Deep Learning

Description

digitalDLSorteR is an R package that implements a Deep Learning based method to enumerate and quantify the cell type composition of bulk RNA-Seq samples from the same environment. Our method makes use of Deep Neural Network (DNN) models to adjust any cell type composition starting from single-cell RNA-Seq (scRNA-Seq) data. The resulting models are context-specific, meaning that each model can predict cell proportions of samples from the same environment as the original scRNA-Seq data (i.e. breast cancer).

Details

The foundation of the method consists of a process that starts from scRNA-Seq data and, after a few steps, a Deep Neural Network (DNN) model is trained with simulated pseudo-bulk RNA-Seq samples whose cell composition is known. These trained models are able to deconvolute any bulk RNA-Seq sample from the same context by determining the proportion of the different cell types present. The main advantage of this method is the possibility to build deconvolution models trained with real data from certain biological environments. For example, to quantify the proportion of tumor infiltrated lymphocytes (TILs) in breast cancer, a specific model for this type of samples can be obtained by using this package. This overcomes the limitation of other methods, as stromal and immune cells change significantly their profiles depending on the tissue and disease context.

The package can be used by two ways: to deconvolute bulk RNA-Seq samples using pre-trained models available at the `digitalDLSorterModels` R package or to build your own models trained with your own scRNA-Seq data. These new models may be published to make them available for other users working with similar data. So far, the available models allows the deconvolution of TILs from breast cancer and colorectal cancer. See the vignettes and <https://diegommcc.github.io/digitalDLSorter/> for more details.

DigitalDLSorter-class *The DigitalDLSorter Class*

Description

The `DigitalDLSorter` object is the core of `digitalDLSorter`. This object stores different intermediate data resulting from the creation of new context-specific deconvolution models from single-cell data. It is only used in the case of building new deconvolution models. To deconvolute bulk samples using pre-trained models, see `deconvDigitalDLSorter` function and the package `digitalDLSorterData`.

Details

This object uses other classes to store the different types of data produced during the process:

- `SingleCellExperiment` class for single-cell RNA-Seq data, using sparse matrix from the `Matrix` package (`dgCMatrix` class) or `HDF5Array` class in the case of using HDF5 files as back-end (see below for more information).
- `ZINBParams` class with estimated parameters for the simulation of new single-cell profiles.
- `SummarizedExperiment` class for large bulk RNA-Seq data storage.
- `ProbMatrixCellTypes` class for the compositional cell matrices constructed during the process. See `?ProbMatrixCellTypes` for details.
- `DigitalDLSorterDNN` class to store the information related to Deep Neural Network models. This step is performed using `keras`. See `?DigitalDLSorterDNN` for details.

`digitalDLSorter` can be used in two ways: to build new deconvolution models from single-cell RNA-Seq data or to deconvolute bulk RNA-Seq samples using pre-trained models available at `digitalDLSorterData` package. If you want to build new models, see `loadSCProfiles` function. On the other hand, if you want to use pre-trained models, see `deconvDigitalDLSorter` function.

In order to provide a way to work with large amounts of data on RAM-constrained machines, we provide the possibility to use HDF5 files as back-end to store count matrices of both real/simulated single-cell and bulk RNA-Seq profiles. For this, the package uses the `HDF5Array` and `DelayedArray` classes from the homonymous packages.

Once the Deep Neural Network model has been trained, it is possible to save it as RDS or HDF5 files. Please see [DigitalDLSorterDNN](#) for more details.

Slots

`single.cell.real` Real single-cell data stored in a `SingleCellExperiment` object. The count matrix is stored as `dgMatrix` or `HDF5Array` objects.

`zinb.params` `ZINBParams` object with estimated parameters for the simulation of new single-cell expression profiles.

`single.cell.simul` Simulated single-cell expression profiles from the ZINB-WaVE model.

`prob.cell.types` `ProbMatrixCellTypes` class with cell composition matrices built for the simulation of pseudo-bulk RNA-Seq profiles with known cell composition.

`bulk.simul` A list of simulated train and test bulk RNA-Seq samples. Each entry is a `SummarizedExperiment` object. The count matrices can be stored as `HDF5Array` files using HDF5 files as back-end in case of RAM limitations.

`trained.model` `DigitalDLSorterDNN` object with all the information related to the trained model. See `?DigitalDLSorterDNN` for more details.

`deconv.data` List of `SummarizedExperiment` objects where it is possible to store new bulk RNA-Seq experiments for deconvolution. The name of the entries corresponds to the name of the data provided. See `deconvDigitalDLSorterObj` for details.

`deconv.results` Slot containing the deconvolution results of applying the deconvolution model to the data present in the `deconv.data` slot. It is a list in which the names corresponds to the data from which they come.

`project` Name of the project.

`version` Version of DigitalDLSorterR this object was built under.

DigitalDLSorterDNN-class

The DigitalDLSorterDNN Class

Description

The `DigitalDLSorterDNN` object stores all the information related to Deep Neural Network models. It contains the trained model, the training history and the results of prediction on test data. After running `calculateEvalMetrics`, it is possible to find the performance evaluation of the model on test data (see `?calculateEvalMetrics` for details).

Details

The steps related to Deep Learning are carried out using the **keras** package which uses the R6 classes system. If you want to save the object as an RDS file, `digitalDLSorter` provides a `saveRDS` generic function that transforms the model stored as an R6 object into a native valid R object. Specifically, the model is converted into a list with the architecture of the network and the weights learned during training. That is the minimum information needed to use the model as predictor. If you want to keep the optimizer state, see [?saveTrainedModelASH5](#). If you want to store `DigitalDLSorter` object on disk as an RDA file, see [?preparingToSave](#).

Slots

`model` Trained Deep Neural Network. This slot can contain an R6 `keras.engine.sequential.Sequential` object or a list with two elements: the architecture of the model and the resulting weights after training.

`training.history` List with the evolution of the selected metrics during training.

`test.metrics` Performance of the model on test data.

`test.pred` Deconvolution results on test data. Columns are cell types, rows are samples and each entry corresponds to the proportion of this cell type in this sample.

`cell.types` Vector with cell types to deconvolute.

`features` Vector with the features used during training. These features will be used in subsequent predictions (the nomenclature used in new bulk RNA-Seq samples must be the same).

`test.deconv.metrics` Performance of the model on each sample of test data compared to known cell proportions. This slot is used after [calculateEvalMetrics](#) (see [?calculateEvalMetrics](#) for more details).

<code>distErrorPlot</code>	<i>Generate box plots or violin plots to show how the errors are distributed</i>
----------------------------	--

Description

Generate violin plots or box plots to show how the errors are distributed by proportion bins of 0.1. Errors can be displayed all mixed or split by cell type (`CellType`) or number of cell types present in the samples (`nCellTypes`). See the `facet.by` argument and examples for more details.

