

Package ‘partykit’

September 20, 2016

Title A Toolkit for Recursive Partytioning

Date 2016-09-20

Version 1.1-1

Description A toolkit with infrastructure for representing, summarizing, and visualizing tree-structured regression and classification models. This unified infrastructure can be used for reading/coercing tree models from different sources ('rpart', 'RWeka', 'PMML') yielding objects that share functionality for print()/plot()/predict() methods. Furthermore, new and improved reimplementations of conditional inference trees (ctree()) and model-based recursive partitioning (mob()) from the 'party' package are provided based on the new infrastructure.

Depends R (>= 3.1.0), graphics, grid

Imports grDevices, stats, utils, survival, Formula (>= 1.2-1)

Suggests XML, pmml, rJava, rpart, mvtnorm, sandwich, strucchange, vcd, AER, mlbench, TH.data (>= 1.0-3), coin (>= 1.1-0), RWeka (>= 0.4-19), datasets, parallel, psychotools, psychotree

LazyData yes

License GPL-2 | GPL-3

URL <http://partykit.R-Forge.R-project.org/partykit>

NeedsCompilation yes

cforest	<i>Conditional Random Forests</i>
---------	-----------------------------------

Description

An implementation of the random forest and bagging ensemble algorithms utilizing conditional inference trees as base learners.

Usage

```
cforest(formula, data, weights, subset, na.action = na.pass,
        control = ctree_control(teststat = "quad",
                               testtype = "Univ", mincriterion = 0, ...),
        ytrafo = NULL, scores = NULL, ntree = 500L,
        perturb = list(replace = FALSE, fraction = 0.632),
        mtry = ceiling(sqrt(nvar)), applyfun = NULL, cores = NULL,
        trace = FALSE, ...)
## S3 method for class 'cforest'
predict(object, newdata = NULL,
        type = c("response", "prob", "weights", "node"),
        OOB = FALSE, FUN = NULL, simplify = TRUE, ...)
```

Arguments

formula	a symbolic description of the model to be fit.
data	a data frame containing the variables in the model.
subset	an optional vector specifying a subset of observations to be used in the fitting process.
weights	an optional vector of weights to be used in the fitting process. Non-negative integer valued weights are allowed as well as non-negative real weights. Observations are sampled (with or without replacement) according to probabilities $\text{weights} / \text{sum}(\text{weights})$. The fraction of observations to be sampled (without replacement) is computed based on the sum of the weights if all weights are integer-valued and based on the number of weights greater zero else. Alternatively, weights can be a double matrix defining case weights for all $\text{ncol}(\text{weights})$ trees in the forest directly. This requires more storage but gives the user more control.
na.action	a function which indicates what should happen when the data contain missing value.
control	a list with control parameters, see ctree_control . The default values correspond to those of the default values used by cforest from the party package.
ytrafo	an optional named list of functions to be applied to the response variable(s) before testing their association with the explanatory variables. Note that this transformation is only performed once for the root node and does not take weights into account. Alternatively, ytrafo can be a function of data and weights. In this case, the transformation is computed for every node. This feature is experimental and the user interface likely to change.
scores	an optional named list of scores to be attached to ordered factors.
nrtree	Number of trees to grow for the forest.
perturb	a list with arguments <code>replace</code> and <code>fraction</code> determining which type of resampling with <code>replace = TRUE</code> referring to the n-out-of-n bootstrap and <code>replace = FALSE</code> to sample splitting. <code>fraction</code> is the number of observations to draw without replacement.
mtry	number of input variables randomly sampled as candidates at each node for random forest like algorithms. Bagging, as special case of a random forest without random input variable sampling, can be performed by setting <code>mtry</code> either equal to <code>Inf</code> or manually equal to the number of input variables.
applyfun	an optional lapply -style function with arguments <code>function(X, FUN, ...)</code> . It is used for computing the variable selection criterion. The default is to use the basic <code>lapply</code> function unless the <code>cores</code> argument is specified (see below).
cores	numeric. If set to an integer the <code>applyfun</code> is set to mclapply with the desired number of cores.
trace	a logical indicating if a progress bar shall be printed while the forest grows.
object	An object as returned by <code>cforest</code>
newdata	An optional data frame containing test data.

type	a character string denoting the type of predicted value returned, ignored when argument FUN is given. For "response", the mean of a numeric response, the predicted class for a categorical response or the median survival time for a censored response is returned. For "prob" the matrix of conditional class probabilities (simplify = TRUE) or a list with the conditional class probabilities for each observation (simplify = FALSE) is returned for a categorical response. For numeric and censored responses, a list with the empirical cumulative distribution functions and empirical survivor functions (Kaplan-Meier estimate) is returned when type = "prob". "weights" returns an integer vector of prediction weights. For type = "where", a list of terminal node ids for each of the trees in the forest is returned.
OOB	a logical defining out-of-bag predictions (only if newdata = NULL).
FUN	a function to compute summary statistics. Predictions for each node have to be computed based on arguments (y, w) where y is the response and w are case weights.
simplify	a logical indicating whether the resulting list of predictions should be converted to a suitable vector or matrix (if possible).
...	additional arguments.

Details

This implementation of the random forest (and bagging) algorithm differs from the reference implementation in [randomForest](#) with respect to the base learners used and the aggregation scheme applied.

Conditional inference trees, see [ctree](#), are fitted to each of the `ntree` perturbed samples of the learning sample. Most of the hyper parameters in [ctree_control](#) regulate the construction of the conditional inference trees.

Hyper parameters you might want to change are:

1. The number of randomly preselected variables `mtry`, which is fixed to the square root of the number of input variables.
2. The number of trees `ntree`. Use more trees if you have more variables.
3. The depth of the trees, regulated by `mincriterion`. Usually unstopped and unpruned trees are used in random forests. To grow large trees, set `mincriterion` to a small value.

The aggregation scheme works by averaging observation weights extracted from each of the `ntree` trees and NOT by averaging predictions directly as in [randomForest](#). See Hothorn et al. (2004) and Meinshausen (2006) for a description.

Predictions can be computed using [predict](#). For observations with zero weights, predictions are computed from the fitted tree when `newdata = NULL`.

Ensembles of conditional inference trees have not yet been extensively tested, so this routine is meant for the expert user only and its current state is rather experimental. However, there are some things available in [cforest](#) that can't be done with [randomForest](#), for example fitting forests to censored response variables (see Hothorn et al., 2004, 2006a) or to multivariate and ordered responses. Using the rich `partykit` infrastructure allows additional functionality in [cforest](#), such as parallel tree growing and probabilistic forecasting (for example via quantile regression forests). Also plotting of single trees from a forest is much easier now.

Unlike `cforest`, `forest` is entirely written in R which makes customisation much easier at the price of longer computing times. However, trees can be grown in parallel with this R only implementation which renders speed less of an issue. Note that the default values are different from those used in package `party`, most importantly the default for `mtry` is now data-dependent. `predict(, type = "node")` replaces the `where` function and `predict(, type = "prob")` the `treeresponse` function.

Moreover, when predictors vary in their scale of measurement of number of categories, variable selection and computation of variable importance is biased in favor of variables with many potential cutpoints in `randomForest`, while in `cforest` unbiased trees and an adequate resampling scheme are used by default. See Hothorn et al. (2006b) and Strobl et al. (2007) as well as Strobl et al. (2009).

Value

An object of class `cforest`.

Examples

```
## basic example: conditional inference forest for cars data
cf <- cforest(dist ~ speed, data = cars)

## prediction of fitted mean and visualization
nd <- data.frame(speed = 4:25)
nd$mean <- predict(cf, newdata = nd, type = "response")
plot(dist ~ speed, data = cars)
lines(mean ~ speed, data = nd)
```

```

## predict quantiles (aka quantile regression forest)
myquantile <- function(y, w) quantile(rep(y, w), probs = c(0.1, 0.5, 0.9))
p <- predict(cf, newdata = nd, type = "response", FUN = myquantile)
colnames(p) <- c("lower", "median", "upper")
nd <- cbind(nd, p)

## visualization with conditional (on speed) prediction intervals
plot(dist ~ speed, data = cars, type = "n")
with(nd, polygon(c(speed, rev(speed)), c(lower, rev(upper)),
  col = "lightgray", border = "transparent"))
points(dist ~ speed, data = cars)
lines(mean ~ speed, data = nd, lwd = 1.5)
lines(median ~ speed, data = nd, lty = 2, lwd = 1.5)
legend("topleft", c("mean", "median", "10% - 90% quantile"),
  lwd = c(1.5, 1.5, 10), lty = c(1, 2, 1),
  col = c("black", "black", "lightgray"), bty = "n")

### we may also use predicted conditional (on speed) densities
mydensity <- function(y, w) approxfun(density(y, weights = w/sum(w))[1:2], rule = 2)
pd <- predict(cf, newdata = nd, type = "response", FUN = mydensity)

## visualization in heatmap (instead of scatterplot)
## with fitted curves as above
dist <- -10:150
dens <- t(sapply(seq_along(pd), function(i) pd[[i]](dist)))
image(nd$speed, dist, dens, xlab = "speed", col = rev(gray.colors(9)))
lines(mean ~ speed, data = nd, lwd = 1.5)
lines(median ~ speed, data = nd, lty = 2, lwd = 1.5)
lines(lower ~ speed, data = nd, lty = 2)
lines(upper ~ speed, data = nd, lty = 2)

### honest (i.e., out-of-bag) cross-classification of
### true vs. predicted classes
data("mammoexp", package = "TH.data")
table(mammoexp$ME, predict(cforest(ME ~ ., data = mammoexp, ntree = 50),
  OOB = TRUE, type = "response"))

### fit forest to censored response
if (require("TH.data") && require("survival")) {
  data("GBSG2", package = "TH.data")
  bst <- cforest(Surv(time, cens) ~ ., data = GBSG2, ntree = 50)

  ### estimate conditional Kaplan-Meier curves
  print(predict(bst, newdata = GBSG2[1:2,], OOB = TRUE, type = "prob"))

  print(bst$nodes[[1]])
}

```

 ctree *Conditional Inference Trees*

Description

Recursive partitioning for continuous, censored, ordered, nominal and multivariate response variables in a conditional inference framework.

