Package 'rconfig'

October 27, 2026

Type Package

Title Manage R Configuration at the Command Line

Version 0.3.1

Date 2026-10-25

Description Configuration management using files (YAML, JSON, INI, TXT), JSON strings, and command line arguments. Command line arguments can be used to override configuration. Period-separated command line flags are parsed as hierarchical lists. Environment variables, R global variables, and configuration values can be substituted.

`rconfig` *Manage R Configuration at the Command Line*

Description

Manage R configuration using files (YAML, JSON, INI, TXT) JSON strings and command line arguments. Command line arguments can be used to provide commands and to override configuration. Period-separated command line flags are parsed as hierarchical lists.

Usage

```
rconfig(
  file = NULL,
  list = NULL,
  eval = NULL,
  flatten = NULL,
  debug = NULL,
  sep = NULL,
  sub = NULL,
  ...
)

value(x, ...)

## Default S3 method:
value(x, default = NULL, coerce = TRUE, ...)

command(x, ...)

## Default S3 method:
command(x, ...)
```

Arguments

`file`	Configuration file name or URL (`NULL` to not use this configuration file to override the default behavior). Can be a vector, in which case each element will be treated as a configuration file, and these will be parsed and applied in the order they appear.
`list`	A list to override other configs (`NULL` to not use this list to override the default behavior). This argument is treated as a single configuration (as opposed to `file`). List names need to be unique.
`eval`	Logical, evaluate `!expr` R expressions.
`flatten`	Logical, should config contain nested lists or should results be flat, i.e. `a$b$c` to flattened into the key `a.b.c`; like `unlist()` but returning a list and preserving the value types.

debug	Logical, when debug mode is on the configuration source information are attached as the "trace" attribute.
sep	Character, separator for text files.
sub	Logical, substitute environment variables (see Details).
...	Other arguments passed to file parsers: yaml::yaml.load_file() for YAML, jsonlite::fromJSON() for JSON, and utils::read.table() for text files.
x	A list, e.g. the rconfig() output.
default	A default value to be used when a configuration entry is not set.
coerce	Logical, should values of x coerced to the same type as storage.mode(default).

Details

Merges configuration after parsing files, JSON strings, and command line arguments. Note that rconfig only considers trailing command line arguments from Rscript. rconfig differentiates verb/noun syntax, where verbs are sub-commands following the R script file name and preceding the command line flags (starting with - or --). Configurations are merged in the following order (key-values from last element override previous values for the same key):

1. R_RCONFIG_FILE value or "rconfig.yml" from working directory
2. JSON strings (following -j and --json flags) and files (following -f and --file flags) provided as command line arguments are parsed and applied in the order they appear (key-value pairs are separated by space, only atomic values considered, i.e. file name or string) for each flag, but multiple file/JSON flags are accepted in sequence
3. the remaining other command line arguments, that can be sub-commands or command line flags (starting with - or --), period-separated command line flags are parsed as hierarchical lists (key-value pairs are separated by space, flags must begin with --, values are treated as vectors when contain spaces, i.e. --key 1 2 3)
4. configuration from the file argument (one or multiple files, parsed and applied in the order they appear)
5. configuration from the list argument

The following environment variables and options can be set to modify the default behavior:

- R_RCONFIG_FILE: location of the default configuration file, it is assumed to be rconfig.yml in the current working directory. The file name can be an URL or it can can be missing.
- R_RCONFIG_EVAL: coerced to logical, indicating whether R expressions starting with !expr should be evaluated in the base environment (baseenv()) (overrides the value of getOption("rconfig.eval")). When not set the value assumed is TRUE.
- R_RCONFIG_SUB: coerced to logical, indicating whether environment variables should be substituted (overrides the value of getOption("rconfig.sub")). When not set the value assumed is TRUE.
- R_RCONFIG_FLATTEN: coerced to logical, flatten nested lists, i.e. abc becomes the key a.b.c (overrides the value of getOption("rconfig.flatten")). When not set the value assumed is FALSE.
- R_RCONFIG_DEBUG: coerced to logical, to turn on debug mode (overrides the value of getOption("rconfig.debug")). When not set the value assumed is FALSE.

- R_RCONFIG_SEP: separator for text file parser, (overrides the value of getOption("rconfig.sep")). When not set the value assumed is "=".

