

Package ‘entropy’

February 19, 2015

Version 1.2.1

Date 2014-11-14

Title Estimation of Entropy, Mutual Information and Related Quantities

Author Jean Hausser and Korbinian Strimmer

Maintainer Korbinian Strimmer <strimmerlab@gmail.com>

Depends R (>= 2.15.1)

Suggests

Description This package implements various estimators of entropy, such as the shrinkage estimator by Hausser and Strimmer, the maximum likelihood and the Millow-Madow estimator, various Bayesian estimators, and the Chao-Shen estimator. It also offers an R interface to the NSB estimator. Furthermore, it provides functions for estimating Kullback-Leibler divergence, chi-squared, mutual information, and chi-squared statistic of independence. In addition there are functions for discretizing continuous random variables.

entropy-package	<i>The entropy Package</i>
-----------------	----------------------------

Description

This package implements various estimators of the Shannon entropy. Most estimators in this package can be applied in “small n, large p” situations, i.e. when there are many more bins than counts.

The main function of this package is `entropy`, which provides a unified interface to various entropy estimators. Other functions included in this package are estimators of Kullback-Leibler divergence (`KL.plugin`) and of mutual information (`mi.plugin`).

If you use this package please cite: Jean Hausser and Korbinian Strimmer. 2009. Entropy inference and the James-Stein estimator, with application to nonlinear gene association networks. *J. Mach. Learn. Res.* **10**: 1469-1484. Available online from <http://jmlr.csail.mit.edu/papers/v10/hausser09a.html>.

This paper contains a detailed statistical comparison of the estimators available in this package. It also describes the shrinkage entropy estimator `entropy.shrink`.

`entropy`

discretize	<i>Discretize Continuous Random Variables</i>
------------	---

Description

`discretize` puts observations from a continuous random variable into bins and returns the corresponding vector of counts.

`discretize2d` puts observations from a pair of continuous random variables into bins and returns the corresponding table of counts.

Usage

```
discretize( x, numBins, r=range(x) )  
discretize2d( x1, x2, numBins1, numBins2, r1=range(x1), r2=range(x2) )
```

Arguments

x	vector of observations.
x1	vector of observations for the first random variable.
x2	vector of observations for the second random variable.
numBins	number of bins.
numBins1	number of bins for the first random variable.
numBins2	number of bins for the second random variable.
r	range of the random variable (default: observed range).
r1	range of the first random variable (default: observed range).
r2	range of the second random variable (default: observed range).

Details

The bins for a random variable all have the same width. It is determined by the length of the range divided by the number of bins.

Value

discretize returns a vector containing the counts for each bin.
discretize2d returns a matrix containing the counts for each bin.

### 1D example ###  
  
# sample from continuous uniform distribution  
x1 = runif(10000)  
hist(x1, xlim=c(0,1), freq=FALSE)  
  
# discretize into 10 categories  
y1 = discretize(x1, numBins=10, r=c(0,1))
```

```

y1

# compute entropy from counts
entropy(y1) # empirical estimate near theoretical maximum
log(10) # theoretical value for discrete uniform distribution with 10 bins

# sample from a non-uniform distribution
x2 = rbeta(10000, 750, 250)
hist(x2, xlim=c(0,1), freq=FALSE)

# discretize into 10 categories and estimate entropy
y2 = discretize(x2, numBins=10, r=c(0,1))
y2
entropy(y2) # almost zero

### 2D example ###

# two independent random variables
x1 = runif(10000)
x2 = runif(10000)

y2d = discretize2d(x1, x2, numBins1=10, numBins2=10)
sum(y2d)

# joint entropy
H12 = entropy(y2d )
H12
log(100) # theoretical maximum for 10x10 table

# mutual information
mi.empirical(y2d) # approximately zero

# another way to compute mutual information

# compute marginal entropies
H1 = entropy(rowSums(y2d))
H2 = entropy(colSums(y2d))

H1+H2-H12 # mutual entropy

```

entropy

Estimating Entropy From Observed Counts

Description

entropy estimates the Shannon entropy H of the random variable Y from the corresponding observed counts y .

freqs estimates bin frequencies from the counts y .

Usage

