Package ‘huge’

February 20, 2015

Type Package
Title High-dimensional Undirected Graph Estimation
Version 1.2.6
Date 2014-02-16
Author Tuo Zhao, Han Liu, Kathryn Roeder, John Lafferty, Larry Wasserman
Maintainer Tuo Zhao <tzhao5@jhu.edu>
Depends R (>= 3.0.0), Matrix, lattice, igraph, MASS
Description The package `huge` provides a general framework for high-dimensional undirected graph estimation. It integrates data preprocessing, neighborhood screening, graph estimation, and model selection techniques into a pipeline. In preprocessing stage, the nonparanormal(npn) transformation is applied to help relax the normality assumption. In the graph estimation stage, the graph structure is estimated by Meinshausen-Buhlmann graph estimation or the graphical lasso, and both methods can be further accelerated by the lossy screening rule preselecting the neighborhood of each variable by correlation thresholding. We target on high-dimensional data analysis usually $d >> n$, and the computation is memory-optimized using the sparse matrix output. We also provide a computationally efficient approach, correlation thresholding graph estimation. Three regularization/thresholding parameter selection methods are included in this package: (1) stability approach for regularization selection (2) rotation information criterion (3) extended Bayesian information criterion which is only available for the graphical lasso.

The package "huge" provides 8 main functions:
(1) the data generator creates random samples from multivariate normal distributions with different graph structures. Please refer to `huge.generator`.
(2) the nonparanormal (npn) transformation helps relax the normality assumption. Please refer to `huge.npn`.
(3) The correlation thresholding graph estimation. Please refer to `huge`.
(4) The Meinshausen-Buhlmann graph estimation. Please refer to `huge`.
(5) The graphical Lasso algorithm using lossless screening rule. Please refer and `huge`. 
**Both (4) and (5) can be further accelerated by the lossy screening rule preselecting the neighborhood of each node via thresholding sample correlation.**

(6) The model selection using the stability approach to regularization selection. Please refer to `huge.select`.

(7) The model selection using the rotation information criterion. Please refer to `huge.select`.

(8) The model selection using the extended Bayesian information criterion. Please refer to `huge.select`.

**Description**

The main function for high-dimensional undirected graph estimation. Three graph estimation methods, including (1) Meinshausen-Buhlmann graph estimation (mb) (2) graphical lasso (glasso) and (3) correlation thresholding graph estimation (ct), are available for data analysis.

**Usage**

```
huge(x, lambda = NULL, nlambda = NULL, lambda.min.ratio = NULL, method = "mb", scr = NULL, scr.num = NULL, cov.output = FALSE, sym = "or", verbose = TRUE)
```

**Arguments**

- **x**: There are 2 options: (1) x is an n by d data matrix (2) a d by d sample covariance matrix. The program automatically identifies the input matrix by checking the symmetry. (n is the sample size and d is the dimension).

- **lambda**: A sequence of decreasing positive numbers to control the regularization when method = "mb" or "glasso", or the thresholding in method = "ct". Typical usage is to leave the input lambda = NULL and have the program compute its own lambda sequence based on nlambda and lambda.min.ratio. Users can also specify a sequence to override this. When method = "mb" or "glasso", use with care - it is better to supply a decreasing sequence values than a single (small) value.

- **nlambda**: The number of regularization/thresholding parameters. The default value is 30 for method = "ct" and 10 for method = "mb" or "glasso".

- **lambda.min.ratio**: If method = "mb" or "glasso", it is the smallest value for lambda, as a fraction of the upperbound (MAX) of the regularization/thresholding parameter which makes all estimates equal to 0. The program can automatically generate lambda as a sequence of length = nlambda starting from MAX to lambda.min.ratio*MAX in log scale. If method = "ct", it is the largest sparsity level for estimated graphs. The program can automatically generate lambda as a sequence of length = nlambda, which makes the sparsity level of the graph path increases from 0 to lambda.min.ratio evenly. The default value is 0.1 when method = "mb" or "glasso", and 0.05 method = "ct".

- **method**: Graph estimation methods with 3 options: "mb", "ct" and "glasso". The default value is "mb".

- **scr**: If scr = TRUE, the lossy screening rule is applied to preselect the neighborhood before the graph estimation. The default value is FALSE. NOT applicable when method = "ct".

