Ecological Models and Data

apply2d

Apply a function to a combination of vectors

Description

applies a (non-vectorized) function to a combination of vectors; substitute for outer

Usage

```
apply2d(fun, x, y, ...)
```

Arguments

fun	a function of two arguments (or a character string such as "*")
x	first vector
y	second vector
...	additional arguments to fun

Value

a matrix of the function applied to the combinations of the vector values

Author(s)

Ben Bolker

See Also

outer

Examples

```
outer(1:3,1:3)
## this example would work with outer() too
apply2d("*",1:3,1:3)
```

 as.mcmc.bugs

Convert WinBUGS output to CODA format

Description

Converts results of a bugs run (class "bugs") to a form that can be used by CODA (class "mcmc")

Usage

```
as.mcmc.bugs(x)
```

Arguments

x an object of class bugs (output from bugs())

Value

an object of class mcmc

Author(s)

Ben Bolker

calcslice

Negative log-likelihood slice

Description

Calculate the negative log-likelihood along a line connecting two mle fits

Usage

```
calcslice(fit1, fit2, fn = fit1@minuslogl, range = c(-0.1, 1.1), n = 400)
```

Arguments

fit1 An mle object
 fit2 Another mle object
 fn Negative log-likelihood function
 range Numeric vector: range of parameters to try, where 0 corresponds to coef(fit1)
 and 1 corresponds to coef(fit2)
 n Number of points to evaluate

Details

Calculates the negative log-likelihood (not a profile, just a "slice") along the line connecting the two sets of coefficients. Intended for diagnosing and visualizing multiple minima in a likelihood surface, especially in higher-dimensional models.

Value

x	Parameter values, along the 0-1 scale described above
y	Negative log-likelihood values

Author(s)

Ben Bolker

contour3d

Superimpose contour lines on a 3D plot

Description

Plot contour lines computed from data in 3D, or add them to an existing 3D (RGL) surface

Usage

```
contour3d(x, y, z, contourArgs=NULL, ...)
```

Arguments

x	numeric vector of x values (as in contour), or a list with components x, y and z
y	numeric vector of y values (as in contour)
z	numeric z matrix (as in contour)
contourArgs	list of arguments to contourLines
...	other arguments to lines3d

Value

Returns a list of contour lines (as in [contourLines](#)), invisibly.

Note

If you are superimposing the contour lines on a surface, it helps to draw the surface with some level of transparency (alpha parameter: see [material3d](#)) so the contour lines are not obscured by the surface.

Author(s)

Ben Bolker

credint *Calculate Bayesian credible intervals*

Description

Calculate Bayesian credible intervals based on various types of information about the posterior distribution

Usage

```
tcredint(dist, parlist, ranges, level = 0.95, eps = 1e-05, verbose=FALSE)
ncredint(pvec, npost, level=0.95, tol=0.01, verbose=FALSE)
```

Arguments

dist	character string giving the name of a distribution for which "d", "q", and "p" function exist, e.g. "beta"
parlist	list of parameters to pass to distribution functions
ranges	lower, middle, and upper values to bracket lower and upper boundaries of the credible interval
level	confidence level
eps	if ranges is missing, set lower and upper brackets to the eps and 1-eps quantiles of the distribution
tol	tolerance on credible interval
verbose	if TRUE, return detailed information on the probability cutoff and realized area of the credible interval; if FALSE, just lower and upper bounds of the credible region
...	additional arguments to density
pvec	numeric vector of parameter values
npost	numeric vector of posterior density values corresponding to pvec

Details

tcredint gives credible intervals for a theoretical posterior density with defined density, cumulative density, and quantile functions; ncredint gives credible intervals for a numerical posterior density.

Value

A numeric vector giving the credible interval. If verbose=FALSE, gives just lower and upper bounds; if verbose=TRUE, also gives information on the probability cutoff and realized area of the credible interval

Note

For credible intervals from a sample (e.g. from an MCMC run), see HPDinterval in the coda package.

