          "Disjoint rectangles")
plotRules(c(.1, .1, .6, .6, NA, .4, .4, .9, .9),
          c(.1, .6, .6, .1, NA, .4, .4, .9, .4),
          "Overlapping rectangles, both clockwise")
plotRules(c(.1, .1, .6, .6, NA, .4, .9, .9, .4),
          c(.1, .6, .6, .1, NA, .4, .4, .9, .9),
          "Overlapping rectangles, one clockwise, other anti-clockwise")

par(op)
```

**rasterImage**

**Draw One or More Raster Images**

**Description**

`rasterImage` draws a raster image at the given locations and sizes.

**Usage**

```r
rasterImage(image,
            xleft, ybottom, xright, ytop,
            angle = 0, interpolate = TRUE, ...)
```

**Arguments**

- `image` a raster object, or an object that can be coerced to one by `as.raster`.
- `xleft` a vector (or scalar) of left x positions.
rect

Description

rect draws a rectangle (or sequence of rectangles) with the given coordinates, fill and border colors.

ybottom  a vector (or scalar) of bottom y positions.
xright   a vector (or scalar) of right x positions.
ytop     a vector (or scalar) of top y positions.
angle    angle of rotation (in degrees, anti-clockwise from positive x-axis, about the bottom-left corner).
interpolate a logical vector (or scalar) indicating whether to apply linear interpolation to the image when drawing.
...
... graphical parameters.

Details

The positions supplied, i.e., xleft, ..., are relative to the current plotting region. If the x-axis goes from 100 to 200 then xleft should be larger than 100 and xright should be less than 200. The position vectors will be recycled to the length of the longest.

Plotting raster images is not supported on all devices and may have limitations where supported, for example (e.g., for postscript and X11(type = "Xlib") is restricted to opaque colors). Problems with the rendering of raster images have been reported by users of windows() devices under Remote Desktop, at least under its default settings.

You should not expect a raster image to be re-sized when an on-screen device is re-sized: whether it is is device-dependent.

See Also

rect, polygon, and segments and others for flexible ways to draw shapes.

dev.capabilities to see if it is supported.

Examples

require(grDevices)
## set up the plot region:
op <- par(bg = "thistle")
plot(c(100, 250), c(300, 450), type = "n", xlab = "", ylab = "")
image <- as.raster(matrix(0:1, ncol = 5, nrow = 3))
rasterImage(image, 100, 300, 150, 350, interpolate = FALSE)
rasterImage(image, 100, 400, 150, 450, interpolate = FALSE)
rasterImage(image, 200, 300, 200 + xinch(.5), 300 + yinch(.3),
            interpolate = FALSE)
rasterImage(image, 200, 400, 250, 450, angle = 15, interpolate = FALSE)
par(op)

rect          Draw One or More Rectangles
Usage

rect(xleft, ybottom, xright, ytop, density = NULL, angle = 45,
     col = NA, border = NULL, lty = par("lty"), lwd = par("lwd"),
     ...)  

Arguments

xleft  a vector (or scalar) of left x positions.
ybottom a vector (or scalar) of bottom y positions.
xright a vector (or scalar) of right x positions.
ytop   a vector (or scalar) of top y positions.
density the density of shading lines, in lines per inch. The default value of NULL means that no shading lines are drawn. A zero value of density means no shading lines whereas negative values (and NA) suppress shading (and so allow color filling).
angle  angle (in degrees) of the shading lines.
col    color(s) to fill or shade the rectangle(s) with. The default NA (or also NULL) means do not fill, i.e., draw transparent rectangles, unless density is specified.
border color for rectangle border(s). The default means par("fg"). Use border = NA to omit borders. If there are shading lines, border = TRUE means use the same colour for the border as for the shading lines.
lty    line type for borders and shading; defaults to "solid".
lwd    line width for borders and shading. Note that the use of lwd = 0 (as in the examples) is device-dependent.
...    graphical parameters such as xpd, lend, ljoin and lmitre can be given as arguments.

Details

The positions supplied, i.e., xleft, ..., are relative to the current plotting region. If the x-axis goes from 100 to 200 then xleft must be larger than 100 and xright must be less than 200. The position vectors will be recycled to the length of the longest.

It is a graphics primitive used in hist, barplot, legend, etc.

box for the standard box around the plot; polygon and segments for flexible line drawing.
par for how to specify colors.

Examples

require(grDevices)
## set up the plot region:
op <- par(bg = "thistle")
plot(c(100, 250), c(300, 450), type = "n", xlab = "", ylab = "",
     main = "2 x 11 rectangles; 'rect(100+i,300+i, 150+i,380+i)'")
i <- 4*(0:10)
## draw rectangles with bottom left (100, 300)+i
## and top right (150, 380)+i
rect(100+i, 300+i, 150+i, 380+i, col = rainbow(11, start = 0.7, end = 0.1))
rect(240-i, 320+i, 250-i, 410+i, col = heat.colors(11), lwd = i/5)
## Background alternating (transparent / "bg")

```r
j <- 10*(0:5)
rect(125+j, 360+j, 141+j, 405+j/2, col = c(NA,0),
    border = "gold", lwd = 2)
rect(125+j, 296+j/2, 141+j, 331+j/5, col = c(NA,"midnightblue"))
mtext("+ 2 x 6 rect(*, col = c(NA,0)) and col = c(NA,"m..blue")")
```

## an example showing colouring and shading

```r
plot(c(100, 200), c(300, 450), type= "n", xlab = 
    "", ylab = "")
rect(100, 300, 125, 350) # transparent
rect(100, 400, 125, 450, col = "green", border = "blue") # coloured
rect(115, 375, 150, 425, col = par("bg"), border = "transparent")
rect(150, 300, 175, 350, density = 10, border = "red")
rect(150, 400, 175, 450, density = 30, col = "blue",
    angle = -30, border = "transparent")
legend(180, 450, legend = 1:4, fill = c(NA, "green", par("fg"), "blue"),
    density = c(NA, NA, 10, 30), angle = c(NA, NA, 30, -30))
par(op)
```

---

### rug

**Add a Rug to a Plot**

**Description**

Adds a rug representation (1-d plot) of the data to the plot.

**Usage**

```r
rug(x, ticksize = 0.03, side = 1, lwd = 0.5, col = par("fg"),
    quiet = getOption("warn") < 0, ...)
```

**Arguments**

- **x**: A numeric vector
- **ticksize**: The length of the ticks making up the ‘rug’. Positive lengths give inwards ticks.
- **side**: On which side of the plot box the rug will be plotted. Normally 1 (bottom) or 3 (top).
- **lwd**: The line width of the ticks. Some devices will round the default width up to 1.
- **col**: The colour the ticks are plotted in.
- **quiet**: logical indicating if there should be a warning about clipped values.
- **...**: further arguments, passed to `axis`, such as `line` or `pos` for specifying the location of the rug.

**Details**

Because of the way rug is implemented, only values of x that fall within the plot region are included. There will be a warning if any finite values are omitted, but non-finite values are omitted silently.
References

*jitter* which you may want for ties in *x*.

Examples

```r
require(stats) # both 'density' and its default method
with(faithful, {
  plot(density(eruptions, bw = 0.15))
  rug(eruptions)
  rug(jitter(eruptions, amount = 0.01), side = 3, col = "light blue")
})
```

---

### screen

Creating and Controlling Multiple Screens on a Single Device

Description

`split.screen` defines a number of regions within the current device which can, to some extent, be treated as separate graphics devices. It is useful for generating multiple plots on a single device. Screens can themselves be split, allowing for quite complex arrangements of plots.

`screen` is used to select which screen to draw in.

`erase.screen` is used to clear a single screen, which it does by filling with the background colour.

`close.screen` removes the specified screen definition(s).

Usage

```r
split.screen(figs, screen, erase = TRUE)
screen(n = , new = TRUE)
erase.screen(n = )
close.screen(n, all.screens = FALSE)
```

Arguments

- **figs**
  - a two-element vector describing the number of rows and the number of columns in a screen matrix or a matrix with 4 columns. If a matrix, then each row describes a screen with values for the left, right, bottom, and top of the screen (in that order) in NDC units, that is 0 at the lower left corner of the device surface, and 1 at the upper right corner.

- **screen**
  - a number giving the screen to be split. It defaults to the current screen if there is one, otherwise the whole device region.

- **erase**
  - logical: should the selected screen be cleared?

- **n**
  - a number indicating which screen to prepare for drawing (`screen`), erase (`erase.screen`), or close (`close.screen`). (`close.screen` will accept a vector of screen numbers.)

- **new**
  - logical value indicating whether the screen should be erased as part of the preparation for drawing in the screen.

- **all.screens**
  - logical value indicating whether all of the screens should be closed.
Details

The first call to `split.screen` places R into split-screen mode. The other split-screen functions only work within this mode. While in this mode, certain other commands should be avoided (see the Warnings section below). Split-screen mode is exited by the command `close.screen(all = TRUE).

If the current screen is closed, `close.screen` sets the current screen to be the next larger screen number if there is one, otherwise to the first available screen.

Value

`split.screen()` returns a vector of screen numbers for the newly-created screens. With no arguments, `split.screen()` returns a vector of valid screen numbers.

`screen(n)` invisibly returns \(n\), the number of the selected screen. With no arguments, `screen()` returns the number of the current screen.

`close.screen()` returns a vector of valid screen numbers.

`screen`, `erase.screen`, and `close.screen` all return `FALSE` if \(R\) is not in split-screen mode.

Warnings

The recommended way to use these functions is to completely draw a plot and all additions (i.e., points and lines) to the base plot, prior to selecting and plotting on another screen. The behavior associated with returning to a screen to add to an existing plot is unpredictable and may result in problems that are not readily visible.

These functions are totally incompatible with the other mechanisms for arranging plots on a device: `par(mfrow)`, `par(mfcol)` and `layout()`.

The functions are also incompatible with some plotting functions, such as `coplot`, which make use of these other mechanisms.

`erase.screen` will appear not to work if the background colour is transparent (as it is by default on most devices).

References

See Also

`par`, `layout`, `Devices`, `dev.*`

Examples

```r
if (interactive()) {
  par(bg = "white")  # default is likely to be transparent
  split.screen(c(2, 1))  # split display into two screens
  split.screen(c(1, 3), screen = 2) # now split the bottom half into 3
  screen(1) # prepare screen 1 for output
  plot(10:1)
  screen(4) # prepare screen 4 for output
  plot(10:1)
  close.screen(all = TRUE)  # exit split-screen mode
}
segments

Add Line Segments to a Plot

Description

Draw line segments between pairs of points.

Usage

segments(x0, y0, x1 = x0, y1 = y0,
          col = par("fg"), lty = par("lty"), lwd = par("lwd"),
          ...)  

Arguments

x0, y0   coordinates of points from which to draw.

x1, y1   coordinates of points to which to draw. At least one must be supplied.

col, lty, lwd   graphical parameters as in par, possibly vectors. NA values in col cause the
               segment to be omitted.

...   further graphical parameters (from par), such as xpd and the line characteristics
       lend, ljoin and lmitre.

Details

For each i, a line segment is drawn between the point (x0[i], y0[i]) and the point (x1[i],
y1[i]). The coordinate vectors will be recycled to the length of the longest.

The graphical parameters col, lty and lwd can be vectors of length greater than one and will be
recycled if necessary.

arrows, polygon for slightly easier and less flexible line drawing, and lines for the usual polygons.

Examples

```r
x <- stats::runif(12); y <- stats::rnorm(12)
i <- order(x, y); x <- x[i]; y <- y[i]
plot(x, y, main = "arrows(.) and segments(.)")
## draw arrows from point to point :
s <- seq(length(x)-1)  # one shorter than data
arrows(x[s], y[s], x[s+1], y[s+1], col= 1:3)
s <- s[-length(s)]
segments(x[s], y[s], x[s+2], y[s+2], col= 'pink')
```

smoothScatter

Scatterplots with Smoothed Densities Color Representation

Description

smoothScatter produces a smoothed color density representation of a scatterplot, obtained through a (2D) kernel density estimate.

Usage

```r
smoothScatter(x, y = NULL, nbin = 128, bandwidth,
              colramp = colorRampPalette(c("white", blues9)),
              nrpoints = 100, ret.selection = FALSE,
              pch = ".", cex = 1, col = "black",
              transformation = function(x) x^.25,
              postPlotHook = box,
              xlab = NULL, ylab = NULL, xlim, ylim,
              xaxs = par("xaxs"), yaxs = par("yaxs"), ...)
```

Arguments

- **x, y**
  the x and y arguments provide the x and y coordinates for the plot. Any reasonable way of defining the coordinates is acceptable. See the function `xy.coords` for details. If supplied separately, they must be of the same length.

- **nbin**
  numeric vector of length one (for both directions) or two (for x and y separately) specifying the number of equally spaced grid points for the density estimation; directly used as `gridsize` in `bkde2D()`.

- **bandwidth**
  numeric vector (length 1 or 2) of smoothing bandwidth(s). If missing, a more or less useful default is used. bandwidth is subsequently passed to function `bkde2D()`.

- **colramp**
  function accepting an integer n as an argument and returning n colors.

- **nrpoints**
  number of points to be superimposed on the density image. The first `nrpoints` points from those areas of lowest regional densities will be plotted. Adding points to the plot allows for the identification of outliers. If all points are to be plotted, choose `nrpoints = Inf`.
smoothScatter

ret.selection  logical indicating to return the ordered indices of “low density” points if nrpoints > 0.

pch, cex, col  arguments passed to points, when nrpoints > 0: point symbol, character expansion factor and color, see also par.

transformation  function mapping the density scale to the color scale.

postPlotHook  either NULL or a function which will be called (with no arguments) after image.

xlab, ylab  character strings to be used as axis labels, passed to image.

xlim, ylim  numeric vectors of length 2 specifying axis limits.

xaxs, yaxs, ...  further arguments passed to image, e.g., add=TRUE or useRaster=TRUE.

Details

smoothScatter produces a smoothed version of a scatter plot. Two dimensional (kernel density) smoothing is performed by bkde2D from package KernSmooth. See the examples for how to use this function together with pairs.

Value

If ret.selection is true, a vector of integers of length nrpoints (or smaller, if there are less finite points inside xlim and ylim) with the indices of the low-density points drawn, ordered with lowest density first.

Author(s)

Florian Hahne at FHCRC, originally

bkde2D from package KernSmooth; densCols which uses the same smoothing computations and blues9 in package grDevices.

scatter.smooth adds a loess regression smoother to a scatter plot.

Examples

## A largish data set
n <- 10000
x1 <- matrix(rnorm(n, ncol = 2)
x2 <- matrix(rnorm(n, mean = 3, sd = 1.5), ncol = 2)
x <- rbind(x1, x2)
oldpar <- par(mfrow = c(2, 2), mar=.1+c(3,3,1,1), mgp = c(1.5, 0.5, 0))
smoothScatter(x, nrpoints = 0)
smoothScatter(x)

## a different color scheme:
Lab.palette <- colorRampPalette(c("blue", "orange", "red"), space = "Lab")
i.s <- smoothScatter(x, colramp = Lab.palette,
  ## pch=NA: do not draw them
nrpoints = 250, ret.selection=TRUE)
## label the 20 very lowest-density points, the “outliers” (with obs.number):
i.20 <- i.s[1:20]
text(x[i.20,], labels = i.20, cex= 0.75)
spineplot

## somewhat similar, using identical smoothing computations,
## but considerably *less* efficient for really large data:
plot(x, col = densCols(x), pch = 20)

## use with pairs:
par(mfrow = c(1, 1))
y <- matrix(rnorm(40000), ncol = 4) + 3*rnorm(10000)
y[, c(2,4)] <- -y[, c(2,4)]
pairs(y, panel = function(...) smoothScatter(..., nrpoints = 0, add = TRUE),
gap = 0.2)
par(oldpar)

---

**spineplot**

### Spine Plots and Spinograms

**Description**

Spine plots are a special cases of mosaic plots, and can be seen as a generalization of stacked (or highlighted) bar plots. Analogously, spinograms are an extension of histograms.

**Usage**

`spineplot(x, ...)`

**Arguments**

- `x` an object, the default method expects either a single variable (interpreted to be the explanatory variable) or a 2-way table. See details.
- `y` a "factor" interpreted to be the dependent variable
- `formula` a "formula" of type `y ~ x` with a single dependent "factor" and a single explanatory variable.
- `data` an optional data frame.
breaks if the explanatory variable is numeric, this controls how it is discretized. breaks is passed to hist and can be a list of arguments.

tol.ylab convenience tolerance parameter for y-axis annotation. If the distance between two labels drops under this threshold, they are plotted equidistantly.

off vertical offset between the bars (in per cent). It is fixed to 0 for spinograms and defaults to 2 for spine plots.

ylevels a character or numeric vector specifying in which order the levels of the dependent variable should be plotted.

col a vector of fill colors of the same length as levels(y). The default is to call gray.colors.

main, xlab, ylab character strings for annotation

xaxlabels, yaxlabels character vectors for annotation of x and y axis. Default to levels(y) and levels(x), respectively for the spine plot. For xaxlabels in the spinogram, the breaks are used.

xlim, ylim the range of x and y values with sensible defaults.

axes logical. If FALSE all axes (including those giving level names) are suppressed.

weights numeric. A vector of frequency weights for each observation in the data. If NULL all weights are implicitly assumed to be 1. If x is already a 2-way table, the weights are ignored.

... additional arguments passed to rect.

subset an optional vector specifying a subset of observations to be used for plotting.

drop.unused.levels should factors have unused levels dropped? Defaults to FALSE.

Details

spineplot creates either a spinogram or a spine plot. It can be called via spineplot(x, y) or spineplot(y ~ x) where y is interpreted to be the dependent variable (and has to be categorical) and x the explanatory variable. x can be either categorical (then a spine plot is created) or numerical (then a spinogram is plotted). Additionally, spineplot can also be called with only a single argument which then has to be a 2-way table, interpreted to correspond to table(x, y).

Both, spine plots and spinograms, are essentially mosaic plots with special formatting of spacing and shading. Conceptually, they plot $P(y|x)$ against $P(x)$. For the spine plot (where both $x$ and $y$ are categorical), both quantities are approximated by the corresponding empirical relative frequencies. For the spinogram (where $x$ is numerical), $x$ is first discretized (by calling hist with breaks argument) and then empirical relative frequencies are taken.

Thus, spine plots can also be seen as a generalization of stacked bar plots where not the heights but the widths of the bars corresponds to the relative frequencies of $x$. The heights of the bars then correspond to the conditional relative frequencies of $y$ in every $x$ group. Analogously, spinograms extend stacked histograms.

Value

The table visualized is returned invisibly.

**stars**

*Star (Spider/Radar) Plots and Segment Diagrams*
1006

stars

Description
Draw star plots or segment diagrams of a multivariate data set. With one single location, also draws
‘spider’ (or ‘radar’) plots.
Usage
stars(x, full = TRUE, scale = TRUE, radius = TRUE,
labels = dimnames(x)[[1]], locations = NULL,
nrow = NULL, ncol = NULL, len = 1,
key.loc = NULL, key.labels = dimnames(x)[[2]],
key.xpd = TRUE,
xlim = NULL, ylim = NULL, flip.labels = NULL,
draw.segments = FALSE,
col.segments = 1:n.seg, col.stars = NA, col.lines = NA,
axes = FALSE, frame.plot = axes,
main = NULL, sub = NULL, xlab = "", ylab = "",
cex = 0.8, lwd = 0.25, lty = par("lty"), xpd = FALSE,
mar = pmin(par("mar"),
1.1+ c(2*axes+ (xlab != ""),
2*axes+ (ylab != ""), 1, 0)),
add = FALSE, plot = TRUE, ...)
Arguments
x

matrix or data frame of data. One star or segment plot will be produced for each
row of x. Missing values (NA) are allowed, but they are treated as if they were 0
(after scaling, if relevant).

full

logical flag: if TRUE, the segment plots will occupy a full circle. Otherwise, they
occupy the (upper) semicircle only.

scale

logical flag: if TRUE, the columns of the data matrix are scaled independently so
that the maximum value in each column is 1 and the minimum is 0. If FALSE,
the presumption is that the data have been scaled by some other algorithm to the
range [0, 1].

radius

logical flag: in TRUE, the radii corresponding to each variable in the data will be
drawn.

labels

vector of character strings for labeling the plots. Unlike the S function stars,
no attempt is made to construct labels if labels = NULL.

locations

Either two column matrix with the x and y coordinates used to place each of the
segment plots; or numeric of length 2 when all plots should be superimposed
(for a ‘spider plot’). By default, locations = NULL, the segment plots will be
placed in a rectangular grid.

nrow, ncol

integers giving the number of rows and columns to use when locations is NULL.
By default, nrow == ncol, a square layout will be used.

len

scale factor for the length of radii or segments.

key.loc

vector with x and y coordinates of the unit key.

key.labels

vector of character strings for labeling the segments of the unit key. If omitted,
the second component of dimnames(x) is used, if available.

key.xpd

clipping switch for the unit key (drawing and labeling), see par("xpd").

xlim

vector with the range of x coordinates to plot.


stars

ylim  vector with the range of y coordinates to plot.
flip.labels  logical indicating if the label locations should flip up and down from diagram to
diagram. Defaults to a somewhat smart heuristic.
draw.segments  logical. If TRUE draw a segment diagram.
col.segments  color vector (integer or character, see par), each specifying a color for one of
def the segments (variables). Ignored if draw.segments = FALSE.
col.stars  color vector (integer or character, see par), each specifying a color for one of
de the stars (cases). Ignored if draw.segments = TRUE.
col.lines  color vector (integer or character, see par), each specifying a color for one of
de the lines (cases). Ignored if draw.segments = TRUE.
axes  logical flag: if TRUE axes are added to the plot.
frame.plot  logical flag: if TRUE, the plot region is framed.
main  a main title for the plot.
sub  a subtitle for the plot.
xlab  a label for the x axis.
ylab  a label for the y axis.
cex  character expansion factor for the labels.
lwd  line width used for drawing.
lty  line type used for drawing.
xpd  logical or NA indicating if clipping should be done, see par(xpd = ).
mar  argument to par(mar = *), typically choosing smaller margins than by default.
...  further arguments, passed to the first call of plot(), see plot.default and to
box() if frame.plot is true.
add  logical, if TRUE add stars to current plot.
plot  logical, if FALSE, nothing is plotted.

Details

Missing values are treated as 0.
Each star plot or segment diagram represents one row of the input x. Variables (columns) start on
the right and wind counterclockwise around the circle. The size of the (scaled) column is shown by
the distance from the center to the point on the star or the radius of the segment representing the
variable.
Only one page of output is produced.

Value

Returns the locations of the plots in a two column matrix, invisibly when plot = TRUE.

Note

This code started life as spatial star plots by David A. Andrews.
Prior to R 1.4.1, scaling only shifted the maximum to 1, although documented as here.

symbols for another way to draw stars and other symbols.

Examples

```r
require(grDevices)
stars(mtcars[, 1:7], key.loc = c(14, 2),
     main = "Motor Trend Cars: stars(*, full = F)", full = FALSE)
stars(mtcars[, 1:7], key.loc = c(14, 1.5),
     main = "Motor Trend Cars: full stars()", flip.labels = FALSE)
```

```r
## 'Spider' or 'Radar' plot:
stars(mtcars[, 1:7], locations = c(0, 0), radius = FALSE,
      key.loc = c(0, 0), main = "Motor Trend Cars", lty = 2)
```

```r
## Segment Diagrams:
palette(rainbow(12, s = 0.6, v = 0.75))
stars(mtcars[, 1:7], len = 0.8, key.loc = c(12, 1.5),
      main = "Motor Trend Cars", draw.segments = TRUE)
stars(mtcars[, 1:7], len = 0.6, key.loc = c(1.5, 0),
      main = "Motor Trend Cars", draw.segments = TRUE,
      frame.plot = TRUE, nrow = 4, cex = .7)
```

```r
## scale linearly (not affinely) to [0, 1]
USJudge <- apply(USJudgeRatings, 2, function(x) x/max(x))
Jnam <- row.names(USJudgeRatings)
Snam <- abbreviate(substring(Jnam, 1, regexpr("[,].",Jnam) - 1), 7)
stars(USJudge, labels = Jnam, scale = FALSE,
      key.loc = c(13, 1.5), main = "Judge not ...", len = 0.8)
stars(USJudge, labels = Snam, scale = FALSE,
      key.loc = c(13, 1.5), radius = FALSE)
```

```r
loc <- stars(USJudge, labels = NULL, scale = FALSE,
             radius = FALSE, frame.plot = TRUE,
             key.loc = c(13, 1.5), main = "Judge not ...", len = 1.2)
text(loc, Snam, col = "blue", cex = 0.8, xpd = TRUE)
```

```r
## 'Segments':
stars(USJudge, draw.segments = TRUE, scale = FALSE, key.loc = c(13, 1.5))
```

```r
## 'Spider':
stars(USJudgeRatings, locations = c(0, 0), scale = FALSE, radius = FALSE,
      col.stars = 1:10, key.loc = c(0, 0), main = "US Judges rated")
```

```r
## Same as above, but with colored lines instead of filled polygons.
stars(USJudgeRatings, locations = c(0, 0), scale = FALSE, radius = FALSE,
      col.lines = 1:10, key.loc = c(0, 0), main = "US Judges rated")
```

```r
## 'Radar-Segments'
stars(USJudgeRatings[1:10,], locations = 0:1, scale = FALSE,
       draw.segments = TRUE, col.segments = 0, col.stars = 1:10, key.loc = 0:1,
       main = "US Judges 1-10")
palette("default")
```
stem

Stem-and-Leaf Plots

Description

stem produces a stem-and-leaf plot of the values in x. The parameter scale can be used to expand the scale of the plot. A value of scale = 2 will cause the plot to be roughly twice as long as the default.

Usage

stem(x, scale = 1, width = 80, atom = 1e-08)

Arguments

x a numeric vector.

scale This controls the plot length.

width The desired width of plot.

atom a tolerance.

Details

Infinite and missing values in x are discarded.

References

Examples

stem(islands)
stem(log10(islands))

stripchart

1-D Scatter Plots

Description

stripchart produces one dimensional scatter plots (or dot plots) of the given data. These plots are a good alternative to boxplots when sample sizes are small.
Usage

stripchart(x, ...)

## S3 method for class 'formula'
stripchart(x, data = NULL, dlab = NULL, ...
subset, na.action = NULL)

## Default S3 method:
stripchart(x, method = "overplot", jitter = 0.1, offset = 1/3,
vertical = FALSE, group.names, add = FALSE,
at = NULL, xlim = NULL, ylim = NULL,
ylab = NULL, xlab = NULL, dlab = ",", glab = "",
log = "", pch = 0, col = par("fg"), cex = par("cex"),
axes = TRUE, frame.plot = axes, ...)

Arguments

x
the data from which the plots are to be produced. In the default method the
data can be specified as a single numeric vector, or as list of numeric vectors,
each corresponding to a component plot. In the formula method, a symbolic
specification of the form y ~ g can be given, indicating the observations in the
vector y are to be grouped according to the levels of the factor g. NAs are allowed
in the data.
data
a data.frame (or list) from which the variables in x should be taken.
subset
an optional vector specifying a subset of observations to be used for plotting.
na.action
a function which indicates what should happen when the data contain NAs. The
default is to ignore missing values in either the response or the group.
...
additional parameters passed to the default method, or by it to plot.window,
points, axis and title to control the appearance of the plot.
method
the method to be used to separate coincident points. The default method
"overplot" causes such points to be overplotted, but it is also possible to spec-
ify "jitter" to jitter the points, or "stack" have coincident points stacked.
The last method only makes sense for very granular data.
jitter
when method = "jitter" is used, jitter gives the amount of jittering applied.
offset
when stacking is used, points are stacked this many line-heights (symbol widths)
apart.
vertical
when vertical is TRUE the plots are drawn vertically rather than the default hori-
zontal.
group.names

group labels which will be printed alongside (or underneath) each plot.
add
logical, if true add the chart to the current plot.
at
numeric vector giving the locations where the charts should be drawn, particu-
larly when add = TRUE; defaults to 1:n where n is the number of boxes.
ylab, xlab
labels: see title.
dlab, glab
alternate way to specify axis labels: see ‘Details’.
xlim, ylim
plot limits: see plot.window.
log
on which axes to use a log scale: see plot.default
Graphical parameters: see `par`.

Axis control: see `plot.default`.

Details

Extensive examples of the use of this kind of plot can be found in Box, Hunter and Hunter (2005) or Wild and Seber (2000).

The `dlab` and `glab` labels may be used instead of `xlab` and `ylab` if those are not specified. `dlab` applies to the continuous data axis (the X axis unless `vertical` is `TRUE`), `glab` to the group axis.

References

Examples

```r
x <- stats::rnorm(50)
xr <- round(x, 1)
stripchart(x) ; m <- mean(par("usr"))[1:2])
text(m, 1.04, "stripchart(x, \"overplot\")")
stripchart(xr, method = "stack", add = TRUE, at = 1.2)
text(m, 1.35, "stripchart(round(x,1), \"stack\")")
stripchart(xr, method = "jitter", add = TRUE, at = 0.7)
text(m, 0.85, "stripchart(round(x,1), \"jitter\")")

stripchart(decrease ~ treatment,
main = "stripchart(OrchardSprays)",
vertical = TRUE, log = "y", data = OrchardSprays)

stripchart(decrease ~ treatment, at = c(1:8)^2,
main = "stripchart(OrchardSprays)",
vertical = TRUE, log = "y", data = OrchardSprays)
```

---

**strwidth**

*Plotting Dimensions of Character Strings and Math Expressions*

**Description**

These functions compute the width or height, respectively, of the given strings or mathematical expressions `s[i]` on the current plotting device in `user` coordinates, `inches` or as fraction of the figure width `par("fin")`.

**Usage**

```r
strwidth(s, units = "user", cex = NULL, font = NULL, vfont = NULL, ...)
strheight(s, units = "user", cex = NULL, font = NULL, vfont = NULL, ...)
```
Arguments

s a character or expression vector whose dimensions are to be determined. Other objects are coerced by \texttt{as.graphicsAnnot}.

units character indicating in which units \textit{s} is measured; should be one of "user", "inches", "figure"; partial matching is performed.

cex numeric character expansion factor; multiplied by \texttt{par("cex")} yields the final character size; the default \texttt{NULL} is equivalent to 1.

font, vfont, … additional information about the font, possibly including the graphics parameter "family": see \texttt{text}.

Details

Note that the ‘height’ of a string is determined only by the number of linefeeds ("\n", aka “newline”)s it contains: it is the (number of linefeeds - 1) times the line spacing plus the height of “M” in the selected font. For an expression it is the height of the bounding box as computed by \texttt{plotmath}. Thus in both cases it is an estimate of how far above the final baseline the typeset object extends. (It may also extend below the baseline.) The inter-line spacing is controlled by \texttt{cex, par("lheight")} and the ‘point size’ (but not the actual font in use).

Measurements in "user" units (the default) are only available after \texttt{plot.new} has been called – otherwise an error is thrown.

Value

Numeric vector with the same length as \textit{s}, giving the estimate of width or height for each \textit{s}[i]. \texttt{NA} strings are given width and height 0 (as they are not plotted).

\texttt{text, nchar}

Examples

```r
cstr.ex <- c("W", "w", "I", ",.", "WwI.")
op <- par(pty = "s"); plot(1:100, 1:100, type = "n")
sw <- strwidth(str.ex); sw
all.equal(sum(sw[1:4]), sw[5])  # since the last string contains the others

sw.i <- strwidth(str.ex, "inches"); 25.4 * sw.i  # width in [mm]
unique(sw / sw.i)
# constant factor: 1 value
mean(sw.i / strwidth(str.ex, "fig")) / par("fin")[1]  # = 1: are the same

# See how letters fall in classes
# -- depending on graphics device and font!
all.lett <- c(letters, LETTERS)
shL <- strheight(all.lett, units = "inches") * 72  # 'big points'
table(shL)  # all have same heights ...
mean(shL)/par("cin")[2]  # around 0.6

(swL <- strwidth(all.lett, units = "inches") * 72)  # 'big points'
split(all.lett, factor(round(swL, 2)))
```
sunflowerplot <- expression(sum(x[i], i=1,n), e^{i * pi} == -1)
strwidth(sumex)
strheight(sumex)
par(op) # reset to previous setting

sunflowerplot Produce a Sunflower Scatter Plot

Description

Multiple points are plotted as ‘sunflowers’ with multiple leaves (‘petals’) such that overplotting is visualized instead of accidental and invisible.

Usage

sunflowerplot(x, ...)

## Default S3 method:
sunflowerplot(x, y = NULL, number, log = "", digits = 6, xlab = NULL, ylab = NULL, xlim = NULL, ylim = NULL, add = FALSE, rotate = FALSE, pch = 16, cex = 0.8, cex.fact = 1.5, col = par("col"), bg = NA, size = 1/8, seg.col = 2, seg.lwd = 1.5, ...)