Usage

```
distErrorPlot(
  object,
  error,
  colors,
  x.by = "pBin",
  facet.by = NULL,
  color.by = "nCellTypes",
  filter.sc = TRUE,
```

```

    error.label = FALSE,
    pos.x.label = 4.6,
    pos.y.label = NULL,
    size.point = 0.1,
    alpha.point = 1,
    type = "violinplot",
    ylimit = NULL,
    nrow = NULL,
    ncol = NULL,
    title = NULL,
    theme = NULL,
    ...
)

```

Arguments

object	DigitalDLSorter object with <code>trained.model</code> slot containing metrics in the <code>test.deconv.metrics</code> slot of a DigitalDLSorterDNN object.
error	The error to be represented. Available errors are absolute error ('AbsErr'), proportional absolute error ('ppAbsErr'), squared error ('SqrErr') and proportional squared error ('ppSqrErr').
colors	Vector of colors to be used. Only vectors with a number of colors equal to or greater than the levels of <code>color.by</code> will be accepted. By default, a custom color list is used.
x.by	Variable used for the X-axis. When <code>facet.by</code> is not NULL, the best choice is <code>pBin</code> (probability bins). The options are <code>nCellTypes</code> (number of different cell types), <code>CellType</code> (cell type) and <code>pBin</code> .
facet.by	Variable used to display data in different panels. If NULL, the plot is not split into different panels. Options are <code>nCellTypes</code> (number of different cell types) and <code>CellType</code> (cell type).
color.by	Variable used to color the data. Options are <code>nCellTypes</code> and <code>CellType</code> .
filter.sc	Boolean indicating whether single-cell profiles are filtered out and only errors associated with pseudo-bulk samples are displayed (TRUE by default).
error.label	Boolean indicating whether to display the average error as a plot annotation (FALSE by default).
pos.x.label	X-axis position of error annotations.
pos.y.label	Y-axis position of error annotations.
size.point	Size of points (0.1 by default).
alpha.point	Alpha of points (0.1 by default).
type	Type of plot: 'boxplot' or 'violinplot'. The latter by default.
ylimit	Upper limit in Y-axis if it is required (NULL by default).
nrow	Number of rows if <code>facet.by</code> is not NULL.
ncol	Number of columns if <code>facet.by</code> is not NULL.
title	Title of the plot.

theme **ggplot2** theme.
 ... Additional arguments for the [facet_wrap](#) function from **ggplot2** if `facet.by` is not NULL.

Value

A ggplot object with the representation of the desired errors.

```

estimateZinbwaveParams

Estimate the parameters of the ZINB-WaVE model to simulate new single-cell RNA-Seq expression profiles

Description

Estimate the parameters of the ZINB-WaVE model using a real single-cell RNA-Seq data set as reference to simulate new single-cell profiles and increase the signal of underrepresented cell types. This step is optional, only is needed if the size of your dataset is too small or there are underrepresented cell types in order to train the Deep Neural Network model in a more balanced way. After this step, the [simSCProfiles](#) function will use the estimated parameters to simulate new single-cell profiles. See [?simSCProfiles](#) for more information.

Usage

```

estimateZinbwaveParams(
  object,

```

```

cell.type.column,
cell.ID.column,
gene.ID.column,
cell.cov.columns,
gene.cov.columns,
subset.cells = NULL,
proportional = TRUE,
set.type = "All",
threads = 1,
verbose = TRUE
)

```

Arguments

object [DigitalDLSorter](#) object with a single `cell.real` slot.

cell.type.column Name or column number corresponding to the cell type of each cell in cells metadata.

cell.ID.column Name or column number corresponding to the cell names of expression matrix in cells metadata.

gene.ID.column Name or column number corresponding to the notation used for features/genes in genes metadata.

cell.cov.columns Name or column number(s) in cells metadata to be used as covariates during model fitting (if no covariates are used, set to empty or NULL).

gene.cov.columns Name or column number(s) in genes metadata that will be used as covariates during model fitting (if no covariates are used, set to empty or NULL).

subset.cells Number of cells to fit the ZINB-WaVE model. Useful when the original data set is too large to fit the model. Set a value according to the original data set and the resources available on your computer. If NULL (by default), all cells will be used. Must be an integer greater than or equal to the number of cell types considered and less than or equal to the total number of cells.

proportional If TRUE, the original cell type proportions in the subset of cells generated by `subset.cells` will not be altered as far as possible. If FALSE, all cell types will have the same number of cells as far as possible (TRUE by default).

set.type Cell type(s) to evaluate ('All' by default). It is recommended fitting the model to all cell types rather than using only a subset of them to capture the total variability present in the original experiment even if only a subset of cell types is simulated.

threads Number of threads used for estimation (1 by default). To set up the parallel environment, the **BiocParallel** package must be installed.

verbose Show informative messages during the execution (TRUE by default).

Details

ZINB-WaVE is a flexible model for zero-inflated count data. This function carries out the model fit to real single-cell data modeling Y_{ij} (the count of feature j for sample i) as a random variable following a zero-inflated negative binomial (ZINB) distribution. The estimated parameters will be used for the simulation of new single-cell expression profiles by sampling a negative binomial distribution and inserting dropouts from a binomial distribution. To do so, **digitalDLSorter** uses the `zinbEstimate` function from the **splatter** package (Zappia et al., 2017), a wrapper around the `zinbFit` function from the **zinbwave** package (Risso et al., 2018). For more details about the model, see Risso et al., 2018.

Value

A `DigitalDLSorter` object with `zinb.params` slot containing a `ZINBParams` object. This object contains the estimated ZINB-WaVE parameters from the real single-cell RNA-Seq data.

Description

Get and set features slot in a [DigitalDLorterDNN](#) object

Usage

```
features(object)
```

```
features(object) <- value
```

Arguments

object [DigitalDLorterDNN](#) object.

value Vector with features (genes) considered by the Deep Neural Network model.

 generateBulkCellMatrix

Generate training and test cell composition matrices

Description

Generate training and test cell composition matrices for the simulation of pseudo-bulk RNA-Seq samples with known cell composition using single-cell expression profiles. The resulting [ProbMatrixCellTypes](#) object contains a matrix that determines the proportion of the different cell types that will compose the simulated pseudo-bulk samples. In addition, this object also contains other information relevant for the process. This function does not simulate pseudo-bulk samples, this task is performed by the [simBulkProfiles](#) or [trainDigitalDLorterModel](#) functions (see Documentation).

Usage