Author(s)

Ben Bolker

Examples

```
tcredint("beta", list(shape1=5, shape2=10), verbose=TRUE)
pvec = seq(0,1,length=100)
postvec = dbeta(pvec, shape1=5, shape2=10)
ncredint(pvec, postvec, verbose=TRUE)
set.seed(1001)
```

curve3d

*Plot a 3D surface representing a 2D curve***Description**

Two-dimensional analogue of curve: generates a surface and plots it

Usage

```
curve3d(expr, from = c(0, 0), to = c(1, 1), n = c(41, 41),
xlim, ylim, add = FALSE,
xlab=varnames[1],
ylab=varnames[2],
zlab = NULL, log = NULL, sys3d = c("persp", "wireframe", "rgl",
"contour", "image", "none"),
varnames=c("x", "y"), ...)
```

Arguments

expr	a mathematical expression using x and y as the independent variables
from	minimum values for x and y
to	maximum values for x and y
xlim	range of values for x
ylim	range of values for y
n	number of grid points in each direction
add	(logical) add to an existing plot? (only possible for contour plots or rgl)
xlab	x label
ylab	y label
zlab	z label
log	(character): "x", "y", or "xy" for logarithmic axes
sys3d	3D plotting system to use: one of "persp", "wireframe", "rgl", "contour", "image", or "none"
varnames	names of variables to substitute
...	additional arguments to the plotting functions

Value

invisibly, a list of

x	x values
y	y values
z	z matrix

  varnames=c("a","b")) ## identical
x <- 4
curve3d(cos(2*pi*a/x)+y*sin(2*pi*b/y),
  from=c(0,0),to=c(1,1),sys3d="image",
  varnames=c("a","b"))
curve3d(cos(2*pi*x)+sin(2*pi*y/3),
  from=c(0,0),to=c(1,1),sys3d="image")
curve3d(cos(2*pi*x)+sin(2*pi*y/3),
  sys3d="contour",add=TRUE)
```

Damselfish

Reef fish (damselfish) data

Description

Two data sets on *Dascyllus trimaculatus* (three-spot damselfish), one on the distribution of settlement densities to empty anemones across time and space, the other on survival (recruitment) of arriving settlers as a function of experimentally manipulated densities from Schmitt et al. (1999)

Usage

```
data(DamselSettlement)
data(DamselRecruitment)
data(DamselRecruitment_sum)
```

Format

Three data frames:

```
site  settlement site (location)
pulse  monthly settlement pulse
obs  observation within pulse
density  density of settlers per 0.1 m2 anemone
area  anemone area in cm2
init  initial settler density
surv  surviving density after 6 months
settler.den  target experimental density of settlers on experimental anemones
surv.den  mean surviving density after 6 months, by target density
SE  standard error of survivor density, by target density
```

Source

dbetabinom

Beta-binomial distribution

Description

Density function and random variate generator for the beta-binomial function, parameterized in terms of probability and overdispersion

Usage

```
dbetabinom(x, prob, size, theta, shape1, shape2, log = FALSE)
rbetabinom(n, prob, size, theta, shape1, shape2)
```

Arguments

x	a numeric vector of values
prob	numeric vector: mean probability of underlying beta distribution
size	integer: number of samples
theta	overdispersion parameter
shape1	shape parameter of per-trial probability distribution
shape2	shape parameter of per-trial probability distribution
log	(logical) return log probability density?
n	integer number of random variates to return

Details

The beta-binomial distribution is the result of compounding a beta distribution of probabilities with a binomial sampling process. The density function is

$$p(x) = \frac{C(N, x) \text{Beta}(N - x + \theta(1 - p), x + \theta p)}{\text{Beta}(\theta(1 - p), \theta p)}$$

The parameters shape1 and shape2 are the more traditional parameterization in terms of the parameters of the per-trial probability distribution.

Value

A vector of probability densities or random deviates.

Note

Although the quantile (qbetabinom) and cumulative distribution (pbetabinom) functions are not available, in a pinch they could be computed from the pghyper and qghyper functions in the SuppDists package – provided that shape2 > 1. As described in ?pghyper, pghyper(q, a = -shape1, N = -shape1 - shape2, k = size) should give the cumulative distribution for the beta-binomial distribution with parameters (shape1, shape2, size), and similarly for qghyper. (Translation to the (theta, size, prob) parameterization is left as an exercise.)

Examples