## S3 method for class 'formula'
sunflowerplot(formula, data = NULL, xlab = NULL, ylab = NULL, ..., subset, na.action = NULL)

Arguments

x numeric vector of x-coordinates of length n, say, or another valid plotting structure, as for \code{plot.default}, see also \code{xy.coords}.

y numeric vector of y-coordinates of length n.

number integer vector of length n. number[i] = number of replicates for (x[i], y[i]), may be 0. Default (missing(number)): compute the exact multiplicity of the points x[i], y[i], via \code{xyTable}().

log character indicating log coordinate scale, see \code{plot.default}.

digits when number is computed (i.e., not specified), x and y are rounded to digits significant digits before multiplicities are computed.

xlab, ylab character label for x-, or y-axis, respectively.

xlim, ylim numeric(2) limiting the extents of the x-, or y-axis.

add logical; should the plot be added on a previous one? Default is \code{FALSE}.

rotate logical; if \code{TRUE}, randomly rotate the sunflowers (preventing artefacts).

cpy plotting character to be used for points (number[i]=1) and center of sunflowers.
sunflowerplot

cex numeric; character size expansion of center points (s. pch).

cex.fact numeric shrinking factor to be used for the center points when there are flower leaves, i.e., cex / cex.fact is used for these.

col, bg colors for the plot symbols, passed to plot.default.

size of sunflower leaves in inches, 1[in] := 2.54[cm]. Default: 1/8", approximately 3.2mm.

seg.col color to be used for the segments which make the sunflowers leaves, see par(col=); col = "gold" reminds of real sunflowers.

seg.lwd numeric; the line width for the leaves’ segments.

... further arguments to plot [if add = FALSE], or to be passed to or from another method.

formula a formula, such as y ~ x.

data a data.frame (or list) from which the variables in formula should be taken.

subset an optional vector specifying a subset of observations to be used in the fitting process.

na.action a function which indicates what should happen when the data contain NAs. The default is to ignore case with missing values.

Details

This is a generic function with default and formula methods.

For number[i] == 1, a (slightly enlarged) usual plotting symbol (pch) is drawn. For number[i] > 1, a small plotting symbol is drawn and number[i] equi-angular ‘rays’ emanate from it.

If rotate = TRUE and number[i] >= 2, a random direction is chosen (instead of the y-axis) for the first ray. The goal is to jitter the orientations of the sunflowers in order to prevent artefactual visual impressions.

Value

A list with three components of same length,

x x coordinates

y y coordinates

number number

Use xyTable() (from package grDevices) if you are only interested in this return value.

Side Effects

A scatter plot is drawn with ‘sunflowers’ as symbols.

Author(s)

**symbols**

**Draw Symbols (Circles, Squares, Stars, Thermometers, Boxplots)**

**Description**

This function draws symbols on a plot. One of six symbols; circles, squares, rectangles, stars, thermometers, and boxplots, can be plotted at a specified set of x and y coordinates. Specific aspects of the symbols, such as relative size, can be customized by additional parameters.

**Usage**

```r
symbols(x, y = NULL, circles, squares, rectangles, stars,
         thermometers, boxplots, inches = TRUE, add = FALSE,
         fg = par("col"), bg = NA,
         xlab = NULL, ylab = NULL, main = NULL,
         xlim = NULL, ylim = NULL, ...)```

**References**

**See Also**

density, xyTable
Arguments

- **x, y**: the x and y co-ordinates for the centres of the symbols. They can be specified in any way which is accepted by `xy.coords`.
- **circles**: a vector giving the radii of the circles.
- **squares**: a vector giving the length of the sides of the squares.
- **rectangles**: a matrix with two columns. The first column gives widths and the second the heights of rectangles.
- **stars**: a matrix with three or more columns giving the lengths of the rays from the center of the stars. NA values are replaced by zeroes.
- **thermometers**: a matrix with three or four columns. The first two columns give the width and height of the thermometer symbols. If there are three columns, the third is taken as a proportion: the thermometers are filled (using colour fg) from their base to this proportion of their height. If there are four columns, the third and fourth columns are taken as proportions and the thermometers are filled between these two proportions of their heights. The part of the box not filled in fg will be filled in the background colour (default transparent) given by bg.
- **boxplots**: a matrix with five columns. The first two columns give the width and height of the boxes, the next two columns give the lengths of the lower and upper whiskers and the fifth the proportion (with a warning if not in [0,1]) of the way up the box that the median line is drawn.
- **inches**: TRUE, FALSE or a positive number. See ‘Details’.
- **add**: if add is TRUE, the symbols are added to an existing plot, otherwise a new plot is created.
- **fg**: colour(s) the symbols are drawn in.
- **bg**: if specified, the symbols are filled with colour(s), the vector bg being recycled to the number of symbols. The default is to leave the symbols unfilled.
- **xlab**: the x label of the plot if add is not true. Defaults to the deparsed expression used for x.
- **ylab**: the y label of the plot. Unused if add = TRUE.
- **main**: a main title for the plot. Unused if add = TRUE.
- **xlim**: numeric vector of length 2 giving the x limits for the plot. Unused if add = TRUE.
- **ylim**: numeric vector of length 2 giving the y limits for the plot. Unused if add = TRUE.
- **...**: graphics parameters can also be passed to this function, as can the plot aspect ratio asp (see `plot.window`).

Details

Observations which have missing coordinates or missing size parameters are not plotted. The exception to this is **stars**. In that case, the length of any ray which is NA is reset to zero.

Argument **inches** controls the sizes of the symbols. If TRUE (the default), the symbols are scaled so that the largest dimension of any symbol is one inch. If a positive number is given the symbols are scaled to make largest dimension this size in inches (so TRUE and 1 are equivalent). If inches is FALSE, the units are taken to be those of the appropriate axes. (For circles, squares and stars the units of the x axis are used. For boxplots, the lengths of the whiskers are regarded as dimensions alongside width and height when scaling by inches, and are otherwise interpreted in the units of the y axis.)
Circles of radius zero are plotted at radius one pixel (which is device-dependent). Circles of a very small non-zero radius may or may not be visible, and may be smaller than circles of radius zero. On windows devices circles are plotted at radius at least one pixel as some Windows versions omit smaller circles.

References

stars for drawing stars with a bit more flexibility.

If you are thinking about doing ‘bubble plots’ by symbols(*, circles=*) you should really consider using sunflowerplot instead.

Examples

```r
require(stats); require(grDevices)
x <- 1:10
y <- sort(10*runif(10))
z <- runif(10)
z3 <- cbind(z, 2*runif(10), runif(10))
symbols(x, y, thermometers = cbind(.5, 1, z), inches = .5, fg = 1:10)
symbols(x, y, thermometers = z3, inches = FALSE)
text(x, y, apply(format(round(z3, digits = 2)), 1, paste, collapse = ","),
     adj = c(-.2,0), cex = .75, col = "purple", xpd = NA)
## Note that example(trees) shows more sensible plots!
N <- nrow(trees)
with(trees, {
## Girth is diameter in inches
  symbols(Height, Volume, circles = Girth/24, inches = FALSE,
          main = "Trees' Girth") # xlab and ylab automatically
  ## Colours too:
  op <- palette(rainbow(N, end = 0.9))
  symbols(Height, Volume, circles = Girth/16, inches = FALSE, bg = 1:N,
          fg = "gray30", main = "symbols(*, circles = Girth/16, bg = 1:N)"
  )
  palette(op)
})
```

Add Text to a Plot

Description

text draws the strings given in the vector labels at the coordinates given by x and y. y may be missing since xy.coords(x, y) is used for construction of the coordinates.
### Usage

text(x, ...)

## Default S3 method:
text(x = NULL, labels = seq_along(x$x), adj = NULL,  
pos = NULL, offset = 0.5, vfont = NULL,  
cex = 1, col = NULL, font = NULL, ...)

#### Arguments

- **x, y** numeric vectors of coordinates where the text labels should be written. If the length of x and y differs, the shorter one is recycled.
- **labels** a character vector or expression specifying the text to be written. An attempt is made to coerce other language objects (names and calls) to expressions, and vectors and other classed objects to character vectors by `as.character`. If labels is longer than x and y, the coordinates are recycled to the length of labels.
- **adj** one or two values in [0, 1] which specify the x (and optionally y) adjustment ('justification') of the labels, with 0 for left/bottom, 1 for right/top, and 0.5 for centered. On most devices values outside [0, 1] will also work. See below.
- **pos** a position specifier for the text. If specified this overrides any adj value given. Values of 1, 2, 3, and 4, respectively indicate positions below, to the left of, above and to the right of the specified (x,y) coordinates.
- **offset** when pos is specified, this value controls the distance ('offset') of the text label from the specified coordinate in fractions of a character width.
- **vfont** NULL for the current font family, or a character vector of length 2 for Hershey vector fonts. The first element of the vector selects a typeface and the second element selects a style. Ignored if labels is an expression.
- **cex** numeric character expansion factor; multiplied by `par("cex")` yields the final character size. NULL and NA are equivalent to 1.0.
- **col, font** the color and (if vfont = NULL) font to be used, possibly vectors. These default to the values of the global graphical parameters in `par()`.
- **...** further graphical parameters (from `par`), such as srt, family and xpd.

#### Details

labels must be of type character or expression (or be coercible to such a type). In the latter case, quite a bit of mathematical notation is available such as sub- and superscripts, Greek letters, fractions, etc.

adj allows adjustment of the text position with respect to (x, y). Values of 0, 0.5, and 1 specify that (x, y) should align with the left/bottom, middle and right/top of the text, respectively. A value of NA means “centre”, which is the same as 0.5 for horizontal justification, but includes descenders for vertical justification (where 0.5 does not). The default is for centered text, although the default horizontal justification is taken from `par(adj)`, i.e., the default is adj = c(par("adj"), NA). If only one value is provided, it is applied to adjust x only, i.e., when `length(adj) == 1L`, adj is applied as adj = c(adj, NA). Accurate vertical centering needs character metric information on individual characters which is only available on some devices. Vertical alignment is done slightly differently for character strings and for expressions: adj = c(0, 0) means to left-justify and to align on the baseline for strings but on the bottom of the bounding box for expressions. This also affects vertical centering: for strings the centering excludes any descenders whereas for expressions it includes them.
The pos and offset arguments can be used in conjunction with values returned by identify to recreate an interactively labelled plot.

Text can be rotated by using graphical parameters srt (see par). When adj is specified, a non-zero srt rotates the label about \((x, y)\). If pos is specified, srt rotates the text about the point on its bounding box which is closest to \((x, y)\): top center for pos = 1, right center for pos = 2, bottom center for pos = 3, and left center for pos = 4. The pos interface is not as useful for rotated text because the result is no longer centered vertically or horizontally with respect to \((x, y)\). At present there is no interface in the graphics package for directly rotating text about its center which is achievable however by fiddling with adj and srt simultaneously.

Graphical parameters col, cex and font can be vectors and will then be applied cyclically to the labels (and extra values will be ignored). NA values of font are replaced by par("font"), and similarly for col.

Labels whose x, y or labels value is NA are omitted from the plot.

What happens when font = 5 (the symbol font) is selected can be both device- and locale-dependent. Most often labels will be interpreted in the Adobe symbol encoding, so e.g. "d" is delta, and "\300" is aleph.

**Euro symbol**

The Euro symbol may not be available in older fonts. In current versions of Adobe symbol fonts it is character 160, so text(x, y, "\xA0", font = 5) may work. People using Western European locales on Unix-alikes can probably select ISO-8895-15 (Latin-9) which has the Euro as character 165: this can also be used for pdf and postscript. It is ‘\u20ac’ in Unicode, which can be used in UTF-8 locales.

The Euro should be rendered correctly by X11 in UTF-8 locales, but the corresponding single-byte encoding in postscript and pdf will need to be selected as ISOLatin9.enc (and the font will need to contain the Euro glyph, which for example older printers may not).

**Examples**

```r
plot(-1:1, -1:1, type = "n", xlab = "Re", ylab = "Im")
K <- 16; text(exp(1i * 2 * pi * (1:K) / K), col = 2)

## The following two examples use latin1 characters: these may not
## appear correctly (or be omitted entirely).
plot(1:10, 1:10, main = "text(...) examples\n------------------",
     sub = "R is GNU ©, but not ® ...")
mtext("<Latin-1 accented chars>: éê àâ â<¢", side = 3)
points(c(6,2), c(2,1), pch = 3, cex = 4, col = "red")
text(6, 2, "the text is CENTERED around (x,y) = (6,2) by default",
     cex = .8)
```
title

Plot Annotation

Description

This function can be used to add labels to a plot. Its first four principal arguments can also be used as arguments in most high-level plotting functions. They must be of type character or expression. In the latter case, quite a bit of mathematical notation is available such as sub- and superscripts, Greek letters, fractions, etc: see plotmath

Usage

title(main = NULL, sub = NULL, xlab = NULL, ylab = NULL, line = NA, outer = FALSE, ...)

Arguments

main The main title (on top) using font, size (character expansion) and color par(c("font.main", "cex.main", "col.main").

sub Sub-title (at bottom) using font, size and color par(c("font.sub", "cex.sub", "col.sub").

xlab X axis label using font, size and color par(c("font.lab", "cex.lab", "col.lab").

ylab Y axis label, same font attributes as xlab.

line specifying a value for line overrides the default placement of labels, and places them this many lines outwards from the plot edge.

outer a logical value. If TRUE, the titles are placed in the outer margins of the plot.

... further graphical parameters from par. Use e.g., col.main or cex. sub instead of just col or cex. adj controls the justification of the titles. xpd can be used to set the clipping region: this defaults to the figure region unless outer = TRUE, otherwise the device region and can only be increased. mgp controls the default placing of the axis titles.
Details

The labels passed to `title` can be character strings or language objects (names, calls or expressions), or a list containing the string to be plotted, and a selection of the optional modifying graphical parameters `cex=`, `col=` and `font=`. Other objects will be coerced by `as.graphicsAnnot`.

The position of `main` defaults to being vertically centered in (outer) margin 3 and justified horizontally according to `par("adj")` on the plot region (device region for `outer = TRUE`).

The positions of `xlab`, `ylab` and `sub` are line (default for `xlab` and `ylab` being `par("mgp")[1]` and increased by 1 for `sub`) lines (of height `par("mex")`) into the appropriate margin, justified in the text direction according to `par("adj")` on the plot/device region.

        plain(cos) * phi)),
    ylab = expression("sin" * phi, "cos" * phi), # only 1st is taken
    xlab = expression(paste(Phase Angle "", phi)),
    col.main = "blue")
axis(1, at = c(-pi, -pi/2, 0, pi/2, pi),
    labels = expression(-pi, -pi/2, 0, pi/2, pi))
abline(h = 0, v = pi/2 * c(-1,1), lty = 2, lwd = .1, col = "gray70")
```

units

Graphical Units
Description

xinch and yinch convert the specified number of inches given as their arguments into the correct units for plotting with graphics functions. Usually, this only makes sense when normal coordinates are used, i.e., no log scale (see the log argument to par).

xyinch does the same for a pair of numbers xy, simultaneously.

Usage

xinch(x = 1, warn.log = TRUE)
yinch(y = 1, warn.log = TRUE)
xyinch(xy = 1, warn.log = TRUE)

Arguments

x, y numeric vector
xy numeric of length 1 or 2.
warn.log logical; if TRUE, a warning is printed in case of active log scale.

Examples

all(c(xinch(), yinch()) == xyinch()) # TRUE
xyinch()

## plot labels offset 0.12 inches to the right
## of plotted symbols in a plot
with(mtcars, {
  plot(mpg, disp, pch = 19, main = "Motor Trend Cars")
  text(mpg + xinch(0.12), disp, row.names(mtcars),
       adj = 0, cex = .7, col = "blue")
})

xspline

Draw an X-spline

Description

Draw an X-spline, a curve drawn relative to control points.

Usage

xspline(x, y = NULL, shape = 0, open = TRUE, repEnds = TRUE,
       draw = TRUE, border = par("fg"), col = NA, ...)

Arguments

x, y vectors containing the coordinates of the vertices of the polygon. See xy.coords for alternatives.
shape A numeric vector of values between -1 and 1, which control the shape of the spline relative to the control points.
open A logical value indicating whether the spline is an open or a closed shape.
xspline

repEnds  For open X-splines, a logical value indicating whether the first and last control points should be replicated for drawing the curve. Ignored for closed X-splines.

draw    logical: should the X-spline be drawn? If false, a set of line segments to draw the curve is returned, and nothing is drawn.

border the color to draw the curve. Use border = NA to omit borders.

col     the color for filling the shape. The default, NA, is to leave unfilled.

...  graphical parameters such as lty, xpd, lend, ljoin and lmitre can be given as arguments.

Details

An X-spline is a line drawn relative to control points. For each control point, the line may pass through (interpolate) the control point or it may only approach (approximate) the control point; the behaviour is determined by a shape parameter for each control point.

If the shape parameter is greater than zero, the spline approximates the control points (and is very similar to a cubic B-spline when the shape is 1). If the shape parameter is less than zero, the spline interpolates the control points (and is very similar to a Catmull-Rom spline when the shape is -1). If the shape parameter is 0, the spline forms a sharp corner at that control point.

For open X-splines, the start and end control points must have a shape of 0 (and non-zero values are silently converted to zero).

For open X-splines, by default the start and end control points are replicated before the curve is drawn. A curve is drawn between (interpolating or approximating) the second and third of each set of four control points, so this default behaviour ensures that the resulting curve starts at the first control point you have specified and ends at the last control point. The default behaviour can be turned off via the repEnds argument.

Value

If draw = TRUE, NULL otherwise a list with elements x and y which could be passed to lines, polygon and so on.

Invisible in both cases.

Note

Two-dimensional splines need to be created in an isotropic coordinate system. Device coordinates are used (with an anisotropy correction if needed.)

y <- sort(stats::rnorm(5))
plot(x, y, pch = 19)
res <- xspline(x, y, 1, draw = FALSE)
lines(res)
## the end points may be very close together,
## so use last few for direction
nr <- length(res$x)
arrows(res$x[1], res$y[1], res$x[4], res$y[4], code = 1, length = 0.1)
arrows(res$x[nr-3], res$y[nr-3], res$x[nr], res$y[nr], code = 2, length = 0.1)

Chapter 6

The grid package

grid-package  The Grid Graphics Package

Description

A rewrite of the graphics layout capabilities, plus some support for interaction.

Details

This package contains a graphics system which supplements S-style graphics (see the graphics package).

Further information is available in the following vignettes:

- grid: Introduction to grid (../doc/grid.pdf)
- displaylist: Display Lists in grid (../doc/displaylist.pdf)
- frame: Frames and packing grobs (../doc/frame.pdf)
- grobs: Working with grid grobs (../doc/grobs.pdf)
- interactive: Editing grid Graphics (../doc/interactive.pdf)
- locndimm: Locations versus Dimensions (../doc/locndimm.pdf)
- moveline: Demonstrating move-to and line-to (../doc/moveline.pdf)
- nonfinite: How grid responds to non-finite values (../doc/nonfinite.pdf)
- plotexample: Writing grid Code (../doc/plotexample.pdf)
- rotated: Rotated Viewports (../doc/rotated.pdf)
- saveload: Persistent representations (../doc/saveload.pdf)
- sharing: Modifying multiple grobs simultaneously (../doc/sharing.pdf)
- viewports: Working with grid viewports (../doc/viewports.pdf)

For a complete list of functions with individual help pages, use library(help="grid").

absolute.size

References

---

**absolute.size**  
*Absolute Size of a Grob*

**Description**

This function converts a unit object into absolute units. Absolute units are unaffected, but non-absolute units are converted into "null" units.

**Usage**

`absolute.size(unit)`

**Arguments**

- `unit`  
  An object of class "unit".

**Details**

Absolute units are things like "inches", "cm", and "lines". Non-absolute units are "npc" and "native".

This function is designed to be used in `widthDetails` and `heightDetails` methods.

**Value**

An object of class "unit".

**Author(s)**

Paul Murrell

**See Also**

`widthDetails` and `heightDetails` methods.
**arrow**  

Describe arrows to add to a line

**Description**

Produces a description of what arrows to add to a line. The result can be passed to a function that draws a line, e.g., `grid.lines`.

**Usage**

```r
arrow(angle = 30, length = unit(0.25, "inches"),
      ends = "last", type = "open")
```

**Arguments**

- **angle**: The angle of the arrow head in degrees (smaller numbers produce narrower, pointier arrows). Essentially describes the width of the arrow head.
- **length**: A unit specifying the length of the arrow head (from tip to base).
- **ends**: One of "last", "first", or "both", indicating which ends of the line to draw arrow heads.
- **type**: One of "open" or "closed" indicating whether the arrow head should be a closed triangle.

**Examples**

```r
arrow()
str(arrow(type = "closed"), give.attr=FALSE)
```

---

**as.mask**  

Define a Soft Mask

**Description**

Define either an alpha mask or a luminance mask, based on a grob.

**Usage**

```r
as.mask(x, type=c("alpha", "luminance"))
```

**Arguments**

- **x**: A grob.
- **type**: The type of mask.

**Details**

A mask may be specified for a viewport either directly as a grob or using this function. In the former case, the result is an alpha mask. This function allows the user to define a luminance mask instead. Not all graphics devices support masks and those that do may only support one type of mask: for example `xfig` and `pictex` do not support masks and Cairo-based devices only support alpha masks.
Value

A "GridMask" object.

  row <- (i - 1) %/% nrowcol[2] + 1
  pushViewport(viewport(layout.pos.row=row, layout.pos.col=col))
  test(tests[[i]])
  popViewport()
}

---

**dataViewport**  
*Create a Viewport with Scales based on Data*

**Description**

This is a convenience function for producing a viewport with x- and/or y-scales based on numeric values passed to the function.

**Usage**

```r
dataViewport(xData = NULL, yData = NULL, xscale = NULL, 
              yscale = NULL, extension = 0.05, ...)```

**Arguments**

- **xData**: A numeric vector of data.
- **yData**: A numeric vector of data.
- **xscale**: A numeric vector (length 2).
- **yscale**: A numeric vector (length 2).
- **extension**: A numeric. If length greater than 1, then first value is used to extend the xscale and second value is used to extend the yscale.
- **...**: All other arguments will be passed to a call to the `viewport()` function.

**Details**

If `xscale` is not specified then the values in `x` are used to generate an x-scale based on the range of `x`, extended by the proportion specified in `extension`. Similarly for the y-scale.

**Value**

A grid viewport object.

**Author(s)**

Paul Murrell
depth

See Also

viewport and plotViewport.

---

### Description

Determine the number of levels in a viewport stack or tree, in a viewport path, or in a grob path.

### Usage

```r
depth(x, ...) 
## S3 method for class 'viewport'
depth(x, ...) 
## S3 method for class 'path'
depth(x, ...)
```

### Arguments

- `x` Typically a viewport or viewport stack or viewport tree or viewport list, or a viewport path, or a grob path.
- `...` Arguments used by other methods.

### Details

Depths of paths are pretty straightforward because they contain no branchings. The depth of a viewport stack is the sum of the depths of the components of the stack. The depth of a viewport tree is the depth of the parent plus the depth of the children. The depth of a viewport list is the depth of the last component of the list.

### Value

An integer value.

### See Also

viewport, vpPath, gPath.

### Examples

```r
vp <- viewport()  
depth(vp)  
depth(vpStack(vp, vp))  
depth(vpList(vpStack(vp, vp), vp))  
depth(vpPath("vp"))  
depth(vpPath("vp1", "vp2"))
```
deviceLoc

Convert Viewport Location to Device Location

Description

These functions take a pair of unit objects and convert them to a pair of device locations (or dimensions) in inches (or native device coordinates).

Usage

deviceLoc(x, y, valueOnly = FALSE, device = FALSE)
deviceDim(w, h, valueOnly = FALSE, device = FALSE)

Arguments

x, y, w, h  A unit object.
valueOnly  A logical indicating. If TRUE then the function does not return a unit object, but rather only the converted numeric values.
device  A logical indicating whether the returned values should be in inches or native device units.

Details

These functions differ from the functions like convertX() because they convert from the coordinate systems within a viewport to inches on the device (i.e., from one viewport to another) and because they only deal with pairs of values (locations or dimensions).

The functions like convertX() convert between different units within the same viewport and convert along a single dimension.

Value

A list with two components, both of which are unit object in inches (unless valueOnly is TRUE in which case both components are numeric).

Warning

The conversion is only valid for the current device size. If the device is resized then at least some conversions will become invalid.

Furthermore, the returned value only makes sense with respect to the entire device (i.e., within the context of the root viewport).

grid.rect()
x <- unit(1, "in")
y <- unit(1, "in")
grid.circle(x, y, r=unit(2, "mm"))
loc <- deviceLoc(x, y)
loc
upViewport()
grid.circle(loc$x, loc$y, r=unit(1, "mm"), gp=gpar(fill="black"))

## Something even less obvious
grid.newpage()
pushViewport(viewport(width=.5, height=.5, angle=30))
grid.rect()
x <- unit(.2, "npc")
y <- unit(2, "in")
grid.circle(x, y, r=unit(2, "mm"))
loc <- deviceLoc(x, y)
loc
upViewport()
grid.circle(loc$x, loc$y, r=unit(1, "mm"), gp=gpar(fill="black"))
```

---

drawDetails  

## Customising grid Drawing

**Description**

These generic hook functions are called whenever a grid grob is drawn. They provide an opportunity for customising the drawing of a new class derived from grob (or gTree).

**Usage**

drawDetails(x, recording)  
preDrawDetails(x)  
postDrawDetails(x)

**Arguments**

- `x`  
  A grid grob.

- `recording`  
  A logical value indicating whether a grob is being added to the display list or redrawn from the display list.
Details

**NOTE:** these functions have been largely superceded by the `makeContent` and `makeContext` functions, though they are still run and may still be useful in some contexts.

These functions are called by the `grid.draw` methods for grobs and gTrees.

`preDrawDetails` is called first during the drawing of a grob. This is where any additional viewports should be pushed. Note that the default behaviour for grobs is to push any viewports in the `vp` slot, and for gTrees is to also push and up any viewports in the `childrenvp` slot so there is typically nothing to do here.

`drawDetails` is called next and is where any additional calculations and graphical output should occur. Note that the default behaviour for gTrees is to draw all grobs in the `children` slot so there is typically nothing to do here.

`postDrawDetails` is called last and should reverse anything done in `preDrawDetails` (i.e., pop or up any viewports that were pushed). Note that the default behaviour for grobs is to pop any viewports that were pushed so there is typically nothing to do here.

Note that `preDrawDetails` and `postDrawDetails` are also called in the calculation of "grobwidth" and "grobheight" units.

Value

None of these functions are expected to return a value.

`grid.draw` and `makeContent`

---

**editDetails**

**Customising grid Editing**

Description

This generic hook function is called whenever a grid grob is edited via `grid.edit` or `editGrob`. This provides an opportunity for customising the editing of a new class derived from grob (or gTree).

Usage

```
editDetails(x, specs)
```

Arguments

- `x` A grid grob.
- `specs` A list of named elements. The names indicate the grob slots to modify and the values are the new values for the slots.
Details

This function is called by grid.edit and editGrob. A method should be written for classes derived from grob or gTree if a change in a slot has an effect on other slots in the grob or children of a gTree (e.g., see grid:::editDetails.xaxis).

Note that the slot already has the new value.

Value

The function MUST return the modified grob.

Author(s)

Paul Murrell

See Also

grid.edit

editViewport

Modify a Viewport

Description

This is a convenience function for producing a new viewport from a copy of an existing viewport (by default the current viewport), with specified modifications.

Usage

editViewport(vp=current.viewport(), ...)

Arguments

vp

A viewport object.

... Modification of the viewport (should all be valid arguments to the viewport() function.

Value

A grid viewport object.

Author(s)

Paul Murrell

See Also

viewport.
**explode**

*Explode a path into its components*

**Description**

Explode a viewport path or grob path into its components.

**Usage**

```r
explode(x)
## S3 method for class 'character'
explode(x)
## S3 method for class 'path'
explode(x)
```

**Arguments**

- `x`
  - Typically a viewport path or a grob path, but a character vector containing zero or more path separators may also be given.

**Value**

A character vector.

**See Also**

`vpPath`, `gPath`.

**Examples**

```r
explode("vp1::vp2")
explode(vpPath("vp1", "vp2"))
```

---

**gEdit**

*Create and Apply Edit Objects*

**Description**

The functions `gEdit` and `gEditList` create objects representing an edit operation (essentially a list of arguments to `editGrob`).

The functions `applyEdit` and `applyEdits` apply one or more edit operations to a graphical object.

These functions are most useful for developers creating new graphical functions and objects.

**Usage**

```r
gEdit(...)
gEditList(...)
applyEdit(x, edit)
applyEdits(x, edits)
```
getNames

Arguments

... one or more arguments to the editGrob function (for gEdit) or one or more "gEdit" objects (for gEditList).

x a grob (grid graphical object).

edit a "gEdit" object.

edits either a "gEdit" object or a "gEditList" object.

Value

gEdit returns an object of class "gEdit".
gEditList returns an object of class "gEditList".
applyEdit and applyEditList return the modified grob.

Author(s)
Paul Murrell

See Also

grob editGrob

Examples

grid.rect(gp=gpar(col="red"))
# same thing, but more verbose
grid.draw(applyEdit(rectGrob(), gEdit(gp=gpar(col="red"))))

getNames

List the names of grobs on the display list

Description

Returns a character vector containing the names of all top-level grobs on the display list.

Usage

getNames()

Value

A character vector.

Author(s)
Paul Murrell

Examples

grid.grill()
getNames()
Description

gpar() should be used to create a set of graphical parameter settings. It returns an object of class "gpar". This is basically a list of name-value pairs.

get.gpar() can be used to query the current graphical parameter settings.

Usage

gpar(...)  
get.gpar(names = NULL)

Arguments

... Any number of named arguments.
names A character vector of valid graphical parameter names.

Details

All grid viewports and (predefined) graphical objects have a slot called gp, which contains a "gpar" object. When a viewport is pushed onto the viewport stack and when a graphical object is drawn, the settings in the "gpar" object are enforced. In this way, the graphical output is modified by the gp settings until the graphical object has finished drawing, or until the viewport is popped off the viewport stack, or until some other viewport or graphical object is pushed or begins drawing.

The default parameter settings are defined by the ROOT viewport, which takes its settings from the graphics device. These defaults may differ between devices (e.g., the default fill setting is different for a PNG device compared to a PDF device).

Valid parameter names are:

  - col Colour for lines and borders.
  - fill Colour for filling rectangles, polygons, ...
  - alpha Alpha channel for transparency
  - lty Line type
  - lwd Line width
  - lex Multiplier applied to line width
  - lineend Line end style (round, butt, square)
  - linejoin Line join style (round, mitre, bevel)
  - linemitre Line mitre limit (number greater than 1)
  - fontsize The size of text (in points)
  - cex Multiplier applied to fontsize
  - fontfamily The font family
  - fontface The font face (bold, italic, ...)
  - lineheight The height of a line as a multiple of the size of text
  - font Font face (alias for fontface; for backward compatibility)

For more details of many of these, see the help for the corresponding graphical parameter par in base graphics. (This may have a slightly different name, e.g. lend, ljoin, lmitre, family.)
Colours can be specified in one of the forms returned by \texttt{rgb}, as a name (see \texttt{colors}) or as a non-negative integer index into the current \texttt{palette} (with zero being taken as transparent). (Negative integer values are now an error.)

The \texttt{alpha} setting is combined with the alpha channel for individual colours by multiplying (with both alpha settings normalised to the range 0 to 1).

The \texttt{fill} setting can also be a linear gradient or a radial gradient or a pattern (see \texttt{patterns}).

The \texttt{cex} setting is cumulative; if a viewport is pushed with a \texttt{cex} of 0.5 then another viewport is pushed with a \texttt{cex} of 0.5, the effective \texttt{cex} is 0.25.

The \texttt{alpha} and \texttt{cex} settings are also cumulative.

Changes to the \texttt{fontfamily} may be ignored by some devices, but is supported by PostScript, PDF, X11, Windows, and Quartz. The \texttt{fontfamily} may be used to specify one of the Hershey Font families (e.g., \texttt{HersheySerif}) and this specification will be honoured on all devices.

The specification of \texttt{fontface} can be an integer or a string. If an integer, then it follows the R base graphics standard: 1 = plain, 2 = bold, 3 = italic, 4 = bold italic. If a string, then valid values are: "plain", "bold", "italic", "oblique", and "bold.italic". For the special case of the HersheySerif font family, "cyrillic", "cyrillic.oblique", and "EUC" are also available.

All parameter values can be vectors of multiple values. (This will not always make sense – for example, viewports will only take notice of the first parameter value.)

\texttt{get.gpar()} returns all current graphical parameter settings.

**Value**

An object of class "gpar".

**Author(s)**

Paul Murrell

**See Also**

\texttt{Hershey}.