```

generateBulkCellMatrix(
  object,
  cell.ID.column,
  cell.type.column,
  prob.design,
  num.bulk.samples,
  n.cells = 100,
  train.freq.cells = 2/3,
  train.freq.bulk = 2/3,
  proportions.train = c(10, 5, 20, 15, 35, 15),
  proportions.test = c(10, 5, 20, 15, 35, 15),
  prob.zero = c(0.5, 0.5, 0.5, 0.5, 0.5, 0.5),
  balanced.type.cells = FALSE,
  verbose = TRUE
)

```

Arguments

object	DigitalDLSorter object with <code>single.cell.real</code> slot and, optionally, with <code>single.cell.simul</code> slot.
cell.ID.column	Name or column number corresponding to the cell names of expression matrix in cells metadata.
cell.type.column	Name or column number corresponding to the cell type of each cell in cells metadata.
prob.design	Data frame with the expected frequency ranges for each cell type present in the experiment. This information can be estimated from literature or from the single-cell experiment itself. This data frame must be constructed by three columns with specific headings (see examples): <ul style="list-style-type: none"> • A cell type column with the same name of the cell type column in cells metadata (<code>cell.type.column</code>). If the name of the column is not the same, the function will return an error. All cell types must appear in the cells metadata. • A second column called 'from' with the start frequency for each cell type. • A third column called 'to' with the ending frequency for each cell type.
num.bulk.samples	Number of bulk RNA-Seq sample proportions (and thus simulated bulk RNA-Seq samples) to be generated taking into account training and test data. We recommend setting this value according to the number of single-cell profiles available in DigitalDLSorter object avoiding an excessive re-sampling, but generating a large number of samples for better training.
n.cells	Number of cells that will be aggregated in order to simulate one bulk RNA-Seq sample (100 by default).
train.freq.cells	Proportion of cells used to simulate training pseudo-bulk samples (2/3 by default).

<code>train.freq.bulk</code>	Proportion of bulk RNA-Seq samples to the total number (<code>num.bulk.samples</code>) used for the training set (2/3 by default).
<code>proportions.train</code>	Vector of six integers that determines the proportions of bulk samples generated by the different methods (see Details and Torroja and Sanchez-Cabo, 2019. for more information). This vector represents proportions, so its entries must add up 100. By default, a majority of random samples will be generated without using predefined ranges.
<code>proportions.test</code>	<code>proportions.train</code> for test samples.
<code>prob.zero</code>	Probability of producing cell type proportions equal to zero. It is a vector of six elements corresponding to the six methods of producing cell type proportions (see <code>proportions.train</code> for more details).
<code>balanced.type.cells</code>	Boolean indicating whether the training and test cells will be split in a balanced way considering the cell types (FALSE by default).
<code>verbose</code>	Show informative messages during the execution (TRUE by default).

Details

First, the available single-cell profiles are split into training and test subsets (2/3 for training and 1/3 for test by default (see `train.freq.cells`)) to avoid falsifying the results during model evaluation. Next, `num.bulk.samples` bulk samples proportions are built and the single-cell profiles to be used to simulate each pseudo-bulk RNA-Seq sample are set, being 100 cells per bulk sample by default (see `n.cells` argument). The proportions of training and test pseudo-bulk samples are set by `train.freq.bulk` (2/3 for training and 1/3 for testing by default). Finally, in order to avoid biases due to the composition of the pseudo-bulk RNA-Seq samples, cell type proportions (w_1, \dots, w_k , where k is the number of cell types available in single-cell profiles) are randomly generated by using six different approaches:

1. Cell proportions are randomly sampled from a truncated uniform distribution with predefined limits according to a priori knowledge of the abundance of each cell type (see `prob.design` argument). This information can be inferred from the single-cell experiment itself or from the literature.
2. A second set is generated by randomly permuting cell type labels from a distribution generated by the previous method.
3. Cell proportions are randomly sampled as by method 1 without replacement.
4. Using the last method for generating proportions, cell types labels are randomly sampled.
5. Cell proportions are randomly sampled from a Dirichlet distribution.
6. Pseudo-bulk RNA-Seq samples composed of the same cell type are generated in order to provide 'pure' pseudo-bulk samples.

If you want to inspect the distribution of cell type proportions generated by each method during the process, they can be visualized by the `showProbPlot` function (see Documentation).

Value

A [DigitalDLSorter](#) object with `prob.cell.types` slot containing a list with two [ProbMatrixCellTypes](#) objects (training and test). For more information about the structure of this class, see `?ProbMatrixCellTypes`.

)
```

getProbMatrix	<i>Getter function for the cell composition matrix</i>
---------------	--

Description

Getter function for the cell composition matrix. This function allows to access to the cell composition matrix of simulated training or test pseudo-bulk RNA-Seq data.

Usage

```
getProbMatrix(object, type.data)
```

Arguments

object	DigitalDLSorter object with prob.cell.types slot.
type.data	Subset of data to e shown: train or test.

Value

A matrix object with the desired cell proportion matrix.

See Also

[generateBulkCellMatrix](#)

installTFpython	<i>Install Python dependencies for digitalDLSorterR</i>
-----------------	---

Description

This is a helper function to install Python dependencies needed: a Python interpreter with TensorFlow Python library and its dependencies. It is performed using the **reticulate** package and the installer of the **tensorflow** R package. The available options are virtual or conda environments. The new environment is called digitaldlsorter-env. In any case, this installation can be manually done as it is explained in <https://diegommcc.github.io/digitalDLSorter/articles/kerasIssues.html>, but we recommend using this function.

Usage

```
installTFpython(conda = "auto", install.conda = FALSE, miniconda.path = NULL)
```

Arguments

conda	Path to a conda executable. Use "auto" (by default) allows reticulate to automatically find an appropriate conda binary.
install.conda	Boolean indicating if install miniconda automatically using reticulate . If TRUE, conda argument is ignored. FALSE by default.
miniconda.path	If install.conda is TRUE, you can set the path where miniconda will be installed. If NULL, conda will find automatically the proper place.

Details

This function is intended to make easier the installation of the requirements needed to use **digitalDLSorter**. It will automatically install Miniconda (if wanted, see Parameters) and create an environment called 'digitaldlsorter-env'. If you want to use other python/conda environment, see ?tensorflow::use_condaenv and/or the vignettes.

Value

No return value, called for side effects: installation of conda environment with a Python interpreter and Tensorflow

Examples

```
## Not run:
notesInstallation <- installTFpython(
  method = "auto", conda = "auto", install.conda = TRUE
)

## End(Not run)
```

listToDDL	<i>Transform DigitalDLSorter-like list into an actual DigitalDLSorterDNN object</i>
-----------	---

Description

Transform DigitalDLSorter-like list into an actual DigitalDLSorter object. This function allows to generate the examples and the vignettes of **digitalDLSorter** package as these are the data used. These data are stored in the digitalDLSorterdata package.