```
entropy(y, lambda.freqs, method=c("ML", "MM", "Jeffreys", "Laplace", "SG",
  "minimax", "CS", "NSB", "shrink"), unit=c("log", "log2", "log10"), verbose=TRUE, ...)
freqs(y, lambda.freqs, method=c("ML", "MM", "Jeffreys", "Laplace", "SG",
  "minimax", "CS", "NSB", "shrink"), verbose=TRUE)
```

Arguments

y	vector of counts.
method	the method employed to estimate entropy (see Details).
unit	the unit in which entropy is measured. The default is "nats" (natural units). For computing entropy in "bits" set unit="log2".
lambda.freqs	shrinkage intensity (for "shrink" option).
verbose	verbose option (for "shrink" option).
...	option passed on to entropy.NSB .

Details

The entropy function allows to estimate entropy from observed counts by a variety of methods:

- method="ML": maximum likelihood, see [entropy.empirical](#)
- method="MM": bias-corrected maximum likelihood, see [entropy.MillerMadow](#)
- method="Jeffreys": [entropy.Dirichlet](#) with $a=1/2$
- method="Laplace": [entropy.Dirichlet](#) with $a=1$
- method="SG": [entropy.Dirichlet](#) with $a=1/\text{length}(y)$
- method="minimax": [entropy.Dirichlet](#) with $a=\sqrt{\text{sum}(y)}/\text{length}(y)$
- method="CS": see [entropy.ChaoShen](#)
- method="NSB": see [entropy.NSB](#)
- method="shrink": see [entropy.shrink](#)

The freqs function estimates the underlying bin frequencies. Note that estimated frequencies are not available for method="MM", method="CS" and method="NSB". In these instances a vector containing NAs is returned.

Value

entropy returns an estimate of the Shannon entropy.

freqs returns a vector with estimated bin frequencies (if available).

Author(s)

Korbinian Strimmer (<http://strimmerlab.org>).

```

entropy.ChaoShen *Chao-Shen Entropy Estimator*

Description

entropy.ChaoShen estimates the Shannon entropy H of the random variable Y from the corresponding observed counts y using the method of Chao and Shen (2003).

Usage

```
entropy.ChaoShen(y, unit=c("log", "log2", "log10"))
```

Arguments

<code>y</code>	vector of counts.
<code>unit</code>	the unit in which entropy is measured. The default is "nats" (natural units). For computing entropy in "bits" set <code>unit="log2"</code> .

Details

The Chao-Shen entropy estimator (2003) is a Horvitz-Thompson (1952) estimator applied to the problem of entropy estimation, with additional coverage correction as proposed by Good (1953).

Note that the Chao-Shen estimator is not a plug-in estimator, hence there are no explicit underlying bin frequencies.

Value

entropy.ChaoShen returns an estimate of the Shannon entropy.

Author(s)

Korbinian Strimmer (<http://strimmerlab.org>).

entropy.Dirichlet	<i>Dirichlet Prior Bayesian Estimators of Entropy, Mutual Information and Other Related Quantities</i>
-------------------	--

Description

freqs.Dirichlet computes the Bayesian estimates of the bin frequencies using the Dirichlet-multinomial pseudocount model.

entropy.Dirichlet estimates the Shannon entropy H of the random variable Y from the corresponding observed counts y by plug-in of Bayesian estimates of the bin frequencies using the Dirichlet-multinomial pseudocount model.

KL.Dirichlet computes a Bayesian estimate of the Kullback-Leibler (KL) divergence from counts y_1 and y_2 .

chi2.Dirichlet computes a Bayesian version of the chi-squared statistic from counts y_1 and y_2 .

mi.Dirichlet computes a Bayesian estimate of mutual information of two random variables.

chi2indep.Dirichlet computes a Bayesian version of the chi-squared statistic of independence from a table of counts y_{2d} .

Usage

```

freqs.Dirichlet(y, a)
entropy.Dirichlet(y, a, unit=c("log", "log2", "log10"))
KL.Dirichlet(y1, y2, a1, a2, unit=c("log", "log2", "log10"))
chi2.Dirichlet(y1, y2, a1, a2, unit=c("log", "log2", "log10"))
mi.Dirichlet(y2d, a, unit=c("log", "log2", "log10"))
chi2indep.Dirichlet(y2d, a, unit=c("log", "log2", "log10"))

```

Arguments

y	vector of counts.
y1	vector of counts.
y2	vector of counts.
y2d	matrix of counts.
a	pseudocount per bin.
a1	pseudocount per bin for first random variable.
a2	pseudocount per bin for second random variable.
unit	the unit in which entropy is measured. The default is "nats" (natural units). For computing entropy in "bits" set unit="log2".