**Examples**

```r
gp <- get.gpar()
utils::str(gp)
## These *do* nothing but produce a "gpar" object:
gpar(col = "red")
gpar(col = "blue", lty = "solid", lwd = 3, fontsize = 16)
get.gpar(c("col", "lty"))
grid.newpage()
vp <- viewport(width = .8, height = .8, gp = gpar(col="blue"))
grid.draw(gTree(children=gList(rectGrob(gp = gpar(col="red")),
                           textGrob(paste("The rect is its own colour (red)",
                                      "but this text is the colour",
                                      "set by the gTree (green)",
                                      sep = "\n"))),
               gp = gpar(col="green"), vp = vp))
grid.text("This text is the colour set by the viewport (blue)",
          y = 1, just = c("center", "bottom"),
          gp = gpar(fontsize=20), vp = vp)
```
grid.newpage()

## example with multiple values for a parameter
pushViewport(viewport())
ggrid.points(1:10/11, 1:10/11, gp = gpar(col=1:10))
popViewport()

gPath

<th>Concatenate Grob Names</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
</tr>
</tbody>
</table>

This function can be used to generate a grob path for use in grid.edit and friends.

A grob path is a list of nested grob names.

Usage

gPath(...)

Arguments

... Character values which are grob names.

Details

Grob names must only be unique amongst grobs which share the same parent in a gTree.

This function can be used to generate a specification for a grob that includes the grob’s parent’s name (and the name of its parent and so on).

For interactive use, it is possible to directly specify a path, but it is strongly recommended that this function is used otherwise in case the path separator is changed in future versions of grid.

Value

A gPath object.

See Also

grob, editGrob, addGrob, removeGrob, getGrob, setGrob

Examples

gPath("g1", "g2")
Grid

Grid Graphics

Description

General information about the grid graphics package.

Details

Grid graphics provides an alternative to the standard R graphics. The user is able to define arbitrary rectangular regions (called viewports) on the graphics device and define a number of coordinate systems for each region. Drawing can be specified to occur in any viewport using any of the available coordinate systems.

Grid graphics and standard R graphics do not mix!

Type `library(help = grid)` to see a list of (public) Grid graphics functions.

Author(s)

Paul Murrell

See Also

`viewport`, `grid.layout`, and `unit`.

Examples

```r
## Diagram of a simple layout
grid.show.layout(grid.layout(4,2,
    heights=unit(rep(1, 4),
    c("lines", "lines", "lines", "null")),
    widths=unit(c(1, 1), "inches")))
## Diagram of a sample viewport
grid.show.viewport(viewport(x=0.6, y=0.6,
    width=unit(1, "inches"), height=unit(1, "inches")))
## A flash plotting example
grid.multipanel(vp=viewport(0.5, 0.5, 0.8, 0.8))
```

Grid Viewports

Create a Grid Viewport

Description

These functions create viewports, which describe rectangular regions on a graphics device and define a number of coordinate systems within those regions.
Grid Viewports

Usage

viewport(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
width = unit(1, "npc"), height = unit(1, "npc"),
default.units = "npc", just = "centre",
gp = gpar(), clip = "inherit", mask = "inherit",
 xscale = c(0, 1), yscale = c(0, 1),
angle = 0,
layout = NULL,
layout.pos.row = NULL, layout.pos.col = NULL,
name = NULL)

vpList(...)

vpStack(...)

vpTree(parent, children)

Arguments

x
A numeric vector or unit object specifying x-location.

y
A numeric vector or unit object specifying y-location.

width
A numeric vector or unit object specifying width.

height
A numeric vector or unit object specifying height.

default.units
A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.

just
A string or numeric vector specifying the justification of the viewport relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment.

gp
An object of class "gpar", typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.

clip
One of "on", "inherit", or "off", indicating whether to clip to the extent of this viewport, inherit the clipping region from the parent viewport, or turn clipping off altogether. For back-compatibility, a logical value of TRUE corresponds to "on" and FALSE corresponds to "inherit".

May also be a grob (or a gTree) that describes a clipping path or the result of a call to as.path.

mask
One of "none" (or FALSE) or "inherit" (or TRUE) or a grob (or a gTree) or the result of call to as.mask. This specifies that the viewport should have no mask, or it should inherit the mask of its parent, or it should have its own mask, as described by the grob.

xscale
A numeric vector of length two indicating the minimum and maximum on the x-scale. The limits may not be identical.

yscale
A numeric vector of length two indicating the minimum and maximum on the y-scale. The limits may not be identical.

angle
A numeric value indicating the angle of rotation of the viewport. Positive values indicate the amount of rotation, in degrees, anticlockwise from the positive x-axis.

layout
A Grid layout object which splits the viewport into subregions.

layout.pos.row
A numeric vector giving the rows occupied by this viewport in its parent’s layout.
layout.pos.col  A numeric vector giving the columns occupied by this viewport in its parent’s layout.

name  A character value to uniquely identify the viewport once it has been pushed onto the viewport tree.

...  Any number of grid viewport objects.

parent  A grid viewport object.

children  A vpList object.

Details

The location and size of a viewport are relative to the coordinate systems defined by the viewport’s parent (either a graphical device or another viewport). The location and size can be specified in a very flexible way by specifying them with unit objects. When specifying the location of a viewport, specifying both layout.pos.row and layout.pos.col as NULL indicates that the viewport ignores its parent’s layout and specifies its own location and size (via its locn). If only one of layout.pos.row and layout.pos.col is NULL, this means occupy ALL of the appropriate row(s)/column(s). For example, layout.pos.row = 1 and layout.pos.col = NULL means occupy all of row 1. Specifying non-NULL values for both layout.pos.row and layout.pos.col means occupy the intersection of the appropriate rows and columns. If a vector of length two is specified for layout.pos.row or layout.pos.col, this indicates a range of rows or columns to occupy. For example, layout.pos.row = c(1, 3) and layout.pos.col = c(2, 4) means occupy cells in the intersection of rows 1, 2, and 3, and columns, 2, 3, and 4.

Clipping obeys only the most recent viewport clip setting. For example, if you clip to viewport1, then clip to viewport2, the clipping region is determined wholly by viewport2, the size and shape of viewport1 is irrelevant (until viewport2 is popped of course).

If a viewport is rotated (because of its own angle setting or because it is within another viewport which is rotated) then the clip flag is ignored.

If clip is a grob, then that grob (which may be more than one shape) defines a clipping path. The function as.path may be used to specify a fill rule for the path.

Viewport names need not be unique. When pushed, viewports sharing the same parent must have unique names, which means that if you push a viewport with the same name as an existing viewport, the existing viewport will be replaced in the viewport tree. A viewport name can be any string, but grid uses the reserved name "ROOT" for the top-level viewport. Also, when specifying a viewport name in downViewport and seekViewport, it is possible to provide a viewport path, which consists of several names concatenated using the separator (currently ::). Consequently, it is not advisable to use this separator in viewport names.

The viewports in a vpList are pushed in parallel. The viewports in a vpStack are pushed in series. When a vpTree is pushed, the parent is pushed first, then the children are pushed in parallel.

Value

An R object of class viewport.

  rect()
  grid.text(current.vpTree(FALSE),  
    x=unit(1, "mm"), y=unit(1, "npc") - unit(1, "mm"),  
    just=c("left", "top"),  
    gp=gpar(fontsize=8))
grid.add

Add a Grid Graphical Object

Description

Add a grob to a gTree or a descendant of a gTree.

Usage

grid.add(gPath, child, strict = FALSE, grep = FALSE,
global = FALSE, allDevices = FALSE, redraw = TRUE)

addGrob(gTree, child, gPath = NULL, strict = FALSE, grep = FALSE,
global = FALSE, warn = TRUE)

setChildren(x, children)

Arguments

gTree, x A gTree object.
gPath A gPath object. For grid.add this specifies a gTree on the display list. For addGrob this specifies a descendant of the specified gTree.
child A grob object.
children A gList object.
strict A boolean indicating whether the gPath must be matched exactly.
grep A boolean indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE) means that every odd element of the gPath will be treated as a regular expression).
global A boolean indicating whether the function should affect just the first match of the gPath, or whether all matches should be affected.
warn A logical to indicate whether failing to find the specified gPath should trigger an error.
allDevices A boolean indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.
redraw A logical value to indicate whether to redraw the grob.

Details

addGrob copies the specified grob and returns a modified grob.
grid.add destructively modifies a grob on the display list. If redraw is TRUE it then redraws everything to reflect the change.
setChildren is a basic function for setting all children of a gTree at once (instead of repeated calls to addGrob).
grid.bezier

**Value**

addGrob returns a grob object; grid.add returns NULL.

**Author(s)**

Paul Murrell

**See Also**

grob, getGrob, addGrob, removeGrob.

---

**grid.bezier**  
**Draw a Bezier Curve**

**Description**

These functions create and draw Bezier Curves (a curve drawn relative to 4 control points).

**Usage**

grid.bezier(...)  
bezierGrob(x = c(0, 0.5, 1, 0.5), y = c(0.5, 1, 0.5, 0),  
id = NULL, id.lengths = NULL,  
default.units = "npc", arrow = NULL,  
name = NULL, gp = gpar(), vp = NULL)

**Arguments**

- **x**: A numeric vector or unit object specifying x-locations of spline control points.
- **y**: A numeric vector or unit object specifying y-locations of spline control points.
- **id**: A numeric vector used to separate locations in x and y into multiple beziers. All locations with the same id belong to the same bezier.
- **id.lengths**: A numeric vector used to separate locations in x and y into multiple bezier. Specifies consecutive blocks of locations which make up separate beziers.
- **default.units**: A string indicating the default units to use if x or y are only given as numeric vectors.
- **arrow**: A list describing arrow heads to place at either end of the bezier, as produced by the arrow function.
- **name**: A character identifier.
- **gp**: An object of class "gpar". typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
- **vp**: A Grid viewport object (or NULL).
- **...**: Arguments to be passed to bezierGrob.
grid.cap

Capture a raster image

Details
Capture the current contents of a graphics device as a raster (bitmap) image.

Usage
grid.cap()

Details
This function is only implemented for on-screen graphics devices.

Value
A matrix of R colour names, or NULL if not available.

Description
Capture the current contents of a graphics device as a raster (bitmap) image.

Usage
grid.cap()

Details
This function is only implemented for on-screen graphics devices.

Value
A matrix of R colour names, or NULL if not available.
Author(s)
Paul Murrell

See Also
grid.raster
dev.capabilities to see if it is supported.

Examples
dev.new(width=0.5, height=0.5)
grid.rect()
grid.text("hi")
cap <- grid.cap()
dev.off()

if(!is.null(cap))
  grid.raster(cap, width=0.5, height=0.5, interpolate=FALSE)

---

grid.circle  Draw a Circle

Description
Functions to create and draw a circle.

Usage
grid.circle(x=0.5, y=0.5, r=0.5, default.units="npc", name=NULL,
gp=gpar(), draw=TRUE, vp=NULL)
circleGrob(x=0.5, y=0.5, r=0.5, default.units="npc", name=NULL,
gp=gpar(), vp=NULL)

Arguments
x  A numeric vector or unit object specifying x-locations.
y  A numeric vector or unit object specifying y-locations.
r  A numeric vector or unit object specifying radii.
default.units  A string indicating the default units to use if x, y, width, or height are only
given as numeric vectors.
name  A character identifier.
gp  An object of class "gpar", typically the output from a call to the function gpar.
    This is basically a list of graphical parameter settings.
draw  A logical value indicating whether graphics output should be produced.
vp  A Grid viewport object (or NULL).
Details

Both functions create a circle grob (a graphical object describing a circle), but only `grid.circle()` draws the circle (and then only if `draw` is `TRUE`).

The radius may be given in any units; if the units are relative (e.g., "npc" or "native") then the radius will be different depending on whether it is interpreted as a width or as a height. In such cases, the smaller of these two values will be the result. To see the effect, type `grid.circle()` and adjust the size of the window.

What happens for very small radii is device-dependent: the circle may become invisible or be shown at a fixed minimum size. Circles of zero radius will not be plotted.

Value

A circle grob. `grid.circle()` returns the value invisibly.

Warning

Negative values for the radius are silently converted to their absolute value.

Author(s)

Paul Murrell

See Also

`Grid`, `viewport`

---

**grid.clip**  Set the Clipping Region

Description

These functions set the clipping region within the current viewport without altering the current coordinate system.

Usage

```r
grid.clip(...)
clipGrob(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
        width = unit(1, "npc"), height = unit(1, "npc"),
        just = "centre", hjust = NULL, vjust = NULL,
        default.units = "npc", name = NULL, vp = NULL)
```

Arguments

- `x`  A numeric vector or unit object specifying x-location.
- `y`  A numeric vector or unit object specifying y-location.
- `width`  A numeric vector or unit object specifying width.
- `height`  A numeric vector or unit object specifying height.
The justification of the clip rectangle relative to its (x, y) location. If there are
two values, the first value specifies horizontal justification and the second value
specifies vertical justification. Possible string values are: "left", "right",
"centre", "center", "bottom", and "top". For numeric values, 0 means left
alignment and 1 means right alignment.

A numeric vector specifying horizontal justification. If specified, overrides the
just setting.

A numeric vector specifying vertical justification. If specified, overrides the
just setting.

A string indicating the default units to use if x, y, width, or height are only
given as numeric vectors.

A character identifier.

A Grid viewport object (or NULL).

Arguments passed to clipGrob.

Both functions create a clip rectangle (a graphical object describing a clip rectangle), but only
grid.clip enforces the clipping.

Pushing or popping a viewport always overrides the clip region set by a clip grob, regardless of
whether that viewport explicitly enforces a clipping region.

clipGrob returns a clip grob.

Paul Murrell

Grid, viewport

 Examples

# draw across entire viewport, but clipped
grid.clip(x = 0.3, width = 0.1)
grid.lines(gp=gpar(col="green", lwd=5))
# draw across entire viewport, but clipped (in different place)
grid.clip(x = 0.7, width = 0.1)
grid.lines(gp=gpar(col="red", lwd=5))
# Viewport sets new clip region
pushViewport(viewport(width=0.5, height=0.5, clip=TRUE))
grid.lines(gp=gpar(col="grey", lwd=3))
# Return to original viewport; get
# clip region from previous grid.clip()
# (NOT from previous viewport clip region)
popViewport()
grid.lines(gp=gpar(col="black"))
Description

These functions take a unit object and convert it to an equivalent unit object in a different coordinate system.

Usage

convertX(x, unitTo, valueOnly = FALSE)
cvtColor(x, unitTo, valueOnly = FALSE)
convertWidth(x, unitTo, valueOnly = FALSE)
convertHeight(x, unitTo, valueOnly = FALSE)
convertUnit(x, unitTo,
  axisFrom = "x", typeFrom = "location",
  axisTo = axisFrom, typeTo = typeFrom,
  valueOnly = FALSE)

Arguments

x A unit object.
unitTo The coordinate system to convert the unit to. See the unit function for valid coordinate systems.
axisFrom Either "x" or "y" to indicate whether the unit object represents a value in the x- or y-direction.
typeFrom Either "location" or "dimension" to indicate whether the unit object represents a location or a length.
axisTo Same as axisFrom, but applies to the unit object that is to be created.
typeTo Same as typeFrom, but applies to the unit object that is to be created.
valueOnly A logical indicating. If TRUE then the function does not return a unit object, but rather only the converted numeric values.

Details

The convertUnit function allows for general-purpose conversions. The other four functions are just more convenient front-ends to it for the most common conversions.

The conversions occur within the current viewport.

It is not currently possible to convert to all valid coordinate systems (e.g., "strwidth" or "grobwidth"). I'm not sure if all of these are impossible, they just seem implausible at this stage.

In normal usage of grid, these functions should not be necessary. If you want to express a location or dimension in inches rather than user coordinates then you should simply do something like unit(1, "inches") rather than something like unit(0.134, "native").

In some cases, however, it is necessary for the user to perform calculations on a unit value and this function becomes necessary. In such cases, please take note of the warning below.
Value

A unit object in the specified coordinate system (unless valueOnly is TRUE in which case the returned value is a numeric).

Warning

The conversion is only valid for the current device size. If the device is resized then at least some conversions will become invalid. For example, suppose that I create a unit object as follows: oneinch <- convertUnit(unit(1, "inches"), "native"). Now if I resize the device, the unit object in oneinch no longer corresponds to a physical length of 1 inch.

    axisFrom="x", axisTo="y")

## Convert several values at once
convertX(unit(c(0.5, 2.54), c("npc", "cm")),
        c("inches", "native"))
popViewport()

## Convert a complex unit
grid.copy

Make a Copy of a Grid Graphical Object

Description

This function is redundant and will disappear in future versions.

Usage

grid.copy(grob)

Arguments

grob A grob object.

Value

A copy of the grob object.

Author(s)

Paul Murrell

See Also

grid.grob.

grid.curve

Draw a Curve Between Locations

Description

These functions create and draw a curve from one location to another.

Usage

grid.curve(...) curveGrob(x1, y1, x2, y2, default.units = "npc", curvature = 1, angle = 90, ncp = 1, shape = 0.5, square = TRUE, squareShape = 1, inflect = FALSE, arrow = NULL, open = TRUE, debug = FALSE, name = NULL, gp = gpar(), vp = NULL) arcCurvature(theta)
Arguments

x1 A numeric vector or unit object specifying the x-location of the start point.
y1 A numeric vector or unit object specifying the y-location of the start point.
x2 A numeric vector or unit object specifying the x-location of the end point.
y2 A numeric vector or unit object specifying the y-location of the end point.
default.units A string indicating the default units to use if x1, y1, x2 or y2 are only given as numeric values.
curvature A numeric value giving the amount of curvature. Negative values produce left-hand curves, positive values produce right-hand curves, and zero produces a straight line.
angle A numeric value between 0 and 180, giving an amount to skew the control points of the curve. Values less than 90 skew the curve towards the start point and values greater than 90 skew the curve towards the end point.
ccp The number of control points used to draw the curve. More control points creates a smoother curve.
shape A numeric vector of values between -1 and 1, which control the shape of the curve relative to its control points. See grid.xspline for more details.
square A logical value that controls whether control points for the curve are created city-block fashion or obliquely. When ncp is 1 and angle is 90, this is typically TRUE, otherwise this should probably be set to FALSE (see Examples below).
squareShape A shape value to control the behaviour of the curve relative to any additional control point that is inserted if square is TRUE.
inflect A logical value specifying whether the curve should be cut in half and inverted (see Examples below).
arro A list describing arrow heads to place at either end of the curve, as produced by the arrow function.
open A logical value indicating whether to close the curve (connect the start and end points).
debug A logical value indicating whether debugging information should be drawn.
name A character identifier.
gp An object of class "gpar", typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
vp A Grid viewport object (or NULL).
... Arguments to be passed to curveGrob.
theta An angle (in degrees).

Details

Both functions create a curve grob (a graphical object describing an curve), but only grid.curve draws the curve.

The arcCurvature function can be used to calculate a curvature such that control points are generated on an arc corresponding to angle theta. This is typically used in conjunction with a large ncp to produce a curve corresponding to the desired arc.

Value

A grob object.
grid.delay

curveTest(2, 3, shape=0)
curveTest(3, 1, curvature=-1)
curveTest(3, 2, square=FALSE)
curveTest(3, 3, debug=TRUE)
popViewport(2)

Description

Encapsulate calculations and generating a grob

Usage

delayGrob(expr, list, name=NULL, gp=NULL, vp=NULL)
grid.delay(expr, list, name=NULL, gp=NULL, vp=NULL)
grid.display.list

Control the Grid Display List

Description

Turn the Grid display list on or off.

Usage

grid.display.list(on=TRUE)
engine.display.list(on=TRUE)

Arguments

expr
object of mode expression or call or an unevaluated expression.
list
a list defining the environment in which expr is to be evaluated.
name
A character identifier.
gp
An object of class "gpar", typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
vp
A Grid viewport object (or NULL).

Details

A grob is created of special class "delayedgrob" (and drawn, in the case of grid.delay). The makeContent method for this class evaluates the expression with the list as the evaluation environment (and the grid Namespace as the parent of that environment).

The expr argument should return a grob as its result.

These functions are analogues of the grid.record() and recordGrob() functions; the difference is that these functions are based on the makeContent() hook, while those functions are based on the drawDetails() hook.

Note

This function must be used instead of the function recordGraphics; all of the dire warnings about using recordGraphics responsibly also apply here.

Paul Murrell

See Also

recordGraphics

Examples

grid.delay(
  w <- convertWidth(unit(1, "inches"), "npc")
  rectGrob(width=w)
),
list())
Arguments

on A logical value to indicate whether the display list should be on or off.

Details

All drawing and viewport-setting operations are (by default) recorded in the Grid display list. This allows redrawing to occur following an editing operation.

This display list could get very large so it may be useful to turn it off in some cases; this will of course disable redrawing.

All graphics output is also recorded on the main display list of the R graphics engine (by default). This supports redrawing following a device resize and allows copying between devices.

Turning off this display list means that grid will redraw from its own display list for device resizes and copies. This will be slower than using the graphics engine display list.

Value

None.

WARNING

Turning the display list on causes the display list to be erased!

Turning off both the grid display list and the graphics engine display list will result in no redrawing whatsoever.

Paul Murrell

grid.DLapply Modify the Grid Display List

Description

Call a function on each element of the current display list.

Usage

grid.DLapply(FUN, ...)

Arguments

FUN A function; the first argument to this function is passed each element of the display list.

... Further arguments to pass to FUN.
Details
This function is insanely dangerous (for the grid display list).
Two token efforts are made to try to avoid ending up with complete garbage on the display list:
1. The display list is only replaced once all new elements have been generated (so an error during generation does not result in a half-finished display list).
2. All new elements must be either NULL or inherit from the class of the element that they are replacing.

Value
The side effect of these functions is usually to modify the grid display list.

See Also
Grid.

Examples
grid.newpage()
grid.rect(width=.4, height=.4, x=.25, y=.75, gp=gpar(fill="black"), name="r1")
grid.rect(width=.4, height=.4, x=.5, y=.5, gp=gpar(fill="grey"), name="r2")
grid.rect(width=.4, height=.4, x=.75, y=.25, gp=gpar(fill="white"), name="r3")
grid.DLapply(function(x) { if (is.grob(x)) x$gp <- gpar(); x })
grid.refresh()

grid.draw(x)

Description
Draw a grid grob

Usage
grid.draw(x, recording=TRUE)

Arguments
x
An object of class "grob" or NULL.

recording
A logical value to indicate whether the drawing operation should be recorded on the Grid display list.

Details
This is a generic function with methods for grob and gTree objects.
The grob and gTree methods automatically push any viewports in a vp slot and automatically apply any gpar settings in a gp slot. In addition, the gTree method pushes and ups any viewports in a childrenvp slot and automatically calls grid.draw for any grobs in a children slot.
The methods for grob and gTree call the generic hook functions preDrawDetails, drawDetails, and postDrawDetails to allow classes derived from grob or gTree to perform additional viewport pushing/popping and produce additional output beyond the default behaviour for grobs and gTrees.
Value
None.

grob.

Examples
grid.newpage()
## Create a graphical object, but don't draw it
l <- linesGrob()
## Draw it
grid.draw(l)

grid.edit
Edit the Description of a Grid Graphical Object

Description
Changes the value of one of the slots of a grob and redraws the grob.

Usage
grid.edit(gPath, ..., strict = FALSE, grep = FALSE,
          global = FALSE, allDevices = FALSE, redraw = TRUE)
grid.gedit(..., grep = TRUE, global = TRUE)
editGrob(grob, gPath = NULL, ..., strict = FALSE, grep = FALSE,
          global = FALSE, warn = TRUE)

Arguments
grob A grob object.
... Zero or more named arguments specifying new slot values.
gPath A gPath object. For grid.edit this specifies a grob on the display list. For
      editGrob this specifies a descendant of the specified grob.
strict A boolean indicating whether the gPath must be matched exactly.
grep A boolean indicating whether the gPath should be treated as a regular expres-
      sion. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE)
      means that every odd element of the gPath will be treated as a regular expres-
      sion).
global A boolean indicating whether the function should affect just the first match of
      the gPath, or whether all matches should be affected.
grid.force

A logical to indicate whether failing to find the specified gPath should trigger an error.

allDevices
A boolean indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.

redraw
A logical value to indicate whether to redraw the grob.

Details

editGrob copies the specified grob and returns a modified grob.

grid.edit destructively modifies a grob on the display list. If redraw is TRUE it then redraws everything to reflect the change.

Both functions call editDetails to allow a grob to perform custom actions and validDetails to check that the modified grob is still coherent.

grid.gedit (g for global) is just a convenience wrapper for grid.edit with different defaults.

Value

editGrob returns a grob object; grid.edit returns NULL.

Author(s)

Paul Murrell

See Also

grob, getGrob, addGrob, removeGrob.

Examples

grid.newpage()
grid.xaxis(name = "xa", vp = viewport(width=.5, height=.5))
grid.edit("xa", gp = gpar(col="red"))
# won't work because no ticks (at is NULL)
try(grid.edit(gPath("xa", "ticks"), gp = gpar(col="green")))
grid.edit("xa", at = 1:4/5)
# Now it should work
try(grid.edit(gPath("xa", "ticks"), gp = gpar(col="green")))

grid.force

Force a grob into its components

Description

Some grobs only generate their content to draw at drawing time; this function replaces such grobs with their at-drawing-time content.
**Usage**

```r
grid.force(x, ...)  
## Default S3 method:  
grid.force(x, redraw = FALSE, ...)  
## S3 method for class 'gPath'  
grid.force(x, strict = FALSE, grep = FALSE, global = FALSE,  
           redraw = FALSE, ...)  
## S3 method for class 'grob'  
grid.force(x, draw = FALSE, ...)  
forceGrob(x)  
grid.revert(x, ...)  
## S3 method for class 'gPath'  
grid.revert(x, strict = FALSE, grep = FALSE, global = FALSE,  
           redraw = FALSE, ...)  
## S3 method for class 'grob'  
grid.revert(x, draw = FALSE, ...)  
```

**Arguments**

- `x`: For the default method, `x` should not be specified. Otherwise, `x` should be a grob or a gPath. If `x` is character, it is assumed to be a gPath.
- `strict`: A boolean indicating whether the path must be matched exactly.
- `grep`: Whether the path should be treated as a regular expression.
- `global`: A boolean indicating whether the function should affect just the first match of the path, or whether all matches should be affected.
- `draw`: Logical value indicating whether a grob should be drawn after it is forced.
- `redraw`: Logical value indicating whether to redraw the grid scene after the forcing operation.
- `...`: Further arguments for use by methods.

**Details**

Some grobs wait until drawing time to generate what content will actually be drawn (an axis, as produced by `grid.xaxis()`, with an at or NULL is a good example because it has to see what viewport it is going to be drawn in before it can decide what tick marks to draw).

The content of such grobs (e.g., the tick marks) are not usually visible to `grid.ls()` or accessible to `grid.edit()`.

The `grid.force()` function replaces a grob with its at-drawing-time contents. For example, an axis will be replaced by a vanilla gTree with lines and text representing the axis tick marks that were actually drawn. This makes the tick marks visible to `grid.ls()` and accessible to `grid.edit()`.

The `forceGrob()` function is the internal work horse for `grid.force()`, so will not normally be called directly by the user. It is exported so that methods can be written for custom grob classes if necessary.

The `grid.revert()` function reverses the effect of `grid.force()`, replacing forced content with the original grob.

**Warning**

Forcing an explicit grob produces a result as if the grob were drawn in the current drawing context. It may not make sense to draw the result in a different drawing context.
grid.frame

Create a Frame for Packing Objects

Description

These functions, together with grid.pack, grid.place, packGrob, and placeGrob are part of a GUI-builder-like interface to constructing graphical images. The idea is that you create a frame with this function then use grid.pack or whatever to pack/place objects into the frame.

Usage

grid.frame(layout=NULL, name=NULL, gp=gpar(), vp=NULL, draw=TRUE)
frameGrob(layout=NULL, name=NULL, gp=gpar(), vp=NULL)
grid.function

Description

Draw a curve representing a function.

Usage

grid.function(...)
  functionGrob(f, n = 101, range = "x", units = "native",
               name = NULL, gp=gpar(), vp = NULL)

grid.abline(intercept, slope, ...)
Arguments

- **f**: A function that must take a single argument and return a list with two numeric components named x and y.
- **n**: The number values that will be generated as input to the function f.
- **range**: Either "x", "y", or a numeric vector. See the ‘Details’ section.
- **units**: A string indicating the units to use for the x and y values generated by the function.
- **intercept**: Numeric.
- **slope**: Numeric.
- **...**: Arguments passed to `grid.function()`
- **name**: A character identifier.
- **gp**: An object of class "gpar", typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- **vp**: A Grid viewport object (or NULL).

Details

n values are generated and passed to the function f and a series of lines are drawn through the resulting x and y values.

The generation of the n values depends on the value of range. In the default case, dim is "x", which means that a set of x values are generated covering the range of the current viewport scale in the x-dimension. If dim is "y" then values are generated from the current y-scale instead. If range is a numeric vector, then values are generated from that range.

`grid.abline()` provides a simple front-end for a straight line parameterized by intercept and slope.

Value

A function grob.

`Grid`, `viewport`

Examples

```r
# abline
# NOTE: in ROOT viewport on screen, (0, 0) at top-left
# and "native" is pixels!
grid.function(function(x) list(x=x, y=0 + 1*x))
# a more "normal" viewport with default normalized "native" coords
grid.newpage()
pushViewport(viewport())
grid.function(function(x) list(x=x, y=0 + 1*x))
# slightly simpler
grid.newpage()
```
grid.get

Get a Grid Graphical Object

Description
Retrieve a grob or a descendant of a grob.

Usage
grid.get(gPath, strict = FALSE, grep = FALSE, global = FALSE, allDevices = FALSE)
g.grid.get(..., grep = TRUE, global = TRUE)
getGrob(gTree, gPath, strict = FALSE, grep = FALSE, global = FALSE)

Arguments

gTree
A gTree object.
gPath
A gPath object. For grid.get this specifies a grob on the display list. For
getGrob this specifies a descendant of the specified gTree.
strict
A boolean indicating whether the gPath must be matched exactly.
grep
A boolean indicating whether the gPath should be treated as a regular expression.
Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE) means that every odd element of the gPath will be treated as a regular expression).
grid.glyph

Draw Typeset Glyphs

Description

These functions create and draw a set of typeset glyphs.

Usage

grid.glyph(...)
glyphGrob(glyphInfo,
    x=.5, y=.5, default.units="npc",
    hjust="centre", vjust="centre",
    gp=gpar(), vp=NULL, name=NULL)
Arguments

glyphInfo An "RGlyphInfo" object from a call to \texttt{glyphInfo}.
x A numeric vector or unit object specifying x-location.
y A numeric vector or unit object specifying y-location.
default.units A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
hjust, vjust The justification of the glyphs relative to the (x, y) location. Can be character (e.g., "left"), numeric (e.g., 0), or the result of a call to \texttt{glyphJust}.
name A character identifier.
gp An object of class "gpar", typically the output from a call to the function \texttt{gpar}. This is basically a list of graphical parameter settings.
vp A Grid viewport object (or NULL).
... Arguments passed to \texttt{glyphGrob()}.  

Details
Both functions create a glyph grob (a graphical object describing glyphs), but only \texttt{grid.glyph} draws the glyphs.

Value
A glyph grob.

Author(s)
Paul Murrell

Grid, glyphInfo

grid.grab \hspace{1cm} \textit{Grab the current grid output}

Description
Creates a gTree object from the current grid display list or from a scene generated by user-specified code.

Usage
\begin{verbatim}
grid.grab(warn = 2, wrap = wrap.grobs, wrap.grobs = FALSE, ...)
grid.grabExpr(expr, warn = 2, wrap = wrap.grobs, wrap.grobs = FALSE, width = 7, height = 7, device = offscreen, ...)
\end{verbatim}
Arguments

expr  An expression to be evaluated. Typically, some calls to grid drawing functions.
warn  An integer specifying the amount of warnings to emit. 0 means no warnings,
      1 means warn when it is certain that the grab will not faithfully represent
      the original scene. 2 means warn if there’s any possibility that the grab will not
      faithfully represent the original scene.
wrap  A logical indicating how the output should be captured. If TRUE, each non-grob
      element on the display list is captured by wrapping it in a grob.
wrap.grobs  A logical indicating whether, if we are wrapping elements (wrap=TRUE), we
            should wrap grobs (or just wrap viewports).
width, height  Size of the device used for temporary rendering.
device  A function that opens a graphics device for temporary rendering. By default
        this is an off-screen, in-memory device based on the pdf device, but this default
        device may not be satisfactory when using custom fonts.
...  arguments passed to gTree, for example, a name and/or class for the gTree that
      is created.

Details

There are four ways to capture grid output as a gTree.

There are two functions for capturing output: use grid.grab to capture an existing drawing and
grid.grabExpr to capture the output from an expression (without drawing anything).

For each of these functions, the output can be captured in two ways. One way tries to be clever and
make a gTree with a childrenvp slot containing all viewports on the display list (including those that
are popped) and every grob on the display list as a child of the new gTree; each child has a vpPath
in the vp slot so that it is drawn in the appropriate viewport. In other words, the gTree contains all
elements on the display list, but in a slightly altered form.

The other way, wrap=TRUE, is to create a grob for every element on the display list (and make all of
those grobs children of the gTree). Only viewports are wrapped unless wrap.grobs is also TRUE.

The first approach creates a more compact and elegant gTree, which is more flexible to work with,
but is not guaranteed to faithfully replicate all possible grid output. The second approach is more
brute force, and harder to work with, but is more likely to replicate the original output.