Usage

```
ctree(formula, data, weights, subset, na.action = na.pass,
      control = ctree_control(...), ytrafo = NULL, scores = NULL, ...)
```

Arguments

formula	a symbolic description of the model to be fit.
data	a data frame containing the variables in the model.
subset	an optional vector specifying a subset of observations to be used in the fitting process.
weights	an optional vector of weights to be used in the fitting process. Only non-negative integer valued weights are allowed.
na.action	a function which indicates what should happen when the data contain missing value.
control	a list with control parameters, see ctree_control .
ytrafo	an optional named list of functions to be applied to the response variable(s) before testing their association with the explanatory variables. Note that this transformation is only performed once for the root node and does not take weights into account. Alternatively, ytrafo can be a function of data and weights. In this case, the transformation is computed for every node. This feature is experimental and the user interface likely to change.
scores	an optional named list of scores to be attached to ordered factors.
...	arguments passed to ctree_control .

Details

Function `partykit::ctree` is a reimplementation of (most of) `party::ctree` employing the new [party](#) infrastructure of the **partykit** infrastructure. Although the new code was already extensively tested, it is not yet as mature as the old code. If you notice differences in the structure/predictions of the resulting trees, please contact the package maintainers. See also `vignette("ctree", package = "partykit")` for some remarks about the internals of the different implementations.

Conditional inference trees estimate a regression relationship by binary recursive partitioning in a conditional inference framework. Roughly, the algorithm works as follows: 1) Test the global null hypothesis of independence between any of the input variables and the response (which may be multivariate as well). Stop if this hypothesis cannot be rejected. Otherwise select the input variable

with strongest association to the response. This association is measured by a p-value corresponding to a test for the partial null hypothesis of a single input variable and the response. 2) Implement a binary split in the selected input variable. 3) Recursively repeat steps 1) and 2).

The implementation utilizes a unified framework for conditional inference, or permutation tests, developed by Strasser and Weber (1999). The stop criterion in step 1) is either based on multiplicity adjusted p-values (`testtype = "Bonferroni"` in `ctree_control`) or on the univariate p-values (`testtype = "Univariate"`). In both cases, the criterion is maximized, i.e., $1 - p$ -value is used. A split is implemented when the criterion exceeds the value given by `mincriterion` as specified in `ctree_control`. For example, when `mincriterion = 0.95`, the p-value must be smaller than 0.05 in order to split this node. This statistical approach ensures that the right-sized tree is grown without additional (post-)pruning or cross-validation. The level of `mincriterion` can either be specified to be appropriate for the size of the data set (and 0.95 is typically appropriate for small to moderately-sized data sets) or could potentially be treated like a hyperparameter (see Section 3.4 in Hothorn, Hornik and Zeileis, 2006). The selection of the input variable to split in is based on the univariate p-values avoiding a variable selection bias towards input variables with many possible cutpoints. The test statistics in each of the nodes can be extracted with the `sctest` method. (Note that the generic is in the `strucchange` package so this either needs to be loaded or `sctest.constparty` has to be called directly.) In cases where splitting stops due to the sample size (e.g., `minsplitlevel` or `minbucket` etc.), the test results may be empty.

Predictions can be computed using `predict`, which returns predicted means, predicted classes or median predicted survival times and more information about the conditional distribution of the response, i.e., class probabilities or predicted Kaplan-Meier curves. For observations with zero weights, predictions are computed from the fitted tree when `newdata = NULL`.

By default, the scores for each ordinal factor `x` are `1:length(x)`, this may be changed for variables in the formula using `scores = list(x = c(1, 5, 6))`, for example.

For a general description of the methodology see Hothorn, Hornik and Zeileis (2006) and Hothorn, Hornik, van de Wiel and Zeileis (2006).

Value

An object of class `party`.

Examples

```
### regression
airq <- subset(airquality, !is.na(Ozone))
```

```

airct <- ctree(Ozone ~ ., data = airq)
airct
plot(airct)
mean((airq$Ozone - predict(airct))^2)

### classification
irisct <- ctree(Species ~ ., data = iris)
irisct
plot(irisct)
table(predict(irisct), iris$Species)

### estimated class probabilities, a list
tr <- predict(irisct, newdata = iris[1:10,], type = "prob")

### survival analysis
if (require("TH.data") && require("survival") && require("coin")) {

  data("GBSG2", package = "TH.data")
  GBSG2ct <- ctree(Surv(time, cens) ~ ., data = GBSG2)
  predict(GBSG2ct, newdata = GBSG2[1:2,], type = "response")
  plot(GBSG2ct)

  ### with weight-dependent log-rank scores
  ctree(Surv(time, cens) ~ ., data = GBSG2)

  ### log-rank trafo for observations in this node only (= weights > 0)
  h <- function(data, weights) {
    s <- data[, "Surv(time, cens)"]
    s <- logrank_trafo(s[weights > 0,])
    r <- rep(0, nrow(data))
    r[weights > 0] <- s
    matrix(as.double(r), ncol = 1)
  }

  ### very much the same tree
  ctree(Surv(time, cens) ~ ., data = GBSG2, ytrafo = h)
}

### multivariate responses
airct2 <- ctree(Ozone + Temp ~ ., data = airq)
airct2
plot(airct2)

```

ctree_control

Control for Conditional Inference Trees

Description

Various parameters that control aspects of the ‘ctree’ fit.

Usage

```
ctree_control(teststat = c("quad", "max"),
             testtype = c("Bonferroni", "Univariate", "Teststatistic"),
             mincriterion = 0.95, minsplit = 20L, minbucket = 7L,
             minprob = 0.01, stump = FALSE, maxsurrogate = 0L, mtry = Inf,
             maxdepth = Inf, multiway = FALSE, splittry = 2L, majority = FALSE,
             applyfun = NULL, cores = NULL)
```

Arguments

teststat	a character specifying the type of the test statistic to be applied.
testtype	a character specifying how to compute the distribution of the test statistic.
mincriterion	the value of the test statistic or 1 - p-value that must be exceeded in order to implement a split.
minsplit	the minimum sum of weights in a node in order to be considered for splitting.
minbucket	the minimum sum of weights in a terminal node.
minprob	proportion of observations needed to establish a terminal node.
stump	a logical determining whether a stump (a tree with three nodes only) is to be computed.
maxsurrogate	number of surrogate splits to evaluate. Note the currently only surrogate splits in ordered covariables are implemented.
mtry	number of input variables randomly sampled as candidates at each node for random forest like algorithms. The default mtry = Inf means that no random selection takes place.
maxdepth	maximum depth of the tree. The default maxdepth = Inf means that no restrictions are applied to tree sizes.
multiway	a logical indicating if multiway splits for all factor levels are implemented for unordered factors.
splittry	number of variables that are inspected for admissible splits if the best split doesn't meet the sample size constraints.
majority	if FALSE, observations which can't be classified to a daughter node because of missing information are randomly assigned (following the node distribution). If FALSE, they go with the majority (the default in ctree).
applyfun	an optional lapply -style function with arguments function(X, FUN, ...). It is used for computing the variable selection criterion. The default is to use the basic lapply function unless the cores argument is specified (see below).
cores	numeric. If set to an integer the applyfun is set to mclapply with the desired number of cores.

Details

The arguments `teststat`, `testtype` and `mincriterion` determine how the global null hypothesis of independence between all input variables and the response is tested (see [ctree](#)). The variable with most extreme p-value or test statistic is selected for splitting. If this isn't possible due to sample

size constraints explained in the next paragraph, up to `splittry` other variables are inspected for possible splits.

A split is established when all of the following criteria are met: 1) the sum of the weights in the current node is larger than `minsplit`, 2) a fraction of the sum of weights of more than `minprob` will be contained in all daughter nodes, 3) the sum of the weights in all daughter nodes exceeds `minbucket`, and 4) the depth of the tree is smaller than `maxdepth`. This avoids pathological splits deep down the tree. When `stump = TRUE`, a tree with at most two terminal nodes is computed.

The argument `mtry > 0` means that a random forest like ‘variable selection’, i.e., a random selection of `mtry` input variables, is performed in each node.

In each inner node, `maxsurrogate` surrogate splits are computed (regardless of any missing values in the learning sample). Factors in test samples whose levels were empty in the learning sample are treated as missing when computing predictions (in contrast to `ctree`. Note also the different behaviour of `majority` in the two implementations.

Value

A list.

glmtree

Generalized Linear Model Trees

Description

Model-based recursive partitioning based on generalized linear models.

Usage

```
glmtree(formula, data, subset, na.action, weights, offset, cluster,
        family = gaussian, epsilon = 1e-8, maxit = 25, ...)
```

Arguments

<code>formula</code>	symbolic description of the model (of type $y \sim z_1 + \dots + z_l$ or $y \sim x_1 + \dots + x_k \mid z_1 + \dots + z_l$; for details see below).
<code>data</code> , <code>subset</code> , <code>na.action</code>	arguments controlling formula processing via <code>model.frame</code> .
<code>weights</code>	optional numeric vector of weights. By default these are treated as case weights but the default can be changed in <code>mob_control</code> .
<code>offset</code>	optional numeric vector with an a priori known component to be included in the model $y \sim x_1 + \dots + x_k$ (i.e., only when <code>x</code> variables are specified).
<code>cluster</code>	optional vector (typically numeric or factor) with a cluster ID to be employed for clustered covariances in the parameter stability tests.
<code>family</code>	specification of a family for <code>glm</code> .
<code>epsilon</code> , <code>maxit</code>	control parameters passed to <code>glm.control</code> .
<code>...</code>	optional control parameters passed to <code>mob_control</code> .