- **scr.num**: The neighborhood size after the lossy screening rule (the number of remaining neighbors per node). ONLY applicable when scr = TRUE. The default value
is \(n-1\). An alternative value is \(n/\log(n)\). ONLY applicable when \(\text{scr} = \text{TRUE}\) and \(\text{method} = "\text{mb}"\).

cov.output

If \(\text{cov.output} = \text{TRUE}\), the output will include a path of estimated covariance matrices. ONLY applicable when \(\text{when} = "\text{glasso}"\). Since the estimated covariance matrices are generally not sparse, please use it with care, or it may take much memory under high-dimensional setting. The default value is \text{FALSE}.

sym

Symmetrize the output graphs. If \(\text{sym} = "\text{and}"\), the edge between node \(i\) and node \(j\) is selected ONLY when both node \(i\) and node \(j\) are selected as neighbors for each other. If \(\text{sym} = "\text{or}"\), the edge is selected when either node \(i\) or node \(j\) is selected as the neighbor for each other. The default value is "or". ONLY applicable when \(\text{method} = "\text{mb}"\).

verbose

If \(\text{verbose} = \text{FALSE}\), tracing information printing is disabled. The default value is \text{TRUE}.

Details

The graph structure is estimated by Meinshausen-Buhlmann graph estimation or the graphical lasso, and both methods can be further accelerated via the lossy screening rule by preselecting the neighborhood of each variable by correlation thresholding. We target on high-dimensional data analysis usually \(d \gg n\), and the computation is memory-optimized using the sparse matrix output. We also provide a highly computationally efficient approaches correlation thresholding graph estimation.

Value

An object with S3 class "huge" is returned:

data

The \(n \times d\) data matrix or \(d \times d\) sample covariance matrix from the input

cov.input

An indicator of the sample covariance.

ind.mat

The \(\text{scr.num} \times k\) matrix with each column corresponding to a variable in \(\text{ind.group}\) and contains the indices of the remaining neighbors after the GSS. ONLY applicable when \(\text{scr} = \text{TRUE}\) and \(\text{approx} = \text{FALSE}\)

lambda

The sequence of regularization parameters used in \(\text{mb}\) or thresholding parameters in \(\text{ct}\).

sym

The \(\text{sym}\) from the input. ONLY applicable when \(\text{method} = "\text{mb}"\).

scr

The \(\text{scr}\) from the input. ONLY applicable when \(\text{method} = "\text{mb}"\) or "glasso".

path

A list of \(k\) by \(k\) adjacency matrices of estimated graphs as a graph path corresponding to \(\lambda\).

sparsity

The sparsity levels of the graph path.

icov

A list of \(d \times d\) precision matrices as an alternative graph path (numerical path) corresponding to \(\lambda\). ONLY applicable when \(\text{method} = "\text{glasso}"\)

cov

A list of \(d \times d\) estimated covariance matrices corresponding to \(\lambda\). ONLY applicable when \(\text{cov.output} = \text{TRUE}\) and \(\text{method} = "\text{glasso}"\)

method

The method used in the graph estimation stage.
If method = "mb", it is a k by nlambda matrix. Each row contains the number of nonzero coefficients along the lasso solution path. If method = "glasso", it is a nlambda dimensional vector containing the number of nonzero coefficients along the graph path ics.

A nlambda dimensional vector containing the likelihood scores along the graph path (ics). ONLY applicable when method = "glasso". For an estimated inverse covariance Z, the program only calculates log(det(Z)) - trace(SZ) where S is the empirical covariance matrix. For the likelihood for n observations, please multiply by n/2.

**Note**

This function ONLY estimates the graph path. For more information about the optimal graph selection, please refer to huge.select.

huge.generator  Data generator

Description

Implements the data generation from multivariate normal distributions with different graph structures, including "random", "hub", "cluster", "band" and "scale-free".