Details

The Dirichlet-multinomial pseudocount entropy estimator is a Bayesian plug-in estimator: in the definition of the Shannon entropy the bin probabilities are replaced by the respective Bayesian estimates of the frequencies, using a model with a Dirichlet prior and a multinomial likelihood.

The parameter a is a parameter of the Dirichlet prior, and in effect specifies the pseudocount per bin. Popular choices of a are:

- a=0: maximum likelihood estimator (see [entropy.empirical](#))
- a=1/2: Jeffreys' prior; Krichevsky-Trovimov (1991) entropy estimator
- a=1: Laplace's prior
- a=1/length(y): Schurmann-Grassberger (1996) entropy estimator
- a=sqrt(sum(y))/length(y): minimax prior

The pseudocount a can also be a vector so that for each bin an individual pseudocount is added.

Value

freqs.Dirichlet returns the Bayesian estimates of the frequencies .

entropy.Dirichlet returns the Bayesian estimate of the Shannon entropy.

KL.Dirichlet returns the Bayesian estimate of the KL divergence.

chi2.Dirichlet returns the Bayesian version of the chi-squared statistic.

mi.Dirichlet returns the Bayesian estimate of the mutual information.

chi2indep.Dirichlet returns the Bayesian version of the chi-squared statistic of independence.

# half of the Bayesian chi-squared statistic of independence
0.5*chi2indep.Dirichlet(y2d, a=1/6)

```

entropy.empirical	<i>Empirical Estimators of Entropy and Mutual Information and Related Quantities</i>
-------------------	--

Description

freqs.empirical computes the empirical frequencies from counts y .

entropy.empirical estimates the Shannon entropy H of the random variable Y from the corresponding observed counts y by plug-in of the empirical frequencies.

KL.empirical computes the empirical Kullback-Leibler (KL) divergence from counts y_1 and y_2 .

chi2.empirical computes the empirical chi-squared statistic from counts y_1 and y_2 .

mi.empirical computes the empirical mutual information from a table of counts y_{2d} .

chi2indep.empirical computes the empirical chi-squared statistic of independence from a table of counts y_{2d} .

Usage

```

freqs.empirical(y)
entropy.empirical(y, unit=c("log", "log2", "log10"))
KL.empirical(y1, y2, unit=c("log", "log2", "log10"))
chi2.empirical(y1, y2, unit=c("log", "log2", "log10"))
mi.empirical(y2d, unit=c("log", "log2", "log10"))
chi2indep.empirical(y2d, unit=c("log", "log2", "log10"))

```

Arguments

y	vector of counts.
y1	vector of counts.
y2	vector of counts.
y2d	matrix of counts.
unit	the unit in which entropy is measured. The default is "nats" (natural units). For computing entropy in "bits" set unit="log2".

Details

The empirical entropy estimator is a plug-in estimator: in the definition of the Shannon entropy the bin probabilities are replaced by the respective empirical frequencies.

The empirical entropy estimator is the maximum likelihood estimator. If there are many zero counts and the sample size is small it is very inefficient and also strongly biased.

Value

freqs.empirical returns the empirical frequencies.

entropy.empirical returns an estimate of the Shannon entropy.

KL.empirical returns an estimate of the KL divergence.

chi2.empirical returns the empirical chi-squared statistic.

mi.empirical returns an estimate of the mutual information.

chi2indep.empirical returns the empirical chi-squared statistic of independence.

Author(s)

Korbinian Strimmer (<http://strimmerlab.org>).

```

entropy.MillerMadow *Miller-Madow Entropy Estimator*

Description

entropy.MillerMadow estimates the Shannon entropy H of the random variable Y from the corresponding observed counts y using the Miller-Madow correction to the empirical entropy).

Usage

```
entropy.MillerMadow(y, unit=c("log", "log2", "log10"))
```

Arguments

<code>y</code>	vector of counts.
<code>unit</code>	the unit in which entropy is measured. The default is "nats" (natural units). For computing entropy in "bits" set <code>unit="log2"</code> .

Details

The Miller-Madow entropy estimator (1955) is the bias-corrected empirical entropy estimate.

Note that the Miller-Madow estimator is not a plug-in estimator, hence there are no explicit underlying bin frequencies.