An example of a case that will NOT be replicated by wrapping, with wrap.grobs=TRUE, is a scene
where the placement of one grob is dependent on another grob (e.g., via grobX or grobWidth).

Value

A gTree object.

See Also

gTree

Examples

grab <- grid.grab()
grid.grep

Search for Grobs and/or Viewports

Description

Given a path, find all matching grobs and/or viewports on the display list or within a given grob.

Usage

```r
grid.grep(path, x = NULL, grobs = TRUE, viewports = FALSE,
        strict = FALSE, grep = FALSE, global = FALSE,
        no.match = character(), vpPath = viewports)
```

Arguments

- `path` a gPath or a vpPath or a character value that could be interpreted as either.
- `x` a grob or NULL. If NULL, the display list is searched.
- `grobs` A logical value indicating whether to search for grobs.
- `viewports` A logical value indicating whether to search for viewports.
- `strict` A boolean indicating whether the path must be matched exactly.
- `grep` Whether the path should be treated as a regular expression.
- `global` A boolean indicating whether the function should affect just the first match of the path, or whether all matches should be affected.
- `no.match` The value to return if no matches are found.
- `vpPath` A logical value indicating whether to return the vpPath for each grob as an attribute of the result.

Value

Either a gPath or a vpPath or, if `global` is TRUE a list of gPaths and/or vpPaths.

If vpPath is TRUE, each gPath result will have an attribute "vpPath".

If there are no matches, `no.match` is returned.

- `grid.ls()`

Examples

```r
# A gTree, called "grandparent", with child gTree,
# called "parent", with children vp Stack (vp2 within vp1)
# and child grob, called "child", with vp vpPath (down to vp2)
sampleGTree <- gTree(name="grandparent",
    children=gList(gTree(name="parent",
        children=gList(grob(name="child", vp="vp1::vp2")),
        children=vpStack(viewport(name="vp1")),
```
# Searching for grobs
grid.grep("parent", sampleGTree)
grid.grep("parent", sampleGTree, strict=TRUE)
grid.grep("grandparent", sampleGTree, strict=TRUE)
grid.grep("grandparent::parent", sampleGTree)
grid.grep("parent::child", sampleGTree)
grid.grep("[a-z]", sampleGTree, grep=TRUE)
grid.grep("[a-z]", sampleGTree, grep=TRUE, global=TRUE)

# Searching for viewports
grid.grep("vp1", sampleGTree, viewports=TRUE)
grid.grep("vp2", sampleGTree, viewports=TRUE)
grid.grep("vp", sampleGTree, viewports=TRUE, grep=TRUE)
grid.grep("vp2", sampleGTree, viewports=TRUE, strict=TRUE)
grid.grep("vp1::vp2", sampleGTree, viewports=TRUE)

# Searching for both
grid.grep("[a-z]", sampleGTree, viewports=TRUE, grep=TRUE, global=TRUE)

---

**grid.grill**  
**Draw a Grill**

**Description**
This function draws a grill within a Grid viewport.

**Usage**
```r
grid.grill(h = unit(seq(0.25, 0.75, 0.25), "npc"),
v = unit(seq(0.25, 0.75, 0.25), "npc"),
default.units = "npc", gp=gpar(col = "grey"), vp = NULL)
```

**Arguments**
- `h`  
  A numeric vector or unit object indicating the horizontal location of the vertical grill lines.
- `v`  
  A numeric vector or unit object indicating the vertical location of the horizontal grill lines.
- `default.units`  
  A string indicating the default units to use if `h` or `v` are only given as numeric vectors.
- `gp`  
  An object of class "gpar", typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- `vp`  
  A Grid viewport object.

**Value**
None.

**Author(s)**
Paul Murrell
grid.grob

grid.grob

Create Grid Graphical Objects, aka "Grob"s

Description

Creating grid graphical objects, short ("grob")s.

grob() and gTree() are the basic creators, grobTree() and gList() take several grobs to build a new one.

Usage

## Grob Creation:

```r
grob (..., name = NULL, gp = NULL, vp = NULL, cl = NULL)
gTree(..., name = NULL, gp = NULL, vp = NULL, children = NULL,
       childrenvp = NULL, cl = NULL)
grobTree(..., name = NULL, gp = NULL, vp = NULL,
       childrenvp = NULL, cl = NULL)
gList(...)
```

## Grob Properties:

```r
childNames(gTree)
is.grob(x)
```

Arguments

... For grob and gTree, the named slots describing important features of the graphical object. For gList and grobTree, a series of grob objects.

name a character identifier for the grob. Used to find the grob on the display list and/or as a child of another grob.

children a "gList" object.

childrenvp a viewport object (or NULL).

gp A "gpar" object, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.

vp a viewport object (or NULL).

cl string giving the class attribute for the new class.

gTree a "gTree" object.

x An R object.
Details

These functions can be used to create a basic "grob", "gTree", or "gLst" object, or a new class derived from one of these.

A grid graphical object ("grob") is a description of a graphical item. These basic classes provide default behaviour for validating, drawing, and modifying graphical objects. Both `grob()` and `gTree()` call the function `validDetails` to check that the object returned is internally coherent.

A "gTree" can have other grobs as children; when a gTree is drawn, it draws all of its children. Before drawing its children, a gTree pushes its `childrenvp` slot and then navigates back up (calls `upViewport`) so that the children can specify their location within the `childrenvp` via a `vpPath`.

Grob names need not be unique in general, but all children of a gTree must have different names. A grob name can be any string, though it is not advisable to use the `gPath` separator (currently `::`) in grob names.

The function `childNames` returns the names of the grobs which are children of a gTree.

All grid primitives (`grid.lines`, `grid.rect`, ...) and some higher-level grid components (e.g., `grid.xaxis` and `grid.yaxis`) are derived from these classes.

`grobTree` is just a convenient wrapper for `gTree` when the only components of the gTree are grobs (so all unnamed arguments become children of the gTree).

The `grid.grob` function is defunct.

Value

An R object of class "grob", a graphical object.

Author(s)

Paul Murrell

See Also

`grid.draw`, `grid.edit`, `grid.get`.

grid.group  Draw a Group

Description

These functions define and draw one or more groups, where a group is a grob that is drawn in isolation before being combined with the main image. The concept of groups allows for compositing operators, object reuse, and affine transformations (see the Details section).

Usage

```r
grid.group(src, op = "over", dst = NULL, coords = TRUE, name = NULL, gp=gpar(), vp=NULL)
grobTree(src, op = "over", dst = NULL, coords = TRUE, name = NULL, gp=gpar(), vp=NULL)
defineGrob(src, op = "over", dst = NULL, coords = TRUE, name = NULL, gp=gpar(), vp=NULL)
```
grid.group

```r
grid.define(src, op = "over", dst = NULL, coords = TRUE,
            name = NULL, gp=gpar(), vp=NULL)
useGrob(group, transform=viewportTransform,
        name=NULL, gp=gpar(), vp=NULL)
grid.use(group, transform=viewportTransform,
         name=NULL, gp=gpar(), vp=NULL)
```

**Arguments**

- `src` A grob.
- `op` The name of a compositing operator (see Details).
- `dst` A grob.
- `coords` A logical indicating whether grob coordinates should be calculated for the group.
- `group` A character identified referring to the name of a defined group.
- `transform` A function that returns an affine transformation matrix; see `viewportTransform`.
- `name` A character identifier.
- `gp` An object of class "gpar", typically the output from a call to the function `gpar`.
  This is basically a list of graphical parameter settings.
- `vp` A Grid viewport object (or NULL).

**Details**

In the simplest usage, we can use `grid.group()` to specify a grob to be drawn in isolation before being combined with the main image. This can be different from normal drawing if, for example, the grob draws more than one shape and there is a mask currently in effect.

Another possible use of `grid.group()` is to specify both `src` and `dst` and combine them using a compositing operator other than the default "over", before combining the result with the main image. For example, if we use the "dest.out" operator then `dst` is only drawn where it is NOT overlapped by `src`. The following (extended) Porter-Duff operators are available: "clear", "source", "over", "in", "out", "atop", "dest", "dest.over", "dest.in", "dest.out", "dest.atop", "xor", "add", and "saturate". In addition, there are operators corresponding to PDF blend modes: "multiply", "screen", "overlay", "darken", "lighten", "color.dodge", "color.burn", "hard.light", "soft.light", "difference", and "exclusion". However, even if a graphics device supports groups, it may not support all compositing operators; see `dev.capabilities`.

It is also possible to break the process into two steps by first using `grid.define()` to define a group and then `grid.use()` to draw the group. This allows for reuse of a group (define the group once and use it several times).

If a group is defined in one viewport and used in a different viewport, an implicit transformation is applied. This could be a simple transformation (if the viewports are in different locations, but are the same size), or it could be more complex if the viewports are also different sizes or at different orientations.

**NOTE:** transformations occur on the graphics device so affect all aspects of drawing. For example, text and line widths are transformed as well as locations.

See `viewportTransform` for more information about transformations and how to customise them.
Not all graphics devices support these functions: for example xfig and pictex do not. For devices that do provide support, that support may only be partial (e.g., the Cairo-based devices support more compositing operators than the pdf() device).

Value

A grob object.

Examples

## NOTE: on devices without support for groups (or masks or patterns),
## there will only be two overlapping opaque circles
grid.newpage()
pat <- pattern(rasterGrob(matrix(c(.5, 1, 1, .5), nrow=2),
               width=unit(1, "cm"),
               height=unit(1, "cm"),
               interpolate=FALSE),
               width=unit(1, "cm"), height=unit(1, "cm"),
               extend="repeat")
grid.rect(gp=gpar(col=NA, fill=pat))
masks <- dev.capabilities()$masks
if (is.character(masks) && "luminance" %in% masks) {
  mask <- as.mask(rectGrob(gp=gpar(col=NA, fill="grey50")), type="luminance")
} else {
  mask <- rectGrob(gp=gpar(col=NA, fill=rgb(0,0,0,.5)))
}
pushViewport(viewport(mask=mask))
pushViewport(viewport(y=.5, height=.5, just="bottom"))
grid.circle(1:2/3, r=.45, gp=gpar(fill=2:3))
popViewport()
pushViewport(viewport(y=0, height=.5, just="bottom"))
grid.group(circleGrob(1:2/3, r=.45, gp=gpar(fill=2:3)))
popViewport()

grid.layout

Create a Grid Layout

Description

This function returns a Grid layout, which describes a subdivision of a rectangular region.
grid.layout

Usage

grid.layout(nrow = 1, ncol = 1,
    widths = unit(rep_len(1, ncol), "null"),
    heights = unit(rep_len(1, nrow), "null"),
    default.units = "null", respect = FALSE,
    just="centre")

Arguments

nrow  An integer describing the number of rows in the layout.
ncol  An integer describing the number of columns in the layout.
widths A numeric vector or unit object describing the widths of the columns in the
        layout.
heights A numeric vector or unit object describing the heights of the rows in the layout.
default.units A string indicating the default units to use if widths or heights are only given
                   as numeric vectors.
respect A logical value or a numeric matrix. If a logical, this indicates whether row
         heights and column widths should respect each other. If a matrix, non-zero
         values indicate that the corresponding row and column should be respected (see
         examples below).
just A string or numeric vector specifying how the layout should be justified if it is
      not the same size as its parent viewport. If there are two values, the first value
      specifies horizontal justification and the second value specifies vertical justi-
      fication. Possible string values are: "left", "right", "centre", "center", "bottom",
      and "top". For numeric values, 0 means left alignment and 1 means right alignment. NOTE
      that in this context, "left", for example, means align the left edge of the left-most layout column
      with the left edge of the parent viewport.

Details

The unit objects given for the widths and heights of a layout may use a special units that only has
meaning for layouts. This is the "null" unit, which indicates what relative fraction of the available
width/height the column/row occupies. See the reference for a better description of relative widths
and heights in layouts.

Value

A Grid layout object.

WARNING

This function must NOT be confused with the base R graphics function layout. In particular, do
not use layout in combination with Grid graphics. The documentation for layout may provide
some useful information and this function should behave identically in comparable situations. The
grid.layout function has added the ability to specify a broader range of units for row heights and
column widths, and allows for nested layouts (see viewport).

Examples

```r
## A variety of layouts (some a bit mid-bending ...)
layout.torture()
## Demonstration of layout justification
grid.newpage()

testlay <- function(just="centre") {
  pushViewport(viewport(layout=grid.layout(1, 1, widths=unit(1, "inches"),
                    heights=unit(0.25, "npc"),
                    just=just)))
  pushViewport(viewport(layout.pos.col=1, layout.pos.row=1))
  grid.rect()
  grid.text(paste(just, collapse="-"))
  popViewport(2)
}

plot()

## Demonstrating layout justification

plot()
```

grid.lines

**Draw Lines in a Grid Viewport**

Description

These functions create and draw a series of lines.

Usage

```r
grid.lines(x = unit(c(0, 1), "npc"),
          y = unit(c(0, 1), "npc"),
          default.units = "npc",
          arrow = NULL, name = NULL,
          gp=gpar(), draw = TRUE, vp = NULL)
```

```r
linesGrob(x = unit(c(0, 1), "npc"),
          y = unit(c(0, 1), "npc"),
          default.units = "npc",
          arrow = NULL, name = NULL,
          gp=gpar(), draw = TRUE, vp = NULL)
```

```r
grid.polyline(...)
```
grid.lines

polylineGrob(x = unit(c(0, 1), "npc"),
            y = unit(c(0, 1), "npc"),
            id=NULL, id.lengths=NULL,
            default.units = "npc",
            arrow = NULL, name = NULL,
            gp=gpar(), vp = NULL)

Arguments

x  A numeric vector or unit object specifying x-values.
y  A numeric vector or unit object specifying y-values.
default.units  A string indicating the default units to use if x or y are only given as numeric vectors.
arrow  A list describing arrow heads to place at either end of the line, as produced by the arrow function.
name  A character identifier.
gp  An object of class "gpar", typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
draw  A logical value indicating whether graphics output should be produced.
vp  A Grid viewport object (or NULL).
id  A numeric vector used to separate locations in x and y into multiple lines. All locations with the same id belong to the same line.
id.lengths  A numeric vector used to separate locations in x and y into multiple lines. Specifies consecutive blocks of locations which make up separate lines.
...  Arguments passed to polylineGrob.

Details

The first two functions create a lines grob (a graphical object describing lines), and grid.lines draws the lines (if draw is TRUE).

The second two functions create or draw a polyline grob, which is just like a lines grob, except that there can be multiple distinct lines drawn.

Value

A lines grob or a polyline grob. grid.lines returns a lines grob invisibly.

Grid, viewport, arrow
Examples

grid.lines()
# Using id (NOTE: locations are not in consecutive blocks)
grid.newpage()
grid.polyline(x=c((0:4)/10, rep(.5, 5), (10:6)/10, rep(.5, 5)),
    y=c(rep(.5, 5), (10:6/10), rep(.5, 5), (0:4)/10),
    id=rep(1:5, 4),
    gp=gpar(col=1:5, lwd=3))
# Using id.lengths
grid.newpage()
grid.polyline(x=outer(c(0, .5, 1, .5), 5:1/5),
    y=outer(c(.5, 1, .5, 0), 5:1/5),
    id.lengths=rep(4, 5),
    gp=gpar(col=1:5, lwd=3))

grid.locator  
Capture a Mouse Click

Description

Allows the user to click the mouse once within the current graphics device and returns the location
of the mouse click within the current viewport, in the specified coordinate system.

Usage

grid.locator(unit = "native")

Arguments

unit  
The coordinate system in which to return the location of the mouse click. See
the unit function for valid coordinate systems.

Details

This function is modal (like the graphics package function locator) so the command line and
graphics drawing is blocked until the use has clicked the mouse in the current device.

Value

A unit object representing the location of the mouse click within the current viewport, in the speci-
fied coordinate system.

If the user did not click mouse button 1, the function (invisibly) returns NULL.

Examples

if (dev.interactive()) {
  ## Need to write a more sophisticated unit as.character method
  unittrim <- function(unit) {
    sub("\^{([0-9]+|[0-9]+\.[0-9]+)}","","as.character(unit))
  }
  do.click <- function(unit) {
    click.locn <- grid.locator(unit)
    grid.segments(unit.c(click.locn$x, unit(0, "npc")),
                   unit.c(0, "npc"), click.locn$y),
                   unit.locn$x, click.locn$y,
                   ptp=gpar(lty="dashed", col="grey"))
    grid.points(click.locn$x, click.locn$y, pch=16, size=unit(1, "mm"))
    clickx <- unittrim(click.locn$x)
    clicky <- unittrim(click.locn$y)
    grid.text(paste0("\((", clickx, ", ", clicky, ")\)",
                 click.locn$x + unit(2, "mm"), click.locn$y,
                 just="left")
  }
  grid.newpage() # (empty slate)
  do.click("inches")
  Sys.sleep(1)
  pushViewport(viewport(width=0.5, height=0.5,
                      xscale=c(0, 100), yscale=c(0, 10)))
  grid.rect()
  grid.xaxis()
  grid.yaxis()
  do.click("native")
  popViewport()
}

grid.ls

List the names of grobs or viewports

Description

Return a listing of the names of grobs or viewports.

This is a generic function with methods for grobs (including gTrees) and viewports (including vpTrees).

Usage

grid.ls(x=NULL, grobs=TRUE, viewports=FALSE, fullNames=FALSE,
         recursive=TRUE, print=TRUE, flatten=TRUE, ...)

nestedListing(x, gindent=" ", vpindent=gindent)

pathListing(x, gvpSep=" | ", gAlign=TRUE)
grobPathListing(x, ...)

Arguments

- **x**: A grob or viewport or NULL. If NULL, the current grid display list is listed. For print functions, this should be the result of a call to `grid.ls`.
- **grobs**: A logical value indicating whether to list grobs.
- **viewports**: A logical value indicating whether to list viewports.
- **fullNames**: A logical value indicating whether to embellish object names with information about the object type.
- **recursive**: A logical value indicating whether recursive structures should also list their children.
- **print**: A logical indicating whether to print the listing or a function that will print the listing.
- **flatten**: A logical value indicating whether to flatten the listing. Otherwise a more complex hierarchical object is produced.
- **gindent**: The indent used to show nesting in the output for grobs.
- **vpinindent**: The indent used to show nesting in the output for viewports.
- **gvpSep**: The string used to separate viewport paths from grob paths.
- **gAlign**: Logical indicating whether to align the left hand edge of all grob paths.
- **...**: Arguments passed to the print function.

Details

If the argument `x` is NULL, the current contents of the grid display list are listed (both viewports and grobs). In other words, all objects representing the current scene are listed.

Otherwise, `x` should be a grob or a viewport.

The default behaviour of this function is to print information about the grobs in the current scene. It is also possible to add information about the viewports in the scene. By default, the listing is recursive, so all children of gTrees and all nested viewports are reported.

The format of the information can be controlled via the print argument, which can be given a function to perform the formatting. The `nestedListing` function produces a line per grob or viewport, with indenting used to show nesting. The `pathListing` function produces a line per grob or viewport, with viewport paths and grob paths used to show nesting. The `grobPathListing` is a simple derivation that only shows lines for grobs. The user can define new functions.

Value

The result of this function is either a "gridFlatListing" object (if flatten is TRUE) or a "gridListing" object.

The former is a simple (flat) list of vectors. This is convenient, for example, for working programmatically with the list of grob and viewport names, or for writing a new display function for the listing.

The latter is a more complex hierarchical object (list of lists), but it does contain more detailed information so may be of use for more advanced customisations.

Author(s)

Paul Murrell
## Description

Grid has the notion of a current location. These functions sets that location.

## Usage

```r
grid.move.to(x = 0, y = 0, default.units = "npc", name = NULL,
            draw = TRUE, vp = NULL)
```

```r
moveToGrob(x = 0, y = 0, default.units = "npc", name = NULL,
           vp = NULL)
```

```r
grid.line.to(x = 1, y = 1, default.units = "npc",
             arrow = NULL, name = NULL,
             gp = gpar(), draw = TRUE, vp = NULL)
```

```r
lineToGrob(x = 1, y = 1, default.units = "npc", arrow = NULL,
           name = NULL, gp = gpar(), vp = NULL)
```
Arguments

- **x**: A numeric value or a unit object specifying an x-value.
- **y**: A numeric value or a unit object specifying a y-value.
- **default.units**: A string indicating the default units to use if x or y are only given as numeric values.
- **arrow**: A list describing arrow heads to place at either end of the line, as produced by the `arrow` function.
- **name**: A character identifier.
- **draw**: A logical value indicating whether graphics output should be produced.
- **gp**: An object of class "gpar", typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- **vp**: A Grid viewport object (or NULL).

Details

Both functions create a move.to/line.to grob (a graphical object describing a move-to/line-to), but only `grid.move.to/line.to()` draws the move.to/line.to (and then only if `draw` is TRUE).

Value

A move.to/line.to grob. `grid.move.to/line.to()` returns the value invisibly.

`Grid, viewport, arrow`

Examples

```r
grid.newpage()
grid.move.to(0.5, 0.5)
grid.line.to(1, 1)
grid.line.to(0.5, 0)
pushViewport(viewport(x=0, y=0, width=0.25, height=0.25, just=c("left", "bottom")))
grid.rect()
grid.grill()
grid.line.to(0.5, 0.5)
popViewport()
```
grid.newpage  

Move to a New Page on a Grid Device

Description

This function erases the current device or moves to a new page.

Usage

grid.newpage(recording = TRUE, clearGroups = TRUE)

Arguments

recording  
A logical value to indicate whether the new-page operation should be saved onto the Grid display list.

clearGroups  
A logical value indicating whether any groups that have been defined on the current page should be released (see grid.group).

Details

The new page is painted with the fill colour (gpar("fill")), which is often transparent. For devices with a canvas colour (the on-screen devices X11, windows and quartz), the page is first painted with the canvas colour and then the background colour.

There are two hooks called "before.grid.newpage" and "grid.newpage" (see setHook). The latter is used in the testing code to annotate the new page. The hook function(s) are called with no argument. (If the value is a character string, get is called on it from within the grid namespace.)

Value

None.

Grid

grid.null  

Null Graphical Object

Description

These functions create a NULL graphical object, which has zero width, zero height, and draw nothing. It can be used as a place-holder or as an invisible reference point for other drawing.
Usage

nullGrob(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
  default.units = "npc",
  name = NULL, vp = NULL)
grid.null(...)

Arguments

x  A numeric vector or unit object specifying x-location.
y  A numeric vector or unit object specifying y-location.
default.units  A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
name  A character identifier.
vp  A Grid viewport object (or NULL).
...  Arguments passed to nullGrob().

Value

A null grob.

Author(s)

Paul Murrell

See Also

Grid, viewport

Examples

grid.newpage()
grid.null(name="ref")
grid.rect(height=grobHeight("ref"))
grid.segments(0, 0, grobX("ref", 0), grobY("ref", 0))

description

these functions, together with grid.frame and frameGrob are part of a GUI-builder-like interface to constructing graphical images. The idea is that you create a frame with grid.frame or frameGrob then use these functions to pack objects into the frame.
Usage

grid.pack(gPath, grob, redraw = TRUE, side = NULL,
  row = NULL, row.before = NULL, row.after = NULL,
  col = NULL, col.before = NULL, col.after = NULL,
  width = NULL, height = NULL,
  force.width = FALSE, force.height = FALSE, border = NULL,
  dynamic = FALSE)

packGrob(frame, grob, side = NULL,
  row = NULL, row.before = NULL, row.after = NULL,
  col = NULL, col.before = NULL, col.after = NULL,
  width = NULL, height = NULL,
  force.width = FALSE, force.height = FALSE, border = NULL,
  dynamic = FALSE)

Arguments

gPath A gPath object, which specifies a frame on the display list.
frame An object of class frame, typically the output from a call to grid.frame.
grob An object of class grob. The object to be packed.
redraw A boolean indicating whether the output should be updated.
side One of "left", "top", "right", "bottom" to indicate which side to pack the object on.
row Which row to add the object to. Must be between 1 and the-number-of-rows-
currently-in-the-frame + 1, or NULL in which case the object occupies all rows.
row.before Add the object to a new row just before this row.
row.after Add the object to a new row just after this row.
col Which col to add the object to. Must be between 1 and the-number-of-cols-
currently-in-the-frame + 1, or NULL in which case the object occupies all cols.
col.before Add the object to a new col just before this col.
col.after Add the object to a new col just after this col.
width Specifies the width of the column that the object is added to (rather than allowing
  the width to be taken from the object).
height Specifies the height of the row that the object is added to (rather than allowing
  the height to be taken from the object).
force.width A logical value indicating whether the width of the column that the grob is being
  packed into should be EITHER the width specified in the call to grid.pack OR
  the maximum of that width and the pre-existing width.
force.height A logical value indicating whether the height of the column that the grob is being
  packed into should be EITHER the height specified in the call to grid.pack OR
  the maximum of that height and the pre-existing height.
border A unit object of length 4 indicating the borders around the object.
dynamic If the width/height is taken from the grob being packed, this boolean flag indicates
  whether the "grobwidth"/"grobheight" unit refers directly to the grob,
  or uses a gPath to the grob. In the latter case, changes to the grob will trigger a
  recalculation of the width/height.
grid.path

Description
These functions create and draw one or more paths. The final point of a path will automatically be connected to the initial point.

Usage
pathGrob(x, y,
    id=NULL, id.lengths=NULL,
    pathId=NULL, pathId.lengths=NULL,
    rule="winding",
    default.units="npc",
    name=NULL, gp=gpar(), vp=NULL)
grid.path(...)

Arguments

x        A numeric vector or unit object specifying x-locations.
y        A numeric vector or unit object specifying y-locations.
id        A numeric vector used to separate locations in x and y into sub-paths. All locations with the same id belong to the same sub-path.
id.lengths        A numeric vector used to separate locations in x and y into sub-paths. Specifies consecutive blocks of locations which make up separate sub-paths.
grid.path

pathId A numeric vector used to separate locations in x and y into distinct paths. All locations with the same pathId belong to the same path.

pathId.lengths A numeric vector used to separate locations in x and y into paths. Specifies consecutive blocks of locations which make up separate paths.

rule A character value specifying the fill rule: either "winding" or "evenodd".

default.units A string indicating the default units to use if x or y are only given as numeric vectors.

name A character identifier.

gp An object of class "gpar", typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.

vp A Grid viewport object (or NULL).

... Arguments passed to pathGrob().

Details

Both functions create a path grob (a graphical object describing a path), but only grid.path draws the path (and then only if draw is TRUE).

A path is like a polygon except that the former can contain holes, as interpreted by the fill rule; these fill a region if the path border encircles it an odd or non-zero number of times, respectively.

Not all graphics devices support this function: for example xfig and pictex do not.

Value

A grob object.

grid.place

Place an Object within a Frame

Description

These functions provide a simpler (and faster) alternative to the grid.pack() and packGrob functions. They can be used to place objects within the existing rows and columns of a frame layout. They do not provide the ability to add new rows and columns nor do they affect the heights and widths of the rows and columns.

Usage

grid.place(gPath, grob, row = 1, col = 1, redraw = TRUE)
placeGrob(frame, grob, row = NULL, col = NULL)

Arguments

gPath A gPath object, which specifies a frame on the display list.
frame An object of class frame, typically the output from a call to grid.frame.
grob An object of class grob. The object to be placed.
row Which row to add the object to. Must be between 1 and the-number-of-rows-currently-in-the-frame.
col Which col to add the object to. Must be between 1 and the-number-of-cols-currently-in-the-frame.
redraw A boolean indicating whether the output should be updated.

Details

placeGrob modifies the given frame grob and returns the modified frame grob.
grid.place destructively modifies a frame grob on the display list (and redraws the display list if redraw is TRUE).

Value

placeGrob returns a frame grob, but grid.place returns NULL.

grid.plot.and.legend  A Simple Plot and Legend Demo

Description

This function is just a wrapper for a simple demonstration of how a basic plot and legend can be drawn from scratch using grid.

Usage

grid.plot.and.legend()

Author(s)

Paul Murrell

Examples

grid.plot.and.legend()

grid.points  Draw Data Symbols

Description

These functions create and draw data symbols.

Usage

grid.points(x = stats::runif(10),
            y = stats::runif(10),
            pch = 1, size = unit(1, "char"),
            default.units = "native", name = NULL,
            gp = gpar(), draw = TRUE, vp = NULL)
pointsGrob(x = stats::runif(10),
           y = stats::runif(10),
           pch = 1, size = unit(1, "char"),
           default.units = "native", name = NULL,
           gp = gpar(), vp = NULL)

Arguments

x
  numeric vector or unit object specifying x-values.
y
  numeric vector or unit object specifying y-values.
pch
  numeric or character vector indicating what sort of plotting symbol to use. See points for the interpretation of these values, and note fill below.
size
  unit object specifying the size of the plotting symbols.
default.units
  string indicating the default units to use if x or y are only given as numeric vectors.
grid.polygon

name      character identifier.
gp        an R object of class "gpar", typically the output from a call to the function gpar. This is basically a list of graphical parameter settings; note that fill (and not bg as in package graphics points) is used to “fill”, i.e., color the background of symbols with pch = 21:25.
draw      logical indicating whether graphics output should be produced.
vp         A Grid viewport object (or NULL).

Details

Both functions create a points grob (a graphical object describing points), but only grid.points draws the points (and then only if draw is TRUE).

Value

A points grob. grid.points returns the value invisibly.

Grid, viewport

grid.polygon | Draw a Polygon

Description

These functions create and draw a polygon. The final point will automatically be connected to the initial point.

Usage

grid.polygon(x=c(0, 0.5, 1, 0.5), y=c(0.5, 1, 0.5, 0),
id=NULL, id.lengths=NULL,
default.units="npc", name=NULL,
gp=gpar(), draw=TRUE, vp=NULL)
polygonGrob(x=c(0, 0.5, 1, 0.5), y=c(0.5, 1, 0.5, 0),
id=NULL, id.lengths=NULL,
default.units="npc", name=NULL,
gp=gpar(), vp=NULL)
grid.polygon

Arguments

x  A numeric vector or unit object specifying x-locations.
y  A numeric vector or unit object specifying y-locations.
id  A numeric vector used to separate locations in x and y into multiple polygons. All locations with the same id belong to the same polygon.
id.lengths  A numeric vector used to separate locations in x and y into multiple polygons. Specifies consecutive blocks of locations which make up separate polygons.
default.units  A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
name  A character identifier.
gp  An object of class "gpar", typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
draw  A logical value indicating whether graphics output should be produced.
vp  A Grid viewport object (or NULL).

Details

Both functions create a polygon grob (a graphical object describing a polygon), but only grid.polygon draws the polygon (and then only if draw is TRUE).

Value

A grob object.

Grid, viewport

Examples

grid.polygon()
# Using id (NOTE: locations are not in consecutive blocks)
grid.newpage()
grid.polygon(x=c((0:4)/10, rep(.5, 5), (10:6)/10, rep(.5, 5)),
y=c(rep(.5, 5), (10:6)/10, rep(.5, 5), (0:4)/10),
id=rep(1:5, 4),
gp=gpar(fill=1:5))
# Using id.lengths
grid.newpage()
grid.polygon(x=outer(c(0, .5, 1, .5), 5:1/5),
y=outer(c(.5, 1, .5, 0), 5:1/5),
id.lengths=rep(4, 5),
gp=gpar(fill=1:5))
grid.pretty

Generate a Sensible ("Pretty") Set of Breakpoints

Description

Produces a pretty set of approximately \( n \) breakpoints within the range given.

This is a direct interface to R’s graphical engine `GEpretty()` function, which also underlies base graphics’ package `axis()`, `axTicks()`, etc.

Usage

```r
grid.pretty(range, n = 5)
```

Arguments

- `range` a numeric vector of length at least two, as e.g., returned by `range()`.
- `n` a non-negative integer specifying the approximate number of breakpoints to be produced.

Value

A numeric vector of “pretty” breakpoints.

Author(s)

Paul Murrell

grid.raster

Render a raster object

Description

Render a raster object (bitmap image) at the given location, size, and orientation.

Usage

```r
grid.raster(image,
            x = unit(0.5, "npc"), y = unit(0.5, "npc"),
            width = NULL, height = NULL,
            just = "centre", hjust = NULL, vjust = NULL,
            interpolate = TRUE, default.units = "npc",
            name = NULL, gp = gpar(), vp = NULL)
```

```r
rasterGrob(image,
           x = unit(0.5, "npc"), y = unit(0.5, "npc"),
           width = NULL, height = NULL,
           just = "centre", hjust = NULL, vjust = NULL,
           interpolate = TRUE, default.units = "npc",
           name = NULL, gp = gpar(), vp = NULL)
```
Arguments

image Any R object that can be coerced to a raster object.
x A numeric vector or unit object specifying x-location.
y A numeric vector or unit object specifying y-location.
width A numeric vector or unit object specifying width.
height A numeric vector or unit object specifying height.
just The justification of the rectangle relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment.
hjust A numeric vector specifying horizontal justification. If specified, overrides the just setting.
vjust A numeric vector specifying vertical justification. If specified, overrides the just setting.
default.units A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
name A character identifier.
gp An object of class "gpar", typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
vp A Grid viewport object (or NULL).
interpolate A logical value indicating whether to linearly interpolate the image (the alternative is to use nearest-neighbour interpolation, which gives a more blocky result).