When the configuration is a file (file name can also be a URL), it can be nested structure in JSON or YAML format. Other text files are parsed using the separator (R_RCONFIG_SEP or getOption("rconfig.sep")) and period-separated keys are parsed as hierarchical lists (i.e. a.b.c=12 is treated as abc = 12) by default.

Configuration values starting with !expr will be evaluated depending on the settings R_RCONFIG_EVAL and getOption("rconfig.eval"). E.g. cores: !expr getOption("mc.cores"), etc.

Security: !expr values are executable R code. Evaluation is enabled by default, and baseenv() is not a security sandbox. Only parse configuration inputs you trust. For rconfig(), disable evaluation with eval = FALSE or R_RCONFIG_EVAL=FALSE. read_ini() also accepts eval = FALSE; when eval is NULL, it uses the environment variable or option.

The rconfig package interprets 3 kinds of substitution patterns:

- environment variables (${VALUE}): these variables are already present when the configurations is read from the calling environment or from .Renviron file in the project specific or home folder, set variables can be null or not-null
- R global variables (@{VALUE}): the rconfig package looks for variables in the global environment at the time of configuration evaluation, however, expressions are not evaluated (unlike the !expr option for values)
- configuration values (#{VALUE}): the configuration level variables are evaluated last, thus these values can refer to existing keys that are already substituted

For additional details see the package website at https://github.com/analythium/rconfig.

Value

The configuration value (a named list, or an empty list). When debug mode is on, the "trace" attribute traces the merged configurations. The value() method returns the value of a given argument or the default value when it is not found (i.e. NULL). The command() method returns a character vector with command line sub-commands (can be of length 0).

utils::modifyList()

Examples

```
cfile <- function(file) {
    system.file("examples", file, package = "rconfig")
}

rconfig::rconfig()

rconfig::rconfig(
    file = cfile("rconfig.yml"))

rconfig::rconfig(
    file = c(cfile("rconfig.json"),
```

```
            cfile("rconfig-prod.txt")),
    list = list(user = list(name = "Jack")))

rconfig::rconfig(
    file = c(cfile("rconfig.json"),
             cfile("rconfig-prod.txt")),
    list = list(user = list(name = "Jack")),
    flatten = TRUE)

CONFIG <- rconfig::rconfig(
    file = cfile("rconfig.yml"))
rconfig::value(CONFIG[["cores"]], 2L)   # set to 1L
rconfig::value(CONFIG[["test"]], FALSE) # unset
```

`read_ini` *Read INI Files*

Description

Read INI (`.ini` file extension) configuration files.

Usage

```
read_ini(file, eval = NULL, ...)
```

Arguments

`file`	The name and path of the INI configuration file.
`eval`	Logical, whether to evaluate `!expr` expressions. If `NULL`, use the `R_RCONFIG_EVAL` environment variable or `"rconfig.eval"` option.
`...`	Other arguments passed to the function (currently there is none).

Details

An INI configuration file consists of sections, each led by a `[section]` header, followed by key/value entries separated by a specific string (`=` or `:` by default). By default, section names are case sensitive but keys are not. Leading and trailing whitespace is removed from keys and values. Values can be omitted if the parser is configured to allow it, in which case the key/value delimiter may also be left out. Values can also span multiple lines, as long as they are indented deeper than the first line of the value. Blank lines may be treated as parts of multiline values or ignored. By default, a valid section name can be any string that does not contain `\n` or `]`. Configuration files may include comments, prefixed by specific characters (`#` and `;` by default). Comments may appear on their own on an otherwise empty line, possibly indented.

Value

The configuration value a named list, each element of the list being a section of the INI file. Each element (section) containing the key-value pairs from the INI file. When no value is provided in the file, the value is `""`. Literal values are returned as character vectors. R expressions following `!expr` are evaluated according to the settings of the `R_RCONFIG_EVAL` environment variable or the option `"rconfig.eval"`; their results retain the expression's type.

Examples

```
inifile <- system.file("examples", "example.ini", package = "rconfig")

## not evaluating R expressions
ini <- rconfig::read_ini(file = inifile, eval = FALSE)
str(ini)

## evaluating R expressions
ini <- rconfig::read_ini(file = inifile, eval = TRUE)
str(ini)
```