Value

entropy.MillerMadow returns an estimate of the Shannon entropy.

Author(s)

Korbinian Strimmer (<http://strimmerlab.org>).

entropy.NSB

R Interface to NSB Entropy Estimator

Description

entropy.NSB estimates the Shannon entropy H of the random variable Y from the corresponding observed counts y using the method of Nemenman, Shafee and Bialek (2002).

Note that this function is an R interface to the "nsb-entropy" program. Hence, this needs to be installed separately from <http://nsb-entropy.sourceforge.net/>.

Usage

```
entropy.NSB(y, unit=c("log", "log2", "log10"), CMD="nsb-entropy")
```

Arguments

y	vector of counts.
unit	the unit in which entropy is measured. The default is "nats" (natural units). For computing entropy in "bits" set unit="log2".
CMD	path to the "nsb-entropy" executable.

Details

The NSB estimator is due to Nemenman, Shafee and Bialek (2002). It is a Dirichlet-multinomial entropy estimator, with a hierarchical prior over the Dirichlet pseudocount parameters.

Note that the NSB estimator is not a plug-in estimator, hence there are no explicit underlying bin frequencies.

Value

entropy.NSB returns an estimate of the Shannon entropy.

Author(s)

Jean Hausser.

```

entropy.plugin	<i>Plug-In Entropy Estimator</i>
----------------	----------------------------------

Description

entropy.plugin computes the Shannon entropy H of a discrete random variable from the specified bin frequencies.

Usage

```
entropy.plugin(freqs, unit=c("log", "log2", "log10"))
```

Arguments

freqs	bin frequencies.
unit	the unit in which entropy is measured. The default is "nats" (natural units). For computing entropy in "bits" set unit="log2".

Details

The Shannon entropy of a discrete random variable is defined as $H = -\sum p(x_i) \log(p(x_i))$, where $p(x_i)$ are the bin probabilities.

Value

entropy.plugin returns the Shannon entropy.

Author(s)

Korbinian Strimmer (<http://strimmerlab.org>).

entropy.plugin(freqs)
```

entropy.shrink	<i>Shrinkage Estimators of Entropy, Mutual Information and Related Quantities</i>
----------------	---

Description

freq.shrink estimates the bin frequencies from the counts `y` using a James-Stein-type shrinkage estimator, where the shrinkage target is the uniform distribution.

entropy.shrink estimates the Shannon entropy H of the random variable Y from the corresponding observed counts `y` by plug-in of shrinkage estimate of the bin frequencies.

KL.shrink computes a shrinkage estimate of the Kullback-Leibler (KL) divergence from counts `y1` and `y2`.

chi2.shrink computes a shrinkage version of the chi-squared statistic from counts `y1` and `y2`.

mi.shrink estimates a shrinkage estimate of mutual information of two random variables.

chi2indep.shrink computes a shrinkage version of the chi-squared statistic of independence from a table of counts `y2d`.

Usage

```
freqs.shrink(y, lambda.freqs, verbose=TRUE)
entropy.shrink(y, lambda.freqs, unit=c("log", "log2", "log10"), verbose=TRUE)
KL.shrink(y1, y2, lambda.freqs1, lambda.freqs2, unit=c("log", "log2", "log10"),
          verbose=TRUE)
chi2.shrink(y1, y2, lambda.freqs1, lambda.freqs2, unit=c("log", "log2", "log10"),
            verbose=TRUE)
mi.shrink(y2d, lambda.freqs, unit=c("log", "log2", "log10"), verbose=TRUE)
chi2indep.shrink(y2d, lambda.freqs, unit=c("log", "log2", "log10"), verbose=TRUE)
```

Arguments

<code>y</code>	vector of counts.
<code>y1</code>	vector of counts.
<code>y2</code>	vector of counts.
<code>y2d</code>	matrix of counts.
<code>unit</code>	the unit in which entropy is measured. The default is "nats" (natural units). For computing entropy in "bits" set <code>unit="log2"</code> .
<code>lambda.freqs</code>	shrinkage intensity. If not specified (default) it is estimated in a James-Stein-type fashion.
<code>lambda.freqs1</code>	shrinkage intensity for first random variable. If not specified (default) it is estimated in a James-Stein-type fashion.
<code>lambda.freqs2</code>	shrinkage intensity for second random variable. If not specified (default) it is estimated in a James-Stein-type fashion.
<code>verbose</code>	report shrinkage intensity.