```

set.seed(100)
n <- 9
z <- rbetabinom(1000, 0.5, size=n, theta=4)
plot(table(z)/length(z),ylim=c(0,0.34),col="gray",lwd=4)
points(0:n,dbinom(0:n,size=n,prob=0.5),col=2,pch=16,type="b")
points(0:n,dbetabinom(0:n,size=n,theta=4,
  prob=0.5),col=3,pch=17,type="b")
## correspondence with SuppDists
if (require(SuppDists)) {
  d1a = dghyper(0:5,a=-5,N=-10,k=5)
  d1b = dbetabinom(0:5,shape1=5,shape2=5,size=5)
  max(abs(d1a-d1b))
  p1a = pghyper(0:5,a=-5,N=-10,k=5,lower.tail=TRUE)
  p1b = cumsum(d1b)
  max(abs(p1a-p1b))
}

```

dchibarsq

*Mixed chi-squared distributions***Description**

Calculates "mixed" chi-squared distributions (mixtures of chi-square(n) and chi-square(n-1)); useful for Likelihood Ratio Tests when parameters are on the boundary

Usage

```

dchibarsq(x, df = 1, mix = 0.5, log = FALSE)
pchibarsq(p, df = 1, mix = 0.5, lower.tail=TRUE, log.p = FALSE)
qchibarsq(q, df = 1, mix = 0.5)
rchibarsq(n, df = 1, mix = 0.5)

```

Arguments

x	numeric vector of positive values
p	numeric vector of positive values
q	numeric vector of quantiles (0-1)
n	integer: number of random deviates to pick
df	degrees of freedom (positive integer)
mix	mixture parameter: fraction of distribution that is chi-square(n-1) distributed
log	return log densities?
log.p	return log probabilities?
lower.tail	return lower tail values?

Value

Vectors of probability densities (dchibarsq), cumulative probabilities (pchibarsq), quantiles (qchibarsq), or random deviates (rchibarsq) from Goldman and Whelan's "chi-bar-squared" distribution. qchibarsq uses simple algebra for $df=1$ and `uniroot` for $df>1$.

             distribution=qchibarsq,
             panel = function(x, ...) {
               panel.qqmathline(x, ...)
               panel.qqmath(x, ...)
             })))

## End(Not run)
## create first line of table in Goldman and Whelan 2000
round(qchibarsq(c(0.01, 0.05, 0.9, 0.95, 0.975, 0.99, 0.995), df=1), 2)
## check second line of table
round(pchibarsq(c(3.81, 5.14, 6.48, 8.27, 9.63), df=2), 3)
## create middle column
round(qchibarsq(0.95, df=1:10))
```

deltamethod

Delta method functions

Description

Delta-method implementations for Jensen's inequality and prediction uncertainty

Usage

```
deltamethod(fun, z, var = "x", params = NULL, max.order = 2)
deltavar(fun, meanval=NULL, vars, Sigma, verbose=FALSE)
```

Arguments

fun	Function of one (deltamethod) or more arguments, expressed in raw form (e.g. $a*x/(b+x)$)
z	numeric vector of values
var	variable name
vars	list of variable names
params	list or named numeric vector of parameter values to substitute
meanval	possibly named vector of mean values of parameters
Sigma	numeric vector of variances or variance-covariance matrix
max.order	maximum order of delta method to compute
verbose	print details?