Usage

```
listToDDL(listTo)
```

Arguments

listTo	A list in which each element must correspond to each slot of an DigitalDLSorter object. The names must be the same as the slot names.
--------	---

Value

DigitalDLorter object the data provided in the original list.

See Also

[listToDDLSDNN](#)

listToDDLSDNN	<i>Transform DigitalDLorterDNN-like list into an actual DigitalDLorterDNN object</i>
---------------	--

Description

Transform DigitalDLorterDNN-like list into an actual DigitalDLorterDNN object. This function allows to use pre-trained models in the **digitalDLorteR** package. These models are stored in the digitalDLorteRmodels package.

Usage

```
listToDDLSDNN(listTo)
```

Arguments

listTo	A list in which each element must correspond to each slot of an DigitalDLorterDNN object. The names must be the same as the slot names.
--------	---

Value

DigitalDLorterDNN object with the data provided in the original list.

See Also

[listToDDL](#)

loadDeconvData	<i>Load data to be deconvoluted into a DigitalDLorter object</i>
----------------	--

Description

Load data to be deconvoluted. Data can be provided from a file path of a tabulated text file (tsv and tsv.gz formats are accepted) or a [SummarizedExperiment](#) object.

Usage

```
loadDeconvData(object, data, name.data = NULL)

## S4 method for signature 'DigitalDLorter,character'
loadDeconvData(object, data, name.data = NULL)

## S4 method for signature 'DigitalDLorter,SummarizedExperiment'
loadDeconvData(object, data, name.data = NULL)
```

Arguments

object	DigitalDLorter object with trained.model slot.
data	File path where the data is stored or a SummarizedExperiment object.
name.data	Name under which the data is stored in the DigitalDLorter object. When data is a file path and name.data is not provided, the base name of file will be used.

Value

A [DigitalDLorter](#) object with deconv.data slot with the new bulk-RNA-Seq samples loaded.

See Also

[trainDigitalDLorterModel deconvDigitalDLorterObj](#)

loadSCProfiles

Create a [DigitalDLorter](#) object from single-cell RNA-seq data

Description

Create a [DigitalDLorter](#) object from single-cell RNA-seq data from files (formats allowed: tsv, tsv.gz, mtx (sparse matrix) and hdf5) or a [SingleCellExperiment](#) object. The data will be stored in single.cell.real slot. The data provided should consist of three pieces of information:

- Single-cell counts: genes as rows and cells as columns.
- Cells metadata: annotations (columns) for each cell (rows).
- Genes metadata: annotations (columns) for each gene (rows).

If the data is provided from files, single.cell.real argument must be a vector of three elements ordered so that the first file corresponds to the count matrix, the second to the cells metadata and the last to the genes metadata. On the other hand, if the data is provided as a [SingleCellExperiment](#) object, it must contain single-cell counts in the assay slot, cells metadata in the colData slot and genes metadata in the rowData. The data must be provided without any transformation (e.g. log-transformation) and raw counts are preferred.

Usage

```
loadSCProfiles(
  single.cell.data,
  cell.ID.column,
  gene.ID.column,
  name.dataset.h5,
  min.counts = 0,
  min.cells = 0,
  fun.aggregate = "sum",
  file.backend = NULL,
  name.dataset.backend = NULL,
  compression.level = NULL,
  chunk.dims = NULL,
  block.processing = FALSE,
  verbose = TRUE,
  project = "DigitalDLSorterProject"
)
```

Arguments

single.cell.data	If data is provided from files, <code>single.cell.real</code> must be a vector of three elements: single-cell counts, cells metadata and genes metadata. If data is provided from a SingleCellExperiment object, single-cell counts must be present in the assay slot, cells metadata in the <code>colData</code> slot and genes metadata in the <code>rowData</code> slot.
cell.ID.column	Name or number of the column in the cells metadata corresponding to cell names in expression matrix.
gene.ID.column	Name or number of the column in the genes metadata corresponding to the names used for features/genes.
name.dataset.h5	Name of the data set if HDF5 file is provided.
min.counts	Minimum gene counts to filter (0 by default).
min.cells	Minimum of cells with more than <code>min.counts</code> (0 by default).
fun.aggregate	In case of duplicated genes, it is possible to set the function used to aggregate them. Allowed functions: 'sum', 'mean', 'median'. Note that this functionality only works when data are provided from an <code>mtx</code> file (sparse matrices) that allows duplicated rownames. Otherwise, R does not allow duplicated rownames.
file.backend	Valid file path where to store the loaded data as HDF5 file. If provided, data is stored in HDF5 files as back-end using DelayedArray and HDF5Array packages instead of being loaded into RAM. This is suitable for situations where you have large amounts of data that cannot be stored in memory. Note that operations on these data will be performed by blocks (i.e subsets of determined size), which may result in longer execution times. NULL by default.
name.dataset.backend	Name of the dataset of the HDF5 file to be used. Note that it cannot exist. If NULL (by default), a random dataset name will be used.

<code>compression.level</code>	The compression level used if <code>file.backend</code> is provided. It is an integer value between 0 (no compression) and 9 (highest and slowest compression). See ?getHDF5DumpCompressionLevel from the HDF5Array package for more information.
<code>chunk.dims</code>	Specifies dimensions that HDF5 chunk will have. If NULL, the default value is a vector of two items: the number of genes considered by DigitalDLSorter object during the simulation, and only one sample in order to increase read times in the following steps. A larger number of columns written in each chunk may lead to longer read times.
<code>block.processing</code>	Boolean indicating whether data should be treated as blocks (only if data is provided as HDF5 file). FALSE by default. Note that using this functionality is suitable for cases where is not possible to load the data into RAM and therefore execution times will be longer.
<code>verbose</code>	Show informative messages during the execution (TRUE by default).
<code>project</code>	Name of the project for DigitalDLSorter object.

Details

This data can be used to simulate new single-cell profiles using the ZINB-WaVE framework with the [estimateZinbwaveParams](#) function. In this way, it is possible to increase the signal of cell types that are underrepresented in the original dataset. If this step is not necessary, these profiles will be used directly to simulate pseudo-bulk RNA-seq samples with known cell composition.

Value

A [DigitalDLSorter](#) object with the single-cell RNA-seq data provided loaded into the `single.cell.real` slot as a [SingleCellExperiment](#) object.