Details

The shrinkage estimator is a James-Stein-type estimator. It is essentially a [entropy.Dirichlet](#) estimator, where the pseudocount is estimated from the data.

For details see Hausser and Strimmer (2009).

Value

`freqs.shrink` returns a shrinkage estimate of the frequencies.

`entropy.shrink` returns a shrinkage estimate of the Shannon entropy.

`KL.shrink` returns a shrinkage estimate of the KL divergence.

`chi2.shrink` returns a shrinkage version of the chi-squared statistic.

`mi.shrink` returns a shrinkage estimate of the mutual information.

`chi2indep.shrink` returns a shrinkage version of the chi-squared statistic of independence.

In all instances the estimated shrinkage intensity is attached to the returned value as attribute `lambda.freqs`.

```

KL.plugin

Plug-In Estimator of the Kullback-Leibler divergence and of the Chi-Squared Statistic

Description

KL.plugin computes the Kullback-Leiber (KL) divergence from random variable X_1 to X_2 . The corresponding probability mass functions are given by freqs1 and freqs2, and the expectation is computed over freqs1.

chi2.plugin computes the chi-squared statistic between an observed X_1 and an expected X_2 , where freqs1 and freqs2 are the corresponding probability mass functions.

Usage

```

KL.plugin(freqs1, freqs2, unit=c("log", "log2", "log10"))
chi2.plugin(freqs1, freqs2, unit=c("log", "log2", "log10"))

```

Arguments

freqs1	bin frequencies for variable X_1 .
freqs2	bin frequencies for variable X_2 .
unit	the unit in which entropy is measured. The default is "nats" (natural units). For computing entropy in "bits" set unit="log2".

Details

Kullback-Leibler divergence between the from random variable X_1 to X_2 is given as $E_{X_1} \log(f(x_1)/f(x_2))$.

The chi-squared statistic is given $\sum(f(x_1) - f(x_2))^2 / f(x_2)$. It can also be seen as a second-order accurate approximation of twice the KL divergence.

Note that both the KL divergence and the chi-squared statistic are not symmetric in X_1 and X_2 .

Value

KL.plugin returns the KL divergence.

chi2.plugin returns the chi-squared statistic.

Examples

```
# load entropy library
library("entropy")

# probabilities for two random variables
freqs1 = c(1/5, 1/5, 3/5)
freqs2 = c(1/10, 4/10, 1/2)

# KL divergence from X1 to X2
KL.plugin(freqs1, freqs2)

# and corresponding (half) chi-squared statistic
0.5*chi2.plugin(freqs1, freqs2)
```

mi.plugin

*Plug-In Estimator of Mutual Information and of the Chi-Squared
Statistic of Independence*

Description

mi.plugin computes the mutual information of two discrete random variables from the specified joint bin frequencies.

chi2indep.plugin computes the chi-squared statistic of independence.

Usage

```
mi.plugin(freqs2d, unit=c("log", "log2", "log10"))
chi2indep.plugin(freqs2d, unit=c("log", "log2", "log10"))
```

Arguments

freqs2d	matrix of joint bin frequencies.
unit	the unit in which entropy is measured. The default is "nats" (natural units). For computing entropy in "bits" set unit="log2".

Details

The mutual information of two random variables X and Y is the Kullback-Leibler divergence between the joint density/probability mass function and the product independence density of the marginals.

It can also be defined using entropy as $MI = H(X) + H(Y) - H(X, Y)$.

Similarly, the chi-squared statistic of independence is the chi-squared statistic between the joint density and the product density. It is a second-order accurate approximation of twice the mutual information.

Value

mi.plugin returns the mutual information.

chi2indep.plugin returns the chi-squared statistic of independence.

Examples

```
# load entropy library
library("entropy")

# joint distribution of two discrete variables
freqs2d = rbind( c(0.2, 0.1, 0.15), c(0.1, 0.2, 0.25) )

# corresponding mutual information
mi.plugin(freqs2d)

# MI computed via entropy
H1 = entropy.plugin(rowSums(freqs2d))
H2 = entropy.plugin(colSums(freqs2d))
H12 = entropy.plugin(freqs2d)
H1+H2-H12
```

```
# and corresponding (half) chi-squared statistic of independence  
0.5*chi2indep.plugin(freqs2d)
```