Details

deltamethod() is for computing delta-method approximations of the mean of a function of data; deltavar() is for estimating variances of a function based on the mean values and variance-covariance matrix of the parameters. If Sigma is a vector, the parameters are assumed to be independently estimated.

Value

For deltavar(), a vector of predicted variances; for deltamethod() a vector containing the observed value of the function average, the function applied to the average, and a series of delta-method approximations

Author(s)

Ben Bolker

References

Lyons (1991), "A practical guide to data analysis for physical science students", Cambridge University Press

Examples

```
deltamethod(a*x/(b+x),runif(50),params=list(a=1,b=1),max.order=9)
deltavar(scale*gamma(1+1/shape),meanval=c(scale=0.8,shape=12),
  Sigma=matrix(c(0.015,0.125,0.125,8.97),nrow=2))
## more complex deltavar example
xvec = seq(-4,4,length=101)
x1 = xvec
x2 = xvec
v = matrix(0.2,nrow=3,ncol=3)
diag(v) = 1
m = c(b0=1,b1=1.5,b2=1)
v3 = deltavar(1/(1+exp(-(b0+b1*x1+b2*x2))),meanval=m,Sigma=v)
plot(xvec,v3)
```

deprecated *Deprecated (obsolete) functions*

Description

Functions that are obsolete for one reason or another

Author(s)

Ben Bolker

dmvnorm *Multivariate normal distribution density function*

Description

Calculates the probability density function of the multivariate normal distribution

Usage

```
dmvnorm(x, mu, Sigma, log = FALSE, tol = 1e-06)
```

Arguments

x	a vector or matrix of multivariate observations
mu	a vector or matrix of mean values
Sigma	a square variance-covariance matrix
log	(logical) return log-likelihood?
tol	tolerance for positive definiteness

Details

uses naive linear algebra – could probably use QR decomposition and/or crossprod.

Value

vector of log-likelihoods

Author(s)

Ben Bolker

See Also

[mvrnorm](#) (in MASS package), [dmvnorm](#) (in mvtnorm package)

Examples

```
M = matrix(c(1,0.5,0.5,0.5,1,0.5,0.5,0.5,1),nrow=3)
dmvnorm(1:3,mu=1:3,Sigma=M,log=TRUE)
dmvnorm(matrix(1:6,nrow=2),mu=1:3,Sigma=M,log=TRUE)
dmvnorm(matrix(1:6,nrow=2),mu=matrix(1:6,nrow=2),Sigma=M,log=TRUE)
```

dzinbinom

*Zero-inflated negative binomial distribution***Description**

Probability distribution function and random variate generation for the zero-inflated negative binomial distribution

Usage

```
dzinbinom(x, mu, size, zprob, log=FALSE)
rzinbinom(n, mu, size, zprob)
```

Arguments

x	vector of integer values
n	number of values to draw
mu	mean parameter (or vector of parameters) of negative binomial
size	number of trials/overdispersion parameter (or vector of parameters) of negative binomial
zprob	probability of structural zeros
log	return log probability?

Details

The zero-inflated negative binomial distribution is widely used to model extra zero counts in count data that otherwise follows a negative binomial distribution. The probability distribution is

$$p(0) = p_z + (1 - p_z)NB(0, \mu, k)$$

and

$$p(x) = (1 - p_z)NB(x, \mu, k)$$

for $x > 0$.

Value

Probabilities of x or random deviates.

Note

Only the "ecological" parameterization is included here (must specify mu, not prob)

get.emdbook.packages *install and update auxiliary packages*

Description

convenience function for downloading and installing all the packages needed for the book (just a list and a wrapper around [install.packages](#))

Usage

```
get.emdbook.packages()
```

Value

none: installs packages as a side effect

Author(s)

Ben Bolker

See Also

[install.packages](#)

`gridsearch2d`*Graphical grid search in 2D*

Description

Given an objective function and starting ranges, computes the values over the ranges and displays them in the graphics window. User can then interactively zoom in to view interesting parts of the surface.