See Also

[estimateZinbwaveParams](#) [generateBulkCellMatrix](#)

Examples

```
set.seed(123) # reproducibility
sce <- SingleCellExperiment::SingleCellExperiment(
  assays = list(
    counts = matrix(
      rpois(100, lambda = 5), nrow = 40, ncol = 30,
      dimnames = list(paste0("Gene", seq(40)), paste0("RHC", seq(30)))
    )
  ),
  colData = data.frame(
    Cell_ID = paste0("RHC", seq(30)),
    Cell_Type = sample(x = paste0("CellType", seq(4)), size = 30,
                      replace = TRUE)
  ),
  rowData = data.frame(
```

```
        Gene_ID = paste0("Gene", seq(40))
    )
)
DDLS <- loadSCProfiles(
  single.cell.data = sce,
  cell.ID.column = "Cell_ID",
  gene.ID.column = "Gene_ID",
  min.cells = 0,
  min.counts = 0,
  project = "Simul_example"
)
```

loadTrainedModelFromH5

Load from an HDF5 file a trained Deep Neural Network model into a [DigitalDLorter](#) object

Description

Load from an HDF5 file a trained Deep Neural Network model into a [DigitalDLorter](#) object. Note that HDF5 file must be a valid trained model (**keras** object).

Usage

```
loadTrainedModelFromH5(object, file.path, reset.slot = FALSE)
```

Arguments

object	DigitalDLorter object with trained.model slot.
file.path	Valid file path where the model are stored.
reset.slot	Deletes trained.slot if it already exists. A new DigitalDLorterDNN object will be formed, but will not contain other slots (FALSE by default).

Value

[DigitalDLorter](#) object with trained.model slot with the new keras DNN model incorporated.

See Also

[trainDigitalDLorterModel](#) [deconvDigitalDLorterObj](#) [saveTrainedModelAsH5](#)

model	<i>Get and set model slot in a DigitalDLorterDNN object</i>
-------	---

Description

Get and set model slot in a [DigitalDLorterDNN](#) object

Usage

```
model(object)
model(object) <- value
```

Arguments

object	DigitalDLorterDNN object.
value	keras.engine.sequential.Sequential object with a trained Deep Neural Network model.

plots	<i>Get and set plots slot in a ProbMatrixCellTypes object</i>
-------	---

Description

Get and set plots slot in a [ProbMatrixCellTypes](#) object

Usage

```
plots(object)
plots(object) <- value
```

Arguments

object	ProbMatrixCellTypes object.
value	List of lists with plots showing the distribution of the cell proportions generated by each method during the process.

plotTrainingHistory	<i>Plot training history of a trained DigitalDLSorter Deep Neural Network model</i>
---------------------	---

Description

Plot training history of a trained DigitalDLSorter Deep Neural Network model.

Usage

```
plotTrainingHistory(  
  object,  
  title = "History of metrics during training",  
  metrics = NULL  
)
```

Arguments

object	DigitalDLSorter object with trained.model slot.
title	Title of plot.
metrics	Metrics to be plotted. If NULL (by default), all metrics available in the DigitalDLSorterDNN object will be plotted.

Value

A ggplot object with the progression of the selected metrics during training.

See Also

[trainDigitalDLSorterModel](#) [deconvDigitalDLSorterObj](#)

preparingToSave	<i>Prepare DigitalDLSorter object to be saved as an RDA file</i>
-----------------	--

Description

Prepare a [DigitalDLSorter](#) object that has a [DigitalDLSorterDNN](#) object with a trained DNN model. keras models cannot be stored natively as R objects (e.g. RData or RDS files). By saving the structure as a JSON-like character object and the weights as a list, it is possible to retrieve the model and make predictions. **Note:** with this option, the state of optimizer is not saved, only the architecture and weights.

Usage

```
preparingToSave(object)
```

Arguments

object [DigitalDLSorter](#) object with the trained.data slot.

Details

It is possible to save the entire model as an HDF5 file with the [saveTrainedModelAsH5](#) function and to load it into a [DigitalDLSorter](#) object with the [loadTrainedModelFromH5](#) function.

It is also possible to save a [DigitalDLSorter](#) object as an RDS file with the `saveRDS` function without any preparation.

Value

A [DigitalDLSorter](#) or [DigitalDLSorterDNN](#) object with its trained keras model transformed from a `keras.engine.sequential.Sequential` class into a list with the architecture as a JSON-like character object and the weights as a list.

See Also

[saveRDS](#) [saveTrainedModelAsH5](#)

prob.cell.types	<i>Get and set prob.cell.types slot in a DigitalDLSorter object</i>
-----------------	---

Description

Get and set prob.cell.types slot in a [DigitalDLSorter](#) object

Usage

```
prob.cell.types(object, type.data = "both")
```

```
prob.cell.types(object, type.data = "both") <- value
```

Arguments

object [DigitalDLSorter](#) object.

type.data Element of the list. Can be 'train', 'test' or 'both' (the last by default).

value List with two elements, train and test, each one with a [ProbMatrixCellTypes](#) object.

prob.matrix	Get and set prob.matrix slot in a ProbMatrixCellTypes object
-------------	--

Description

Get and set prob.matrix slot in a [ProbMatrixCellTypes](#) object

Usage

```
prob.matrix(object)

prob.matrix(object) <- value
```

Arguments

object	ProbMatrixCellTypes object.
value	Matrix with cell types as columns and samples as rows.

ProbMatrixCellTypes-class

The Class ProbMatrixCellTypes

Description

The ProbMatrixCellTypes class is a data storage class that contains information related to the cell composition matrices used for the simulation of pseudo-bulk RNA-Seq samples. The matrix is stored in the prob.matrix slot. The other of slots contain additional information generated during the process and required in subsequent steps.

Details

As described in Torroja and Sanchez-Cabo, 2019, the proportions are constructed using six different methods in order to avoid biases due to the composition of the simulated bulk samples. In plots slot, plots are stored that visually represent the distribution of these probabilities in order to provide a way to monitor the different sets of samples generated. These plots can be shown using the [showProbPlot](#) function (see [?showProbPlot](#) for more details).

Slots

`prob.matrix` Matrix of cell proportions generated for the simulation of bulk samples. Rows correspond to the bulk samples to be generated (i), columns are the cell types present in the provided single-cell data (j) and each entry is the proportion of j cell type in i sample.

`cell.names` Matrix containing the names of the cells that will make up each simulated pseudo-bulk sample.

`set.list` List of cells sorted according to the cell type they belong to.

- `set` Vector containing the cell names present in the object.
- `plots` List of lists with plots showing the distribution of the cell proportions generated by each method during the process. In each list, `boxplot`, `violinplot`, `linesplot` or `ncelltypes` can be found. Please see [showProbPlot](#) for more details.
- `type.data` Character with the type of data contained: training or test.

<code>project</code>	<i>Get and set project slot in a DigitalDLSorter object</i>
----------------------	---

Description

Get and set project slot in a [DigitalDLSorter](#) object

Usage

```
project(object)

project(object) <- value
```

Arguments

<code>object</code>	DigitalDLSorter object.
<code>value</code>	Character indicating the name of the project.