Details

Convenience interface for fitting MOBs (model-based recursive partitions) via the `mob` function. `glmtree` internally sets up a model `fit` function for `mob`, using `glm.fit`. Then `mob` is called using the negative log-likelihood as the objective function.

Compared to calling `mob` by hand, the implementation tries to avoid unnecessary computations while growing the tree. Also, it provides a more elaborate plotting function.

Value

An object of class `glmtree` inheriting from `modelparty`. The `info` element of the overall party and the individual nodes contain various informations about the models.

}

```

HuntingSpiders

Abundance of Hunting Spiders

Description

Abundances for 12 species of hunting spiders along with environmental predictors, all rated on a 0–9 scale.

Usage

```
data("HuntingSpiders")
```

Format

A data frame containing 28 observations on 18 variables (12 species abundances and 6 environmental predictors).

arct.lute numeric. Abundance of species *Arctosa lutetiana* (on a scale 0–9).
pard.lugu numeric. Abundance of species *Pardosa lugubris* (on a scale 0–9).
zora.spin numeric. Abundance of species *Zora spinimana* (on a scale 0–9).
pard.nigr numeric. Abundance of species *Pardosa nigriceps* (on a scale 0–9).
pard.pull numeric. Abundance of species *Pardosa pullata* (on a scale 0–9).
aulo.albi numeric. Abundance of species *Aulonia albimana* (on a scale 0–9).
troc.terr numeric. Abundance of species *Trochosa terricola* (on a scale 0–9).
alop.cune numeric. Abundance of species *Alopecosa cuneata* (on a scale 0–9).
pard.mont numeric. Abundance of species *Pardosa monticola* (on a scale 0–9).
alop.acce numeric. Abundance of species *Alopecosa accentuata* (on a scale 0–9).
alop.fabr numeric. Abundance of species *Alopecosa fabrilis* (on a scale 0–9).
arct.peri numeric. Abundance of species *Arctosa perita* (on a scale 0–9).
water numeric. Environmental predictor on a scale 0–9.
sand numeric. Environmental predictor on a scale 0–9.
moss numeric. Environmental predictor on a scale 0–9.
reft numeric. Environmental predictor on a scale 0–9.
twigs numeric. Environmental predictor on a scale 0–9.
herbs numeric. Environmental predictor on a scale 0–9.

Details

The data were originally analyzed by Van der Aart and Smeenk-Enserink (1975). De'ath (2002) transformed all variables to the 0–9 scale and employed multivariate regression trees.

 lmtree

Linear Model Trees

Description

Model-based recursive partitioning based on least squares regression.

Usage

```
lmtree(formula, data, subset, na.action, weights, offset, cluster, ...)
```

Arguments

formula	symbolic description of the model (of type $y \sim z_1 + \dots + z_l$ or $y \sim x_1 + \dots + x_k \mid z_1 + \dots + z_l$; for details see below).
data, subset, na.action	arguments controlling formula processing via model.frame .
weights	optional numeric vector of weights. By default these are treated as case weights but the default can be changed in mob_control .

offset	optional numeric vector with an a priori known component to be included in the model $y \sim x_1 + \dots + x_k$ (i.e., only when x variables are specified).
cluster	optional vector (typically numeric or factor) with a cluster ID to be employed for clustered covariances in the parameter stability tests.
...	optional control parameters passed to <code>mob_control</code> .

Details

Convenience interface for fitting MOBs (model-based recursive partitions) via the `mob` function. `lmtree` internally sets up a model `fit` function for `mob`, using either `lm.fit` or `lm.wfit` (depending on whether weights are used or not). Then `mob` is called using the residual sum of squares as the objective function.

Compared to calling `mob` by hand, the implementation tries to avoid unnecessary computations while growing the tree. Also, it provides a more elaborate plotting function.

Value

An object of class `lmtree` inheriting from `modelparty`. The `info` element of the overall party and the individual nodes contain various informations about the models.

mob

Model-based Recursive Partitioning

Description

MOB is an algorithm for model-based recursive partitioning yielding a tree with fitted models associated with each terminal node.

Usage

```

mob(formula, data, subset, na.action, weights, offset, cluster,
  fit, control = mob_control(), ...)

```

Arguments

formula symbolic description of the model (of type $y \sim z_1 + \dots + z_l$ or $y \sim x_1 + \dots + x_k \mid z_1 + \dots + z_l$; for details see below).

data, subset, na.action arguments controlling formula processing via [model.frame](#).

<code>weights</code>	optional numeric vector of weights. By default these are treated as case weights but the default can be changed in <code>mob_control</code> .
<code>offset</code>	optional numeric vector with an a priori known component to be included in the model $y \sim x_1 + \dots + x_k$ (i.e., only when x variables are specified).
<code>cluster</code>	optional vector (typically numeric or factor) with a cluster ID to be passed on to the <code>fit</code> function and employed for clustered covariances in the parameter stability tests.
<code>fit</code>	function. A function for fitting the model within each node. For details see below.
<code>control</code>	A list with control parameters as returned by <code>mob_control</code> .
<code>...</code>	Additional arguments passed to the <code>fit</code> function.

Details

Model-based partitioning fits a model tree using two groups of variables: (1) The model variables which can be just a (set of) response(s) y or additionally include regressors x_1, \dots, x_k . These are used for estimating the model parameters. (2) Partitioning variables z_1, \dots, z_l , which are used for recursively partitioning the data. The two groups of variables are either specified as $y \sim z_1 + \dots + z_l$ (when there are no regressors) or $y \sim x_1 + \dots + x_k \mid z_1 + \dots + z_l$ (when the model part contains regressors). Both sets of variables may in principle be overlapping.

To fit a tree model the following algorithm is used.

1. `fit` a model to the y or y and x variables using the observations in the current node
2. Assess the stability of the model parameters with respect to each of the partitioning variables z_1, \dots, z_l . If there is some overall instability, choose the variable z associated with the smallest p value for partitioning, otherwise stop.
3. Search for the locally optimal split in z by minimizing the objective function of the model. Typically, this will be something like `deviance` or the negative `logLik`.
4. Refit the model in both kid subsamples and repeat from step 2.

More details on the conceptual design of the algorithm can be found in Zeileis, Hothorn, Hornik (2008) and some illustrations are provided in `vignette("MOB")`. For specifying the `fit` function two approaches are possible:

(1) It can be a function `fit(y, x = NULL, start = NULL, weights = NULL, offset = NULL, ...)`. The arguments `y`, `x`, `weights`, `offset` will be set to the corresponding elements in the current node of the tree. Additionally, starting values will sometimes be supplied via `start`. Of course, the `fit` function can choose to ignore any arguments that are not applicable, e.g., if there are no regressors x in the model or if starting values are not supported. The returned object needs to have a class that has associated `coef`, `logLik`, and `estfun` methods for extracting the estimated parameters, the maximized log-likelihood, and the empirical estimating function (i.e., score or gradient contributions), respectively.

(2) It can be a function `fit(y, x = NULL, start = NULL, weights = NULL, offset = NULL, ..., estfun = FALSE, objfun = ...)`. The arguments have the same meaning as above but the returned object needs to have a different structure. It needs to be a list with elements `coefficients` (containing the estimated parameters), `objfun` (containing the minimized objective function), `estfun` (the empirical estimating functions),

and object (the fitted model object). The elements `estfun`, or `object` should be `NULL` if the corresponding argument is set to `FALSE`.

Internally, a function of type (2) is set up by `mob()` in case a function of type (1) is supplied. However, to save computation time, a function of type (2) may also be specified directly.

For the fitted MOB tree, several standard methods are provided such as `print`, `predict`, `residuals`, `logLik`, `deviance`, `weights`, `coef` and `summary`. Some of these rely on reusing the corresponding methods for the individual model objects in the terminal nodes. Functions such as `coef`, `print`, `summary` also take a node argument that can specify the node IDs to be queried. Some examples are given below.

More details can be found in `vignette("mob", package = "partykit")`. An overview of the connections to other functions in the package is provided by Hothorn and Zeileis (2015).

Value

An object of class `modelparty` inheriting from `party`. The `info` element of the overall party and the individual nodes contain various informations about the models.

mob_control

Control Parameters for Model-Based Partitioning

Description

Various parameters that control aspects the fitting algorithm for recursively partitioned **mob** models.

Usage