Usage

huge.generator(n = 200, d = 50, graph = "random", v = NULL, u = NULL, g = NULL, prob = NULL, vis = FALSE, verbose = TRUE)

Arguments

n  The number of observations (sample size). The default value is 200.
d  The number of variables (dimension). The default value is 50.
graph  The graph structure with 4 options: "random", "hub", "cluster", "band" and "scale-free".
v  The off-diagonal elements of the precision matrix, controlling the magnitude of partial correlations with u. The default value is 0.3.
u  A positive number being added to the diagonal elements of the precision matrix, to control the magnitude of partial correlations. The default value is 0.1.
g  For "cluster" or "hub" graph, g is the number of hubs or clusters in the graph. The default value is about d/20 if d >= 40 and 2 if d < 40. For "band" graph, g is the bandwidth and the default value is 1. NOT applicable to "random" graph.
prob  For "random" graph, it is the probability that a pair of nodes has an edge. The default value is 3/d. For "cluster" graph, it is the probability that a pair of nodes has an edge in each cluster. The default value is 6g/d if d/g <= 30 and 0.3 if d/g > 30. NOT applicable to "hub" or "band" graphs.
vis  Visualize the adjacency matrix of the true graph structure, the graph pattern, the covariance matrix and the empirical covariance matrix. The default value is FALSE.
verbose  If verbose = FALSE, tracing information printing is disabled. The default value is TRUE.

Details

Given the adjacency matrix theta, the graph patterns are generated as below:

(I) "random": Each pair of off-diagonal elements are randomly set theta[i,j]=theta[j,i]=1 for i!=j with probability prob, and 0 otherwise. It results in about d*(d-1)*prob/2 edges in the graph.

(II)"hub":The row/columns are evenly partitioned into g disjoint groups. Each group is associated
with a "center" row i in that group. Each pair of off-diagonal elements are set \( \theta[i, j] = \theta[j, i] = 1 \) for \( i \neq j \) if \( j \) also belongs to the same group as \( i \) and \( 0 \) otherwise. It results in \( d \sim g \) edges in the graph.

(III) "cluster": The row/columns are evenly partitioned into \( g \) disjoint groups. Each pair of off-diagonal elements are set \( \theta[i, j] = \theta[j, i] = 1 \) for \( i \neq j \) with the probability \( \text{prob} \) if both \( i \) and \( j \) belong to the same group, and \( 0 \) otherwise. It results in about \( g*(d/g)\) edges in the graph.

(IV) "band": The off-diagonal elements are set to be \( \theta[i, j] = 1 \) if \( 1 \leq |i-j| \leq g \) and \( 0 \) otherwise. It results in \( (2d-1-g)g/2 \) edges in the graph.

(V) "scale-free": The graph is generated using B-A algorithm. The initial graph has two connected nodes and each new node is connected to only one node in the existing graph with the probability proportional to the degree of the each node in the existing graph. It results in \( d \) edges in the graph.

The adjacency matrix \( \theta \) has all diagonal elements equal to \( 0 \). To obtain a positive definite precision matrix, the smallest eigenvalue of \( \theta^*v \) (denoted by \( e \)) is computed. Then we set the precision matrix equal to \( \theta^*v + (|e| + 0.1 + u)I \). The covariance matrix is then computed to generate multivariate normal data.

Value

An object with S3 class "sim" is returned:

- **data**: The \( n \) by \( d \) matrix for the generated data
- **sigma**: The covariance matrix for the generated data
- **omega**: The precision matrix for the generated data
- **sigmahat**: The empirical covariance matrix for the generated data
- **theta**: The adjacency matrix of true graph structure (in sparse matrix representation) for the generated data

huge and huge-package

Examples

```r
## band graph with bandwidth 3
L = huge.generator(graph = "band", g = 3)
plot(L)

## random sparse graph
L = huge.generator(vis = TRUE)

## random dense graph
L = huge.generator(prob = 0.5, vis = TRUE)

## hub graph with 6 hubs
L = huge.generator(graph = "hub", g = 6, vis = TRUE)

## hub graph with 8 clusters
L = huge.generator(graph = "cluster", g = 8, vis = TRUE)

## scale-free graphs
L = huge.generator(graph="scale-free", vis = TRUE)
```

### huge.npn

Nonparanormal(npn) transformation

Description

Implements the Gaussianization to help relax the assumption of normality.
Usage

huge.npn(x, npn.func = "shrinkage", npn.thresh = NULL, verbose = TRUE)

Arguments

x
The n by d data matrix representing n observations in d dimensions

npn.func
The transformation function used in the npn transformation. If npn.func = "truncation", the truncated ECDF is applied. If npn.func = "shrinkage", the shrunken ECDF is applied. The default is "shrinkage". If npn.func = "skeptic", the nonparanormal skeptic is applied.

npn.thresh
The truncation threshold used in nonparanormal transformation, ONLY applicable when npn.func = "truncation". The default value is \(1/(4*(n^{0.25})*sqrt(pi*log(n)))\).

verbose
If verbose = FALSE, tracing information printing is disabled. The default value is TRUE.