Usage

```
gridsearch2d(fun, v1min, v2min, v1max, v2max, n1 = 20, n2 = 20, logz = FALSE, sys3d = c("both", "contour"))
```

Arguments

<code>fun</code>	Objective function to be minimized: function of two arguments
<code>v1min</code>	Minimum starting value of variable 1
<code>v2min</code>	Minimum starting value of variable 2
<code>v1max</code>	Maximum starting value of variable 1
<code>v2max</code>	Maximum starting value of variable 2
<code>n1</code>	Number of grid points for variable 1
<code>n2</code>	Number of grid points for variable 2
<code>logz</code>	Display image or contour on log scale?
<code>sys3d</code>	Display surface as an image, contour, or both?
<code>...</code>	Other arguments to fun

Details

If `log=TRUE`, the value of the surface is rescaled to $\log_{10}(m - \min(m) + \text{mindm})$, where `mindm` is the difference between the minimum and the next-largest value (or $1e-10$ if this difference is zero).

At each iteration, the user is prompted to select two corners of the new range with the mouse; if this choice is confirmed then the view zooms in. When the user chooses to quit, they are asked whether they want to choose a final point (e.g. an estimate of the minimum) with the mouse.

Value

If a final point is chosen, a list with elements `x` and `y`, otherwise `NULL`.

[curve3d](#)

`HPDregionplot`*Plot highest posterior density region*

Description

Given a sample from a posterior distribution (an `mcmc` object from the `coda` package), plot the bivariate region of highest marginal posterior density for two variables, using `kde2d` from `MASS` to calculate a bivariate density.

Usage

```
HPDregionplot(x, vars = 1:2, h, n = 50, lump = TRUE, prob = 0.95, xlab = NULL, ylab = NULL, ...)
```

Arguments

<code>x</code>	an <code>mcmc</code> or <code>mcmc.list</code> object
<code>vars</code>	which variables to plot: numeric or character vector
<code>h</code>	bandwidth of 2D kernel smoother (previous default value was <code>c(1,1)</code> , which worked poorly with some plots with very small scales; if not specified, defaults to values in kde2d)
<code>n</code>	number of points at which to evaluate the density grid
<code>lump</code>	if <code>x</code> is an <code>mcmc.list</code> object, lump the chains together for plotting?
<code>prob</code>	probability level
<code>xlab</code>	x axis label
<code>ylab</code>	y axis label
<code>...</code>	other arguments to contour

Details

Uses `kde2d` to calculate a bivariate density, then normalizes the plot and calculates the contour corresponding to a contained volume of `prob` of the total volume under the surface (a two-dimensional Bayesian credible region).

Value

Draws a plot on the current device, and invisibly returns a list of contour lines ([contourLines](#)).

Note

Accuracy may be limited by density estimation; you may need to tinker with `h` and `n` (see `kde2d` in the `MASS` package).

library(MASS)
library(coda)
z <- mvrnorm(1000,mu=c(0,0),Sigma=matrix(c(2,1,1,2),nrow=2))
z2 <- mvrnorm(1000,mu=c(0,0),Sigma=matrix(c(2,1,1,2),nrow=2))
HPDregionplot(mcmc(z))
HPDregionplot(mcmc.list(mcmc(z),mcmc(z2)))
```

lambertW

Lambert W function

Description

Computes the Lambert W function, giving efficient solutions to the equation $x \cdot \exp(x) = z$

Usage