<code>saveRDS</code>	<i>Save DigitalDLSorter objects as RDS files</i>
----------------------	--

Description

Save [DigitalDLSorter](#) and [DigitalDLSorterDNN](#) objects as RDS files. **keras** models cannot be stored natively as R objects (e.g. `RData` or RDS files). By saving the structure as a JSON-like character object and the weights as a list, it is possible to retrieve the model and make predictions. If the `trained.model` slot is empty, the function will behave as usual. **Note:** with this option, the state of optimizer is not saved, only the architecture and weights. It is possible to save the entire model as an HDF5 file with the [saveTrainedModelAsH5](#) function and to load it into a [DigitalDLSorter](#) object with the [loadTrainedModelFromH5](#) function. See documentation for details.

Usage

```

saveRDS(
  object,
  file,
  ascii = FALSE,
  version = NULL,
  compress = TRUE,
  refhook = NULL
)

## S4 method for signature 'DigitalDLSorterDNN'
saveRDS(
  object,
  file,
  ascii = FALSE,
  version = NULL,
  compress = TRUE,
  refhook = NULL
)

## S4 method for signature 'DigitalDLSorter'
saveRDS(
  object,
  file,
  ascii = FALSE,
  version = NULL,
  compress = TRUE,
  refhook = NULL
)

```

Arguments

object	DigitalDLSorter or DigitalDLSorterDNN object to be saved
file	File path where the object will be saved
ascii	a logical. If TRUE or NA, an ASCII representation is written; otherwise (default), a binary one is used. See the comments in the help for save .
version	the workspace format version to use. NULL specifies the current default version (3). The only other supported value is 2, the default from R 1.4.0 to R 3.5.0.
compress	a logical specifying whether saving to a named file is to use "gzip" compression, or one of "gzip", "bzip2" or "xz" to indicate the type of compression to be used. Ignored if file is a connection.
refhook	a hook function for handling reference objects.

Value

No return value, saves a [DigitalDLSorter](#) object as an RDS file on disk.

See Also

[DigitalDLSorter saveTrainedModelAsH5](#)

saveTrainedModelAsH5 *Save a trained [DigitalDLSorter](#) Deep Neural Network model to disk as an HDF5 file*

Description

Save a trained [DigitalDLSorter](#) Deep Neural Network model to disk as an HDF5 file. Note that this function does not save the [DigitalDLSorterDNN](#) object, but the trained keras model. This is the alternative to the [saveRDS](#) and [preparingToSave](#) functions if you want to keep the state of the optimizer.

Usage

```
saveTrainedModelAsH5(object, file.path, overwrite = FALSE)
```

Arguments

object [DigitalDLSorter](#) object with trained.model slot.
file.path Valid file path where to save the model to.
overwrite Overwrite file if it already exists.

Value

No return value, saves a keras DNN trained model as HDF5 file on disk.

See Also

[trainDigitalDLSorterModel loadTrainedModelFromH5](#)

set *Get and set set slot in a [ProbMatrixCellTypes](#) object*

Description

Get and set set slot in a [ProbMatrixCellTypes](#) object

Usage

```
set(object)

set(object) <- value
```

Arguments

object	ProbMatrixCellTypes object.
value	Vector with names of cells present in the object.

set.list *Get and set set.list slot in a [ProbMatrixCellTypes](#) object*

Description

Get and set set.list slot in a [ProbMatrixCellTypes](#) object

Usage

```
set.list(object)

set.list(object) <- value
```

Arguments

object	ProbMatrixCellTypes object.
value	List of cells sorted according to the cell type to which they belong.

showProbPlot *Show distribution plots of the cell proportions generated by [generateBulkCellMatrix](#)*

Description

Show distribution plots of the cell proportions generated by [generateBulkCellMatrix](#). These frequencies will determine the proportion of different cell types used during the simulation of pseudo-bulk RNA-Seq samples. There are 6 subsets of proportions generated by different approaches that can be visualized in three ways: box plots, violin plots and lines plots. You can also plot the probabilities based on the number of different cell types present in the samples by setting type.plot = 'nCellTypes'.

Usage

```
showProbPlot(object, type.data, set, type.plot = "boxplot")
```

Arguments

object	DigitalDLSorter object with prob.cell.types slot with plot slot.
type.data	Subset of data to show: train or test.
set	Integer determining which of the 6 different subsets to display.
type.plot	Character determining which type of visualization to display. It can be 'boxplot', 'violinplot', 'linesplot' or 'ncelltypes'. See Description for more information.

Details

These plots are only for diagnostic purposes. This is the reason because they are generated without any parameter introduced by the user.

Value

A ggplot object.

See Also

    )
}
)

```

simBulkProfiles

Simulate training and test pseudo-bulk RNA-Seq profiles

Description

Simulate training and test pseudo-bulk RNA-Seq profiles using the cell composition matrices generated by the [generateBulkCellMatrix](#) function. The samples are generated under the assumption that the expression level of the i gene in the j bulk sample is given by the sum of the expression levels of the cell types X_{ijk} that make them up weighted by the proportions of these k cell types in each sample. In practice, as described in Torroja and Sanchez-Cabo, 2019, these profiles are generated by summing a number of cells of different cell types determined by proportions from a matrix of known cell composition. The number of simulated pseudo-bulk RNA-Seq samples and the number of cells composing each sample are determined by [generateBulkCellMatrix](#) (see Documentation) **Note:** this step can be avoided by using the `on.the.fly` argument in the [trainDigitalDLorterModel](#) function. See Documentation for more information.

Usage