Details

The nonparanormal extends Gaussian graphical models to semiparametric Gaussian copula models. Motivated by sparse additive models, the nonparanormal method estimates the Gaussian copula by marginally transforming the variables using smooth functions. Computationally, the estimation of a nonparanormal transformation is very efficient and only requires one pass of the data matrix.

Value

data
A d by d nonparanormal correlation matrix if npn.func = "skeptic", and A n by d data matrix representing n observations in d transformed dimensions otherwise.

huge and huge-package.

Examples

```r
# generate nonparanormal data
L = huge.generator(graph = "cluster", g = 5)
L$data = L$data^5

# transform the data using the shrunken ECDF
Q = huge.npn(L$data)

# transform the non-Gaussian data using the truncated ECDF
Q = huge.npn(L$data, npn.func = "truncation")

# transform the non-Gaussian data using the truncated ECDF
Q = huge.npn(L$data, npn.func = "skeptic")
```

---

**huge.plot**  
*Graph visualization*

**Description**

Implements the graph visualization using adjacency matrix. It can automatic organize 2D embedding layout.

**Usage**

```
huge.plot(G, epsflag = FALSE, graph.name = "default", cur.num = 1, location)
```
Arguments

G
  The adjacency matrix corresponding to the graph.
epsflag
  If epsflag = TRUE, save the plot as an eps file in the target directory. The
default value is FALSE.
graph.name
  The name of the output eps files. The default value is "default".
cur.num
  The number of plots saved as eps files. Only applicable when epsflag = TRUE.
The default value is 1.
location
  Target directory. The default value is the current working directory.

Details

The user can change cur.num to plot several figures and select the best one. The implementation is based on the popular package "igraph".

Examples

```r
## visualize the hub graph
L = huge.generator(graph = "hub")
huge.plot(L$theta)

## visualize the band graph
L = huge.generator(graph = "band", g=5)
huge.plot(L$theta)

## visualize the cluster graph
L = huge.generator(graph = "cluster")
huge.plot(L$theta)

# show working directory
getwd()
# plot 5 graphs and save the plots as eps files in the working directory
huge.plot(L$theta, epsflag = TRUE, cur.num = 5)
```

---

`huge.roc`  

*Draw ROC Curve for a graph path*

**Description**

Draws ROC curve for a graph path according to the true graph structure

**Usage**

```r
huge.roc(path, theta, verbose = TRUE)
```

**Arguments**

- `path`: A graph path.
- `theta`: The true graph structure.
- `verbose`: If `verbose = FALSE`, tracing information printing is disabled. The default value is `TRUE`.

**Details**

To avoid the horizontal oscillation, false positive rates is automatically sorted in the ascent order and true positive rates also follow the same order.
Value

An object with S3 class "roc" is returned:

- **F1**: The F1 scores along the graph path.
- **tp**: The true positive rates along the graph path.
- **fp**: The false positive rates along the graph paths.
- **AUC**: Area under the ROC curve.

Note

For a lasso regression, the number of nonzero coefficients is at most \( n^1 \). If \( d \gg n \), even when regularization parameter is very small, the estimated graph may still be sparse. In this case, the AUC may not be a good choice to evaluate the performance.

Z1 = huge.roc(out1$path, L$theta)

# Maximum F1 score
max(Z1$F1)
```

huge.select  
Model selection for high-dimensional undirected graph estimation

Description

Implements the regularization parameter selection for high dimensional undirected graph estimation. The optional approaches are rotation information criterion (ric), stability approach to regularization selection (stars) and extended Bayesian information criterion (ebic).

Usage