```
lambertW_base(z, b = 0, maxiter = 10, eps = .Machine$double.eps, min.imag =
1e-09)
lWasymp(z, logz)
lambertW(z, ...)
```

Arguments

z	(complex) vector of values for which to compute the function
logz	(complex (?)) vector of $\log(z)$ values (to be specified by name instead of z)
b	(integer) b=0 specifies the principal branch, 0 and -1 are the ones that can take non-complex values
maxiter	maximum numbers of iterations for convergence
eps	convergence tolerance
min.imag	maximum magnitude of imaginary part to chop when returning solutions
...	arguments to pass to lambertW_base

Details

Compute the Lambert W function of z. This function satisfies $W(z) \exp(W(z)) = z$, and can thus be used to express solutions of transcendental equations involving exponentials or logarithms. For $z > 10^307$, an asymptotic formula (from Corless et al by way of <http://mathworld.wolfram.com/LambertW-Function.html>) is used: lambertW is a wrapper that automatically selects the asymptotic formula where appropriate.

- In ecology, the Lambert W can be used to solve the so-called "Rogers equation" for predator functional response with depletion.
- In epidemiology, the Lambert W function solves the final-size equation of a simple SIR epidemic model.

Value

Complex or real vector of solutions.

Note

This implementation should return values within $2.5 \cdot \text{eps}$ of its counterpart in Maple V, release 3 or later. Please report any discrepancies to the author or translator.

The derivative of the `lambertW` function is `plogis(-lambertW)`.

Author(s)

Nici Schraudolph <schraudo@inf.ethz.ch> (original version (c) 1998), Ben Bolker (R translation)

```

Lily

Glacier lily occurrence and fecundity data

Description

Data on sample quadrats of the glacier lily, *Erythronium grandiflorum*, from Thomson et al 1996

Usage

```
data(Lily_sum)
```

Format

```

x location of quadrat
y location of quadrat
flowers number of flowers
seedlings number of seedlings
vegetative number of vegetative plants
gopher index of gopher activity
rockiness rockiness index
moisture moisture index
flowcol inverse quintile of flowering plants

```

seedcol inverse quintile of seedlings
 vegcol inverse quintile of number of vegetative plants for image plots
 gophcol inverse quintile of gopher activity
 rockcol inverse quintile of rockiness
 moiscol inverse quintile of moisture

Details

16x16 grid of 2x2m quadrats in Washington Gulch, sampled 1992

Source

Thomson et al 1996, "Untangling multiple factors in spatial distributions", Ecology 77:1698-1715.
 Data from James D. Thomson, with file format conversion help from Jennifer Schmidt

Examples

```
data(Lily_sum)
par(mfrow=c(3,2))
for (i in 9:14) {
  image(matrix(Lily_sum[,i],nrow=16),main=names(Lily_sum)[i])
}
```

lseq

Log-spaced sequence

Description

Generates a logarithmically spaced sequence

Usage

```
lseq(from, to, length.out)
```

Arguments

from	starting value
to	ending value
length.out	number of intervening values

Details

lseq() is just a wrapper for `exp(seq(log(from), log(to), length.out = length.out))`

Value

logarithmically spaced sequence

Examples

```
lseq(10, 1000, 9)
```

`lump.mcmc.list`

Utility functions for mcmc objects

Description

Creates traceplots or combine mcmc list into mcmc objects

Usage

```
lump.mcmc.list(x)
```

Arguments

`x` an `mcmc.list` object

Value

a single mcmc object with the chains lumped together

Author(s)

coda package

metropSB

*Metropolis-Szymura-Barton algorithm***Description**

Stochastic global optimization using the Metropolis-Szymura-Barton algorithm. New parameters are chosen from a uniform candidate distribution with an adaptively tuned scale, and accepted or rejected according to a Metropolis rule.

Usage

```
metropSB(fn, start, deltap = NULL, scale = 1, rptfreq = -1, acceptscale
= 1.01, rejectscale = 0.99, nmax = 10000,
retvals = FALSE, retfreq = 100, verbose = FALSE, ...)
```

Arguments

fn	Objective function, taking a vector of parameters as its first argument. The function is minimized, so it should be a negative log-likelihood or a negative log-posterior density.
start	Vector of starting values
deltap	Starting jump size; half-width of uniform distribution
scale	Scaling factor for acceptance
rptfreq	Frequency for reporting interim results (<0 means no reporting)
acceptscale	Amount to inflate candidate distribution if last jump was accepted
rejectscale	Amount to shrink candidate distribution if last jump was rejected
nmax	Number of iterations
retvals	Return detailed statistics?
retfreq	Sampling frequency for detailed statistics
verbose	Print status?
...	Other arguments to fn