```

mob_control(alpha = 0.05, bonferroni = TRUE, minsize = NULL, maxdepth = Inf,
  mtry = Inf, trim = 0.1, breakties = FALSE, parm = NULL, dfsplit = TRUE, prune = NULL,
  restart = TRUE, verbose = FALSE, caseweights = TRUE, ytype = "vector", xtype = "matrix",
  terminal = "object", inner = terminal, model = TRUE, numsplit = "left",
  catsplit = "binary", vcov = "opg", ordinal = "chisq", nrep = 10000,
  minsplit = minsize, minbucket = minsize, applyfun = NULL, cores = NULL)

```

Arguments

alpha	numeric significance level. A node is splitted when the (possibly Bonferroni-corrected) p value for any parameter stability test in that node falls below alpha (and the stopping criteria minsize and maxdepth are not fulfilled).
bonferroni	logical. Should p values be Bonferroni corrected?

minsize, minsplit, minbucket	integer. The minimum number of observations in a node. If NULL, the default is to use 10 times the number of parameters to be estimated (divided by the number of responses per observation if that is greater than 1). minsize is the recommended name and minsplit/minbucket are only included for backward compatibility with previous versions of mob and compatibility with ctree, respectively.
maxdepth	integer. The maximum depth of the tree.
mtry	integer. The number of partitioning variables randomly sampled as candidates in each node for forest-style algorithms. If mtry is greater than the number of partitioning variables, no random selection is performed. (Thus, by default all available partitioning variables are considered.)
trim	numeric. This specifies the trimming in the parameter instability test for the numerical variables. If smaller than 1, it is interpreted as the fraction relative to the current node size.
breakties	logical. Should ties in numeric variables be broken randomly for computing the associated parameter instability test?
parm	numeric or character. Number or name of model parameters included in the parameter instability tests (by default all parameters are included).
dfsplitt	logical or numeric. <code>as.integer(dfsplitt)</code> is the degrees of freedom per selected split employed when computing information criteria etc.
prune	character, numeric, or function for specifying post-pruning rule. If prune is NULL (the default), no post-pruning is performed. For likelihood-based mob() trees, prune can be set to "AIC" or "BIC" for post-pruning based on the corresponding information criteria. More general rules (also in scenarios that are not likelihood-based), can be specified by function arguments to prune, for details see below.
restart	logical. When determining the optimal split point in a numerical variable: Should model estimation be restarted with NULL starting values for each split? The default is TRUE. If FALSE, then the parameter estimates from the previous split point are used as starting values for the next split point (because in practice the difference are often not huge). (Note that in that case a for loop is used instead of the applyfun for fitting models across sample splits.)
verbose	logical. Should information about the fitting process of mob (such as test statistics, p values, selected splitting variables and split points) be printed to the screen?
caseweights	logical. Should weights be interpreted as case weights? If TRUE, the number of observations is <code>sum(weights)</code> , otherwise it is <code>sum(weights > 0)</code> .
ytype, xtype	character. Specification of how mob should preprocess y and x variables. Possible choices are: "vector" (for y only), i.e., only one variable; "matrix", i.e., the model matrix of all variables; "data.frame", i.e., a data frame of all variables.
terminal, inner	character. Specification of which additional information ("estfun", "object", or both) should be stored in each node. If NULL, no additional information is stored.

model	logical. Should the full model frame be stored in the resulting object?
numsplit	character indicating how splits for numeric variables should be justified. Because any splitpoint in the interval between the last observation from the left child segment and the first observation from the right child segment leads to the same observed split, two options are available in <code>mob_control</code> : Either, the split is "left"-justified (the default for backward compatibility) or "center"-justified using the midpoint of the possible interval.
catsplit	character indicating how (unordered) categorical variables should be splitted. By default the best "binary" split is searched (by minimizing the objective function). Alternatively, if set to "multiway", the node is simply splitted into all levels of the categorical variable.
vcov	character indicating which type of covariance matrix estimator should be employed in the parameter instability tests. The default is the outer product of gradients ("opg"). Alternatively, <code>vcov = "info"</code> employs the information matrix and <code>vcov = "sandwich"</code> the sandwich matrix (both of which are only sensible for maximum likelihood estimation).
ordinal	character indicating which type of parameter instability test should be employed for ordinal partitioning variables (i.e., ordered factors). This can be "chisq", "max", or "L2". If "chisq" then the variable is treated as unordered and a chi-squared test is performed. If "L2", then a maxLM-type test as for numeric variables is carried out but correcting for ties. This requires simulation of p-values via <code>catL2BB</code> and requires some computation time. For "max" a weighted double maximum test is used that computes p-values via <code>pmvnorm</code> .
nrep	numeric. Number of replications in the simulation of p-values for the ordinal "L2" statistic (if used).
applyfun	an optional <code>lapply</code> -style function with arguments <code>function(X, FUN, ...)</code> . It is used for refitting the model across potential sample splits. The default is to use the basic <code>lapply</code> function unless the <code>cores</code> argument is specified (see below).
cores	numeric. If set to an integer the <code>applyfun</code> is set to <code>mclapply</code> with the desired number of cores.

Details

See [mob](#) for more details and references.

For post-pruning, `prune` can be set to a `function(objfun, df, nobs)` which either returns TRUE to signal that a current node can be pruned or FALSE. All supplied arguments are of length two: `objfun` is the sum of objective function values in the current node and its child nodes, respectively. `df` is the degrees of freedom in the current node and its child nodes, respectively. `nobs` is vector with the number of observations in the current node and the total number of observations in the dataset, respectively.

If the objective function employed in the `mob()` call is the negative log-likelihood, then a suitable function is set up on the fly by comparing $(2 * \text{objfun} + \text{penalty} * \text{df})$ in the current and the daughter nodes. The penalty can then be set via a numeric or character value for `prune`: AIC is used if `prune = "AIC"` or `prune = 2` and BIC if `prune = "BIC"` or `prune = log(n)`.

Value

A list of class `mob_control` containing the control parameters.

See Also

[mob](#)

<code>model.frame.rpart</code>	<i>Model Frame Method for rpart</i>
--------------------------------	-------------------------------------

Description

A `model.frame` method for `rpart` objects.

Usage

```
## S3 method for class 'rpart'
model.frame(formula, ...)
```

Arguments

<code>formula</code>	an object of class rpart .
<code>...</code>	additional arguments.

Details

A `model.frame` method for `rpart` objects.

Value

A model frame.

<code>nodeapply</code>	<i>Apply Functions Over Nodes</i>
------------------------	-----------------------------------

Description

Returns a list of values obtained by applying a function to `party` or `partynode` objects.

Usage

```
nodeapply(obj, ids = 1, FUN = NULL, ...)
## S3 method for class 'partynode'
nodeapply(obj, ids = 1, FUN = NULL, ...)
## S3 method for class 'party'
nodeapply(obj, ids = 1, FUN = NULL, by_node = TRUE, ...)
```

Arguments

obj	an object of class <code>partynode</code> or <code>party</code> .
ids	integer vector of node identifiers to apply over.
FUN	a function to be applied to nodes. By default, the node itself is returned.
by_node	a logical indicating if FUN is applied to subsets of <code>party</code> objects or <code>partynode</code> objects (default).
...	additional arguments.

Details

Function FUN is applied to all nodes with node identifiers in `ids` for a `partynode` object. The method for `party` by default calls the `nodeapply` method on it's node slot. If `by_node` is FALSE, it is applied to a `party` object with root node `ids`.

Value

A list of results of length `length(ids)`.

Examples

```
## a tree as flat list structure
nodelist <- list(
  # root node
  list(id = 1L, split = partysplit(varid = 4L, breaks = 1.9),
    kids = 2:3),
  # V4 <= 1.9, terminal node
  list(id = 2L, info = "terminal A"),
  # V4 > 1.9
  list(id = 3L, split = partysplit(varid = 5L, breaks = 1.7),
    kids = c(4L, 7L)),
  # V5 <= 1.7
  list(id = 4L, split = partysplit(varid = 4L, breaks = 4.8),
    kids = 5:6),
  # V4 <= 4.8, terminal node
  list(id = 5L, info = "terminal B"),
  # V4 > 4.8, terminal node
  list(id = 6L, info = "terminal C"),
  # V5 > 1.7, terminal node
  list(id = 7L, info = "terminal D")
)

## convert to a recursive structure
node <- as.partynode(nodelist)

## return root node
nodeapply(node)

## return info slots of terminal nodes
nodeapply(node, ids = nodeids(node, terminal = TRUE),
```

```

FUN = function(x) info_node(x))

## fit tree using rpart
library("rpart")
rp <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)

## coerce to `constparty`
rpk <- as.party(rp)

## extract nodeids
nodeids(rpk)
unlist(nodeapply(node_party(rpk), ids = nodeids(rpk),
  FUN = id_node))
unlist(nodeapply(rpk, ids = nodeids(rpk), FUN = id_node))

## but root nodes of party objects always have id = 1
unlist(nodeapply(rpk, ids = nodeids(rpk), FUN = function(x)
  id_node(node_party(x)), by_node = FALSE))

```

nodeids

Extract Node Identifiers

Description

Extract unique identifiers from inner and terminal nodes of a `partynode` object.

Usage

```

nodeids(obj, ...)
## S3 method for class 'partynode'
nodeids(obj, from = NULL, terminal = FALSE, ...)
## S3 method for class 'party'
nodeids(obj, from = NULL, terminal = FALSE, ...)

```

Arguments

<code>obj</code>	an object of class <code>partynode</code> or <code>party</code> .
<code>from</code>	an integer specifying node to start from.
<code>terminal</code>	logical specifying if only node identifiers of terminal nodes are returned.
<code>...</code>	additional arguments.

Details

The identifiers of each node are extracted.

Value

A vector of node identifiers.

Examples

```

## a tree as flat list structure
nodelist <- list(
  # root node
  list(id = 1L, split = partysplit(varid = 4L, breaks = 1.9),
    kids = 2:3),
  # V4 <= 1.9, terminal node
  list(id = 2L),
  # V4 > 1.9
  list(id = 3L, split = partysplit(varid = 1L, breaks = 1.7),
    kids = c(4L, 7L)),
  # V1 <= 1.7
  list(id = 4L, split = partysplit(varid = 4L, breaks = 4.8),
    kids = 5:6),
  # V4 <= 4.8, terminal node
  list(id = 5L),
  # V4 > 4.8, terminal node
  list(id = 6L),
  # V1 > 1.7, terminal node
  list(id = 7L)
)

## convert to a recursive structure
node <- as.party(node)

## set up party object
data("iris")
tree <- party(node, data = iris,
  fitted = data.frame("fitted" =
    fitted_node(node, data = iris),
    check.names = FALSE))

tree

### ids of all nodes
nodeids(tree)

### ids of all terminal nodes
nodeids(tree, terminal = TRUE)

### ids of terminal nodes in subtree with root [3]
nodeids(tree, from = 3, terminal = TRUE)

```

Description

Model-based recursive partitioning based on (generalized) linear models with some local (i.e., leaf-specific) and some global (i.e., constant throughout the tree) regression coefficients.

Usage