Details

Neither width nor height needs to be specified, in which case, the aspect ratio of the image is preserved. If both width and height are specified, it is likely that the image will be distorted.

Not all graphics devices are capable of rendering raster images and some may not be able to produce rotated images (i.e., if a raster object is rendered within a rotated viewport). See also the comments under rasterImage.

All graphical parameter settings in gp will be ignored, including alpha.

Value

A rastergrob grob.

Author(s)

Paul Murrell

See Also

as.raster.
dev.capabilities to see if it is supported.
Examples

```r
redGradient <- matrix(hcl(0, 80, seq(50, 80, 10)),
                      nrow=4, ncol=5)
# interpolated
grid.newpage()
grid.raster(redGradient)
# blocky
grid.newpage()
grid.raster(redGradient, interpolate=FALSE)
# blocky and stretched
grid.newpage()
grid.raster(redGradient, interpolate=FALSE, height=unit(1, "npc"))

# The same raster drawn several times
grid.newpage()
grid.raster(0, x=1:3/4, y=1:3/4, width=.1, interpolate=FALSE)
```

grid.record

Encapsulate calculations and drawing

Description

Evaluates an expression that includes both calculations and drawing that depends on the calculations so that both the calculations and the drawing will be rerun when the scene is redrawn (e.g., device resize or editing).

Intended only for expert use.

Usage

```r
recordGrob(expr, list, name=NULL, gp=NULL, vp=NULL)
grid.record(expr, list, name=NULL, gp=NULL, vp=NULL)
```

Arguments

- **expr**: object of mode `expression` or call or an unevaluated expression.
- **list**: a list defining the environment in which `expr` is to be evaluated.
- **name**: A character identifier.
- **gp**: An object of class "gpar", typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- **vp**: A Grid viewport object (or NULL).

Details

A grob is created of special class "recordedGrob" (and drawn, in the case of `grid.record`). The `drawDetails` method for this class evaluates the expression with the list as the evaluation environment (and the grid Namespace as the parent of that environment).

Note

This function must be used instead of the function `recordGraphics`; all of the dire warnings about using `recordGraphics` responsibly also apply here.
grid.rect

Draw rectangles

These functions create and draw rectangles.

Usage

grid.rect(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
          width = unit(1, "npc"), height = unit(1, "npc"),
          just = "centre", hjust = NULL, vjust = NULL,
          default.units = "npc", name = NULL,
          gp=gpar(), draw = TRUE, vp = NULL)
rectGrob(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
         width = unit(1, "npc"), height = unit(1, "npc"),
         just = "centre", hjust = NULL, vjust = NULL,
         default.units = "npc", name = NULL,
         gp=gpar(), vp = NULL)

Arguments

x  A numeric vector or unit object specifying x-location.
y  A numeric vector or unit object specifying y-location.
width  A numeric vector or unit object specifying width.
height  A numeric vector or unit object specifying height.
just  The justification of the rectangle relative to its (x, y) location. If there are two
       values, the first value specifies horizontal justification and the second value
       specifies vertical justification. Possible string values are: "left", "right",
       "centre", "center", "bottom", and "top". For numeric values, 0 means left
       alignment and 1 means right alignment.
hjust  A numeric vector specifying horizontal justification. If specified, overrides the
       just setting.
vjust  A numeric vector specifying vertical justification. If specified, overrides the
       just setting.
**grid.rect**

default.units A string indicating the default units to use if \( x, y, \text{width}, \) or \( \text{height} \) are only given as numeric vectors.

name A character identifier.

gp An object of class "gpars", typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.

draw A logical value indicating whether graphics output should be produced.

vp A Grid viewport object (or NULL).

**Details**

Both functions create a rect grob (a graphical object describing rectangles), but only `grid.rect` draws the rectangles (and then only if `draw` is TRUE).

**Value**

A rect grob. `grid.rect` returns the value invisibly.

**grid.refresh**

Refresh the current grid scene

**Description**

Replays the current grid display list.

**Usage**

`grid.refresh()`

**Author(s)**

Paul Murrell
grid.remove  Remove a Grid Graphical Object

Description
Remove a grob from a gTree or a descendant of a gTree.

Usage
grid.remove(gPath, warn = TRUE, strict = FALSE, grep = FALSE,  
global = FALSE, allDevices = FALSE, redraw = TRUE)
grid.gremove(..., grep = TRUE, global = TRUE)
removeGrob(gTree, gPath, strict = FALSE, grep = FALSE,  
global = FALSE, warn = TRUE)

Arguments
gTree  A gTree object.
gPath  a gPath object. For grid.remove this specifies a gTree on the display list. For removeGrob this specifies a descendant of the specified gTree.
strict  a logical indicating whether the gPath must be matched exactly.
grep  a logical indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE) means that every odd element of the gPath will be treated as a regular expression).
global  a logical indicating whether the function should affect just the first match of the gPath, or whether all matches should be affected.
allDevices  a logical indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.
warn  A logical to indicate whether failing to find the specified grob should trigger an error.
redraw  A logical value to indicate whether to redraw the grob.
...  arguments passed to grid.get.

Details
removeGrob copies the specified grob and returns a modified grob.
grid.remove destructively modifies a grob on the display list. If redraw is TRUE it then redraws everything to reflect the change.
grid.gremove (g for global) is just a convenience wrapper for grid.remove with different defaults.

Value
removeGrob returns a grob object; grid.remove returns NULL.
**grid.reorder**

Reorder the children of a gTree

**Description**

Change the order in which the children of a gTree get drawn.

**Usage**

```r
grid.reorder(gPath, order, back=TRUE, grep=FALSE, redraw=TRUE)
reorderGrob(x, order, back=TRUE)
```

**Arguments**

- `gPath` A gPath object specifying a gTree within the current scene.
- `x` A gTree object to be modified.
- `order` A character vector or a numeric vector that specifies the new drawing order for the children of the gTree. May not refer to all children of the gTree (see Details).
- `back` Controls what happens when the `order` does not specify all children of the gTree (see Details).
- `grep` Should the `gPath` be treated as a regular expression?
- `redraw` Should the modified scene be redrawn?

**Details**

In the simplest case, `order` specifies a new ordering for all of the children of the gTree. The children may be specified either by name or by existing numerical order.

If the `order` does not specify all children of the gTree then, by default, the children specified by `order` are drawn first and then all remaining children are drawn. If `back=FALSE` then the children not specified in `order` are drawn first, followed by the specified children. This makes it easy to specify a send-to-back or bring-to-front reordering. The `order` argument is always in back-to-front order.

It is not possible to reorder the grid display list (the top-level grobs in the current scene) because the display list is a mixture of grobs and viewports (so it is not clear what reordering even means and it would be too easy to end up with a scene that would not draw). If you want to reorder the grid display list, try `grid.grab()` to create a gTree and then reorder (and redraw) that gTree.

**Value**

- `grid.reorder()` is called for its side-effect of modifying the current scene. `reorderGrob()` returns the modified gTree.
Warning

This function may return a gTree that will not draw. For example, a gTree has two children, A and B (in that order), and the width of child B depends on the width of child A (e.g., a box around a piece of text). Switching the order so that B is drawn before A will not allow B to be drawn. If this happens with `grid.reorder()`, the modification will not be performed. If this happens with `reorderGrob()` it should be possible simply to restore the original order.

Author(s)

Paul Murrell

Examples

```r
# gTree with two children, "red-rect" and "blue-rect" (in that order)
gt <- gTree(children=gList(
  rectGrob(gp=gpar(col=NA, fill="red"),
    width=.8, height=.2, name="red-rect"),
  rectGrob(gp=gpar(col=NA, fill="blue"),
    width=.2, height=.8, name="blue-rect")),
  name="gt")
grid.newpage()
grid.draw(gt)
# Spec entire order as numeric (blue-rect, red-rect)
grid.reorder("gt", 2:1)
# Spec entire order as character
grid.reorder("gt", c("red-rect", "blue-rect"))
# Only spec the one I want behind as character
grid.reorder("gt", "blue-rect")
# Only spec the one I want in front as character
grid.reorder("gt", "blue-rect", back=FALSE)
```

grid.segments  Draw Line Segments

Description

These functions create and draw line segments.

Usage

```r
grid.segments(x0 = unit(0, "npc"), y0 = unit(0, "npc"),
  x1 = unit(1, "npc"), y1 = unit(1, "npc"),
  default.units = "npc",
  arrow = NULL,
  name = NULL, gp = gpar(), draw = TRUE, vp = NULL)
segmentsGrob(x0 = unit(0, "npc"), y0 = unit(0, "npc"),
  x1 = unit(1, "npc"), y1 = unit(1, "npc"),
  default.units = "npc",
  arrow = NULL, name = NULL, gp = gpar(), vp = NULL)
```
Arguments

\[x0\] Numeric indicating the starting x-values of the line segments.
\[y0\] Numeric indicating the starting y-values of the line segments.
\[x1\] Numeric indicating the stopping x-values of the line segments.
\[y1\] Numeric indicating the stopping y-values of the line segments.
\[default.units\] A string.
\[arrow\] A list describing arrow heads to place at either end of the line segments, as produced by the `arrow` function.
\[name\] A character identifier.
\[gp\] An object of class "gpars", typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
\[draw\] A logical value indicating whether graphics output should be produced.
\[vp\] A Grid viewport object (or NULL).

Details

Both functions create a segments grob (a graphical object describing segments), but only `grid.segments` draws the segments (and then only if `draw` is TRUE).

Value

A segments grob. `grid.segments` returns the value invisibly.

Author(s)

Paul Murrell

See Also

`Grid`, `viewport`, `arrow`
Arguments

- **gTree**: A gTree object.
- **gPath**: A gPath object. For grid.set this specifies a grob on the display list. For setGrob this specifies a descendant of the specified gTree.
- **newGrob**: A grob object.
- **strict**: A boolean indicating whether the gPath must be matched exactly.
- **grep**: A boolean indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., `c(TRUE, FALSE)` means that every odd element of the gPath will be treated as a regular expression).
- **redraw**: A logical value to indicate whether to redraw the grob.

Details

- **setGrob** copies the specified grob and returns a modified grob.
- **grid.set** destructively replaces a grob on the display list. If **redraw** is TRUE it then redraws everything to reflect the change.

These functions should not normally be called by the user.

Value

- **setGrob** returns a grob object; **grid.set** returns NULL.

Author(s)

Paul Murrell

- `grid.grob`

---

**grid.show.layout**  
Draw a Diagram of a Grid Layout

Description

This function uses Grid graphics to draw a diagram of a Grid layout.

Usage

```r
grid.show.layout(l, newpage=TRUE, vp.ex = 0.8, bg = "light grey", cell.border = "blue", cell.fill = "light blue", cell.label = TRUE, label.col = "blue", unit.col = "red", vp = NULL, ...)
```
Arguments

l A Grid layout object.
newpage A logical value indicating whether to move on to a new page before drawing the diagram.
vp.ex positive number, typically in \( [0, 1] \), specifying the scaling of the layout.
bg The colour used for the background.
cell.border The colour used to draw the borders of the cells in the layout.
cell.fill The colour used to fill the cells in the layout.
cell.label A logical indicating whether the layout cells should be labelled.
label.col The colour used for layout cell labels.
unit.col The colour used for labelling the widths/heights of columns/rows.
vp A Grid viewport object (or NULL).
... Arguments passed to \texttt{format} for formatting the layout width and height annotations.

Details

A viewport is created within \texttt{vp} to provide a margin for annotation, and the layout is drawn within that new viewport. The margin is filled with light grey, the new viewport is filled with white and framed with a black border, and the layout regions are filled with light blue and framed with a blue border. The diagram is annotated with the widths and heights (including units) of the columns and rows of the layout using red text. (All colours are defaults and may be customised via function arguments.)

Value

None.

Author(s)

Paul Murrell

See Also

\texttt{Grid}, \texttt{viewport}, \texttt{grid.layout}

Examples

```r
## Diagram of a simple layout
grid.show.layout(grid.layout(4,2,
    heights=unit(rep(1, 4),
        c("lines", "lines", "lines", "null")),
    widths=unit(c(1, 1), "inches")))
```
grid.show.viewport  

Draw a Diagram of a Grid Viewport

Description

This function uses Grid graphics to draw a diagram of a Grid viewport.

Usage

grid.show.viewport(v, parent.layout = NULL, newpage = TRUE, 
  vp.ex = 0.8, border.fill="light grey", 
  vp.col="blue", vp.fill="light blue", 
  scale.col="red", 
  vp = NULL)

Arguments

v                A Grid viewport object.
parent.layout    A grid layout object. If this is not NULL and the viewport given in v has its
    location specified relative to the layout, then the diagram shows the layout and
    which cells v occupies within the layout.
newpage          A logical value to indicate whether to move to a new page before drawing the
    diagram.
vp.ex            positive number, typically in (0, 1], specifying the scaling of the layout.
border.fill      Colour to fill the border margin.
vp.col           Colour for the border of the viewport region.
vp.fill          Colour to fill the viewport region.
scale.col        Colour to draw the viewport axes.
vp               A Grid viewport object (or NULL).

Details

A viewport is created within vp to provide a margin for annotation, and the diagram is drawn within
that new viewport. By default, the margin is filled with light grey, the new viewport is filled with
white and framed with a black border, and the viewport region is filled with light blue and framed
with a blue border. The diagram is annotated with the width and height (including units) of the
viewport, the (x, y) location of the viewport, and the x- and y-scales of the viewport, using red lines
and text.

Value

None.

Author(s)

Paul Murrell

    grid.layout(3, 4))
```

**grid.stroke**

**Stroke or Fill a Path**

Description

These functions stroke (draw a line along the border) or fill (or both) a path, where the path is defined by a grob.

Usage

```r
strokeGrob(x, ...)
## S3 method for class 'grob'
strokeGrob(x, name=NULL, gp=gpar(), vp=NULL, ...)
## S3 method for class 'GridPath'
strokeGrob(x, name=NULL, vp=NULL, ...)

grid.stroke(...)
fillGrob(x, ...)
## S3 method for class 'grob'
fillGrob(x, rule=c("winding", "evenodd"),
    name=NULL, gp=gpar(), vp=NULL, ...)
## S3 method for class 'GridPath'
fillGrob(x, name=NULL, vp=NULL, ...)

grid.fill(...)
fillStrokeGrob(x, ...)
## S3 method for class 'grob'
fillStrokeGrob(x, rule=c("winding", "evenodd"),
    name=NULL, gp=gpar(), vp=NULL, ...)
## S3 method for class 'GridPath'
fillStrokeGrob(x, name=NULL, vp=NULL, ...)

grid.fillStroke(...)
as.path(x, gp=gpar(), rule=c("winding", "evenodd"))
```

Arguments

- `x` A grob or the result of a call to `as.path()`.
- `rule` A fill rule.
- `name` A character identifier.
- `gp` An object of class "gpar", typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- `vp` A Grid viewport object (or NULL).
- `...` Arguments to `grid.*()` passed on to *Grob(), or additional arguments passed on to methods.
Details
A path is defined by the shapes that the grob given in x would draw. The grob only contributes to the outline of the path; graphical parameter settings such as line colour and fill are ignored.

grid.stroke() will only ever draw the border (even when a fill is specified).

grid.fill() will only ever fill the path (even when a line colour is specified).

A stroke will only ever happen if a non-transparent line colour is specified and a fill will only ever happen if a non-transparent fill is specified.

as.path() allows graphical parameter settings and a fill rule to be associated with a grob. This can be useful when specifying a clipping path for a viewport (see viewport).

Not all graphics devices support these functions: for example xfig and pictex do not.

Value
A grob object.

Author(s)
Paul Murrell

Grid

Examples
## NOTE: on devices without support for stroking and filling
## nothing will be drawn
grid.newpage()
grid.stroke(textGrob("hello", gp=gpar(cex=10)))
grid.fill(circleGrob(1:2/3, r=.3), gp=gpar(fill=rgb(1,0,0,.5)))

---

grid.text

Draw Text

Description
These functions create and draw text and plotmath expressions.

Usage

grid.text(label, x = unit(0.5, "npc"), y = unit(0.5, "npc"),
  just = "centre", hjust = NULL, vjust = NULL, rot = 0,
  check.overlap = FALSE, default.units = "npc",
  name = NULL, gp = gpar(), draw = TRUE, vp = NULL)

textGrob(label, x = unit(0.5, "npc"), y = unit(0.5, "npc"),
  just = "centre", hjust = NULL, vjust = NULL, rot = 0,
  check.overlap = FALSE, default.units = "npc",
  name = NULL, gp = gpar(), vp = NULL)
Arguments

- **label**: A character or expression vector. Other objects are coerced by `as.graphicsAnnot`.
- **x**: A numeric vector or unit object specifying x-values.
- **y**: A numeric vector or unit object specifying y-values.
- **just**: The justification of the text relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left (bottom) alignment and 1 means right (top) alignment.
- **hjust**: A numeric vector specifying horizontal justification. If specified, overrides the just setting.
- **vjust**: A numeric vector specifying vertical justification. If specified, overrides the just setting.
- **rot**: The angle to rotate the text.
- **check.overlap**: A logical value to indicate whether to check for and omit overlapping text (within that grob).
- **default.units**: A string indicating the default units to use if x or y are only given as numeric vectors.
- **name**: A character identifier.
- **gp**: An object of class "gpar", typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- **draw**: A logical value indicating whether graphics output should be produced.
- **vp**: A Grid viewport object (or NULL).

Details

Both functions create a text grob (a graphical object describing text), but only `grid.text` draws the text (and then only if `draw` is TRUE).

If the `label` argument is an expression, the output is formatted as a mathematical annotation, as for base graphics text.

Value

A text grob. `grid.text()` returns the value invisibly.

Author(s)

Paul Murrell

**grid.xaxis**  
**Draw an X-Axis**

**Description**

These functions create and draw an x-axis.

**Usage**

```r
grid.xaxis(at = NULL, label = TRUE, main = TRUE, edits = NULL, name = NULL, gp = gpar(), draw = TRUE, vp = NULL)
```

```r
xaxisGrob(at = NULL, label = TRUE, main = TRUE,
```
grid.xaxis

edits = NULL, name = NULL,
gp = gpar(), vp = NULL)

Arguments

at A numeric vector of x-value locations for the tick marks.

label A logical value indicating whether to draw the labels on the tick marks, or an expression or character vector which specify the labels to use. If not logical, must be the same length as the at argument.

main A logical value indicating whether to draw the axis at the bottom (TRUE) or at the top (FALSE) of the viewport.

edits A gEdit or gEditList containing edit operations to apply (to the children of the axis) when the axis is first created and during redrawing whenever at is NULL.

name A character identifier.

gp An object of class "gpar", typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.

draw A logical value indicating whether graphics output should be produced.

vp A Grid viewport object (or NULL).

Details

Both functions create an xaxis grob (a graphical object describing an xaxis), but only grid.xaxis draws the xaxis (and then only if draw is TRUE).

Value

An xaxis grob. grid.xaxis returns the value invisibly.

Children

If the at slot of an xaxis grob is not NULL then the xaxis will have the following children:

major representing the line at the base of the tick marks.

ticks representing the tick marks.

labels representing the tick labels.

If the at slot is NULL then there are no children and ticks are drawn based on the current viewport scale.

grid.xspline \hspace{1cm} \textit{Draw an Xspline}

\textbf{Description}

These functions create and draw an xspline, a curve drawn relative to control points.

\textbf{Usage}

\begin{verbatim}
grid.xspline(...) xsplineGrob(x = c(0, 0.5, 1, 0.5), y = c(0.5, 1, 0.5, 0), id = NULL, id.lengths = NULL, default.units = "npc", shape = 0, open = TRUE, arrow = NULL, repEnds = TRUE, name = NULL, gp = gpar(), vp = NULL)
\end{verbatim}

\textbf{Arguments}

- \textbf{x} \hspace{1cm} A numeric vector or unit object specifying x-locations of spline control points.
- \textbf{y} \hspace{1cm} A numeric vector or unit object specifying y-locations of spline control points.
- \textbf{id} \hspace{1cm} A numeric vector used to separate locations in \textit{x} and \textit{y} into multiple xsplines. All locations with the same \textit{id} belong to the same xspline.
- \textbf{id.lengths} \hspace{1cm} A numeric vector used to separate locations in \textit{x} and \textit{y} into multiple xsplines. Specifies consecutive blocks of locations which make up separate xsplines.
- \textbf{default.units} \hspace{1cm} A string indicating the default units to use if \textit{x} or \textit{y} are only given as numeric vectors.
- \textbf{shape} \hspace{1cm} A numeric vector of values between -1 and 1, which control the shape of the spline relative to the control points.
- \textbf{open} \hspace{1cm} A logical value indicating whether the spline is a line or a closed shape.
- \textbf{arrow} \hspace{1cm} A list describing arrow heads to place at either end of the xspline, as produced by the \texttt{arrow} function.
- \textbf{repEnds} \hspace{1cm} A logical value indicating whether the first and last control points should be replicated for drawing the curve (see Details below).
- \textbf{name} \hspace{1cm} A character identifier.
- \textbf{gp} \hspace{1cm} An object of class "gpar", typically the output from a call to the function \texttt{gpar}. This is basically a list of graphical parameter settings.
- \textbf{vp} \hspace{1cm} A Grid viewport object (or NULL).
- \ldots \hspace{1cm} Arguments to be passed to \texttt{xsplineGrob}.

\textbf{Details}

Both functions create an xspline grob (a graphical object describing an xspline), but only \texttt{grid.xspline} draws the xspline.

An xspline is a line drawn relative to control points. For each control point, the line may pass through (interpolate) the control point or it may only approach (approximate) the control point; the behaviour is determined by a shape parameter for each control point.
If the shape parameter is greater than zero, the spline approximates the control points (and is very similar to a cubic B-spline when the shape is 1). If the shape parameter is less than zero, the spline interpolates the control points (and is very similar to a Catmull-Rom spline when the shape is -1). If the shape parameter is 0, the spline forms a sharp corner at that control point.

For open xsplines, the start and end control points must have a shape of 0 (and non-zero values are silently converted to zero without warning).

For open xsplines, by default the start and end control points are actually replicated before the curve is drawn. A curve is drawn between (interpolating or approximating) the second and third of each set of four control points, so this default behaviour ensures that the resulting curve starts at the first control point you have specified and ends at the last control point. The default behaviour can be turned off via the repEnds argument, in which case the curve that is drawn starts (approximately) at the second control point and ends (approximately) at the first and second-to-last control point.

The repEnds argument is ignored for closed xsplines.

Missing values are not allowed for x and y (i.e., it is not valid for a control point to be missing).

For closed xsplines, a curve is automatically drawn between the final control point and the initial control point.

Value

A grob object.

xspline.

Examples

```r
x <- c(0.25, 0.25, 0.75, 0.75)
y <- c(0.25, 0.75, 0.75, 0.25)

xsplineTest <- function(s, i, j, open) {
  pushViewport(viewport(layout.pos.col=j, layout.pos.row=i))
  grid.points(x, y, default.units="npc", pch=16, size=unit(2, "mm"))
  grid.xspline(x, y, shape=s, open=open, gp=gpar(fill="grey"))
  grid.text(s, gp=gpar(col="grey"),
            x=unit(x, "npc") + unit(c(-1, -1, 1, 1), "mm"),
            y=unit(y, "npc") + unit(c(-1, 1, 1, -1), "mm"),
            hjust=c(1, 1, 0, 0),
            vjust=c(1, 0, 0, 1))
  popViewport()
}

pushViewport(viewport(width=.5, x=0, just="left",
                       layout=grid.layout(3, 3, respect=TRUE)))
pushViewport(viewport(layout.pos.row=1))
grid.text("Open Splines", y=1, just="bottom")
```
grid.yaxis

Draw a Y-Axis

Description

These functions create and draw a y-axis.

Usage

grid.yaxis(at = NULL, label = TRUE, main = TRUE, edits = NULL, name = NULL, gp = gpar(), draw = TRUE, vp = NULL)

yaxisGrob(at = NULL, label = TRUE, main = TRUE, edits = NULL, name = NULL, gp = gpar(), vp = NULL)

Arguments

at A numeric vector of y-value locations for the tick marks.
label A logical value indicating whether to draw the labels on the tick marks, or an expression or character vector which specify the labels to use. If not logical, must be the same length as the at argument.
main A logical value indicating whether to draw the axis at the left (TRUE) or at the right (FALSE) of the viewport.
edits
A gEdit or gEditList containing edit operations to apply (to the children of the axis) when the axis is first created and during redrawing whenever at is NULL.

name
A character identifier.

gp
An object of class "gpar", typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.

draw
A logical value indicating whether graphics output should be produced.

vp
A Grid viewport object (or NULL).

Details
Both functions create a yaxis grob (a graphical object describing a yaxis), but only grid.yaxis draws the yaxis (and then only if draw is TRUE).

Value
A yaxis grob. grid.yaxis returns the value invisibly.

Children
If the at slot of an xaxis grob is not NULL then the xaxis will have the following children:

- **major** representing the line at the base of the tick marks.
- **ticks** representing the tick marks.
- **labels** representing the tick labels.

If the at slot is NULL then there are no children and ticks are drawn based on the current viewport scale.

gridCoords

Create Sets of Coordinates for Grid Grobs

Description
These functions support the development of grobPoints methods for custom grobs.

Usage

```r
gridCoords(x, y)
gridGrobCoords(x, name, rule = NULL)
gridGTreeCoords(x, name)
emptyCoords
eemptyGrobCoords(name)
eemptyGTreeCoords(name)
isEmptyCoords(coords)
```
Arguments

- **x**
  - For `gridCoords` a numeric vector. For `gridGrobCoords` a list of "GridCoords" objects. For `gridGTreeCoords` a list of either "GridGrobCoords" or "GridGTreeCoords" objects.

- **y**
  - A numeric vector.

- **name**
  - A character value.

- **rule**
  - A fill rule, either "winding" or "evenodd", or NULL.

- **coords**
  - A set of grob coordinates (as generated by `grobCoords`).

Details

These functions help the developer of a `grobPoints` method to generate the coordinates from a custom grob.

The `emptyCoords` object can be used to return a "null" result (e.g., when asking for closed coordinates on an open line) and the `isEmptyCoords` function can be used to check for "null" results.

Value

- For `gridCoords` a "GridCoords" object. For `gridGrobCoords` a "GridGrobCoords" object. For `gridGTreeCoords` a "GridGTreeCoords" object.

Author(s)

Paul Murrell

---

**grobCoords**

*Calculate Points on the Perimeter of a Grob*

Description

These functions calculate points along the perimeter (or length) of a grob.

Usage

```r
grobCoords(x, closed, ...)
grobPoints(x, closed, ...)
isClosed(x, ...)
```

Arguments

- **x**
  - A grob object.

- **closed**
  - Whether we are asking for points along the perimeter of a closed object or points along the length of an open object. Some grobs (e.g., X-splines) can do both. This defaults to TRUE except for known cases that are not closed (e.g., lines and segments).

- **...**
  - Arguments to be used by methods.
Details

The difference between `grobCoords` and `grobPoints` is that `grobCoords` performs all pre- and post-drawing operations on the grob that would normally occur if the grob was being drawn, then calls `grobPoints`. So the former takes into account any `vp` and `gp` settings on the grob. This means that users should usually only want to call `grobCoords`; only (expert) developers may have a need to call `grobPoints`.

Custom grobs can write their own methods for `grobPoints` (see `gridCoords`).

The `isClosed` function returns `TRUE` or `FALSE` to indicate whether a grob is a closed shape. The default response is `TRUE`, unless a method has been defined otherwise (e.g., for lines and line segments).

Value

Either a "GridGrobCoords" object (a list of lists with components `x` and `y`) or a "GridGTreeCoords" object (a list of "GridGrobCoords" and/or "GridGTreeCoords" objects).

All locations are in inches relative to the current `grid` viewport.

Author(s)

Paul Murrell
grobWidth  
Create a Unit Describing the Width of a Grob

Description
These functions create a unit object describing the width or height of a grob. They are generic.

Usage
  grobWidth(x)  
grobHeight(x)  
grobAscent(x)  
grobDescent(x)

Arguments
  x  A grob object.

Value
A unit object.

Author(s)
Paul Murrell

See Also
  unit and stringWidth

---

grobX  
Create a Unit Describing a Grob Boundary Location

Description
These functions create a unit object describing a location somewhere on the boundary of a grob. They are generic.

Usage
  grobX(x, theta)  
grobY(x, theta)

Arguments
  x  A grob, or gList, or gTree, or gPath.
  theta  An angle indicating where the location is on the grob boundary. Can be one of "east", "north", "west", or "south", which correspond to angles 0, 90, 180, and 270, respectively.
Details

The angle is anti-clockwise with zero corresponding to a line with an origin centred between the extreme points of the shape, and pointing at 3 o’clock.

If the grob describes a single shape, the boundary value should correspond to the exact edge of the shape.

If the grob describes multiple shapes, the boundary value will either correspond to the edge of a bounding box around all of the shapes described by the grob (for multiple rectangles, circles, xsplines, or text), or to a convex hull around all vertices of all shapes described by the grob (for multiple polygons, points, lines, polylines, and segments).

Points grobs are currently a special case because the convex hull is based on the data symbol locations and does not take into account the extent of the data symbols themselves.

The extents of any arrow heads are currently not taken into account.

Value

A unit object.

unit and grobWidth

Description

Constructing a legend grob (in progress)

Usage

legendGrob(labels, nrow, ncol, byrow = FALSE,
  do.lines = has.lty || has.lwd, lines.first = TRUE,
  hgap = unit(1, "lines"), vgap = unit(1, "lines"),
  default.units = "lines", pch, gp = gpar(), vp = NULL)

grid.legend(..., draw=TRUE)

Arguments

labels legend labels (expressions)
nrow, ncol integer; the number of rows or columns, respectively of the legend “layout”. nrow is optional and typically computed from the number of labels and ncol.
byrow logical indicating whether rows of the legend are filled first.
do.lines logical indicating whether legend lines are drawn.
lines.first  logical indicating whether legend lines are drawn first and hence in a plain “below” legend symbols.

hgap  horizontal space between the legend entries

vgap  vertical space between the legend entries

default.units  default units, see unit.

pch  legend symbol, numeric or character, passed to pointsGrob(); see also points for interpretation of the numeric codes.

gp  an R object of class “gpar”, typically the output from a call to the function gpar, is basically a list of graphical parameter settings.

vp  a Grid viewport object (or NULL).

... for grid.legend(): all the arguments above are passed to legendGrob().

draw  logical indicating whether graphics output should be produced.

Value

Both functions create a legend grob (a graphical object describing a plot legend), but only grid.legend draws it (only if draw is TRUE).

See Also

Grid, viewport; pointsGrob, linesGrob.

ggrid.plot.and.legend contains a simple example.

Examples

## Data:
n <- 10
x <- stats::runif(n) ; y1 <- stats::runif(n) ; y2 <- stats::runif(n)
## Construct the grobs:
plot <- gTree(children=gList(rectGrob(),
          pointsGrob(x, y1, pch=21, gp=gpar(col=2, fill="gray")),
          pointsGrob(x, y2, pch=22, gp=gpar(col=3, fill="gray")),
          xaxisGrob(),
          yaxisGrob()))
legd <- legendGrob(c("Girls", "Boys", "Other"), pch=21:23,
          gp=gpar(col = 2:4, fill = "gray"))
        gg <- packGrob(packGrob(frameGrob(), plot),
                  legd, height=unit(1,"null"), side="right")

## Now draw it on a new device page:
grid.newpage()
pushViewport(viewport(width=0.8, height=0.8))
grid.draw(gg)
**Description**

These generic hook functions are called whenever a grid grob is drawn. They provide an opportunity for customising the drawing context and drawing content of a new class derived from grob (or gTree).

**Usage**

```r
makeContext(x)
makeContent(x)
```

**Arguments**

- `x`  
  A grid grob.

**Details**

These functions are called by the `grid.draw` methods for grobs and gTrees.

`makeContext` is called first during the drawing of a grob. This function should be used to modify the `vp` slot of `x` (and/or the children `vp` slot if `x` is a gTree). The function must return the modified `x`. Note that the default behaviour for grobs is to push any viewports in the `vp` slot, and for gTrees is to also push up any viewports in the `childrenvp` slot, so this function is used to customise the drawing context for a grob or gTree.

`makeContent` is called next and is where any additional calculations should occur and graphical content should be generated (see, for example, `grid:::makeContent.xaxis`). This function should be used to modify the children of a gTree. The function must return the modified `x`. Note that the default behaviour for gTrees is to draw all grobs in the `children` slot, so this function is used to customise the drawing content for a gTree. It is also possible to customise the drawing content for a simple grob, but more care needs to be taken; for example, the function should return a standard grid primitive with a `drawDetails()` method in this case.

Note that these functions should be *cumulative* in their effects, so that the `x` returned by `makeContent()` *includes* any changes made by `makeContext()`.

Note that `makeContext` is also called in the calculation of "grobwidth" and "grobheight" units.

**Value**

Both functions are expected to return a grob or gTree (a modified version of `x`).

**Author(s)**

Paul Murrell

patterns

Define Gradient and Pattern Fills

Description

Functions to define gradient fills and pattern fills.

Usage

linearGradient(colours = c("black", "white"),
   stops = seq(0, 1, length.out = length(colours)),
   x1 = unit(0, "npc"), y1 = unit(0, "npc"),
   x2 = unit(1, "npc"), y2 = unit(1, "npc"),
   default.units = "npc",
   extend = c("pad", "repeat", "reflect", "none"),
   group = TRUE)

radialGradient(colours = c("black", "white"),
   stops = seq(0, 1, length.out = length(colours)),
   cx1 = unit(.5, "npc"), cy1 = unit(.5, "npc"),
   r1 = unit(0, "npc"),
   cx2 = unit(.5, "npc"), cy2 = unit(.5, "npc"),
   r2 = unit(.5, "npc"),
   default.units = "npc",
   extend = c("pad", "repeat", "reflect", "none"),
   group = TRUE)

pattern(grob,
   x = 0.5, y = 0.5, width = 1, height = 1,
   default.units = "npc",
   just="centre", hjust=NULL, vjust=NULL,
   extend = c("pad", "repeat", "reflect", "none"),
   gp = gpar(fill="transparent"),
   group = TRUE)

Arguments

colours Two or more colours for the gradient to transition between.

stops Locations of the gradient colours between the start and end points of the gradient
(as a proportion of the distance from the start point to the end point).

x1, y1, x2, y2 The start and end points for a linear gradient.

default.units The coordinate system to use if any location or dimension is specified as just a
numeric value.

extend What happens outside the start and end of the gradient (see Details).

cx1, cy1, r1, cx2, cy2, r2 The centre and radius of the start and end circles for a radial gradient.

grob A grob (or a gTree) that will be drawn as the tile in a pattern fill.
**patterns**

x, y, width, height

The size of the tile for a pattern fill.

just, hjust, vjust

The justification of the tile relative to its location.

gp

Default graphical parameter settings for the tile.

group

A logical indicating whether the gradient or pattern is relative to the bounding box of the grob or whether it is relative to individual shapes within the grob.

**Details**

Use these functions to define a gradient fill or pattern fill and then use the resulting object as the value for fill in a call to the gpar() function.

The possible values of extend, and their meanings, are:

- [pad:] propagate the value of the gradient at its boundary.
- [none:] produce no fill beyond the limits of the gradient.
- [repeat:] repeat the fill.
- [reflect:] repeat the fill in reverse.

To create a tiling pattern, provide a simple grob (like a circle), specify the location and size of the pattern to include the simple grob, and specify `extend="repeat"`.

On viewports, gradients and patterns are relative to the entire viewport, unless `group = FALSE`, in which case they are relative to individual grobs as they are drawn. On gTrees, gradients and patterns are relative to a bounding box around all of the children of the gTree, unless `group = FALSE`, in which case they are relative to individual children as they are drawn. On grobs, gradients and patterns are relative to a bounding box around all of the shapes that are drawn by the grob, unless `group = FALSE`, in which case they are relative to individual shapes.

**Value**

A linear gradient or radial gradient or pattern object.

**Warning**

Gradient fills and pattern fills are not supported on all graphics devices. Where they are not supported, closed shapes will be rendered with a transparent fill. Where they are supported, not all values of `extend` are supported.

On Cairo devices, use of clipping in the pattern definition should be avoided because it is very likely to result in distortion of the pattern tile.

`gpar`
plotViewport  

Create a Viewport with a Standard Plot Layout

Description

This is a convenience function for producing a viewport with the common S-style plot layout – i.e., a central plot region surrounded by margins given in terms of a number of lines of text.

Usage

```r
plotViewport(margins=c(5.1, 4.1, 4.1, 2.1), ...)```

Arguments

- `margins`  
  A numeric vector interpreted in the same way as `par(mar)` in base graphics.
- `...`  
  All other arguments will be passed to a call to the `viewport()` function.