Details

Metropolis-Szymura-Barton algorithm: given function and starting value, try to find parameters that minimize the function Algorithm: at a given step, 1. pick a new set of parameters, each of which is uniformly distributed in $(p[i]-deltap[i], p[i]+deltap[i])$ 2. calculate function value at new parameter values 3. if $f(\text{new}) < f(\text{old})$, accept 4. if $f(\text{new}) > f(\text{old})$, accept with probability $(\exp(-scale * (f(\text{new}) - f(\text{old}))))$ 5. if accept, increase all deltap values by `acceptscale`; if reject, decrease by `rejectscale` 6. if better than min so far, save function and parameter values 7. if reject, restore old values

Value

minimum	minimum value achieved
estimate	parameters corresponding to minimum
funcalls	number of function evaluations
If retvals=TRUE:	
retvals	matrix of periodic samples including parameters, jump scale, current value, and minimum achieved value

Note

If scale=1 the algorithm satisfies MCMC rules, provided that the other properties of the MC (irreducibility and aperiodicity) are satisfied.

Myxo

Myxomatosis titer data

Description

Myxomatosis viral titer in blood samples from European rabbits, as a function of day-of-infection and virus grade, from Dwyer et al. 1990, ultimately from Fenner et al. 1956

Usage

```
data(MyxoTiter_sum)
```

Format

```
grade virus grade (1, least virulent; 5, most virulent)
day day of infection
titer blood virus titer (in log10 rabbit infectious doses)
```

Note

Pulled graphically from figure in Dwyer et al.; to be replaced (eventually) with original tabular data in Fenner et al.

Source

Dwyer, Levin and Buttel, "A Simulation Model of the Population Dynamics and Evolution of Myxomatosis", Ecological Monographs 60(4):423-447 (1990). Original source: Fenner et al. 1956

Examples

```
data(MyxoTiter_sum)
library(lattice)
xyplot(titer~day|factor(grade),data=MyxoTiter_sum,xlim=c(0,30))
```

perturb.params

Create a list of perturbed parameters

Description

Takes a baseline set of parameters and perturbs it to create a variety of starting points for maximum likelihood estimation or MCMC

Usage

```
perturb.params(base, alt, which, mult = FALSE, use.base = TRUE)
```

Arguments

base	a named list (or vector) of parameters
alt	a list of lists (or vectors) of alternative parameter values or multipliers
which	which parameters to perturb (currently unused)
mult	(logical) multiply baseline values rather than replacing them?
use.base	(logical) include baseline parameters in the list?

Details

Takes the baseline parameter list and substitutes alternative values.

Value

A list of named lists of parameters.

Note

To be extended.

Author(s)

Ben Bolker

Examples

```
perturb.params(list(x=1,y=2,z=3),alt=list(x=c(2,4),z=5))
```

Reedfrog

*Data on reed frog predation experiments***Description**

Data on lab experiments on the density- and size-dependent predation rate of an African reed frog, *Hyperolius spinigularis*, from Vonesh and Bolker 2005

Usage

```
data(ReedfrogPred)
data(ReedfrogSizepred)
data(ReedfrogFuncresp)
```

Format

Various data with variables:

density initial tadpole density (number of tadpoles in a 1.2 x 0.8 x 0.4 m tank) [experiment 1]

pred factor: predators present or absent [experiment 1]

size factor: big or small tadpoles [experiment 1]

surv number surviving

propsurv proportion surviving (=surv/density) [experiment 1]

TBL tadpole body length in mm [size-predation experiment]

Kill number killed out of 10, in 3 days [size-predation]

Initial initial number/density (300 L tank) [functional response]