```

simBulkProfiles(
  object,
  type.data = "both",
  file.backend = NULL,
  compression.level = NULL,
  block.processing = FALSE,
  block.size = 1000,
  chunk.dims = NULL,
  threads = 1,
  verbose = TRUE
)

```

Arguments

object	DigitalDLorter object with <code>single.cell.real/single.cell.simul</code> and <code>prob.cell.types</code> slots.
type.data	Type of data to generate between 'train', 'test' or 'both' (the last by default).

<code>file.backend</code>	Valid file path to store the simulated single-cell expression profiles as an HDF5 file (NULL by default). If provided, the data is stored in HDF5 files used as back-end by using the DelayedArray , HDF5Array and rhdf5 packages instead of loading all data into RAM memory. This is suitable for situations where you have large amounts of data that cannot be loaded into memory. Note that operations on this data will be performed in blocks (i.e subsets of determined size) which may result in longer execution times.
<code>compression.level</code>	The compression level used if <code>file.backend</code> is provided. It is an integer value between 0 (no compression) and 9 (highest and slowest compression). See ?getHDF5DumpCompressionLevel from the HDF5Array package for more information.
<code>block.processing</code>	Boolean indicating whether the data should be simulated in blocks (only if <code>file.backend</code> is used, FALSE by default). This functionality is suitable for cases where is not possible to load all data into memory and it leads to larger execution times.
<code>block.size</code>	Only if <code>block.processing = TRUE</code> . Number of pseudo-bulk expression profiles that will be simulated in each iteration during the process. Larger numbers result in higher memory usage but shorter execution times. Set according to available computational resources (1000 by default).
<code>chunk.dims</code>	Specifies the dimensions that HDF5 chunk will have. If NULL, the default value is a vector of two items: the number of genes considered by DigitalDLSorter object during the simulation, and a single sample to reduce read times in the following steps. A larger number of columns written in each chunk can lead to longer read times.
<code>threads</code>	Number of threads used during the simulation of pseudo-bulk samples (1 by default). Set according to computational resources and avoid it if <code>block.size</code> will be used.
<code>verbose</code>	Show informative messages during the execution (TRUE by default).

Details

digitalDLSorter allows the use of HDF5 files as back-end to store the resulting data using the **DelayedArray** and **HDF5Array** packages. This functionality allows to work without keeping the data loaded into RAM, which could be of vital importance during some computationally heavy steps such as neural network training on RAM-limited machines. You must provide a valid file path in the `file.backend` argument to store the resulting file with the `.h5` extension. The data will be accessible from R without being loaded into memory. This option slightly slows down execution times, as subsequent transformations of the data will be done in blocks rather than using all the data. We recommend this option according to the computational resources available and the number of pseudo-bulk samples to be generated.

Note that if you use the `file.backend` argument with `block.processing = FALSE`, all pseudo-bulk profiles will be simulated in one step and, therefore, loaded into RAM. Then, the data will be written to an HDF5 file. To avoid the RAM collapse, pseudo-bulk profiles can be simulated and written to HDF5 files in blocks of `block.size` size by setting `block.processing = TRUE`.

It is possible to avoid this step by using the `on.the.fly` argument in the `trainDigitalDLorterModel` function. In this way, data is generated 'on the fly' during the neural network training. For more details, see `?trainDigitalDLorterModel`.

Value

A `DigitalDLorter` object with `bulk.simul` slot containing a list with one or two entries (depending on selected `type.data` argument): 'train' and 'test'. Each entry contains a `SummarizedExperiment` object with simulated bulk samples in the `assay` slot, sample names in the `colData` slot and feature names in the `rowData` slot.

simSCProfiles	<i>Simulate new single-cell RNA-Seq expression profiles using the ZINB-WaVE model parameters</i>
---------------	--

Description

Simulate single-cell expression profiles by randomly sampling from a negative binomial distribution and inserting dropouts by sampling from a binomial distribution using the ZINB-WaVE parameters estimated by the [estimateZinbwaveParams](#) function.

Usage

```

simSCProfiles(
  object,
  cell.ID.column,
  cell.type.column,
  n.cells,
  suffix.names = "_Simul",
  cell.types = NULL,
  file.backend = NULL,
  name.dataset.backend = NULL,
  compression.level = NULL,
  block.processing = FALSE,
  block.size = 1000,
  chunk.dims = NULL,
  verbose = TRUE
)

```

Arguments

object	DigitalDLSorter object with single.cell.real and zinb.params slots.
cell.ID.column	Name or column number corresponding to the cell names of expression matrix in cells metadata.
cell.type.column	Name or column number corresponding to the cell type of each cell in cells metadata.

n.cells	Number of simulated cells generated per cell type (i.e. if you have 10 different cell types in your dataset, if n.cells = 100, then 1000 cell profiles will be simulated).
suffix.names	Suffix used on simulated cells. This suffix must be unique in the simulated cells, so make sure that this suffix does not appear in the real cell names.
cell.types	Vector indicating the cell types to simulate. If NULL (by default), n.cells single-cell profiles for all cell types will be simulated.
file.backend	Valid file path to store the simulated single-cell expression profiles as an HDF5 file (NULL by default). If provided, the data is stored in HDF5 files used as back-end by using the DelayedArray , HDF5Array and rhdf5 packages instead of loading all data into RAM memory. This is suitable for situations where you have large amounts of data that cannot be loaded into memory. Note that operations on this data will be performed in blocks (i.e subsets of determined size) which may result in longer execution times.
name.dataset.backend	Name of the dataset in HDF5 file to be used. Note that it cannot exist. If NULL (by default), a random dataset name will be used.
compression.level	The compression level used if file.backend is provided. It is an integer value between 0 (no compression) and 9 (highest and slowest compression). See ?getHDF5DumpCompressionLevel from the HDF5Array package for more information.
block.processing	Boolean indicating whether the data should be simulated in blocks (only if file.backend is used, FALSE by default). This functionality is suitable for cases where is not possible to load all data into memory and it leads to larger execution times.
block.size	Only if block.processing = TRUE. Number of single-cell expression profiles that will be simulated in each iteration during the process. Larger numbers result in higher memory usage but shorter execution times. Set according to available computational resources (1000 by default). Note that it cannot be greater than the total number of simulated cells.
chunk.dims	Specifies the dimensions that HDF5 chunk will have. If NULL, the default value is a vector of two items: the number of genes considered by the ZINB-WaVE model during the simulation and a single sample in order to reduce read times in the following steps. A larger number of columns written in each chunk can lead to longer read times in subsequent steps. Note that it cannot be greater than the dimensions of the simulated matrix.
verbose	Show informative messages during the execution (TRUE by default).

Details

Before this step, see [?estimateZinbwaveParams](#). As described in Torroja and Sanchez-Cabo, 2019, this function simulates a given number of transcriptional profiles for each cell type provided by randomly sampling from a negative binomial distribution with μ and θ estimated parameters and inserting dropouts by sampling from a binomial distribution with probability π . All

parameters are estimated from single-cell real data using the `estimateZinbwaveParams` function. It uses the ZINB-WaVE model (Risso et al., 2018). For more details about the model, see `?estimateZinbwaveParams` and Risso et al., 2018.

The `file.backend` argument allows to create a HDF5 file with simulated single-cell profiles to be used as back-end to work with data stored on disk instead of loaded into RAM. If the `file.backend` argument is used with `block.processing = FALSE`, all the single-cell profiles will be simulated in one step and, therefore, loaded into in RAM memory. Then, data will be written in HDF5 file. To avoid to collapse RAM memory if too many single-cell profiles are simulated, single-cell profiles can be simulated and written to HDF5 files in blocks of `block.size` size by setting `block.processing = TRUE`.

Value

A `DigitalDLSorter` object with `single.cell.simul` slot containing a `SingleCellExperiment` object with the simulated single-cell expression profiles.

single.cell.real *Get and set single.cell.real slot in a [DigitalDLorter](#) object*

Description

Get and set single.cell.real slot in a [DigitalDLorter](#) object

Usage