Value

A grid viewport object.

Author(s)

Paul Murrell

See Also

`viewport` and `dataViewport`.

---

Querying the Viewport Tree

Get the Current Grid Viewport (Tree)

Description

- `current.viewport()` returns the viewport that Grid is going to draw into.
- `current.parent` returns the parent of the current viewport.
- `current.vpTree` returns the entire Grid viewport tree.
- `current.vpPath` returns the viewport path to the current viewport.
- `current.transform` returns the transformation matrix for the current viewport.
- `current.rotation` returns the (total) rotation for the current viewport.

Usage

```r
current.viewport()
current.parent(n=1)
current.vpTree(all=TRUE)
current.vpPath()
current.transform()
```
Querying the Viewport Tree

Arguments

n        The number of generations to go up.
all      A logical value indicating whether the entire viewport tree should be returned.

Details

It is possible to get the grandparent of the current viewport (or higher) using the n argument to current.parent().

The parent of the ROOT viewport is NULL. It is an error to request the grandparent of the ROOT viewport.

If all is FALSE then current.vpTree only returns the subtree below the current viewport.

Value

A Grid viewport object from current.viewport or current.vpTree.

current.transform returns a 4x4 transformation matrix.

The viewport path returned by current.vpPath is NULL if the current viewport is the ROOT viewport.

pushViewport(viewport(x=0.1, width=0.3, height=0.6, just="left", name="B"))
upViewport(1)
pushViewport(viewport(x=0.5, width=0.4, height=0.8, just="left", name="C"))
pushViewport(viewport(width=0.8, height=0.8, name="D"))
current.vpPath()
upViewport(1)
current.vpPath()
current.vpTree()
current.viewport()
current.vpTree(all=FALSE)
popViewport(0)
resolveRasterSize  
Utility function to resolve the size of a raster grob

Description

Determine the width and height of a raster grob when one or both are not given explicitly.

The result depends on both the aspect ratio of the raster image and the aspect ratio of the physical
drawing context, so the result is only valid for the drawing context in which this function is called.

Usage

resolveRasterSize(x)

Arguments

x  
A raster grob

Details

A raster grob can be specified with width and/or height of NULL, which means that the size at which
the raster is drawn will be decided at drawing time.

Value

A raster grob, with explicit width and height.

See Also

grid.raster

Examples

# Square raster
rg <- rasterGrob(matrix(0))
# Fill the complete page (if page is square)
grid.newpage()
resolveRasterSize(rg)$height
grid.draw(rg)
# Forced to fit tall thin region
grid.newpage()
pushViewport(viewport(width=.1))
resolveRasterSize(rg)$height
grid.draw(rg)
roundrect

Draw a rectangle with rounded corners

Description

Draw a single rectangle with rounded corners.

Usage

```r
roundrectGrob(x=0.5, y=0.5, width=1, height=1,
    default.units="npc",
    r=unit(0.1, "snpc"),
    just="centre",
    name=NULL, gp=NULL, vp=NULL)
grid.roundrect(...)```

Arguments

- `x, y, width, height` The location and size of the rectangle.
- `default.units` A string indicating the default units to use if `x, y, width, or height` are only given as numeric vectors.
- `r` The radius of the rounded corners.
- `just` The justification of the rectangle relative to its location.
- `name` A name to identify the grob.
- `gp` Graphical parameters to apply to the grob.
- `vp` A viewport object or `NULL`.
- `...` Arguments to be passed to `roundrectGrob()`.

Details

At present, this function can only be used to draw one rounded rectangle.

Examples

```r
grid.roundrect(width=.5, height=.5, name="rr")
theta <- seq(0, 360, length.out=50)
for (i in 1:50)
    grid.circle(x=grobX("rr", theta[i]),
                y=grobY("rr", theta[i]),
                r=unit(1, "mm"),
                gp=gpar(fill="black"))```
showGrob

Label grid grobs

Description

Produces a graphical display of (by default) the current grid scene, with labels showing the names of each grob in the scene. It is also possible to label only specific grobs in the scene.

Usage

showGrob(x = NULL,
          gPath = NULL, strict = FALSE, grep = FALSE,
          recurse = TRUE, depth = NULL,
          labelfun = grobLabel, ...)

Arguments

x
  If NULL, the current grid scene is labelled. Otherwise, a grob (or gTree) to draw and then label.

gPath
  A path identifying a subset of the current scene or grob to be labelled.

strict
  Logical indicating whether the gPath is strict.

grep
  Logical indicating whether the gPath is a regular expression.

recurse
  Should the children of gTrees also be labelled?

depth
  Only display grobs at the specified depth (may be a vector of depths).

labelfun
  Function used to generate a label from each grob.

...
  Arguments passed to labelfun to control fine details of the generated label.

Details

None of the labelling is recorded on the grid display list so the original scene can be reproduced by calling grid.refresh.

grob and gTree

Examples

grid.newpage()
gt <- gTree(childrenenvp=vpStack(
               viewport(x=0, width=.5, just="left", name="vp"),
               viewport(y=.5, height=.5, just="bottom", name="vp2")),
               children=gList(rectGrob(vp="vp::vp2", name="child")),
               name="parent")
grid.draw(gt)
showGrob()
showGrob(gPath="child")
showGrob(recurse=FALSE)
showGrob(depth=1)
showGrob(depth=2)
showViewport

Description

Produces a graphical display of (by default) the current grid viewport tree. It is also possible to display only specific viewports. Each viewport is drawn as a rectangle and the leaf viewports are labelled with the viewport name.

Usage

showViewport(vp = NULL, recurse = TRUE, depth = NULL, newpage = FALSE, leaves = FALSE, col = rgb(0, 0, 1, 0.2), fill = rgb(0, 0, 1, 0.1), label = TRUE, nrow = 3, ncol = nrow)
Arguments

- **vp**: If NULL, the current viewport tree is displayed. Otherwise, a viewport (or vpList, or vpStack, or vpTree) or a vpPath that specifies which viewport to display.
- **recurse**: Should the children of the specified viewport also be displayed?
- **depth**: Only display viewports at the specified depth (may be a vector of depths).
- **newpage**: Start a new page for the display? Otherwise, the viewports are displayed on top of the current plot.
- **leaves**: Produce a matrix of smaller displays, with each leaf viewport in its own display.
- **col**: The colour used to draw the border of the rectangle for each viewport and to draw the label for each viewport. If a vector, then the first colour is used for the top-level viewport, the second colour is used for its children, the third colour for their children, and so on.
- **fill**: The colour used to fill each viewport. May be a vector as per **col**.
- **label**: Should the viewports be labelled (with the viewport name)?
- **nrow, ncol**: The number of rows and columns when **leaves** is TRUE. Otherwise ignored.

See Also

- `viewport` and `grid.show.viewport`

Examples

```r
showViewport(viewport(width=.5, height=.5, name="vp"))
grid.newpage()
pushViewport(viewport(width=.5, height=.5, name="vp"))
upViewport()
showViewport(vpPath("vp"))

showViewport(vpStack(viewport(width=.5, height=.5, name="vp1"),
                      viewport(width=.5, height=.5, name="vp2")),
             newpage=TRUE)

showViewport(vpStack(viewport(width=.5, height=.5, name="vp1"),
                      viewport(width=.5, height=.5, name="vp2"),
                      fill=rgb(1:0, 0:1, 0, .1),
                      newpage=TRUE)
```

---

**stringWidth**

Create a Unit Describing the Width and Height of a String or Math Expression

Description

These functions create a unit object describing the width or height of a string.

Usage

- `stringWidth(string)`
- `stringHeight(string)`
- `stringAscent(string)`
- `stringDescent(string)`
**Arguments**

- `string`: A character vector or a language object (as used for `plotmath` calls).

**Value**

A `unit` object.

**Author(s)**

Paul Murrell

**See Also**

- `unit` and `grobWidth`
- `strwidth` in the `graphics` package for more details of the typographic concepts behind the computations.

---

**Description**

This function creates a unit object — a vector of unit values. A unit value is typically just a single numeric value with an associated unit.

**Usage**

```r
unit(x, units, data=NULL)
is.unit(x)
```

**Arguments**

- `x`: A numeric vector.
  For `is.unit`, any R object.
- `units`: A character vector specifying the units for the corresponding numeric values.
- `data`: This argument is used to supply extra information for special `unit` types.

**Details**

Unit objects allow the user to specify locations and dimensions in a large number of different coordinate systems. All drawing occurs relative to a viewport and the `units` specifies what coordinate system to use within that viewport.

Possible `units` (coordinate systems) are:

- "npc": Normalised Parent Coordinates (the default). The origin of the viewport is (0, 0) and the viewport has a width and height of 1 unit. For example, (0.5, 0.5) is the centre of the viewport.
- "cm": Centimetres.
- "inches": Inches. 1 in = 2.54 cm.
- "mm": Millimetres. 10 mm = 1 cm.
"points" Points. 72.27 pt = 1 in.
"picas" Picas. 1 pc = 12 pt.
"bigpts" Big Points. 72 bp = 1 in.
"dida" Dida. 1157 dd = 1238 pt.
"cicero" Cicero. 1 cc = 12 dd.
"scaledpts" Scaled Points. 65536 sp = 1 pt.

"lines" Lines of text. Locations and dimensions are in terms of multiples of the default text size of the viewport (as specified by the viewport's fontsize and lineheight).
"char" Multiples of nominal font height of the viewport (as specified by the viewport's fontsize).
"native" Locations and dimensions are relative to the viewport's xscale and yscale.
"snpc" Square Normalised Parent Coordinates. Same as Normalised Parent Coordinates, except gives the same answer for horizontal and vertical locations/dimensions. It uses the lesser of npc-width and npc-height. This is useful for making things which are a proportion of the viewport, but have to be square (or have a fixed aspect ratio).
"strwidth" Multiples of the width of the string specified in the data argument. The font size is determined by the pointsize of the viewport.
"strheight" Multiples of the height of the string specified in the data argument. The font size is determined by the pointsize of the viewport.
"grobwidth" Multiples of the width of the grob specified in the data argument.
"grobheight" Multiples of the height of the grob specified in the data argument.

A number of variations are also allowed for the most common units. For example, it is possible to use "in" or "inch" instead of "inches" and "centimetre" or "centimeter" instead of "cm".
A special units value of "null" is also allowed, but only makes sense when used in specifying widths of columns or heights of rows in grid layouts (see grid.layout).

The data argument must be a list when the unit.length() is greater than 1. For example,

```r
unit(rep(1, 3), c("npc", "strwidth", "inches"),
data = list(NULL, "my string", NULL))
```

It is possible to subset unit objects in the normal way and to perform subassignment (see the examples), but a special function unit.c is provided for combining unit objects.

Certain arithmetic and summary operations are defined for unit objects. In particular, it is possible to add and subtract unit objects (e.g., unit(1, "npc") - unit(1, "inches")), and to specify the minimum or maximum of a list of unit objects (e.g., min(unit(0.5, "npc"), unit(1, "inches"))).

There is a format method for units, which should respond to the arguments for the default format method, e.g., digits to control the number of significant digits printed for numeric values.

The Is.unit() function is a convenience for checking whether x inherits from the "unit" class.

Value

An object of class "unit".

WARNING

There is a special function unit.c for concatenating several unit objects.
The c function will not give the right answer.

There used to be "mylines", "mychar", "mystrwidth", "mystrheight" units. These will still be accepted, but work exactly the same as "lines", "char", "strwidth", "strheight".
unit.c

unit.c

Examples

unit(1, "npc")
unit(1:3/4, "npc")
unit(1:3/4, "npc") + unit(1, "inches")
min(unit(0.5, "npc"), unit(1, "inches"))
unit.c(unit(0.5, "npc"), unit(2, "inches") + unit(1:3/4, "npc"),
      unit(1, "strwidth", "hi there"))
x <- unit(1:5, "npc")
x[2:4]
x[2:4] <- unit(1, "mm")
x

unit.c Combine Unit Objects

Description

This function produces a new unit object by combining the unit objects specified as arguments.

Usage

unit.c(..., check = TRUE)

Arguments

... An arbitrary number of unit objects.

check Should input be checked? If you are certain all arguments are unit objects this can be set to FALSE

Value

An object of class unit.

Author(s)

Paul Murrell

See Also

unit.
unit.length  \hspace{1cm} \textit{Length of a Unit Object}

\textbf{Description}

The length of a unit object is defined as the number of unit values in the unit object.
This function has been deprecated in favour of a unit method for the generic \texttt{length} function.

\textbf{Usage}

\begin{verbatim}
unit.length(unit)
\end{verbatim}

\textbf{Arguments}

\begin{verbatim}
unit  \hspace{0.5cm} \text{A unit object.}
\end{verbatim}

\textbf{Value}

An integer value.

\textbf{Author(s)}

Paul Murrell

\textbf{See Also}

unit

\textbf{Examples}

\begin{verbatim}
length(unit(1:3, "npc"))
length(unit(1:3, "npc") + unit(1, "inches"))
length(max(unit(1:3, "npc") + unit(1, "inches")))
length(max(unit(1:3, "npc") + unit(1, "strwidth", "a")*4))
length(unit(1:3, "npc") + unit(1, "strwidth", "a")*4)
\end{verbatim}

unit.pmin  \hspace{1cm} \textit{Parallel Unit Minima and Maxima}

\textbf{Description}

Returns a unit object whose i-th value is the minimum (or maximum) of the i-th values of the arguments.

\textbf{Usage}

\begin{verbatim}
unit.pmin(...)  
unit.pmax(...)  
unit.psum(...)  
\end{verbatim}
unit.rep

Arguments

... One or more unit objects.

Details

The length of the result is the maximum of the lengths of the arguments; shorter arguments are recycled in the usual manner.

Value

A unit object.

Author(s)

Paul Murrell

Examples

max(unit(1:3, "cm"), unit(0.5, "npc"))
unit.pmax(unit(1:3, "cm"), unit(0.5, "npc"))

unit.rep  Replicate Elements of Unit Objects

Description

Replicates the units according to the values given in times and length.out.

This function has been deprecated in favour of a unit method for the generic rep function.

Usage

unit.rep(x, ...)

Arguments

x An object of class "unit".
...

arguments to be passed to rep such as times and length.out.

Value

An object of class "unit".

Author(s)

Paul Murrell

See Also

rep
Examples

```r
rep(unit(1:3, "npc"), 3)
rep(unit(1:3, "npc"), 1:3)
rep(unit(1:3, "npc") + unit(1, "inches"), 3)
rep(max(unit(1:3, "npc") + unit(1, "inches")), 3)
rep(max(unit(1:3, "npc") + unit(1, "strwidth", "a")*4), 3)
rep(unit(1:3, "npc") + unit(1, "strwidth", "a")*4, 3)
```

Description

This function returns the units of a unit object.

Usage

```r
unitType(x, recurse = FALSE)
```

Arguments

- `x`  
  A unit object.
- `recurse`  
  Whether to recurse into complex units.

Value

For simple units, this will be just a vector of coordinate systems, like "inches" or "npc". More complex units that involve an operation on units return an operator, like "sum", "min", or "max".

When `recurse = TRUE`, the result is always a list and more complex units generate sublists (see the Examples below).

- `unit`

Examples

```r
u <- unit(1:5, c("cm", "mm", "in", "pt", "null"))
unitType(u)
unitType(unit(1, "npc"))
unitType(unit(1:3/4, "npc"))
unitType(unit(1:3/4, "npc") + unit(1, "inches"))
unitType(min(unit(0.5, "npc"), unit(1, "inches")))
unitType(unit.c(unit(0.5, "npc"), unit(2, "inches") + unit(1:3/4, "npc"),
               unit(1, "strwidth", "hi there")))
unitType(min(unit(1, "in"), unit(1, "npc") + unit(1, "mm")))
```
valid.just

## Description

Utility functions for determining whether a justification specification is valid and for resolving a single justification value from a combination of character and numeric values.

## Usage

```r
valid.just(just)
resolveHJust(just, hjust)
resolveVJust(just, vjust)
```

## Arguments

- `just` A justification either as a character value, e.g., "left", or as a numeric value, e.g., 0.
- `hjust` A numeric horizontal justification
- `vjust` A numeric vertical justification

## Details

These functions may be useful within a `validDetails` method when writing a new grob class.

## Value

A numeric representation of the justification (e.g., "left" becomes 0, "right" becomes 1, etc, ...). An error is given if the justification is not valid.

## Author(s)

Paul Murrell
validDetails

Customising grid grob Validation

Description

This generic hook function is called whenever a grid grob is created or edited via grob, gTree, grid.edit or editGrob. This provides an opportunity for customising the validation of a new class derived from grob (or gTree).

Usage

validDetails(x)

Arguments

x A grid grob.

Details

This function is called by grob, gTree, grid.edit and editGrob. A method should be written for classes derived from grob or gTree to validate the values of slots specific to the new class. (e.g., see grid:::validDetails.axis).

Note that the standard slots for grobs and gTrees are automatically validated (e.g., vp, gp slots for grobs and, in addition, children, and childrenvp slots for gTrees) so only slots specific to a new class need to be addressed.

Value

The function MUST return the validated grob.

Author(s)

Paul Murrell

See Also

grid.edit

viewportTransform

Define a Group Transformation

Description

These functions define the transformation that will be applied when a grid.define()d group is grid.use()d.
Usage

```
viewportTransform(group, shear=groupShear(), flip=groupFlip(), device=TRUE)
viewportTranslate(group, device=TRUE)
viewportScale(group, device=TRUE)
viewportRotate(group, device=TRUE)
defnTranslate(group, inverse=FALSE, device=TRUE)
defnScale(group, inverse=FALSE)
defnRotate(group, inverse=FALSE, device=TRUE)
useTranslate(inverse=FALSE, device=TRUE)
useScale(inverse=FALSE, device=TRUE)
useRotate(inverse=FALSE, device=TRUE)
groupTranslate(dx=0, dy=0)
groupRotate(r=0, device=TRUE)
groupScale(sx=1, sy=1)
groupShear(sx=0, sy=0)
groupFlip(flipX=FALSE, flipY=FALSE)
```

Arguments

- **group**: The group that is being transformed.
- **inverse**: A logical indicating whether we want the forward or backward transformation.
- **shear**: An affine transformation matrix that describes a shear transformation.
- **flip**: An affine transformation matrix that describes a scaling inversion.
- **dx, dy**: The translation to apply.
- **r**: The rotation to apply.
- **sx, sy**: The scaling (or shear) to apply.
- **flipX, flipY**: Whether to negate the x-scaling or y-scaling (logical).
- **device**: A logical indicating whether transformation should be relative to the device or relative to the current viewport.

Details

The `viewport*()` functions are not called directly. They are passed as the `transform` argument to `grid.use`.

The `defn*()` and `use*()` functions are also not called directly, but can be useful to create custom transformation functions. For example, see the source code for `viewportTransform`.

The `group*()` functions generate basic affine transformation matrices and may also be useful to create custom transformation functions. For example, the `groupShear()` function can be used to specify a shear transform to `viewportTransform()`.

It is also possible to define any function that returns a 3x3 matrix (as long as the last column contains 0, 0, and 1) and use it as the `transform` argument to `grid.use`, but the results will probably be device-dependent, and may be very difficult to predict. The function will be called with two arguments: group and device.

Value

An affine transformation matrix.

Grid

Examples

## NOTE: on devices without support for groups nothing will be drawn
grid.newpage()
## Define and use group in same viewport
pushViewport(viewport(width=.2, height=.2))
grid.define(circleGrob(gp=gpar(lwd=5)), name="circle")
grid.use("circle")
popViewport()
## Use group in viewport that is translated and scaled
pushViewport(viewport(x=.2, y=.2, width=.1, height=.1))
grid.use("circle")
popViewport()
## Use group in viewport that is translated and scaled
## BUT only make use of the translation
pushViewport(viewport(x=.2, y=.8, width=.1, height=.1))
grid.use("circle", transform=viewportTranslate)
popViewport()
## Use group in viewport that is translated and scaled
## unevenly (distorted)
pushViewport(viewport(x=.8, y=.7, width=.2, height=.4))
grid.use("circle")
popViewport()

## vpPath

### Concatenate Viewport Names

vpPath

Description

This function can be used to generate a viewport path for use in downViewport or seekViewport.
A viewport path is a list of nested viewport names.

Usage

vpPath(...)

Arguments

... Character values which are viewport names.
Viewport names must only be unique amongst viewports which share the same parent in the viewport tree.

This function can be used to generate a specification for a viewport that includes the viewport’s parent’s name (and the name of its parent and so on).

For interactive use, it is possible to directly specify a path, but it is strongly recommended that this function is used otherwise in case the path separator is changed in future versions of grid.

Value

A vpPath object.

See Also

viewport, pushViewport, popViewport, downViewport, seekViewport, upViewport

Examples

vpPath("vp1", "vp2")

widthDetails

Width and Height of a grid grob

These generic functions are used to determine the size of grid grobs.

Usage

widthDetails(x)
heightDetails(x)
ascentDetails(x)
descentDetails(x)

Arguments

x A grid grob.

Details

These functions are called in the calculation of "grobwidth" and "grobheight" units. Methods should be written for classes derived from grob or gTree where the size of the grob can be determined (see, for example grid::widthDetails.frame).

The ascent of a grob is the height of the grob by default and the descent of a grob is zero by default, except for text grobs where the label is a single character value or expression.

Value

A unit object.
Working with Viewports

Maintaining and Navigating the Grid Viewport Tree

Description

Grid maintains a tree of viewports — nested drawing contexts. These functions provide ways to add or remove viewports and to navigate amongst viewports in the tree.

Usage

pushViewport(..., recording=TRUE)
popViewport(n = 1, recording=TRUE)
downViewport(name, strict=FALSE, recording=TRUE)
seekViewport(name, recording=TRUE)
upViewport(n = 1, recording=TRUE)

Arguments

... One or more objects of class "viewport".
n An integer value indicating how many viewports to pop or navigate up. The special value 0 indicates to pop or navigate viewports right up to the root viewport.
name A character value to identify a viewport in the tree.
strict A boolean indicating whether the vpPath must be matched exactly.
recording A logical value to indicate whether the viewport operation should be recorded on the Grid display list.

Details

Objects created by the \texttt{viewport()} function are only descriptions of a drawing context. A viewport object must be pushed onto the viewport tree before it has any effect on drawing.

The viewport tree always has a single root viewport (created by the system) which corresponds to the entire device (and default graphical parameter settings). Viewports may be added to the tree using \texttt{pushViewport()} and removed from the tree using \texttt{popViewport()}.

There is only ever one current viewport, which is the current position within the viewport tree. All drawing and viewport operations are relative to the current viewport. When a viewport is pushed it becomes the current viewport. When a viewport is popped, the parent viewport becomes the current viewport. Use \texttt{upViewport} to navigate to the parent of the current viewport, without removing the current viewport from the viewport tree. Use \texttt{downViewport} to navigate to a viewport further down the viewport tree and \texttt{seekViewport} to navigate to a viewport anywhere else in the tree.

If a viewport is pushed and it has the same name as a viewport at the same level in the tree, then it replaces the existing viewport in the tree.
Value

downViewport returns the number of viewports it went down.
This can be useful for returning to your starting point by doing something like depth <-
downViewport() then upViewport(depth).

popViewport(0)

---

**xDetails**

*Boundary of a grid grob*

**Description**

These generic functions are used to determine a location on the boundary of a grid grob.

**Usage**

```
xDetails(x, theta)
yDetails(x, theta)
```

**Arguments**

- **x** A grid grob.
- **theta** A numeric angle, in degrees, measured anti-clockwise from the 3 o’clock or one of the following character strings: "north", "east", "west", "south".

**Details**

The location on the grob boundary is determined by taking a line from the centre of the grob at the angle theta and intersecting it with the convex hull of the grob (for the basic grob primitives, the centre is determined as half way between the minimum and maximum values in x and y directions). These functions are called in the calculation of "grobx" and "groby" units as produced by the grobx and groby functions. Methods should be written for classes derived from grob or gTree where the boundary of the grob can be determined.
Value

A unit object.

Author(s)

Paul Murrell

See Also

grobX, grobY.

xsplinePoints

Return the points that would be used to draw an xspline (or a Bezier curve)

Description

Rather than drawing an xspline (or Bezier curve), this function returns the points that would be used to draw the series of line segments for the xspline. This may be useful to post-process the xspline curve, for example, to clip the curve.

Usage

xsplinePoints(x)
bezirierPoints(x)

Arguments

x
An xspline grob, as produced by the xsplineGrob() function (or a bezierGrob, as produced by the bezierGrob() function).

Details

The points returned by this function will only be relevant for the drawing context in force when this function was called.

Value

Depends on how many xsplines would be drawn. If only one, then a list with two components, named x and y, both of which are unit objects (in inches). If several xsplines would be drawn then the result of this function is a list of lists.

popViewport()

grid.newpage()
bg <- bezierGrob(c(.2, .2, .8, .8), c(.2, .8, .8, .2))
grid.draw(bg)
trace <- bezierPoints(bg)
grid.circle(trace$x, trace$y, default.units="inches", r=unit(.5, "mm"))
Chapter 7

The methods package

Description

Formally defined methods and classes for R objects, plus other programming tools, as described in the references.

Details

This package provides the “S4” or “S version 4” approach to methods and classes in a functional language.

For basic use of the techniques, start with Introduction and follow the links there to the key functions for programming, notably setClass and setMethod.

Some specific topics:

Classes: Creating one, see setClass; examining definitions, see getClassDef and classRepresentation; inheritance and coercing, see is and as

Generic functions: Basic programming, see setGeneric; the class of objects, see genericFunction; other functions to examine or manipulate them, see GenericFunctions.

S3: Using classes, see setOldClass; methods, see Methods_for_S3.

Reference classes: See ReferenceClasses.

Class unions; virtual classes See setClassUnion.

These pages will have additional links to related topics.

For a complete list of functions and classes, use library(help=“methods”).

*.BasicFunsList*  
*List of Built-in and Special Functions*

**Description**

A named list providing instructions for turning built-in and special functions into generic functions. Functions in R that are defined as `.Primitive(<name>)` are not suitable for formal methods, because they lack the basic reflectance property. You can’t find the argument list for these functions by examining the function object itself.

Future versions of R may fix this by attaching a formal argument list to the corresponding function. While generally the names of arguments are not checked by the internal code implementing the function, the number of arguments frequently is.

In any case, some definition of a formal argument list is needed if users are to define methods for these functions. In particular, if methods are to be merged from multiple packages, the different sets of methods need to agree on the formal arguments.

In the absence of reflectance, this list provides the relevant information via a dummy function associated with each of the known specials for which methods are allowed.

At the same, the list flags those specials for which methods are meaningless (e.g., `for`) or just a very bad idea (e.g., `.Primitive`).

A generic function created via `setMethod`, for example, for one of these special functions will have the argument list from `.BasicFunsList`. If no entry exists, the argument list `(x, ...)` is assumed.

---

**as**  
*Force an Object to Belong to a Class*

**Description**

Coerce an object to a given class.

**Usage**

```r
as(object, Class, strict=TRUE, ext)

as(object, Class) <- value
```
as

Arguments

object any R object.
Class the name of the class to which object should be coerced.
strict logical flag. If TRUE, the returned object must be strictly from the target class (unless that class is a virtual class, in which case the object will be from the closest actual class, in particular the original object, if that class extends the virtual class directly).

If strict = FALSE, any simple extension of the target class will be returned, without further change. A simple extension is, roughly, one that just adds slots to an existing class.
value The value to use to modify object (see the discussion below). You should supply an object with class Class; some coercion is done, but you’re unwise to rely on it.
ext an optional object defining how Class is extended by the class of the object (as returned by possibleExtends). This argument is used internally; do not use it directly.

Description

as(object) returns the version of this object coerced to be the given Class. When used in the replacement form on the left of an assignment, the portion of the object corresponding to Class is replaced by value.

The operation of as() in either form depends on the definition of coerce methods. Methods are defined automatically when the two classes are related by inheritance; that is, when one of the classes is a subclass of the other.

Coerce methods are also predefined for basic classes (including all the types of vectors, functions and a few others).

Beyond these two sources of methods, further methods are defined by calls to the setAs function. See that documentation also for details of how coerce methods work. Use showMethods(coerce) for a list of all currently defined methods, as in the example below.

Basic Coercion Methods

Methods are pre-defined for coercing any object to one of the basic datatypes. For example, as(x, "numeric") uses the existing as.numeric function. These and all other existing methods can be listed as shown in the example.

References

Chambers, John M. (2016) Extending R, Chapman & Hall. (Chapters 9 and 10.)

See Also

If you think of using try(as(x, cl)), consider canCoerce(x, cl) instead.

Examples

## Show all the existing methods for as()
showMethods("coerce")
**Description**

Formal classes exist corresponding to the basic R object types, allowing these types to be used in method signatures, as slots in class definitions, and to be extended by new classes.