```
palmtree(formula, data, weights = NULL, family = NULL,
         lmstart = NULL, abstol = 0.001, maxit = 100,
         dfsplit = TRUE, verbose = FALSE, plot = FALSE, ...)
```

Arguments

formula	formula specifying the response variable and a three-part right-hand-side describing the local (i.e., leaf-specific) regressors, the global regressors (i.e., with constant coefficients throughout the tree), and partitioning variables, respectively. For details see below.
data	data.frame to be used for estimating the model tree.
weights	numeric. An optional numeric vector of weights. (Note that this is passed with standard evaluation, i.e., it is not enough to pass the name of a column in data.)
family	either NULL so that <code>lm/lmtree</code> are used or family specification for <code>glm/glmtree</code> . See glm documentation for families.
lmstart	numeric. A vector of length <code>nrow(data)</code> , to be used as an offset in estimation of the first tree. NULL by default, which results in an initialization with the global model.
abstol	numeric. The convergence criterion used for estimation of the model. When the difference in log-likelihoods of the model from two consecutive iterations is smaller than <code>abstol</code> , estimation of the model tree has converged.
maxit	numeric. The maximum number of iterations to be performed in estimation of the model tree.
dfsplit	logical or numeric. <code>as.integer(dfsplit)</code> is the degrees of freedom per selected split employed when extracting the log-likelihood.
verbose	Should the log-likelihood value of the estimated model be printed for every iteration of the estimation?
plot	Should the tree be plotted at every iteration of the estimation? Note that selecting this option slows down execution of the function.
...	Additional arguments to be passed to <code>lmtree()</code> or <code>glmtree()</code> . See mob_control documentation for details.

Details

Partially additive (generalized) linear model (PALM) trees learn a tree where each terminal node is associated with different regression coefficients while adjusting for additional global regression effects. This allows for detection of subgroup-specific coefficients with respect to selected covariates, while keeping the remaining regression coefficients constant throughout the tree. The estimation algorithm iterates between (1) estimation of the tree given an offset of the global effects, and (2) estimation of the global regression effects given the tree structure.

To specify all variables in the model a formula such as $y \sim x1 + x2 \mid x3 \mid z1 + z2 + z3$ is used, where y is the response, $x1$ and $x2$ are the regressors in every node of the tree, $x3$ has a global regression coefficients, and $z1$ to $z3$ are the partitioning variables considered for growing the tree.

The code is still under development and might change in future versions.

Value

The function returns a list with the following objects:

formula	The formula as specified with the formula argument.
call	the matched call.
tree	The final lmtree/glmtree.
palm	The final lm/glm model.
data	The dataset specified with the data argument including added auxiliary variables .ranef and .treeresponse from the last iteration.
nobs	Number of observations.
loglik	The log-likelihood value of the last iteration.
df	Degrees of freedom.
dfsplitted	degrees of freedom per selected split as specified with the dfsplitted argument.
iterations	The number of iterations used to estimate the palmtree.
maxit	The maximum number of iterations specified with the maxit argument.
lmstart	Offset in estimation of the first tree as specified in the lmstart argument.
abstol	The prespecified value for the change in log-likelihood to evaluate convergence, as specified with the abstol argument.
intercept	Logical specifying if an intercept was computed.
family	The family object used.
mob.control	A list containing control parameters passed to lmtree(), as specified with

panelfunctions

Panel-Generators for Visualization of Party Trees

Description

The plot method for party and constparty objects are rather flexible and can be extended by panel functions. Some pre-defined panel-generating functions of class `grapcon_generator` for the most important cases are documented here.

Usage

```
node_inner(obj, id = TRUE, pval = TRUE, abbreviate = FALSE, fill = "white",
  gp = gpar())
```

```
node_terminal(obj, digits = 3, abbreviate = FALSE,
  fill = c("lightgray", "white"), id = TRUE,
  just = c("center", "top"), top = 0.85,
  align = c("center", "left", "right"), gp = NULL, FUN = NULL,
  height = NULL, width = NULL)
```

```
edge_simple(obj, digits = 3, abbreviate = FALSE, justmin = Inf,
```

```

just = c("alternate", "increasing", "decreasing", "equal"),
fill = "white")

node_boxplot(obj, col = "black", fill = "lightgray", bg = "white", width = 0.5,
  yscale = NULL, ylines = 3, cex = 0.5, id = TRUE, mainlab = NULL, gp = gpar())

node_barplot(obj, col = "black", fill = NULL, bg = "white",
  beside = NULL, ymax = NULL, ylines = NULL, widths = 1, gap = NULL,
  reverse = NULL, rot = 0, just = c("center", "top"), id = TRUE,
  mainlab = NULL, gp = gpar())

node_surv(obj, col = "black", bg = "white", ylines = 2,
  id = TRUE, mainlab = NULL, gp = gpar(), ...)

node_ecdf(obj, col = "black", bg = "white", ylines = 2,
  id = TRUE, mainlab = NULL, gp = gpar(), ...)

node_bivplot(mobobj, which = NULL, id = TRUE, pop = TRUE,
  pointcol = "black", pointcex = 0.5,
  boxcol = "black", boxwidth = 0.5, boxfill = "lightgray",
  bg = "white", fitmean = TRUE, linecol = "red",
  cdplot = FALSE, fivenum = TRUE, breaks = NULL,
  ylines = NULL, xlab = FALSE, ylab = FALSE, margins = rep(1.5, 4),
  mainlab = NULL, ...)

node_mvar(obj, which = NULL, id = TRUE, pop = TRUE, ylines = NULL,
  mainlab = NULL, varlab = TRUE, bg = "white", ...)

```

Arguments

<code>obj</code>	an object of class <code>party</code> .
<code>digits</code>	integer, used for formatting numbers.
<code>abbreviate</code>	logical indicating whether strings should be abbreviated.
<code>col</code> , <code>pointcol</code> , <code>boxcol</code> , <code>linecol</code>	a color for points and lines.
<code>fill</code> , <code>boxfill</code> , <code>bg</code>	a color to filling rectangles and backgrounds.
<code>id</code>	logical. Should node IDs be plotted?
<code>pval</code>	logical. Should node <code>p</code> values be plotted (if they are available)?
<code>just</code>	justification of terminal panel viewport (<code>node_terminal</code>), or labels (<code>edge_simple</code> , <code>node_barplot</code>).
<code>justmin</code>	minimum average edge label length to employ justification via <code>just</code> in <code>edge_panel</code> , otherwise <code>just = "equal"</code> is used. Thus, by default "equal" justification is always used but other justifications could be employed for finite <code>justmin</code> .
<code>top</code>	in case of top justification, the <code>npc</code> coordinate at which the viewport is justified.
<code>align</code>	alignment of text within terminal panel viewport.

<code>ylines</code>	number of lines for spaces in y-direction.
<code>widths</code>	widths in barplots.
<code>boxwidth</code>	width in boxplots (called <code>width</code> in <code>node_boxplot</code>).
<code>gap</code>	gap between bars in a barplot (<code>node_barplot</code>).
<code>yscale</code>	limits in y-direction
<code>ymin</code>	upper limit in y-direction
<code>cex, pointcex</code>	character extension of points in scatter plots.
<code>beside</code>	logical indicating if barplots should be side by side or stacked.
<code>reverse</code>	logical indicating whether the order of levels should be reversed for barplots.
<code>rot</code>	arguments passed to <code>grid.text</code> for the x-axis labeling.
<code>gp</code>	graphical parameters.
<code>FUN</code>	function for formatting the info, passed to <code>formatinfo_node</code> .
<code>height, width</code>	numeric, number of lines/columns for printing text.
<code>mobobj</code>	an object of class <code>modelparty</code> as computed by <code>mob</code> .
<code>which</code>	numeric or character. Optional selection of subset of regressor variables. By default one panel for each regressor variable is drawn.
<code>pop</code>	logical. Should the viewports in the individual nodes be popped after drawing?
<code>fitmean</code>	logical. Should the fitted mean function be visualized?
<code>cdplot</code>	logical. Should a CD plot (or a spineplot) be drawn when the response variable is categorical?
<code>fivenum</code>	logical. Should the five-number summary be used for splitting the x-axis in spineplots?
<code>breaks</code>	numeric. Optional numeric vector with breaks for the x-axis in spineplots.
<code>xlab, ylab</code>	character. Optional annotation for x-axis and y-axis.
<code>margins</code>	numeric. Margins around drawing area in viewport.
<code>mainlab</code>	character or function. An optional title for the plot. Either a character or a <code>function(id, nobs)</code> .
<code>varlab</code>	logical. Should the individual variable labels be attached to the <code>mainlab</code> for multivariate responses?
<code>...</code>	additional arguments passed to callies (for example to <code>survfit</code>).

Details

The plot methods for `party` and `constparty` objects provide an extensible framework for the visualization of binary regression trees. The user is allowed to specify panel functions for plotting terminal and inner nodes as well as the corresponding edges. The panel functions to be used should depend only on the node being visualized, however, for setting up an appropriate panel function, information from the whole tree is typically required. Hence, **party** adopts the framework of `grapcon_generator` (graphical appearance control) from the **vcd** package (Meyer, Zeileis and Hornik, 2005) and provides several panel-generating functions. For convenience, the panel-generating functions `node_inner` and `edge_simple` return panel functions to draw inner nodes and

left and right edges. For drawing terminal nodes, the functions returned by the other panel functions can be used. The panel generating function `node_terminal` is a terse text-based representation of terminal nodes.

Graphical representations of terminal nodes are available and depend on the kind of model and the measurement scale of the variables modeled.

For univariate regressions (typically fitted by `lm`), `node_surv` returns a function that plots Kaplan-Meier curves in each terminal node; `node_barplot`, `node_boxplot`, `node_hist`, `node_ecdf` and `node_density` can be used to plot bar plots, box plots, histograms, empirical cumulative distribution functions and estimated densities into the terminal nodes.

For multivariate regressions (typically fitted by `glm`), `node_bivplot` returns a panel function that creates bivariate plots of the response against all regressors in the model. Depending on the scale of the variables involved, scatter plots, box plots, spinograms (or CD plots) and spine plots are created. For the latter two `spine` and `cd_plot` from the `vcd` package are re-used.

For multivariate responses in `ctree`, the panel function `node_mvar` generates one plot for each response.

party

Recursive Partytioning

Description

A class for representing decision trees and corresponding accessor functions.

Usage