```
single.cell.real(object)
```

```
single.cell.real(object) <- value
```

Arguments

object [DigitalDLorter](#) object.

value [SingleCellExperiment](#) object with real single-cell profiles.

single.cell.simul *Get and set single.cell.simul slot in a [DigitalDLorter](#) object*

Description

Get and set single.cell.simul slot in a [DigitalDLorter](#) object

Usage

```
single.cell.simul(object)

single.cell.simul(object) <- value
```

Arguments

object [DigitalDLSorter](#) object.
value [SingleCellExperiment](#) object with simulated single-cell profiles.

test.deconv.metrics *Get and set test.deconv.metrics slot in a [DigitalDLSorterDNN](#) object*

Description

Get and set test.deconv.metrics slot in a [DigitalDLSorterDNN](#) object

Usage

```
test.deconv.metrics(object, metrics = "All")

test.deconv.metrics(object, metrics = "All") <- value
```

Arguments

object [DigitalDLSorterDNN](#) object.
metrics Metrics to show ('All' by default)
value List with evaluation metrics used to assess the performance of the model on each sample of test data.

test.metrics *Get and set test.metrics slot in a [DigitalDLSorterDNN](#) object*

Description

Get and set test.metrics slot in a [DigitalDLSorterDNN](#) object

Usage

```
test.metrics(object)

test.metrics(object) <- value
```

Arguments

object	DigitalDLSorterDNN object.
value	List object with the resulting metrics after prediction on test data with the Deep Neural Network model.

test.pred	<i>Get and set test.pred slot in a DigitalDLSorterDNN object</i>
-----------	--

Description

Get and set test.pred slot in a [DigitalDLSorterDNN](#) object

Usage

```
test.pred(object)
test.pred(object) <- value
```

Arguments

object	DigitalDLSorterDNN object.
value	Matrix object with the prediction results on test data.

trainDigitalDLSorterModel	<i>Train Deep Neural Network model</i>
---------------------------	--

Description

Train a Deep Neural Network model using the training data from [DigitalDLSorter](#) object. In addition, the trained model is evaluated with test data and prediction results are obtained to determine its performance (see [?calculateEvalMetrics](#)). Training and evaluation can be performed using simulated profiles stored in the [DigitalDLSorter](#) object or 'on the fly' by simulating the pseudo-bulk profiles at the same time as the training/evaluation is performed (see [Details](#)).

Usage

```
trainDigitalDLSorterModel(
  object,
  on.the.fly = FALSE,
  combine = "both",
  batch.size = 64,
  num.epochs = 10,
  num.hidden.layers = 2,
```

```

num.units = c(200, 200),
activation.fun = "relu",
dropout.rate = 0.25,
loss = "kullback_leibler_divergence",
metrics = c("accuracy", "mean_absolute_error", "categorical_accuracy"),
custom.model = NULL,
shuffle = FALSE,
threads = 1,
view.metrics.plot = TRUE,
verbose = TRUE
)

```

Arguments

object	<code>DigitalDLSorter</code> object with <code>single.cell.real/single.cell.simul,prob.cell.matrix</code> and <code>bulk.simul</code> slots.
on.the.fly	Boolean indicating whether data will be generated 'on the fly' during training (FALSE by default).
combine	Type of profiles to be used for training. Can be 'both', 'single-cell' or 'bulk' ('both' by default). For test data, both types of profiles will be used.
batch.size	Number of samples per gradient update. If not specified, <code>batch.size</code> will default to 64.
num.epochs	Number of epochs to train the model (10 by default).
num.hidden.layers	Number of hidden layers of the neural network (2 by default). This number must be equal to the length of <code>num.units</code> argument.
num.units	Vector indicating the number of neurons per hidden layer (<code>c(200,200)</code> by default). The length of this vector must be equal to <code>num.hidden.layers</code> argument.
activation.fun	Activation function to use ('relu' by default). See the keras documentation to know available activation functions.
dropout.rate	Float between 0 and 1 indicating the fraction of the input neurons to drop in layer dropouts (0.25 by default). By default, digitalDLSorter implements 1 dropout layer per hidden layer.
loss	Character indicating loss function selected for model training ('kullback_leibler_divergence' by default). See the keras documentation to know available loss functions.
metrics	Vector of metrics used to assess model performance during training and evaluation (<code>c("accuracy", "mean_absolute_error", "categorical_accuracy")</code> by default). See the keras documentation to know available performance metrics.
custom.model	Allows to use a custom neural network. It must be a <code>keras.engine.sequential.Sequential</code> object in which the number of input neurons is equal to the number of considered features/genes, and the number of output neurons is equal to the number of cell types considered (NULL by default). If provided, the arguments related to the neural network architecture will be ignored.
shuffle	Boolean indicating whether data will be shuffled (TRUE by default). Note that if <code>bulk.simul</code> is not NULL, the data already has been shuffled and <code>shuffle</code> will be ignored.

threads	Number of threads used during simulation of pseudo-bulk samples if <code>on.the.fly = TRUE</code> (1 by default).
view.metrics.plot	Boolean indicating whether to show plots of loss and metrics progression during training (TRUE by default). keras for R allows to see the progression of the model during training if you are working in RStudio.
verbose	Boolean indicating whether to display model progression during training and model architecture information (TRUE by default).

Details

Keras/Tensorflow environment

All Deep Learning related steps in the **digitalDLorter** package are performed by using the **keras** package, an API in R for **keras** in Python available on CRAN. We recommend using the installation guide available at <https://keras.rstudio.com/> in order to set a more customized configuration.

Simulation of bulk RNA-Seq profiles 'on the fly'

`trainDigitalDLorterModel` allows to avoid storing bulk RNA-Seq profiles by using `on.the.fly` argument. This functionality aims to avoid execution times and memory usage of the `simBulkProfiles` function, as the simulated pseudo-bulk profiles are built in each batch during training/evaluation.

Neural network architecture

By default, `trainDigitalDLorterModel` implements the architecture selected in Torroja and Sánchez-Cabo, 2019. However, as the default architecture may not produce good results depending on the dataset, it is possible to change its parameters by using the corresponding argument: number of hidden layers, number of neurons for each hidden layer, dropout rate, activation function and loss function. For more customized models, it is possible to provide a pre-built model in the `custom.model` argument (a `keras.engine.sequential.Sequential` object) where it is necessary that the number of input neurons is equal to the number of considered features/genes and the number of output neurons is equal to the number of considered cell types.

Value

A `DigitalDLorter` object with `trained.model` slot containing a `DigitalDLorterDNN` object. For more information about the structure of this class, see `?DigitalDLorterDNN`.