**Usage**

```r
### The following are all basic vector classes.
### They can appear as class names in method signatures,
### in calls to as(), is(), and new().
"character"
"complex"
"double"
"expression"
"integer"
"list"
"logical"
"numeric"
"single"
"raw"

### the class
"vector"
### is a virtual class, extended by all the above

### the class
"S4"
### is an object type for S4 objects that do not extend
### any of the basic vector classes. It is a virtual class.

### The following are additional basic classes
"NULL"  # NULL objects
"Function" # function objects, including primitives
"externalptr" # raw external pointers for use in C code

"ANY"  # virtual classes used by the methods package itself
"VIRTUAL"
"missing"

"namedList" # the alternative to "list" that preserves
  # the names attribute
```

**Objects from the Classes**

If a class is not virtual (see section in *Classes_Details*), objects can be created by calls of the form `new(Class, ...)`, where `Class` is the quoted class name, and the remaining arguments if any are objects to be interpreted as vectors of this class. Multiple arguments will be concatenated.
The class "expression" is slightly odd, in that the ... arguments will not be evaluated; therefore, don't enclose them in a call to quote().

Note that class "list" is a pure vector. Although lists with names go back to the earliest versions of S, they are an extension of the vector concept in that they have an attribute (which can now be a slot) and which is either NULL or a character vector of the same length as the vector. If you want to guarantee that list names are preserved, use class "namedList", rather than "list". Objects from this class must have a names attribute, corresponding to slot "names", of type "character". Internally, R treats names for lists specially, which makes it impractical to have the corresponding slot in class "namedList" be a union of character names and NULL.

Classes and Types

The basic classes include classes for the basic R types. Note that objects of these types will not usually be S4 objects (isS4 will return FALSE), although objects from classes that contain the basic class will be S4 objects, still with the same type. The type as returned by typeof will sometimes differ from the class, either just from a choice of terminology (type "symbol" and class "name", for example) or because there is not a one-to-one correspondence between class and type (most of the classes that inherit from class "language" have type "language", for example).

Extends

The vector classes extend "vector", directly.

Methods

coerce  Methods are defined to coerce arbitrary objects to the vector classes, by calling the corresponding basic function, for example, as(x, "numeric") calls as.numeric(x).

---

**callGeneric**

Call the Current Generic Function from a Method

**Description**

A call to callGeneric can only appear inside a method definition. It then results in a call to the current generic function. The value of that call is the value of callGeneric. While it can be called from any method, it is useful and typically used in methods for group generic functions.

**Usage**

callGeneric(...)  

**Arguments**

...  

Optionally, the arguments to the function in its next call. If no arguments are included in the call to callGeneric, the effect is to call the function with the current arguments. See the detailed description for what this really means.
callGeneric

Details

The name and package of the current generic function is stored in the environment of the method definition object. This name is looked up and the corresponding function called.

The statement that passing no arguments to `callGeneric` causes the generic function to be called with the current arguments is more precisely as follows. Arguments that were missing in the current call are still missing (remember that "missing" is a valid class in a method signature). For a formal argument, say \( x \), that appears in the original call, there is a corresponding argument in the generated call equivalent to \( x = x \). In effect, this means that the generic function sees the same actual arguments, but arguments are evaluated only once.

Using `callGeneric` with no arguments is prone to creating infinite recursion, unless one of the arguments in the signature has been modified in the current method so that a different method is selected.

Value

The value returned by the new call.

Examples

```r
## the method for group generic function Ops
## for signature( e1="structure", e2="vector")
function (e1, e2)
{
  value <- callGeneric(e1@.Data, e2)
  if (length(value) == length(e1)) {
    e1@.Data <- value
    e1
  }
  else value
}

## For more examples
## Not run:
showMethods("Ops", includeDefs = TRUE)

## End(Not run)
```
**callNextMethod**

**Call an Inherited Method**

**Description**

A call to `callNextMethod` can only appear inside a method definition. It then results in a call to the first inherited method after the current method, with the arguments to the current method passed down to the next method. The value of that method call is the value of `callNextMethod`.

**Usage**

```plaintext
callNextMethod(...)  
```

**Arguments**

```plaintext
...  
```

Optionally, the arguments to the function in its next call (but note that the dispatch is as in the detailed description below; the arguments have no effect on selecting the next method.)

If no arguments are included in the call to `callNextMethod`, the effect is to call the method with the current arguments. See the detailed description for what this really means.

Calling with no arguments is often the natural way to use `callNextMethod`; see the examples.

**Details**

The ‘next’ method (i.e., the first inherited method) is defined to be that method which would have been called if the current method did not exist. This is more-or-less literally what happens: The current method (to be precise, the method with signature given by the defined slot of the method from which `callNextMethod` is called) is deleted from a copy of the methods for the current generic, and `selectMethod` is called to find the next method (the result is cached in the method object where the call occurred, so the search typically happens only once per session per combination of argument classes).

The next method is defined from the signature of the current method, not from the actual classes of the arguments. In particular, modifying any of the arguments has no effect on the selection. As a result, the selected next method can be called with invalid arguments if the calling function assigns objects of a different class before the `callNextMethod()` call. Be careful of any assignments to such arguments.

It is possible for the selection of the next method to be ambiguous, even though the original set of methods was consistent. See the section “Ambiguous Selection”.

The statement that the method is called with the current arguments is more precisely as follows. Arguments that were missing in the current call are still missing (remember that “missing” is a valid class in a method signature). For a formal argument, say `x`, that appears in the original call, there is a corresponding argument in the next method call equivalent to `x = x`. In effect, this means that the next method sees the same actual arguments, but arguments are evaluated only once.

**Value**

The value returned by the selected method.
Ambiguous Selection

There are two fairly common situations in which the choice of a next method is ambiguous, even when the original set of methods uniquely defines all method selection unambiguously. In these situations, `callNextMethod()` should be replaced, either by a call to a specific function or by recalling the generic with different arguments.

The most likely situation arises with methods for binary operators, typically through one of the group generic functions. See the example for class "rnum" below. Examples of this sort usually require three methods: two for the case that the first or the second argument comes from the class, and a third for the case that both arguments come from the class. If that last method uses `callNextMethod`, the other two methods are equally valid. The ambiguity is exactly the same that required defining the two-argument method in the first place.

In fact, the two possibilities are equally valid conceptually as well as formally. As in the example below, the logic of the application usually requires selecting a computation explicitly or else calling the generic function with modified arguments to select an appropriate method.

The other likely source of ambiguity arises from a class that inherits directly from more than one other class (a “mixin” in standard terminology). If the generic has methods corresponding to both superclasses, a method for the current class is again needed to resolve ambiguity. Using `callNextMethod` will again reimpose the ambiguity. Again, some explicit choice has to be made in the calling method instead.

These ambiguities are not the result of bad design, but they do require workarounds. Other ambiguities usually reflect inconsistencies in the tree of inheritances, such as a class appearing in more than one place among the superclasses. Such cases should be rare, but with the independent definition of classes in multiple packages, they can’t be ruled out.

See Also

`callGeneric` to call the generic function with the current dispatch rules (typically for a group generic function); `Methods_Details` for the general behavior of method dispatch.

Examples

```r
## callNextMethod() used for the Math, Math2 group generic functions
## A class to automatically round numeric results to "d" digits
rnum <- setClass("rnum", slots = c(d = "integer"), contains = "numeric")

## Math functions operate on the rounded numbers, return a plain
## vector. The next method will always be the default, usually a primitive.
setMethod("Math", "rnum",
  function(x)
    callNextMethod(round(as.numeric(x), x@d)))
setMethod("Math2", "rnum",
  function(x, digits)
    callNextMethod(round(as.numeric(x), x@d), digits))

## Examples of callNextMethod with two arguments in the signature.
## For arithmetic and one rnum with anything, callNextMethod with no arguments
```
## round the full accuracy result, and return as plain vector
setMethod("Arith", c(e1 = "rnum"),
  function(e1, e2)
    as.numeric(round(callNextMethod(), e1@d)))
setMethod("Arith", c(e2 = "rnum"),
  function(e1, e2)
    as.numeric(round(callNextMethod(), e2@d)))

## A method for BOTH arguments from "rnum" would be ambiguous
## for callNextMethod(): the two methods above are equally valid.
## The method chooses the smaller number of digits,
## and then calls the generic function, postponing the method selection
## until it’s not ambiguous.
setMethod("Arith", c(e1 = "rnum", e2 = "rnum"),
  function(e1, e2) {
    if(e1@d <= e2@d)
      callGeneric(e1, as.numeric(e2))
    else
      callGeneric(as.numeric(e1), e2)
  })

## For comparisons, callNextMethod with the rounded arguments
setMethod("Compare", c(e1 = "rnum"),
  function(e1, e2)
    callNextMethod(round(e1, e1@d), round(e2, e1@d)))
setMethod("Compare", c(e2 = "rnum"),
  function(e1, e2)
    callNextMethod(round(e1, e2@d), round(e2, e2@d)))

## similarly to the Arith case, the method for two "rnum" objects
## can not unambiguously use callNextMethod(). Instead, we rely on
## The rnum() method inherited from Math2 to return plain vectors.
setMethod("Compare", c(e1 = "rnum", e2 = "rnum"),
  function(e1, e2) {
    d <- min(e1@d, e2@d)
    callGeneric(round(e1, d), round(e2, d))
  })

set.seed(867)
x1 <- rnum(10*runif(5), d=1L)
x2 <- rnum(10*runif(5), d=2L)
x1+1
x2*2
x1-x2

## Simple examples to illustrate callNextMethod with and without arguments
B0 <- setClass("B0", slots = c(s0 = "numeric"))

## and a function to illustrate callNextMethod
f <- function(x, text = "default") {
  str(x) # print a summary
callNextMethod

```r
paste(text, ":", class(x))
}

setGeneric("f")
setMethod("f", "B0", function(x, text = "B0") {
  cat("B0 method called with s0 =", x@s0, "\n")
callNextMethod()
})
b0 <- B0(s0 = 1)

## call f() with 2 arguments: callNextMethod passes both to the default method
f(b0, "first test")

## call f() with 1 argument: the default "B0" is not passed by callNextMethod
f(b0)

## Now, a class that extends B0, with no methods for f()
B1 <- setClass("B1", slots = c(s1 = "character"), contains = "B0")
b1 <- B1(s0 = 2, s1 = "Testing B1")

## the two cases work as before, by inheriting the "B0" method
f(b1, b1@s1)

f(b1)

B2 <- setClass("B2", contains = "B1")

## And, a method for "B2" that calls with explicit arguments.
## Note that the method selection in callNextMethod
## uses the class of the *argument* to consistently select the "B0" method
setMethod("f", "B2", function(x, text = "B1 method") {
  y <- B1(s0 = -x@s0, s1 = "Modified x")
callNextMethod(y, text)
})
b2 <- B2(s1 = "Testing B2", s0 = 10)

f(b2, b2@s1)

f(b2)

## Be careful: the argument passed must be legal for the method selected
## Although the argument here is numeric, it's still the "B0" method that's called
setMethod("f", "B2", function(x, text = "B1 method") {
  callNextMethod(x@s0, text)
})

## Now the call will cause an error:
tryCatch(f(b2), error = function(e) cat(e$message,"\n"))
```
Can an Object be Coerced to a Certain S4 Class?

Description
Test if an object can be coerced to a given S4 class. Maybe useful inside if() to ensure that calling as(object, Class) will find a method.

Usage
canCoerce(object, Class)

Arguments
- object: any R object, typically of a formal S4 class.
- Class: an S4 class (see isClass).

Value
a scalar logical, TRUE if there is a coerce method (as defined by e.g. setAs) for the signature (from = class(object), to = Class).

See Also
as, setAs, selectMethod, setClass.

Examples
m <- matrix(pi, 2,3)
canCoerce(m, "numeric") # TRUE
canCoerce(m, "array") # TRUE

Combine two Objects by Columns or Rows

Description
Combine two matrix-like R objects by columns (cbind2) or rows (rbind2). These are (S4) generic functions with default methods.

Usage
cbind2(x, y, ...)
rbind2(x, y, ...)

cbind2

Arguments

- **x**: any R object, typically matrix-like.
- **y**: any R object, typically similar to **x**, or missing completely.
- **...**: optional arguments for methods.

Details

The main use of `cbind2` (and `rbind2`) is to be called recursively by `cbind()` (and `rbind()`) when both of these requirements are met:

- There is at least one argument that is an S4 object, and
- S3 dispatch fails (see the Dispatch section under `cbind`).

The methods on `cbind2` and `rbind2` effectively define the type promotion policy when combining a heterogeneous set of arguments. The homogeneous case, where all objects derive from some S4 class, can be handled via S4 dispatch on the `...` argument via an externally defined S4 `cbind` (or `rbind`) generic.

Since (for legacy reasons) S3 dispatch is attempted first, it is generally a good idea to additionally define an S3 method on `cbind` (or `rbind`) for the S4 class. The S3 method will be invoked when the arguments include objects of the S4 class, along with arguments of classes for which no S3 method exists. Also, in case there is an argument that selects a different S3 method (like the one for `data.frame`), this S3 method serves to introduce an ambiguity in dispatch that triggers the recursive fallback to `cbind2` (or `rbind2`). Otherwise, the other S3 method would be called, which may not be appropriate.

Value

A matrix (or matrix like object) combining the columns (or rows) of **x** and **y**. Note that methods must construct colnames and rownames from the corresponding column and row names of **x** and **y** (but not from deparsing argument names such as in `cbind(..., deparse.level = d)` for \( d \geq 1 \)).

Methods

- `signature(x = "ANY", y = "ANY")`: the default method using R’s internal code.
- `signature(x = "ANY", y = "missing")`: the default method for one argument using R’s internal code.

See Also

`cbind`, `rbind`; further, `cBind`, `rBind` in the Matrix package.

Examples

```
cbind2(1:3, 4)
m <- matrix(3:8, 2,3, dimnames=list(c("a","b"), LETTERS[1:3]))
cbind2(1:2, m) # keeps dimnames from m
```

```r
## rbind() and cbind() now make use of rbind2()/cbind2() methods
setClass("Num", contains="numeric")
setMethod("cbind2", c("Num", "missing"),
          function(x,y, ...) { cat("Num-miss--meth\n"); as.matrix(x) })
setMethod("rbind2", c("Num","ANY"), function(x,y, ...) {
   cat("Num-A.--method\n") ; cbind(getDataPart(x), y, ...) })
```
setMethod("cbind2", c("ANY","Num"), function(x,y, ...) {
    cat("A.-Num--method\n") ; cbind(x, getDataPart(y), ...) })

a <- new("Num", 1:3)
trace("cbind2")
cbind(a)
cbind(a, four=4, 7:9)# calling cbind2() twice

cbind(m,a, ch=c("D","E"), a*3)
cbind(l,a, m) # ok with a warning
untrace("cbind2")

---

**Description**

You have navigated to an old link to documentation of S4 classes.

**classesToAM**

*Compute an Adjacency Matrix for Superclasses of Class Definitions*

**Description**

Given a vector of class names or a list of class definitions, the function returns an adjacency matrix of the superclasses of these classes; that is, a matrix with class names as the row and column names and with element [i, j] being 1 if the class in column j is a direct superclass of the class in row i, and 0 otherwise.

The matrix has the information implied by the `contains` slot of the class definitions, but in a form that is often more convenient for further analysis; for example, an adjacency matrix is used in packages and other software to construct graph representations of relationships.

**Usage**

`classesToAM(classes, includeSubclasses = FALSE, abbreviate = 2)`
Arguments

classes Either a character vector of class names or a list, whose elements can be either
class names or class definitions. The list is convenient, for example, to include
the package slot for the class name. See the examples.

includeSubclasses A logical flag: if TRUE, then the matrix will include all the known subclasses of
the specified classes as well as the superclasses. The argument can also be a
logical vector of the same length as classes, to include subclasses for some but
not all the classes.

abbreviate Control of the abbreviation of the row and/or column labels of the matrix re-
turned: values 0, 1, 2, or 3 abbreviate neither, rows, columns or both. The
default, 2, is useful for printing the matrix, since class names tend to be more
than one character long, making for spread-out printing. Values of 0 or 3 would
be appropriate for making a graph (3 avoids the tendency of some graph plotting
software to produce labels in minuscule font size).

Details

For each of the classes, the calculation gets all the superclass names from the class definition,
and finds the edges in those classes’ definitions; that is, all the superclasses at distance 1. The
.corresponding elements of the adjacency matrix are set to 1.

The adjacency matrices for the individual class definitions are merged. Note two possible kinds
of inconsistency, neither of which should cause problems except possibly with identically named
classes from different packages. Edges are computed from each superclass definition, so that in-
formation overrides a possible inference from extension elements with distance > 1 (and it should).
When matrices from successive classes in the argument are merged, the computations do not cur-ently check for inconsistencies—this is the area where possible multiple classes with the same
name could cause confusion. A later revision may include consistency checks.

Value

As described, a matrix with entries 0 or 1, non-zero values indicating that the class corresponding to
the column is a direct superclass of the class corresponding to the row. The row and column names
are the class names (without package slot).

See Also

eextends and classRepresentation for the underlying information from the class definition.

Examples

## the super- and subclasses of "standardGeneric"
R ## and "derivedDefaultMethod"
> am <- classesToAM(list(class(show), class(getMethod(show))), TRUE)

> am

## Not run:
## the following function depends on the Bioconductor package Rgraphviz
plotInheritance <- function(classes, subclasses = FALSE, ...) {
  if(!require("Rgraphviz", quietly=TRUE))
    stop("Only implemented if Rgraphviz is available")
  mm <- classesToAM(classes, subclasses)
  classes <- rownames(mm); rownames(mm) <- colnames(mm)
Classes_Details

Class Definitions

Description

Class definitions are objects that contain the formal definition of a class of R objects, usually referred to as an S4 class, to distinguish them from the informal S3 classes. This document gives an overview of S4 classes; for details of the class representation objects, see help for the class `classRepresentation`.

Metadata Information

When a class is defined, an object is stored that contains the information about that class. The object, known as the metadata defining the class, is not stored under the name of the class (to allow programmers to write generating functions of that name), but under a specially constructed name. To examine the class definition, call `getClass`. The information in the metadata object includes:

Slots: The data contained in an object from an S4 class is defined by the slots in the class definition. Each slot in an object is a component of the object; like components (that is, elements) of a list, these may be extracted and set, using the function `slot()` or more often the operator `@`. However, they differ from list components in important ways. First, slots can only be referred to by name, not by position, and there is no partial matching of names as with list elements. All the objects from a particular class have the same set of slot names; specifically, the slot names that are contained in the class definition. Each slot in each object always is an object of the class specified for this slot in the definition of the current class. The word "is" corresponds to the R function of the same name (is), meaning that the class of the object in the slot must be the same as the class specified in the definition, or some class that extends the one in the definition (a subclass).

A special slot name, .Data, stands for the ‘data part’ of the object. An object from a class with a data part is defined by specifying that the class contains one of the R object types or one of the special pseudo-classes, matrix or array, usually because the definition of the class, or of one of its superclasses, has included the type or pseudo-class in its contains argument. A second special slot name, .xData, is used to enable inheritance from abnormal types such as "environment" See the section on inheriting from non-S4 classes for details on the representation and for the behavior of S3 methods with objects from these classes.

Some slot names correspond to attributes used in old-style S3 objects and in R objects without an explicit class, for example, the names attribute. If you define a class for which that attribute

```r
graph <- new("graphAM", mm, "directed", ...)
plot(graph)
cat("Key:
", paste(abbreviate(classes), " = ", classes, ", ",
    sep = " ", fill = TRUE)
invisible(graph)
}
## The plot of the class inheritance of the package "graph"
require(graph)
plotInheritance(getClasses("package:graph"))
## End(Not run)
```
will be set, such as a subclass of named vectors, you should include "names" as a slot. See the definition of class "namedList" for an example. Using the names() assignment to set such names will generate a warning if there is no names slot and an error if the object in question is not a vector type. A slot called "names" can be used anywhere, but only if it is assigned as a slot, not via the default names() assignment.

**Superclasses:** The definition of a class includes the *superclasses* — the classes that this class extends. A class Fancy, say, extends a class Simple if an object from the Fancy class has all the capabilities of the Simple class (and probably some more as well). In particular, and very usefully, any method defined to work for a Simple object can be applied to a Fancy object as well.

This relationship is expressed equivalently by saying that Simple is a superclass of Fancy, or that Fancy is a subclass of Simple.

The direct superclasses of a class are those superclasses explicitly defined. Direct superclasses can be defined in three ways. Most commonly, the superclasses are listed in the contains= argument in the call to setClass that creates the subclass. In this case the subclass will contain all the slots of the superclass, and the relation between the class is called *simple*, as it in fact is. Superclasses can also be defined explicitly by a call to setIs; in this case, the relation requires methods to be specified to go from subclass to superclass. Thirdly, a class union is a superclass of all the members of the union. In this case too the relation is simple, but notice that the relation is defined when the superclass is created, not when the subclass is created as with the contains= mechanism.

The definition of a superclass will also potentially contain its own direct superclasses. These are considered (and shown) as superclasses at distance 2 from the original class; their direct superclasses are at distance 3, and so on. All these are legitimate superclasses for purposes such as method selection.

When superclasses are defined by including the names of superclasses in the contains= argument to setClass, an object from the class will have all the slots defined for its own class and all the slots defined for all its superclasses as well.

The information about the relation between a class and a particular superclass is encoded as an object of class SClassExtension. A list of such objects for the superclasses (and sometimes for the subclasses) is included in the metadata object defining the class. If you need to compute with these objects (for example, to compare the distances), call the function extends with argument fullInfo=TRUE.

**Prototype:** The objects from a class created by a call to new are defined by the prototype object for the class and by additional arguments in the call to new, which are passed to a method for that class for the function initialize.

Each class representation object contains a prototype object for the class (although for a virtual class the prototype may be NULL). The prototype object must have values for all the slots of the class. By default, these are the prototypes of the corresponding slot classes. However, the definition of the class can specify any valid object for any of the slots.

### Basic classes

There are a number of 'basic' classes, corresponding to the ordinary kinds of data occurring in R. For example, "numeric" is a class corresponding to numeric vectors. The other vector basic classes are "logical", "integer", "complex", "character", "raw", "list" and "expression". The prototypes for the vector classes are vectors of length 0 of the corresponding type. Notice that basic classes are unusual in that the prototype object is from the class itself.

In addition to the vector classes there are also basic classes corresponding to objects in the language, such as "function" and "call". These classes are subclasses of the virtual class "language". Finally, there are object types and corresponding basic classes for "abnormal" objects, such as
"environment" and "externalptr". These objects do not follow the functional behavior of the language; in particular, they are not copied and so cannot have attributes or slots defined locally.

All these classes can be used as slots or as superclasses for any other class definitions, although they do not themselves come with an explicit class. For the abnormal object types, a special mechanism is used to enable inheritance as described below.

Inheriting from non-S4 Classes

A class definition can extend classes other than regular S4 classes, usually by specifying them in the `contains=` argument to `setClass`. Three groups of such classes behave distinctly:

1. S3 classes, which must have been registered by a previous call to `setOldClass` (you can check that this has been done by calling `getClass`, which should return a class that extends `oldClass`);

2. One of the R object types, typically a vector type, which then defines the type of the S4 objects, but also a type such as `environment` that can not be used directly as a type for an S4 object. See below.

3. One of the pseudo-classes `matrix` and `array`, implying objects with arbitrary vector types plus the `dim` and `dimnames` attributes.

This section describes the approach to combining S4 computations with older S3 computations by using such classes as superclasses. The design goal is to allow the S4 class to inherit S3 methods and default computations in as consistent a form as possible.

As part of a general effort to make the S4 and S3 code in R more consistent, when objects from an S4 class are used as the first argument to a non-default S3 method, either for an S3 generic function (one that calls `UseMethod`) or for one of the primitive functions that dispatches S3 methods, an effort is made to provide a valid object for that method. In particular, if the S4 class extends an S3 class or `matrix` or `array`, and there is an S3 method matching one of these classes, the S4 object will be coerced to a valid S3 object, to the extent that is possible given that there is no formal definition of an S3 class.

For example, suppose "myFrame" is an S4 class that includes the S3 class "data.frame" in the `contains=` argument to `setClass`. If an object from this S4 class is passed to a function, say `as.matrix`, that has an S3 method for "data.frame", the internal code for `UseMethod` will convert the object to a data frame; in particular, to an S3 object whose class attribute will be the vector corresponding to the S3 class (possibly containing multiple class names). Similarly for an S4 object inheriting from "matrix" or "array", the S4 object will be converted to a valid S3 matrix or array.

Note that the conversion is not applied when an S4 object is passed to the default S3 method. Some S3 generics attempt to deal with general objects, including S4 objects. Also, no transformation is applied to S4 objects that do not correspond to a selected S3 method; in particular, to objects from a class that does not contain either an S3 class or one of the basic types. See `asS4` for the transformation details.

In addition to explicit S3 generic functions, S3 methods are defined for a variety of operators and functions implemented as primitives. These methods are dispatched by some internal C code that operates partly through the same code as real S3 generic functions and partly via special considerations (for example, both arguments to a binary operator are examined when looking for methods). The same mechanism for adapting S4 objects to S3 methods has been applied to these computations as well, with a few exceptions such as generating an error if an S4 object that does not extend an appropriate S3 class or type is passed to a binary operator.

The remainder of this section discusses the mechanisms for inheriting from basic object types. See `matrix` or `array` for inhering from the matrix and array pseudo-classes, or from time-series. For the corresponding details for inheritance from S3 classes, see `setOldClass`.
An object from a class that directly and simply contains one of the basic object types in R, has implicitly a corresponding .Data slot of that type, allowing computations to extract or replace the data part while leaving other slots unchanged. If the type is one that can accept attributes and is duplicated normally, the inheritance also determines the type of the object; if the class definition has a .Data slot corresponding to a normal type, the class of the slot determines the type of the object (that is, the value of typeof(x)). For such classes, .Data is a pseudo-slot; that is, extracting or setting it modifies the non-slot data in the object. The functions getDataPart and setDataPart are a cleaner, but essentially equivalent way to deal with the data part.

Extending a basic type this way allows objects to use old-style code for the corresponding type as well as S4 methods. Any basic type can be used for .Data, but a few types are treated differently because they do not behave like ordinary objects; for example, "NULL", environments, and external pointers. Classes extend these types by having a slot, .xData, itself inherited from an internally defined S4 class. This slot actually contains an object of the inherited type, to protect computations from the reference semantics of the type. Coercing to the nonstandard object type then requires an actual computation, rather than the "simple" inclusion for other types and classes. The intent is that programmers will not need to take account of the mechanism, but one implication is that you should not explicitly use the type of an S4 object to detect inheritance from an arbitrary object type. Use is and similar functions instead.

Methods_Details for analogous discussion of methods, setClass for details of specifying class definitions, is, as, new, slot

```

<table>
<thead>
<tr>
<th>className</th>
<th>Class names including the corresponding package</th>
</tr>
</thead>
</table>

Description

The function `className()` generates a valid references to a class, including the name of the package containing the class definition. The object returned, from class "className", is the unambiguous way to refer to a class, for example when calling `setMethod`, just in case multiple definitions of the class exist.

Function "multipleClasses" returns information about multiple definitions of classes with the same name from different packages.

Usage

`className(class, package)`

`multipleClasses(details = FALSE)`

```
Arguments

class, package  The character string name of a class and, optionally, of the package to which it
belongs. If argument package is missing and the class argument has a package
slot, that is used (in particular, passing in an object from class "className"
returns itself in this case, but changes the package slot if the second argument is
supplied).

If there is no package argument or slot, a definition for the class must exist and
will be used to define the package. If there are multiple definitions, one will be
chosen and a warning printed giving the other possibilities.

details  If FALSE, the default, multipleClasses() returns a character vector of those
classes currently known with multiple definitions.

If TRUE, a named list of those class definitions is returned. Each element of
the list is itself a list of the corresponding class definitions, with the package
names as the names of the list. Note that identical class definitions will not be
considered “multiple” definitions (see the discussion of the details below).

Details

The table of class definitions used internally can maintain multiple definitions for classes with the
same name but coming from different packages. If identical class definitions are encountered, only
one class definition is kept; this occurs most often with S3 classes that have been specified in calls to
setOldClass. For true classes, multiple class definitions are unavoidable in general if two packages
happen to have used the same name, independently.

Overriding a class definition in another package with the same name deliberately is usually a bad
idea. Although R attempts to keep and use the two definitions (as of version 2.14.0), ambiguities
are always possible. It is more sensible to define a new class that extends an existing class but has
a different name.

Value

A call to className() returns an object from class "className".

A call to multipleClasses() returns either a character vector or a named list of class definitions.
In either case, testing the length of the returned value for being greater than 0 is a check for the
existence of multiply defined classes.

Objects from the Class

The class "className" extends "character" and has a slot "package", also of class
"character".

Examples

## Not run:
className("vector")  # will be found, from package "methods"
className("vector", "magic")  # OK, even though the class doesn't exist

className("An unknown class")  # Will cause an error

## End(Not run)
Description

These are the objects that hold the definition of classes of objects. They are constructed and stored as metadata by calls to the function `setClass`. Don’t manipulate them directly, except perhaps to look at individual slots.

Details

Class definitions are stored as metadata in various packages. Additional metadata supplies information on inheritance (the result of calls to `setIs`). Inheritance information implied by the class definition itself (because the class contains one or more other classes) is also constructed automatically.

When a class is to be used in an R session, this information is assembled to complete the class definition. The completion is a second object of class "classRepresentation", cached for the session or until something happens to change the information. A call to `getClass` returns the completed definition of a class; a call to `getClassDef` returns the stored definition (uncompleted).

In particular, completion fills in the upward- and downward-pointing inheritance information for the class, in slots `contains` and `subclasses` respectively. It’s in principle important to note that this information can depend on which packages are installed, since these may define additional subclasses or superclasses.

Slots

- `slots`: A named list of the slots in this class; the elements of the list are the classes to which the slots must belong (or extend), and the names of the list gives the corresponding slot names.
- `contains`: A named list of the classes this class ‘contains’; the elements of the list are objects of `SClassExtension`. The list may be only the direct extensions or all the currently known extensions (see the details).
- `virtual`: Logical flag, set to `TRUE` if this is a virtual class.
- `prototype`: The object that represents the standard prototype for this class; i.e., the data and slots returned by a call to `new` for this class with no special arguments. Don’t mess with the prototype object directly.
- `validity`: Optionally, a function to be used to test the validity of objects from this class. See `validObject`.
- `access`: Access control information. Not currently used.
- `className`: The character string name of the class.
- `package`: The character string name of the package to which the class belongs. Nearly always the package on which the metadata for the class is stored, but in operations such as constructing inheritance information, the internal package name rules.
- `subclasses`: A named list of the classes known to extend this class; the elements of the list are objects of class `SClassExtension`. The list is currently only filled in when completing the class definition (see the details).
- `versionKey`: Object of class "externalptr"; eventually will perhaps hold some versioning information, but not currently used.
- `sealed`: Object of class "logical"; is this class sealed? If so, no modifications are allowed.
Documentation

Using and Creating On-line Documentation for Classes and Methods

Description

Special documentation can be supplied to describe the classes and methods that are created by the software in the methods package. Techniques to access this documentation and to create it in R help files are described here.

Getting documentation on classes and methods

You can ask for on-line help for class definitions, for specific methods for a generic function, and for general discussion of methods for a generic function. These requests use the ? operator (see help for a general description of the operator). Of course, you are at the mercy of the implementer as to whether there is any documentation on the corresponding topics.

Documentation on a class uses the argument class on the left of the ?, and the name of the class on the right; for example,

class ? genericFunction
to ask for documentation on the class "genericFunction".

When you want documentation for the methods defined for a particular function, you can ask either for a general discussion of the methods or for documentation of a particular method (that is, the method that would be selected for a particular set of actual arguments).

Overall methods documentation is requested by calling the ? operator with methods as the left-side argument and the name of the function as the right-side argument. For example,

methods ? initialize
asks for documentation on the methods for the initialize function.

Asking for documentation on a particular method is done by giving a function call expression as the right-hand argument to the "?" operator. There are two forms, depending on whether you prefer to give the class names for the arguments or expressions that you intend to use in the actual call.

If you planned to evaluate a function call, say myFun(x, sqrt(wt)) and wanted to find out something about the method that would be used for this call, put the call on the right of the "?" operator:

?myFun(x, sqrt(wt))

A method will be selected, as it would be for the call itself, and documentation for that method will be requested. If myFun is not a generic function, ordinary documentation for the function will be requested.

If you know the actual classes for which you would like method documentation, you can supply these explicitly in place of the argument expressions. In the example above, if you want method documentation for the first argument having class "maybeNumber" and the second "logical", call the "?" operator, this time with a left-side argument method, and with a function call on the right using the class names as arguments:

method ? myFun("maybeNumber", "logical")
Once again, a method will be selected, this time corresponding to the specified classes, and method documentation will be requested. This version only works with generic functions.

The two forms each have advantages. The version with actual arguments doesn’t require you to figure out (or guess at) the classes of the arguments. On the other hand, evaluating the arguments may take some time, depending on the example. The version with class names does require you to pick classes, but it’s otherwise unambiguous. It has a subtler advantage, in that the classes supplied may be virtual classes, in which case no actual argument will have specifically this class. The class "maybeNumber", for example, might be a class union (see the example for `setClassUnion`).

In either form, methods will be selected as they would be in actual computation, including use of inheritance and group generic functions. See `selectMethod` for the details, since it is the function used to find the appropriate method.