Killed number killed by 3 dragonfly larvae in 14 days [functional response]

Source

Vonesh and Bolker (2005) Compensatory larval responses shift trade-offs associated with predator-induced hatching plasticity. *Ecology* 86:1580-1591

Examples

```
data(ReedfrogPred)
boxplot(propsurv~size*density*pred,data=ReedfrogPred)
data(ReedfrogSizepred)
data(ReedfrogFuncresp)
```

 scinot

Scientific notation as LaTeX/expression()

Description

Takes a number and returns a version formatted in LaTeX (suitable for use with `Sexpr()` in an Sweave document) or in `expression()` (suitable for plotting), or plots an axis with labels in scientific notation

Usage

```
scinot(x, format = c("latex", "expression"), delim="$",
pref="", ...)
axis.scinot(side,at)
```

Arguments

<code>x</code>	a numeric vector (of length 1)
<code>format</code>	produce LaTeX or <code>expression()</code> format?
<code>delim</code>	delimiter to add at beginning and end (latex only)
<code>pref</code>	text to put before expression (expression only)
<code>side</code>	side on which to plot axis
<code>at</code>	list of locations/labels
<code>...</code>	additional arguments to <code>formatC</code>

Value

a character vector (if latex) or `expression` (if `expression`); `axis.scinot` draws an axis on the current plot

Author(s)

Ben Bolker

See Also

[formatC](#), [expression](#), [plotmath](#), [axis](#), [axTicks](#), `latexSN` in the `Hmisc` package, `eaxis` in the `sfsmisc` package

Examples

```
scinot(1e-5)
scinot(1e-5,digits=0)
scinot(1e-5,"expression")
scinot(1e-5,"expression",pref="p=")
set.seed(1001)
```

```
plot(1:100,rlnorm(100,0,2),log="y",axes=FALSE)
axis(side=1)
axis.scinot(side=2) ## fix bug!
```

SeedPred

Seed predation data set from Duncan and Duncan 2000

Description

Data on seed predation over time from Duncan and Duncan (2000)

Usage

```
data(SeedPred)
data(SeedPred_wide)
data(SeedPred_mass)
```

Format

station a factor specifying the station number
species a factor with levels abz cd cor dio mmu pol psd uva
date sample date
seeds number of seeds present
tcum cumulative time elapsed
tint time since last sample
taken seeds removed since last sample
dist distance from forest edge (m)

Details

SeedPred is in long format, SeedPred_wide is in wide format; SeedPred_wide has lots of NA values because stations at 10 and 25 m from the forest were sampled on different days. SeedPred_mass is a numeric vector containing the approximate seed masses for each species.

Source

R. Scot Duncan and Virginia E. Duncan (2000) Forest Succession and Distance from Forest Edge in an Afro-Tropical Grassland, *Biotropica* 32(1):33-41. (Data from Scot Duncan.)

Examples

```
data(SeedPred)
```

trcoef	<i>Transform coefficients</i>
--------	-------------------------------

Description

Perform standard transformations of coefficients based on information encoded in the names or the `transf` attribute of the vector or list

Usage

```
trcoef(x, inverse = FALSE)
```

Arguments

<code>x</code>	A numeric vector of coefficients with names and/or a <code>transf</code> attribute
<code>inverse</code>	(logical) Perform inverse transform?

Details

If `inverse=FALSE` and coefficient names begin with "logit", "log", or "sqrt" the function will back-transform them (using `plogis`, `exp`, or squaring), strip the descriptor from the names, and set the `transf` attribute. Naturally, `inverse=TRUE` will do the opposite. If the `transf` attribute is all empty strings after an inverse transformation, it will be deleted.

Value

A vector of transformed variables with modified names and `transf` attributes.

Author(s)

Ben Bolker

Examples

```
x = c(loga=1, logitb=2, sqrtc=2)
trx = trcoef(x); trx
trcoef(trx, inverse=TRUE)
```