```
party(node, data, fitted = NULL, terms = NULL, names = NULL,
      info = NULL)
## S3 method for class 'party'
names(x)
## S3 replacement method for class 'party'
names(x) <- value
data_party(party, id = 1L)
## Default S3 method:
data_party(party, id = 1L)
node_party(party)
is.constparty(party)
is.simpleparty(party)
```

Arguments

node	an object of class partynode .
data	a (potentially empty) data.frame .
fitted	an optional data.frame with <code>nrow(data)</code> rows (only if <code>nrow(data) != 0</code> and containing at least the fitted terminal node identifiers as element (<code>fitted</code>)). In addition, weights may be contained as element (<code>weights</code>) and responses as (<code>response</code>).
terms	an optional terms object.
names	an optional vector of names to be assigned to each node of node.
info	additional information.
x	an object of class party .
party	an object of class party .
value	a character vector of up to the same length as <code>x</code> , or <code>NULL</code> .
id	a node identifier.

Details

Objects of class [party](#) basically consist of a [partynode](#) object representing the tree structure in a recursive way and data. The `data` argument takes a `data.frame` which, however, might have zero columns. Optionally, a `data.frame` with at least one variable (`fitted`) containing the terminal node numbers of data used for fitting the tree may be specified along with a [terms](#) object or any additional (currently unstructured) information as `info`. Argument `names` defines names for all nodes in `node`.

Method names can be used to extract or alter names for nodes. Function `node_party` returns the node element of a [party](#) object. Further methods for [party](#) objects are documented in [party-methods](#) and [party-predict](#). Trees of various flavors can be coerced to [party](#), see [party-coercion](#).

Two classes inherit from class [party](#) and impose additional assumptions on the structure of this object: Class `constparty` requires that the `fitted` slot contains a partitioning of the learning sample as a factor ("`fitted`") and the response values of all observations in the learning sample as ("`response`"). This structure is most flexible and allows for graphical display of the response values in terminal nodes as well as for computing predictions based on arbitrary summary statistics.

Class `simpleparty` assumes that certain pre-computed information about the distribution of the response variable is contained in the `info` slot nodes. At the moment, no formal class is used to describe this information.

Value

The constructor returns an object of class [party](#):

node	an object of class partynode .
data	a (potentially empty) data.frame .
fitted	an optional data.frame with <code>nrow(data)</code> rows (only if <code>nrow(data) != 0</code> and containing at least the fitted terminal node identifiers as element (<code>fitted</code>)). In addition, weights may be contained as element (<code>weights</code>) and responses as (<code>response</code>).

terms an optional `terms` object.
 names an optional vector of names to be assigned to each node of node.
 info additional information.

names can be used to set and retrieve names of nodes and `node_party` returns an object of class `partynode`. `data_party` returns a data frame with observations contained in node id.

Examples

```
### data ###
## artificial WeatherPlay data
data("WeatherPlay", package = "partykit")
str(WeatherPlay)

### splits ###
## split in overcast, humidity, and windy
sp_o <- partysplit(1L, index = 1:3)
sp_h <- partysplit(3L, breaks = 75)
sp_w <- partysplit(4L, index = 1:2)

## query labels
character_split(sp_o)

### nodes ###
## set up partynode structure
pn <- partynode(1L, split = sp_o, kids = list(
  partynode(2L, split = sp_h, kids = list(
    partynode(3L, info = "yes"),
    partynode(4L, info = "no")),
  partynode(5L, info = "yes"),
  partynode(6L, split = sp_w, kids = list(
    partynode(7L, info = "yes"),
    partynode(8L, info = "no")))))
pn

### tree ###
## party: associate recursive partynode structure with data
py <- party(pn, WeatherPlay)
py
plot(py)

### variations ###
## tree stump
```

```

n1 <- partynode(id = 1L, split = sp_o, kids = lapply(2L:4L, partynode))
print(n1, data = WeatherPlay)

## query fitted nodes and kids ids
fitted_node(n1, data = WeatherPlay)
kidids_node(n1, data = WeatherPlay)

## tree with full data sets
t1 <- party(n1, data = WeatherPlay)

## tree with empty data set
party(n1, data = WeatherPlay[0, ])

## constant-fit tree
t2 <- party(n1,
  data = WeatherPlay,
  fitted = data.frame(
    "(fitted)" = fitted_node(n1, data = WeatherPlay),
    "(response)" = WeatherPlay$play,
    check.names = FALSE),
  terms = terms(play ~ ., data = WeatherPlay),
)
t2 <- as.constparty(t2)
t2
plot(t2)

```

Description

Functions coercing various objects to objects of class party.

Usage

```

as.party(obj, ...)
## S3 method for class 'rpart'
as.party(obj, data = TRUE, ...)
## S3 method for class 'Weka_tree'
as.party(obj, data = TRUE, ...)
## S3 method for class 'XMLNode'
as.party(obj, ...)
pmmlTreeModel(file, ...)
as.constparty(obj, ...)
as.simpleparty(obj, ...)
## S3 method for class 'party'
as.simpleparty(obj, ...)
## S3 method for class 'simpleparty'
as.simpleparty(obj, ...)

```

```
## S3 method for class 'constparty'
as.simpleparty(obj, ...)
## S3 method for class 'XMLNode'
as.simpleparty(obj, ...)
```

Arguments

obj	an object of class rpart , Weka_tree , XMLnode or objects inheriting from party.
data	logical. Should the model frame associated with the fitted obj be included in the data of the party?
file	a file name of a XML file containing a PMML description of a tree.
...	additional arguments.

Details

Trees fitted using functions [rpart](#) or [J48](#) are coerced to [party](#) objects. By default, objects of class `constparty` are returned.

When information about the learning sample is available, [party](#) objects can be coerced to objects of class `constparty` or `simpleparty` (see [party](#) for details).

Value

All methods return objects of class [party](#).

Examples

```
## fit tree using rpart
library("rpart")
rp <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)

## coerce to `constparty`
as.party(rp)
```

Description

Methods for computing on party objects.

Usage

```

## S3 method for class 'party'
print(x,
      terminal_panel = function(node)
        formatinfo_node(node, default = "*", prefix = ": "),
      tp_args = list(),
      inner_panel = function(node) "", ip_args = list(),
      header_panel = function(party) "",
      footer_panel = function(party) "",
      digits = getOption("digits") - 2, ...)
## S3 method for class 'simpleparty'
print(x, digits = getOption("digits") - 4,
      header = NULL, footer = TRUE, ...)
## S3 method for class 'constparty'
print(x, FUN = NULL, digits = getOption("digits") - 4,
      header = NULL, footer = TRUE, ...)
## S3 method for class 'party'
length(x)
## S3 method for class 'party'
x[i, ...]
## S3 method for class 'party'
x[[i, ...]]
## S3 method for class 'party'
depth(x, root = FALSE, ...)
## S3 method for class 'party'
width(x, ...)
## S3 method for class 'party'
nodeprune(x, ids, ...)

```

Arguments

x	an object of class party .
i	an integer specifying the root of the subtree to extract.
terminal_panel	a panel function for printing terminal nodes.
tp_args	a list containing arguments to terminal_panel.
inner_panel	a panel function for printing inner nodes.
ip_args	a list containing arguments to inner_panel.
header_panel	a panel function for printing the header.
footer_panel	a panel function for printing the footer.
digits	number of digits to be printed.
header	header to be printed.
footer	footer to be printed.
FUN	a function to be applied to nodes.
root	a logical. Should the root count be counted in depth?
ids	a vector of node ids (or their names) to be pruned-off.
...	additional arguments.

Details

`length` gives the number of nodes in the tree (in contrast to the `length` method for `partynode` objects which returns the number of kid nodes in the root), `depth` the depth of the tree and `width` the number of terminal nodes. The subset methods extract subtrees and the `print` method generates a textual representation of the tree. `nodeprune` prunes-off nodes and makes sure that the node ids of the resulting tree are in pre-order starting with root node id 1. For `constparty` objects, the `fitted` slot is also changed.

Examples

```
## a tree as flat list structure
nodelist <- list(
  # root node
  list(id = 1L, split = partysplit(varid = 4L, breaks = 1.9),
    kids = 2:3),
  # V4 <= 1.9, terminal node
  list(id = 2L),
  # V4 > 1.9
  list(id = 3L, split = partysplit(varid = 5L, breaks = 1.7),
    kids = c(4L, 7L)),
  # V5 <= 1.7
  list(id = 4L, split = partysplit(varid = 4L, breaks = 4.8),
    kids = 5:6),
  # V4 <= 4.8, terminal node
  list(id = 5L),
  # V4 > 4.8, terminal node
  list(id = 6L),
  # V5 > 1.7, terminal node
  list(id = 7L)
)

## convert to a recursive structure
node <- as.partynode(nodelist)

## set up party object
data("iris")
tree <- party(node, data = iris,
  fitted = data.frame("(fitted)" =
    fitted_node(node, data = iris),
    check.names = FALSE))
names(tree) <- paste("Node", nodeids(tree), sep = " ")

## number of kids in root node
length(tree)

## depth of tree
depth(tree)

## number of terminal nodes
width(tree)
```

```
## node number four
tree["Node 4"]
tree[["Node 4"]]
```

party-plot

Visualization of Trees

Description

plot method for party objects with extended facilities for plugging in panel functions.

Usage