```r
huge.select(est, criterion = NULL, ebic.gamma = 0.5, stars.thresh = 0.1,
stars.subsample.ratio = NULL, rep.num = 20, verbose = TRUE)
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>est</td>
<td>An object with S3 class &quot;huge&quot;</td>
</tr>
<tr>
<td>criterion</td>
<td>Model selection criterion. &quot;ric&quot; and &quot;stars&quot; are available for all 3 graph estimation methods. ebic is only applicable when est$method = &quot;glasso&quot; in huge(). The default value is &quot;ric&quot;.</td>
</tr>
<tr>
<td>ebic.gamma</td>
<td>The tuning parameter for ebic. The default value is 0.5. Only applicable when est$method = &quot;glasso&quot; and criterion = &quot;ebic&quot;.</td>
</tr>
<tr>
<td>stars.thresh</td>
<td>The variability threshold in stars. The default value is 0.1. An alternative value is 0.05. Only applicable when criterion = &quot;stars&quot;.</td>
</tr>
<tr>
<td>stars.subsample.ratio</td>
<td>The subsampling ratio. The default value is 10*sqrt(n)/n when n&gt;144 and 0.8 when n&lt;=144, where n is the sample size. Only applicable when criterion = &quot;stars&quot;.</td>
</tr>
<tr>
<td>rep.num</td>
<td>The number of subsamplings when criterion = &quot;stars&quot; or rotations when criterion = &quot;ric&quot;. The default value is 20. NOT applicable when criterion = &quot;ebic&quot;</td>
</tr>
<tr>
<td>verbose</td>
<td>If verbose = FALSE, tracing information printing is disabled. The default value is TRUE.</td>
</tr>
</tbody>
</table>
Details

Stability approach to regularization selection (stars) is a natural way to select optimal regularization parameter for all three estimation methods. It selects the optimal graph by variability of subsamplings and tends to overselect edges in Gaussian graphical models. Besides selecting the regularization parameters, stars can also provide an additional estimated graph by merging the corresponding subsampled graphs using the frequency counts. The subsampling procedure in stars may NOT be very efficient, we also provide the recent developed highly efficient, rotation information criterion approach (ric). Instead of tuning over a grid by cross-validation or subsampling, we directly estimate the optimal regularization parameter based on random Rotations. However, ric usually has very good empirical performances but suffers from underselections sometimes. Therefore, we suggest if user are sensitive of false negative rates, they should either consider increasing \( r_{num} \) or applying the stars to model selection. Extended Bayesian information criterion (ebic) is another competitive approach, but the \( \text{ebic.gamma} \) can only be tuned by experience.

Value

An object with S3 class "select" is returned:

- **refit**: The optimal graph selected from the graph path
- **opt.icov**: The optimal precision matrix from the path only applicable when method = "glasso"
- **opt.cov**: The optimal covariance matrix from the path only applicable when method = "glasso" and est$\text{cov} is available.
- **merge**: The graph path estimated by merging the subsampling paths. Only applicable when the input criterion = "stars".
- **variability**: The variability along the subsampling paths. Only applicable when the input criterion = "stars".
- **ebic.scores**: Extended BIC scores for regularization parameter selection. Only applicable when criterion = "ebic".
- **opt.index**: The index of the selected regularization parameter. NOT applicable when the input criterion = "ric".
- **opt.lambda**: The selected regularization/thresholding parameter.
- **opt.sparsity**: The sparsity level of "refit".

and anything else included in the input est

Note

The model selection is NOT available when the data input is the sample covaraince matrix.

huge roc and huge

Description

Print the information about the model usage, graph dimension, model selection criterion, sparsity level of the optimal graph
Usage

```r
## S3 method for class 'select'
print(x, ...)
```

Arguments

- `x`: An object with S3 class "select"
- `...`: System reserved (No specific usage)

Author(s)

Tuo Zhao, Han Liu, Kathryn Roeder, John Lafferty, and Larry Wasserman
Maintainers: Tuo Zhao<tzhao5@jhu.edu>

`huge.select` and `huge`
Description
Print the information about the sample size, the dimension, the pattern and sparsity of the true graph structure.

Usage
```r
## S3 method for class 'sim'
print(x, ...)
```

Arguments
- `x`: An object with S3 class "sim"
- `...`: System reserved (No specific usage)

stockdata

*Stock price of S&P 500 companies from 2003 to 2008*

---

### Description

This data set consists of stock price and company information.

### Usage

```r
data(stockdata)
```

### Format

The format is a list containing two matrices. 1. `data` - 1258x452, represents the 452 stocks’ close prices for 1258 trading days. 2. `info` - 452x3: The 1st column: the query symbol for each company. The 2nd column: the category for each company. The 3rd column: the full name of each company.

### Details

This data set can be used to perform high-dimensional graph estimation to analyze the relationships between S&P 500 companies.