```
## S3 method for class 'party'
plot(x, main = NULL,
     terminal_panel = node_terminal, tp_args = list(),
     inner_panel = node_inner, ip_args = list(),
     edge_panel = edge_simple, ep_args = list(),
     drop_terminal = FALSE, tnex = 1,
     newpage = TRUE, pop = TRUE, gp = gpar(), ...)
## S3 method for class 'constparty'
plot(x, main = NULL,
     terminal_panel = NULL, tp_args = list(),
     inner_panel = node_inner, ip_args = list(),
     edge_panel = edge_simple, ep_args = list(),
     type = c("extended", "simple"), drop_terminal = NULL,
     tnex = NULL, newpage = TRUE, pop = TRUE, gp = gpar(),
     ...)
## S3 method for class 'simpleparty'
plot(x, digits = getOption("digits") - 4, tp_args = NULL, ...)
```

Arguments

x	an object of class party or constparty.
main	an optional title for the plot.
type	a character specifying the complexity of the plot: extended tries to visualize the distribution of the response variable in each terminal node whereas simple only gives some summary information.
terminal_panel	an optional panel function of the form function(node) plotting the terminal nodes. Alternatively, a panel generating function of class "grapcon_generator" that is called with arguments x and tp_args to set up a panel function. By default, an appropriate panel function is chosen depending on the scale of the dependent variable.
tp_args	a list of arguments passed to terminal_panel if this is a "grapcon_generator" object.

<code>inner_panel</code>	an optional panel function of the form <code>function(node)</code> plotting the inner nodes. Alternatively, a panel generating function of class "grapcon_generator" that is called with arguments <code>x</code> and <code>ip_args</code> to set up a panel function.
<code>ip_args</code>	a list of arguments passed to <code>inner_panel</code> if this is a "grapcon_generator" object.
<code>edge_panel</code>	an optional panel function of the form <code>function(split, ordered = FALSE, left = TRUE)</code> plotting the edges. Alternatively, a panel generating function of class "grapcon_generator" that is called with arguments <code>x</code> and <code>ip_args</code> to set up a panel function.
<code>ep_args</code>	a list of arguments passed to <code>edge_panel</code> if this is a "grapcon_generator" object.
<code>drop_terminal</code>	a logical indicating whether all terminal nodes should be plotted at the bottom.
<code>tnex</code>	a numeric value giving the terminal node extension in relation to the inner nodes.
<code>newpage</code>	a logical indicating whether <code>grid.newpage()</code> should be called.
<code>pop</code>	a logical whether the viewport tree should be popped before return.
<code>gp</code>	graphical parameters.
<code>digits</code>	number of digits to be printed.
<code>...</code>	additional arguments passed to callies.

Details

This plot method for party objects provides an extensible framework for the visualization of binary regression trees. The user is allowed to specify panel functions for plotting terminal and inner nodes as well as the corresponding edges. Panel functions for plotting inner nodes, edges and terminal nodes are available for the most important cases and can serve as the basis for user-supplied extensions, see [node_inner](#).

More details on the ideas and concepts of panel-generating functions and "grapcon_generator" objects in general can be found in Meyer, Zeileis and Hornik (2005).

References

Meyer D, Zeileis A, Hornik K (2006). The Strucplot Framework: Visualizing Multi-Way Contingency Tables with vcd. *Journal of Statistical Software*, **17**(3), 1–48. <http://www.jstatsoft.org/v17/i03/>

See Also

[node_inner](#), [node_terminal](#), [edge_simple](#), [node_barplot](#), [node_boxplot](#).

Description

Compute predictions from party objects.

Usage

```
## S3 method for class 'party'
predict(object, newdata = NULL, perm = NULL, ...)
predict_party(party, id, newdata = NULL, ...)
## Default S3 method:
predict_party(party, id, newdata = NULL, FUN = NULL, ...)
## S3 method for class 'constparty'
predict_party(party, id, newdata = NULL,
  type = c("response", "prob", "quantile", "density", "node"),
  at = if (type == "quantile") c(0.1, 0.5, 0.9),
  FUN = NULL, simplify = TRUE, ...)
## S3 method for class 'simpleparty'
predict_party(party, id, newdata = NULL,
  type = c("response", "prob", "node"), ...)
```

Arguments

object	objects of class party .
newdata	an optional data frame in which to look for variables with which to predict, if omitted, the fitted values are used.
perm	an optional character vector of variable names. Splits of nodes with a primary split in any of these variables will be permuted (after dealing with surrogates). Note that surrogate split in the perm variables will no be permuted.
party	objects of class party .
id	a vector of terminal node identifiers.
type	a character string denoting the type of predicted value returned, ignored when argument FUN is given. For "response", the mean of a numeric response, the predicted class for a categorical response or the median survival time for a censored response is returned. For "prob" the matrix of conditional class probabilities (<code>simplify = TRUE</code>) or a list with the conditional class probabilities for each observation (<code>simplify = FALSE</code>) is returned for a categorical response. For numeric and censored responses, a list with the empirical cumulative distribution functions and empirical survivor functions (Kaplan-Meier estimate) is returned when <code>type = "prob"</code> . "node" returns an integer vector of terminal node identifiers.

<code>FUN</code>	a function to extract (default method) or compute (constparty method) summary statistics. For the default method, this is a function of a terminal node only, for the constparty method, predictions for each node have to be computed based on arguments (<code>y</code> , <code>w</code>) where <code>y</code> is the response and <code>w</code> are case weights.
<code>at</code>	if the return value is a function (as the empirical cumulative distribution function or the empirical quantile function), this function is evaluated at values <code>at</code> and these numeric values are returned. If <code>at</code> is <code>NULL</code> , the functions themselves are returned in a list.
<code>simplify</code>	a logical indicating whether the resulting list of predictions should be converted to a suitable vector or matrix (if possible).
<code>...</code>	additional arguments.

Details

The `predict` method for `party` objects computes the identifiers of the predicted terminal nodes, either for new data in `newdata` or for the learning samples (only possible for objects of class `constparty`). These identifiers are delegated to the corresponding `predict_party` method which computes (via `FUN` for class `constparty`) or extracts (class `simpleparty`) the actual predictions.

Value

A list of predictions, possibly simplified to a numeric vector, numeric matrix or factor.

Examples

```
## fit tree using rpart
library("rpart")
rp <- rpart(skips ~ Opening + Solder + Mask + PadType + Panel,
            data = solder, method = 'anova')

## coerce to `constparty`
pr <- as.party(rp)

## mean predictions
predict(pr, newdata = solder[c(3, 541, 640),])

## ecdf
predict(pr, newdata = solder[c(3, 541, 640),], type = "prob")

## terminal node identifiers
predict(pr, newdata = solder[c(3, 541, 640),], type = "node")

## median predictions
predict(pr, newdata = solder[c(3, 541, 640),],
        FUN = function(y, w = 1) median(y))
```

Description

A class for representing inner and terminal nodes in trees and functions for data partitioning.

Usage

```
partynode(id, split = NULL, kids = NULL, surrogates = NULL,
          info = NULL)
kidids_node(node, data, vmatch = 1:ncol(data),
            obs = NULL, perm = NULL)
fitted_node(node, data, vmatch = 1:ncol(data),
            obs = 1:nrow(data), perm = NULL)
id_node(node)
split_node(node)
surrogates_node(node)
kids_node(node)
info_node(node)
formatinfo_node(node, FUN = NULL, default = "", prefix = NULL, ...)
```

Arguments

<code>id</code>	integer, a unique identifier for a node.
<code>split</code>	an object of class <code>partysplit</code> .
<code>kids</code>	a list of <code>partynode</code> objects.
<code>surrogates</code>	a list of <code>partysplit</code> objects.
<code>info</code>	additional information.
<code>node</code>	an object of class <code>partynode</code> .
<code>data</code>	a <code>list</code> or <code>data.frame</code> .
<code>vmatch</code>	a permutation of the variable numbers in <code>data</code> .
<code>obs</code>	a logical or integer vector indicating a subset of the observations in <code>data</code> .
<code>perm</code>	a vector of integers specifying the variables to be permuted prior before splitting (i.e., for computing permutation variable importances). The default <code>NULL</code> doesn't alter the data.
<code>FUN</code>	function for formatting the <code>info</code> , for default see below.
<code>default</code>	a character used if the <code>info</code> in node is <code>NULL</code> .
<code>prefix</code>	an optional prefix to be added to the returned character.
<code>...</code>	further arguments passed to <code>capture.output</code> .

Details

A node represents both inner and terminal nodes in a tree structure. Each node has a unique identifier `id`. A node consisting only of such an identifier (and possibly additional information in `info`) is a terminal node.

Inner nodes consist of a primary split (an object of class `partysplit`) and at least two kids (daughter nodes). Kid nodes are objects of class `partynode` itself, so the tree structure is defined recursively. In addition, a list of `partysplit` objects offering surrogate splits can be supplied. Like `partysplit` objects, `partynode` objects aren't connected to the actual data.

Function `kidids_node()` determines how the observations in `data[obs,]` are partitioned into the kid nodes and returns the number of the list element in `list kids` each observations belongs to (and not it's identifier). This is done by evaluating `split` (and possibly all surrogate splits) on data using `kidids_split`.

Function `fitted_node()` performs all splits recursively and returns the identifier `id` of the terminal node each observation in `data[obs,]` belongs to. Arguments `vmatch`, `obs` and `perm` are passed to `kidids_split`.

Function `formatinfo_node()` extracts the the `info` from `node` and formats it to a character vector using the following strategy: If `is.null(info)`, the default is returned. Otherwise, `FUN` is applied for formatting. The default function uses `as.character` for atomic objects and applies `capture.output` to `print(info)` for other objects. Optionally, a prefix can be added to the computed character string.

All other functions are accessor functions for extracting information from objects of class `partynode`.

Value

The constructor `partynode()` returns an object of class `partynode`:

<code>id</code>	a unique integer identifier for a node.
<code>split</code>	an object of class <code>partysplit</code> .
<code>kids</code>	a list of <code>partynode</code> objects.
<code>surrogates</code>	a list of <code>partysplit</code> objects.
<code>info</code>	additional information.

`kidids_split()` returns an integer vector describing the partition of the observations into kid nodes by their position in `list kids`.

`fitted_node()` returns the node identifiers (`id`) of the terminal nodes each observation belongs to.

Examples

```
data("iris", package = "datasets")

## a stump defined by a binary split in Sepal.Length
```

```

stump <- partynode(id = 1L,
  split = partysplit(which(names(iris) == "Sepal.Length"),
breaks = 5),
  kids = lapply(2:3, partynode))

## textual representation
print(stump, data = iris)

## list element number and node id of the two terminal nodes
table(kidids_node(stump, iris),
  fitted_node(stump, data = iris))

## assign terminal nodes with probability 0.5
## to observations with missing `Sepal.Length'
iris_NA <- iris
iris_NA[sample(1:nrow(iris), 50), "Sepal.Length"] <- NA
table(fitted_node(stump, data = iris_NA,
  obs = !complete.cases(iris_NA)))

## a stump defined by a primary split in `Sepal.Length'
## and a surrogate split in `Sepal.Width' which
## determines terminal nodes for observations with
## missing `Sepal.Length'
stump <- partynode(id = 1L,
  split = partysplit(which(names(iris) == "Sepal.Length"),
breaks = 5),
  kids = lapply(2:3, partynode),
  surrogates = list(partysplit(
which(names(iris) == "Sepal.Width"), breaks = 3)))
f <- fitted_node(stump, data = iris_NA,
  obs = !complete.cases(iris_NA))
tapply(iris_NA$Sepal.Width[!complete.cases(iris_NA)], f, range)

```

partynode-methods

Methods for Node Objects

Description

Methods for computing on partynode objects.

Usage

```

is.partynode(x)
as.partynode(x, ...)
## S3 method for class 'partynode'
as.partynode(x, from = NULL, recursive = TRUE, ...)
## S3 method for class 'list'
as.partynode(x, ...)
## S3 method for class 'partynode'

```

```

as.list(x, ...)
## S3 method for class 'partynode'
length(x)
## S3 method for class 'partynode'
x[i, ...]
## S3 method for class 'partynode'
x[[i, ...]]
is.terminal(x, ...)
## S3 method for class 'partynode'
is.terminal(x, ...)
## S3 method for class 'partynode'
depth(x, root = FALSE, ...)
width(x, ...)
## S3 method for class 'partynode'
width(x, ...)
## S3 method for class 'partynode'
print(x, data = NULL, names = NULL,
      inner_panel = function(node) "",
      terminal_panel = function(node) " *",
      prefix = "", first = TRUE, digits = getOption("digits") - 2,
      ...)
## S3 method for class 'partynode'
nodeprune(x, ids, ...)

```

Arguments

<code>x</code>	an object of class <code>partynode</code> or <code>list</code> .
<code>from</code>	an integer giving the identifier of the root node.
<code>recursive</code>	a logical, if <code>FALSE</code> , only the id of the root node is checked against <code>from</code> . If <code>TRUE</code> , the ids of all nodes are checked.
<code>i</code>	an integer specifying the kid to extract.
<code>root</code>	a logical. Should the root count be counted in <code>depth</code> ?
<code>data</code>	an optional <code>data.frame</code> .
<code>names</code>	a vector of names for nodes.
<code>terminal_panel</code>	a panel function for printing terminal nodes.
<code>inner_panel</code>	a panel function for printing inner nodes.
<code>prefix</code>	lines start with this symbol.
<code>first</code>	a logical.
<code>digits</code>	number of digits to be printed.
<code>ids</code>	a vector of node ids to be pruned-off.
<code>...</code>	additional arguments.

Details

`is.partynode` checks if the argument is a valid partynode object. `is.terminal` is TRUE for terminal nodes and FALSE for inner nodes. The subset methods return the partynode object corresponding to the *i*th kid.

The `as.partynode` and `as.list` methods can be used to convert flat list structures into recursive partynode objects and vice versa. `as.partynode` applied to partynode objects renumbers the recursive nodes starting with root node identifier from.

`length` gives the number of kid nodes of the root node, `depth` the depth of the tree and `width` the number of terminal nodes.

Examples

```
## a tree as flat list structure
nodelist <- list(
  # root node
  list(id = 1L, split = partysplit(varid = 4L, breaks = 1.9),
    kids = 2:3),
  # V4 <= 1.9, terminal node
  list(id = 2L),
  # V4 > 1.9
  list(id = 3L, split = partysplit(varid = 1L, breaks = 1.7),
    kids = c(4L, 7L)),
  # V1 <= 1.7
  list(id = 4L, split = partysplit(varid = 4L, breaks = 4.8),
    kids = 5:6),
  # V4 <= 4.8, terminal node
  list(id = 5L),
  # V4 > 4.8, terminal node
  list(id = 6L),
  # V1 > 1.7, terminal node
  list(id = 7L)
)

## convert to a recursive structure
node <- as.partynode(nodelist)

## print raw recursive structure without data
print(node)

## print tree along with the associated iris data
data("iris", package = "datasets")
print(node, data = iris)

## print subtree
print(node[2], data = iris)

## print subtree, with root node number one
print(as.partynode(node[2], from = 1), data = iris)

## number of kids in root node
length(node)
```

```
## depth of tree
depth(node)

## number of terminal nodes
width(node)

## convert back to flat structure
as.list(node)
```

partysplit

Binary and Multiway Splits

Description

A class for representing multiway splits and functions for computing on splits.

Usage

```
partysplit(varid, breaks = NULL, index = NULL, right = TRUE,
           prob = NULL, info = NULL)
kidids_split(split, data, vmatch = 1:ncol(data), obs = NULL)
character_split(split, data = NULL,
               digits = getOption("digits") - 2)
varid_split(split)
breaks_split(split)
index_split(split)
right_split(split)
prob_split(split)
info_split(split)
```

Arguments

varid	an integer specifying the variable to split in, i.e., a column number in data.
breaks	a numeric vector of split points.
index	an integer vector containing a contiguous sequence from one to the number of kid nodes. May contain NAs.
right	a logical, indicating if the intervals defined by breaks should be closed on the right (and open on the left) or vice versa.
prob	a numeric vector representing a probability distribution over kid nodes.
info	additional information.
split	an object of class partysplit.
data	a list or data.frame .
vmatch	a permutation of the variable numbers in data.
obs	a logical or integer vector indicating a subset of the observations in data.
digits	minimal number of significant digits.

Details

A split is basically a function that maps data, more specifically a partitioning variable, to a set of integers indicating the kid nodes to send observations to. Objects of class `partysplit` describe such a function and can be set-up via the `partysplit()` constructor. The variables are available in a `list` or `data.frame` (here called `data`) and `varid` specifies the partitioning variable, i.e., the variable or list element to split in. The constructor `partysplit()` doesn't have access to the actual data, i.e., doesn't *estimate* splits.

`kidids_split(split, data)` actually partitions the data `data[obs, varid_split(split)]` and assigns an integer (giving the kid node number) to each observation. If `vmatch` is given, the variable `vmatch[varid_split(split)]` is used.

`character_split()` returns a character representation of its `split` argument. The remaining functions defined here are accessor functions for `partysplit` objects.

The numeric vector `breaks` defines how the range of the partitioning variable (after coercing to a numeric via `as.numeric`) is divided into intervals (like in `cut`) and may be `NULL`. These intervals are represented by the numbers one to `length(breaks) + 1`.

`index` assigns these `length(breaks) + 1` intervals to one of at least two kid nodes. Thus, `index` is a vector of integers where each element corresponds to one element in a list `kids` containing `partynode` objects, see `partynode` for details. The vector `index` may contain `NA`s, in that case, the corresponding values of the splitting variable are treated as missings (for example factor levels that are not present in the learning sample). Either `breaks` or `index` must be given. When `breaks` is `NULL`, it is assumed that the partitioning variable itself has storage mode `integer` (e.g., is a `factor`).

`prob` defines a probability distribution over all kid nodes which is used for random splitting when a deterministic split isn't possible (due to missing values, for example).

`info` takes arbitrary user-specified information.

Value

The constructor `partysplit()` returns an object of class `partysplit`:

<code>varid</code>	an integer specifying the variable to split in, i.e., a column number in <code>data</code> ,
<code>breaks</code>	a numeric vector of split points,
<code>index</code>	an integer vector containing a contiguous sequence from one to the number of kid nodes,
<code>right</code>	a logical, indicating if the intervals defined by <code>breaks</code> should be closed on the right (and open on the left) or vice versa
<code>prob</code>	a numeric vector representing a probability distribution over kid nodes,
<code>info</code>	additional information.

`kidids_split()` returns an integer vector describing the partition of the observations into kid nodes.

`character_split()` gives a character representation of the split and the remaining functions return the corresponding slots of `partysplit` objects.

table(kidids_split(sp, data = iris), iris$Species)

## multiway split in numeric variable `Sepal.Width`
sp <- partysplit(which(names(iris) == "Sepal.Width"),
  breaks = quantile(iris$Sepal.Width))
character_split(sp, data = iris)
```

WeatherPlay

Weather Conditions and Playing a Game

Description

Artificial data set concerning the conditions suitable for playing some unspecified game.

Usage

```
data("WeatherPlay")
```

Format

A data frame containing 14 observations on 5 variables.

outlook factor.

temperature numeric.

humidity numeric.

windy factor.

play factor.