**Writing Documentation for Methods**

The on-line documentation for methods and classes uses some extensions to the R documentation format to implement the requests for class and method documentation described above. See the document *Writing R Extensions* for the available markup commands (you should have consulted this document already if you are at the stage of documenting your software).

In addition to the specific markup commands to be described, you can create an initial, overall file with a skeleton of documentation for the methods defined for a particular generic function:

```r
promptMethods("myFun")
```

will create a file, ‘myFun-methods.Rd’ with a skeleton of documentation for the methods defined for function `myFun`. The output from `promptMethods` is suitable if you want to describe all or most of the methods for the function in one file, separate from the documentation of the generic function itself. Once the file has been filled in and moved to the ‘man’ subdirectory of your source package, requests for methods documentation will use that file, both for specific methods documentation as described above, and for overall documentation requested by

```r
methods ? myFun
```

You are not required to use `promptMethods`, and if you do, you may not want to use the entire file created:

- If you want to document the methods in the file containing the documentation for the generic function itself, you can cut-and-paste to move the `\alias` lines and the `Methods` section from the file created by `promptMethods` to the existing file.

- On the other hand, if these are auxiliary methods, and you only want to document the added or modified software, you should strip out all but the relevant `\alias` lines for the methods of interest, and remove all but the corresponding `\item` entries in the `Methods` section. Note that in this case you will usually remove the first `\alias` line as well, since that is the marker for general methods documentation on this function (in the example, `\alias(myFun-methods)`).

If you simply want to direct documentation for one or more methods to a particular R documentation file, insert the appropriate alias.
**Description**

The “….” argument in R functions is treated specially, in that it matches zero, one or more actual arguments (and so, objects). A mechanism has been added to R to allow “….” as the signature of a generic function. Methods defined for such functions will be selected and called when all the arguments matching “….” are from the specified class or from some subclass of that class.

**Using "..." in a Signature**

Beginning with version 2.8.0 of R, S4 methods can be dispatched (selected and called) corresponding to the special argument “….”. Currently, “….” cannot be mixed with other formal arguments: either the signature of the generic function is “….” only, or it does not contain “….”. (This restriction may be lifted in a future version.)

Given a suitable generic function, methods are specified in the usual way by a call to `setMethod`. The method definition must be written expecting all the arguments corresponding to “….” to be from the class specified in the method’s signature, or from a class that extends that class (i.e., a subclass of that class).

Typically the methods will pass “….” down to another function or will create a list of the arguments and iterate over that. See the examples below.

When you have a computation that is suitable for more than one existing class, a convenient approach may be to define a union of these classes by a call to `setClassUnion`. See the example below.

**Method Selection and Dispatch for "..."**

See Methods_Details for a general discussion. The following assumes you have read the “Method Selection and Dispatch” section of that documentation.

A method selecting on “….” is specified by a single class in the call to `setMethod`. If all the actual arguments corresponding to “….” have this class, the corresponding method is selected directly.

Otherwise, the class of each argument and that class’ superclasses are computed, beginning with the first “….” argument. For the first argument, eligible methods are those for any of the classes. For each succeeding argument that introduces a class not considered previously, the eligible methods are further restricted to those matching the argument’s class or superclasses. If no further eligible classes exist, the iteration breaks out and the default method, if any, is selected.

At the end of the iteration, one or more methods may be eligible. If more than one, the selection looks for the method with the least distance to the actual arguments. For each argument, any inherited method corresponds to a distance, available from the `contains` slot of the class definition. Since the same class can arise for more than one argument, there may be several distances associated with it. Combining them is inevitably arbitrary: the current computation uses the minimum distance. Thus, for example, if a method matched one argument directly, one as first generation superclass and another as a second generation superclass, the distances are 0, 1 and 2. The current selection computation would use distance 0 for this method. In particular, this selection criterion tends to use a method that matches exactly one or more of the arguments’ class.

As with ordinary method selection, there may be multiple methods with the same distance. A warning message is issued and one of the methods is chosen (the first encountered, which in this case is rather arbitrary).

Notice that, while the computation examines all arguments, the essential cost of dispatch goes up with the number of distinct classes among the arguments, likely to be much smaller than the number of arguments when the latter is large.
Implementation Details

Methods dispatching on “…” were introduced in version 2.8.0 of R. The initial implementation of the corresponding selection and dispatch is in an R function, for flexibility while the new mechanism is being studied. In this implementation, a local version of standardGeneric is inserted in the generic function’s environment. The local version selects a method according to the criteria above and calls that method, from the environment of the generic function. This is slightly different from the action taken by the C implementation when “…” is not involved. Aside from the extra computing time required, the method is evaluated in a true function call, as opposed to the special context constructed by the C version (which cannot be exactly replicated in R code.) However, situations in which different computational results would be obtained have not been encountered so far, and seem very unlikely.

Methods dispatching on arguments other than “…” are cached by storing the inherited method in the table of all methods, where it will be found on the next selection with the same combination of classes in the actual arguments (but not used for inheritance searches). Methods based on “…” are also cached, but not found quite as immediately. As noted, the selected method depends only on the set of classes that occur in the “…” arguments. Each of these classes can appear one or more times, so many combinations of actual argument classes will give rise to the same effective signature. The selection computation first computes and sorts the distinct classes encountered. This gives a label that will be cached in the table of all methods, avoiding any further search for inherited classes after the first occurrence. A call to showMethods will expose such inherited methods.

The intention is that the “…” features will be added to the standard C code when enough experience with them has been obtained. It is possible that at the same time, combinations of “…” with other arguments in signatures may be supported.

Examples

```r
cc <- function(...) c(...)
setGeneric("cc")
setMethod("cc", "character", function(...) paste(...))
setClassUnion("Number", c("numeric", "complex"))
setMethod("cc", "Number", function(...) sum(...))
setClass("cdate", contains = "character", slots = c(date = "Date"))
setClass("vdate", contains = "vector", slots = c(date = "Date"))

cd1 <- new("cdate", "abcdef", date = Sys.Date())

cd2 <- new("vdate", "abcdef", date = Sys.Date())
```
environment-class

Class "environment"

Description
A formal class for R environments.

Objects from the Class
Objects can be created by calls of the form new("environment", ...). The arguments in ..., if any, should be named and will be assigned to the newly created environment.

Methods
coerce signature(from = "ANY", to = "environment"): calls as.environment.
initialize signature(object = "environment"): Implements the assignments in the new environment. Note that the object argument is ignored; a new environment is always created, since environments are not protected by copying.

envRefClass-class Class "envRefClass"

Description

Support Class to Implement R Objects using Reference Semantics

NOTE:

The software described here is an initial version. The eventual goal is to support reference-style classes with software in R itself or using inter-system interfaces. The current implementation (R version 2.12.0) is preliminary and subject to change, and currently includes only the R-only implementation. Developers are encouraged to experiment with the software, but the description here is more than usually subject to change.

Purpose of the Class

This class implements basic reference-style semantics for R objects. Objects normally do not come directly from this class, but from subclasses defined by a call to setRefClass. The documentation below is technical background describing the implementation, but applications should use the interface documented under setRefClass, in particular the $ operator and field accessor functions as described there.

A Basic Reference Class

The design of reference classes for R divides those classes up according to the mechanism used for implementing references, fields, and class methods. Each version of this mechanism is defined by a basic reference class, which must implement a set of methods and provide some further information used by setRefClass.

The required methods are for operators $ and $<-$ to get and set a field in an object, and for initialize to initialize objects.

To support these methods, the basic reference class needs to have some implementation mechanism to store and retrieve data from fields in the object. The mechanism needs to be consistent with reference semantics; that is, changes made to the contents of an object are global, seen by any code accessing that object, rather than only local to the function call where the change takes place. As described below, class envRefClass implements reference semantics through specialized use of environment objects. Other basic reference classes may use an interface to a language such as Java or C++ using reference semantics for classes.

Usually, the R user will be able to invoke class methods on the class, using the $ operator. The basic reference class method for $ needs to make this possible. Essentially, the operator must return an R function corresponding to the object and the class method name.

Class methods may include an implementation of data abstraction, in the sense that fields are accessed by “get” and “set” methods. The basic reference class provides this facility by setting the "fieldAccessorGenerator" slot in its definition to a function of one variable. This function will be called by setRefClass with the vector of field names as arguments. The generator function must return a list of defined accessor functions. An element corresponding to a get operation is invoked with no arguments and should extract the corresponding field; an element for a set operation will
be invoked with a single argument, the value to be assigned to the field. The implementation needs to supply the object, since that is not an argument in the method invocation. The mechanism used currently by envRefClass is described below.

Support Classes

Two virtual classes are supplied to test for reference objects: \texttt{is(x, "refClass")} tests whether \texttt{x} comes from a class defined using the reference class mechanism described here; \texttt{is(x, "refObject")} tests whether the object has reference semantics generally, including the previous classes and also classes inheriting from the \texttt{R} types with reference semantics, such as "environment".

Installed class methods are "classMethodDefinition" objects, with slots that identify the name of the function as a class method and the other class methods called from this method. The latter information is determined heuristically when the class is defined by using the codetools recommended package. This package must be installed when reference classes are defined, but is not needed in order to use existing reference classes.

\textbf{evalSource}

\textit{Use Function Definitions from a Source File without Reinstalling a Package}

\textbf{Description}

Definitions of functions and/or methods from a source file are inserted into a package, using the \texttt{trace} mechanism. Typically, this allows testing or debugging modified versions of a few functions without reinstalling a large package.

\textbf{Usage}

\begin{verbatim}

evalSource(source, package = ",", lock = TRUE, cache = FALSE)

insertSource(source, package = ",", functions = , methods = , force = )

\end{verbatim}

\textbf{Arguments}

\texttt{source} \quad A file to be parsed and evaluated by \texttt{evalSource} to find the new function and method definitions.

The argument to \texttt{insertSource} can be an object of class "sourceEnvironment" returned from a previous call to \texttt{evalSource} If a file name is passed to \texttt{insertSource} it calls \texttt{evalSource} to obtain the corresponding object. See the section on the class for details.

\texttt{package} \quad Optionally, the name of the package to which the new code corresponds and into which it will be inserted. Although the computations will attempt to infer the package if it is omitted, the safe approach is to supply it. In the case of a package that is not attached to the search list, the package name must be supplied.
functions, methods

Optional, the character-string names of the functions to be used in the insertion. Names supplied in the functions argument are expected to be defined as functions in the source. For names supplied in the methods argument, a table of methods is expected (as generated by calls to \texttt{setMethod}, see the details section); methods from this table will be inserted by \texttt{insertSource}. In both cases, the revised function or method is inserted only if it differs from the version in the corresponding package as loaded.

If what is omitted, the results of evaluating the source file will be compared to the contents of the package (see the details section).

lock, cache

Optional arguments to control the actions taken by \texttt{evalSource}. If \texttt{lock} is \texttt{TRUE}, the environment in the object returned will be locked, and so will all its bindings. If \texttt{cache} is \texttt{FALSE}, the normal caching of method and class definitions will be suppressed during evaluation of the source file.

The default settings are generally recommended, the lock to support the credibility of the object returned as a snapshot of the source file, and the second so that method definitions can be inserted later by \texttt{insertSource} using the trace mechanism.

force

If \texttt{FALSE}, only functions currently in the environment will be redefined, using \texttt{trace}. If \texttt{TRUE}, other objects/functions will be simply assigned. By default, \texttt{TRUE} if neither the functions nor the methods argument is supplied.

Details

The source file is parsed and evaluated, suppressing by default the actual caching of method and class definitions contained in it, so that functions and methods can be tested out in a reversible way. The result, if all goes well, is an environment containing the assigned objects and metadata corresponding to method and class definitions in the source file.

From this environment, the objects are inserted into the package, into its namespace if it has one, for use during the current session or until reverting to the original version by a call to \texttt{untrace}. The insertion is done by calls to the internal version of \texttt{trace}, to make reversion possible.

Because the trace mechanism is used, only function-type objects will be inserted, functions themselves or S4 methods.

When the functions and methods arguments are both omitted, \texttt{insertSource} selects all suitable objects from the result of evaluating the source file.

In all cases, only objects in the source file that differ from the corresponding objects in the package are inserted. The definition of “differ” is that either the argument list (including default expressions) or the body of the function is not identical. Note that in the case of a method, there need be no specific method for the corresponding signature in the package: the comparison is made to the method that would be selected for that signature.

Nothing in the computation requires that the source file supplied be the same file as in the original package source, although that case is both likely and sensible if one is revising the package. Nothing in the computations compares source files: the objects generated by evaluating source are compared as objects to the content of the package.

Value

An object from class “sourceEnvironment”, a subclass of “environment” (see the section on the class) The environment contains the versions of all object resulting from evaluation of the source file. The class also has slots for the time of creation, the source file and the package name. Future extensions may use these objects for versioning or other code tools.
The object returned can be used in debugging (see the section on that topic) or as the source argument in a future call to `insertSource`. If only some of the revised functions were inserted in the first call, others can be inserted in a later call without re-evaluating the source file, by supplying the environment and optionally suitable functions and/or methods argument.

### Debugging

Once a function or method has been inserted into a package by `insertSource`, it can be studied by the standard debugging tools; for example, `debug` or the various versions of `trace`. Calls to `trace` should take the extra argument `edit = env`, where `env` is the value returned by the call to `evalSource`. The trace mechanism has been used to install the revised version from the source file, and supplying the argument ensures that it is this version, not the original, that will be traced. See the example below.

To turn tracing off, but retain the source version, use `trace(x, edit = env)` as in the example. To return to the original version from the package, use `untrace(x)`.

### Class 

"sourceEnvironment"

Objects from this class can be treated as environments, to extract the version of functions and methods generated by `evalSource`. The objects also have the following slots:

- `packageName`: The character-string name of the package to which the source code corresponds.
- `dateCreated`: The date and time that the source file was evaluated (usually from a call to `Sys.time`).
- `sourceFile`: The character-string name of the source file used.

Note that using the environment does not change the `dateCreated`.

### See Also

`trace` for the underlying mechanism, and also for the `edit=` argument that can be used for somewhat similar purposes; that function and also `debug` and `setBreakpoint`, for techniques more oriented to traditional debugging styles. The present function is directly intended for the case that one is modifying some of the source for an existing package, although it can be used as well by inserting debugging code in the source (more useful if the debugging involved is non-trivial). As noted in the details section, the source file need not be the same one in the original package source.

### Examples

```r
## Not run:
## Suppose package P0 has a source file "all.R"
## First, evaluate the source, and from it
## insert the revised version of methods for summary()
env <- insertSource("./P0/R/all.R", package = "P0", methods = "summary")
## now test one of the methods, tracing the version from the source
trace("summary", signature = "myMat", browser, edit = env)
## After testing, remove the browser() call but keep the source
trace("summary", signature = "myMat", edit = env)
## Now insert all the (other) revised functions and methods
## without re-evaluating the source file.
insertSource(env)
## The package name is included in the object env.
## End(Not run)
```
findClass

Find Class Definitions

Description

Functions to find classes: isClass tests for a class; findClass returns the name(s) of packages containing the class; getClasses returns the names of all the classes in an environment, typically a namespace. To examine the definition of a class, use getClass.

Usage

isClass(Class, formal=TRUE, where)
getClasses(where, inherits = missing(where))
findClass(Class, where, unique = "")

## The remaining functions are retained for compatibility
## but not generally recommended
removeClass(Class, where)
resetClass(Class, classDef, where)
sealClass(Class, where)

Arguments

Class character string name for the class. The functions will usually take a class definition instead of the string. To restrict the class to those defined in a particular package, set the packageSlot of the character string.

where the environment in which to search for the class definition. Defaults to the top-level environment of the calling function. When called from the command line, this has the effect of using all the package environments in the search list. To restrict the search to classes in a particular package, use where = asNamespace(pkg) with pkg the package name; to restrict it to the exported classes, use where = "package:pkg" after the package is attached to the search list.

formal logical is a formal definition required? For S compatibility, and always treated as TRUE.

unique if findClass expects a unique location for the class, unique is a character string explaining the purpose of the search (and is used in warning and error messages). By default, multiple locations are possible and the function always returns a list.

inherits in a call to getClasses, should the value returned include all parent environments of where, or that environment only? Defaults to TRUE if where is omitted, and to FALSE otherwise.

classDef For resetClass, the optional class definition.
findMethods

Functions

isClass: Is this the name of a formally defined class?

getClasses: The names of all the classes formally defined on where. If called with no argument, all the classes visible from the calling function (if called from the top-level, all the classes in any of the environments on the search list). The where argument is used to search only in a particular package.

findClass: The list of environments in which a class definition of Class is found. If where is supplied, a list is still returned, either empty or containing the environment corresponding to where. By default when called from the R session, the global environment and all the currently attached packages are searched. If unique is supplied as a character string, findClass will warn if there is more than one definition visible (using the string to identify the purpose of the call), and will generate an error if no definition can be found.

removeClass: Remove the definition of this class. This can’t be used if the class is in another package, and would rarely be needed in source code defining classes in a package.

resetClass: Reset the internal definition of a class. Not legitimate for a class definition not in this package and rarely needed otherwise.

sealClass: Seal the current definition of the specified class, to prevent further changes, by setting the corresponding slot in the class definition. This is rarely used, since classes in loaded packages are sealed by locking their namespace.

findMethods

Description of the Methods Defined for a Generic Function

Description

The function findMethods converts the methods defined in a table for a generic function (as used for selection of methods) into a list, for study or display. The list is actually from the class listOfMethods (see the section describing the class, below).

The list will be limited to the methods defined in environment where if that argument is supplied and limited to those including one or more of the specified classes in the method signature if that argument is supplied.

To see the actual table (an environment) used for methods dispatch, call getMethodsForDispatch. The names of the list returned by findMethods are the names of the objects in the table.
The function `findMethodSignatures` returns a character matrix whose rows are the class names from the signature of the corresponding methods; it operates either from a list returned by `findMethods`, or by computing such a list itself, given the same arguments as `findMethods`.

The function `hasMethods` returns TRUE or FALSE according to whether there is a non-empty table of methods for function `f` in the environment or search position `where` (or for the generic function generally if `where` is missing).

The defunct function `getMethods` is an older alternative to `findMethods`, returning information in the form of an object of class `MethodsList`, previously used for method dispatch. This class of objects is deprecated generally and will disappear in a future version of R.

**Usage**

```r
findMethods(f, where, classes = character(), inherited = FALSE, package = "")

findMethodSignatures(..., target = TRUE, methods = )

hasMethods(f, where, package)
```

```r
## Deprecated in 2010 and defunct in 2015 for 'table = FALSE':
getMethods(f, where, table = FALSE)
```

**Arguments**

- `f` A generic function or the character-string name of one.
- `where` Optionally, an environment or position on the search list to look for methods metadata.
  
  If `where` is missing, `findMethods` uses the current table of methods in the generic function itself, and `hasMethods` looks for metadata anywhere in the search list.
- `table` If TRUE in a call to `getMethods` the returned value is the table used for dispatch, including inherited methods discovered to date. Used internally, but since the default result is the now unused `mlist` object, the default will likely be changed at some point.
- `classes` If supplied, only methods whose signatures contain at least one of the supplied classes will be included in the value returned.
- `inherited` Logical flag; if TRUE, the table of all methods, inherited or defined directly, will be used; otherwise, only the methods explicitly defined. Option TRUE is meaningful only if `where` is missing.
- `...` In the call to `findMethodSignatures`, any arguments that might be given to `findMethods`.
- `target` Optional flag to `findMethodSignatures`; if TRUE, the signatures used are the target signatures (the classes for which the method will be selected); if FALSE, they will be the signatures are defined. The difference is only meaningful if `inherited` is TRUE.
- `methods` In the call to `findMethodSignatures`, an optional list of methods, presumably returned by a previous call to `findMethods`. If missing, that function will be call with the ...arguments.
In a call to `hasMethods`, the package name for the generic function (e.g., "base" for primitives). If missing this will be inferred either from the "package" attribute of the function name, if any, or from the package slot of the generic function. See 'Details'.

The functions obtain a table of the defined methods, either from the generic function or from the stored metadata object in the environment specified by where. In a call to `getMethods`, the information in the table is converted as described above to produce the returned value, except with the table argument.

Note that `hasMethods`, but not the other functions, can be used even if no generic function of this name is currently found. In this case package must either be supplied as an argument or included as an attribute of f, since the package name is part of the identification of the methods tables.

The Class for lists of methods

The class "listOfMethods" returns the methods as a named list of method definitions (or a primitive function, see the slot documentation below). The names are the strings used to store the corresponding objects in the environment from which method dispatch is computed. The current implementation uses the names of the corresponding classes in the method signature, separated by "#" if more than one argument is involved in the signature.

Slots

`.Data`: Object of class "list" The method definitions.

Note that these may include the primitive function itself as default method, when the generic corresponds to a primitive. (Basically, because primitive functions are abnormal R objects, which cannot currently be extended as method definitions.) Computations that use the returned list to derive other information need to take account of this possibility. See the implementation of `findMethodSignatures` for an example.

`arguments`: Object of class "character". The names of the formal arguments in the signature of the generic function.

`signatures`: Object of class "list". A list of the signatures of the individual methods. This is currently the result of splitting the names according to the "#" separator.

If the object has been constructed from a table, as when returned by `findMethods`, the signatures will all have the same length. However, a list rather than a character matrix is used for generality. Calling `findMethodSignatures` as in the example below will always convert to the matrix form.

`generic`: Object of class "genericFunction". The generic function corresponding to these methods. There are plans to generalize this slot to allow reference to the function.

`names`: Object of class "character". The names as noted are the class names separated by "#".

Extends

Class "namedList", directly.

Class "list", by class "namedList", distance 2.

Class "vector", by class "namedList", distance 3.

---

**fixPre1.8**  
*Fix Objects Saved from R Versions Previous to 1.8*

Description

Beginning with R version 1.8.0, the class of an object contains the identification of the package in which the class is defined. The function `fixPre1.8` fixes and re-assigns objects missing that information (typically because they were loaded from a file saved with a previous version of R.)

Usage

```r
fixPre1.8(names, where)
```

Arguments

- `names` Character vector of the names of all the objects to be fixed and re-assigned.
- `where` The environment from which to look for the objects, and for class definitions. Defaults to the top environment of the call to `fixPre1.8`, the global environment if the function is used interactively.

Details

The named object will be saved where it was found. Its class attribute will be changed to the full form required by R 1.8; otherwise, the contents of the object should be unchanged.

Objects will be fixed and re-assigned only if all the following conditions hold:

1. The named object exists.
2. It is from a defined class (not a basic datatype which has no actual class attribute).
3. The object appears to be from an earlier version of R.
4. The class is currently defined.
5. The object is consistent with the current class definition.

If any condition except the second fails, a warning message is generated.

Note that `fixPre1.8` currently fixes only the change in class attributes. In particular, it will not fix binary versions of packages installed with earlier versions of R if these use incompatible features. Such packages must be re-installed from source, which is the wise approach always when major version changes occur in R.

Value

The names of all the objects that were in fact re-assigned.
Description

Generic functions (objects from or extending class genericFunction) are extended function objects, containing information used in creating and dispatching methods for this function. They also identify the package associated with the function and its methods.

Objects from the Class

Generic functions are created and assigned by setGeneric or setGroupGeneric and, indirectly, by setMethod.

As you might expect setGeneric and setGroupGeneric create objects of class "genericFunction" and "groupGenericFunction" respectively.

Slots

.Data: Object of class "function", the function definition of the generic, usually created automatically as a call to standardGeneric.

generic: Object of class "character", the name of the generic function.

package: Object of class "character", the name of the package to which the function definition belongs (and not necessarily where the generic function is stored). If the package is not specified explicitly in the call to setGeneric, it is usually the package on which the corresponding non-generic function exists.

group: Object of class "list", the group or groups to which this generic function belongs. Empty by default.

valueClass: Object of class "character"; if not an empty character vector, identifies one or more classes. It is asserted that all methods for this function return objects from these class (or from classes that extend them).

signature: Object of class "character", the vector of formal argument names that can appear in the signature of methods for this generic function. By default, it is all the formal arguments, except for .... Order matters for efficiency: the most commonly used arguments in specifying methods should come first.

default: Object of class "optionalMethod" (a union of classes "function" and "NULL"), containing the default method for this function if any. Generated automatically and used to initialize method dispatch.

skeleton: Object of class "call", a slot used internally in method dispatch. Don’t expect to use it directly.

Extends

Class "function", from data part.
Class "OptionalMethods", by class "function".
Class "PossibleMethod", by class "function".
Methods

Generic function objects are used in the creation and dispatch of formal methods; information from the object is used to create methods list objects and to merge or update the existing methods for this generic.

Description

The functions documented here manage collections of methods associated with a generic function, as well as providing information about the generic functions themselves.

Usage

- `isGeneric(f, where, fdef, getName = FALSE)`
- `isGroup(f, where, fdef)`
- `removeGeneric(f, where)`
- `dumpMethod(f, signature, file, where, def)`
- `findFunction(f, generic = TRUE, where = topenv(parent.frame()))`
- `dumpMethods(f, file, signature, methods, where)`
- `signature(...)`
- `removeMethods(f, where = topenv(parent.frame()), all = missing(where))`
- `setReplaceMethod(f, ..., where = topenv(parent.frame()))`
- `getGenerics(where, searchForm = FALSE)`

Arguments

- **f**
  - The character string naming the function.

- **where**
  - The environment, namespace, or search-list position from which to search for objects. By default, start at the top-level environment of the calling function, typically the global environment (i.e., use the search list), or the namespace of a package from which the call came. It is important to supply this argument when calling any of these functions indirectly. With package namespaces, the default is likely to be wrong in such calls.

- **signature**
  - The class signature of the relevant method. A signature is a named or unnamed vector of character strings. If named, the names must be formal argument names for the generic function. Signatures are matched to the arguments specified in the signature slot of the generic function (see the Details section of the `setMethod` documentation).
  - The signature argument to `dumpMethods` is ignored (it was used internally in previous implementations).

- **file**
  - The file or connection on which to dump method definitions.

- **def**
  - The function object defining the method; if omitted, the current method definition corresponding to the signature.
... Named or unnamed arguments to form a signature.
generic In testing or finding functions, should generic functions be included. Supply as FALSE to get only non-generic functions.
fdef Optional, the generic function definition. Usually omitted in calls to isGeneric
getName If TRUE, isGeneric returns the name of the generic. By default, it returns TRUE.
methods The methods object containing the methods to be dumped. By default, the methods defined for this generic (optionally on the specified where location).
all in removeMethods, logical indicating if all (default) or only the first method found should be removed.
searchForm In getGenerics, if TRUE, the package slot of the returned result is in the form used by search(), otherwise as the simple package name (e.g, "package:base" vs "base").

Summary of Functions

isGeneric: Is there a function named f, and if so, is it a generic?

The getName argument allows a function to find the name from a function definition. If it is TRUE then the name of the generic is returned, or FALSE if this is not a generic function definition.

The behavior of isGeneric and getGeneric for primitive functions is slightly different. These functions don’t exist as formal function objects (for efficiency and historical reasons), regardless of whether methods have been defined for them. A call to isGeneric tells you whether methods have been defined for this primitive function, anywhere in the current search list, or in the specified position where. In contrast, a call to getGeneric will return what the generic for that function would be, even if no methods have been currently defined for it.

removeGeneric, removeMethods: Remove all the methods for the generic function of this name.

In addition, removeGeneric removes the function itself; removeMethods restores the non-generic function which was the default method. If there was no default method, removeMethods leaves a generic function with no methods.

standardGeneric: Dispatches a method from the current function call for the generic function f. It is an error to call standardGeneric anywhere except in the body of the corresponding generic function.

Note that standardGeneric is a primitive function in the base package for efficiency reasons, but rather documented here where it belongs naturally.

dumpMethod: Dump the method for this generic function and signature.

findFirst: return a list of either the positions on the search list, or the current top-level environment, on which a function object for name exists. The returned value is always a list, use the first element to access the first visible version of the function. See the example.

NOTE: Use this rather than find with mode="function", which is not as meaningful, and has a few subtle bugs from its use of regular expressions. Also, findFunction works correctly in the code for a package when attaching the package via a call to library.

dumpMethods: Dump all the methods for this generic.

signature: Returns a named list of classes to be matched to arguments of a generic function.

getGenerics: returns the names of the generic functions that have methods defined on where; this argument can be an environment or an index into the search list. By default, the whole search list is used.
The methods definitions are stored with package qualifiers; for example, methods for function "initialize" might refer to two different functions of that name, on different packages. The package names corresponding to the method list object are contained in the slot `package` of the returned object. The form of the returned name can be plain (e.g., "base"), or in the form used in the search list ("package:base") according to the value of `searchForm`.

**Details**

`isGeneric`: If the `fdef` argument is supplied, take this as the definition of the generic, and test whether it is really a generic, with `f` as the name of the generic. (This argument is not available in S-Plus.)

`removeGeneric`: If `where` supplied, just remove the version on this element of the search list; otherwise, removes the first version encountered.

`standardGeneric`: Generic functions should usually have a call to `standardGeneric` as their entire body. They can, however, do any other computations as well. The usual `setGeneric` (directly or through calling `setMethod`) creates a function with a call to `standardGeneric`.

`dumpMethod`: The resulting source file will recreate the method.

`findFunction`: If `generic` is `FALSE`, ignore generic functions.

`dumpMethods`: If `signature` is supplied only the methods matching this initial signature are dumped. (This feature is not found in S-Plus: don’t use it if you want compatibility.)

`signature`: The advantage of using `signature` is to provide a check on which arguments you meant, as well as clearer documentation in your method specification. In addition, `signature` checks that each of the elements is a single character string.

`removeMethods`: Returns `TRUE` if `f` was a generic function, `FALSE` (silently) otherwise.

If there is a default method, the function will be re-assigned as a simple function with this definition. Otherwise, the generic function remains but with no methods (so any call to it will generate an error). In either case, a following call to `setMethod` will consistently re-establish the same generic function as before.

**Examples**

```r
require(stats) # for lm

## get the function "myFun" -- throw an error if 0 or > 1 versions visible:
findFuncStrict <- function(fName) {
  allF <- findFunction(fName)
  if(length(allF) == 0)
    stop("No versions of ",fName," visible")
  else if(length(allF) > 1)
    stop(fName," is ambiguous: ", length(allF), ", versions")
  else
    get(fName, allF[[1]])
}
```
try(findFuncStrict("myFun")) # Error: no version
lm <- function(x) x+1
try(findFuncStrict("lm")) # Error: 2 versions
findFuncStrict("findFuncStrict") # just 1 version
rm(lm)

## method dumping ------------------------------------
setClass("A", slots = c(a="numeric"))
setMethod("plot", "A", function(x,y,...){ cat("A meth\n") })
dumpMethod("plot","A", file="")
## Not run:
setMethod("plot", "A",
function (x, y, ...)
{
    cat("AAAAA\n")
})
## End(Not run)
tmp <- tempfile()
dumpMethod("plot","A", file=tmp)
## now remove, and see if we can parse the dump
stopifnot(removeMethod("plot", "A"))
source(tmp)
stopifnot(is(getMethod("plot", "A"), "MethodDefinition"))

## same with dumpMethods():
setClass("B", contains="A")
setMethod("plot", "B", function(x,y,...){ cat("B ...
") })
dumpMethods("plot", file=tmp)
stopifnot(removeMethod("plot", "A"),
          removeMethod("plot", "B"))
source(tmp)
stopifnot(is(getMethod("plot", "A"), "MethodDefinition"),
          is(getMethod("plot", "B"), "MethodDefinition"))

---

**getClass**  

*Get Class Definition*

**Description**

Get the definition of a class.

**Usage**

```r
getClass (Class, .Force = FALSE, where)
getClassDef(Class, where, package, inherits = TRUE)
```
Arguments

Class the character-string name of the class, often with a "package" attribute as noted below under package.

Force if TRUE, return NULL if the class is undefined; otherwise, an undefined class results in an error.

where environment from which to begin the search for the definition; by default, start at the top-level (global) environment and proceed through the search list.

package the name or environment of the package asserted to hold the definition. If it is a non-empty string it is used instead of where, as the first place to look for the class. Note that the package must be loaded but need not be attached. By default, the package attribute of the Class argument is used, if any. There will usually be a package attribute if Class comes from class(x) for some object.

inherits logical; should the class definition be retrieved from any enclosing environment and also from the cache? If FALSE only a definition in the environment where will be returned.

Details

Class definitions are stored in metadata objects in a package namespace or other environment where they are defined. When packages are loaded, the class definitions in the package are cached in an internal table. Therefore, most calls to getClassDef will find the class in the cache or fail to find it at all, unless inherits is FALSE, in which case only the environment(s) defined by package or where are searched.

The class cache allows for multiple definitions of the same class name in separate environments, with of course the limitation that the package attribute or package name must be provided in the call to

Value

The object defining the class. If the class definition is not found, getClassDef returns NULL, while getClass, which calls getClassDef, either generates an error or, if .Force is TRUE, returns a simple definition for the class. The latter case is used internally, but is not typically sensible in user code.

The non-null returned value is an object of class classRepresentation.

Use functions such as setClass and setClassUnion to create class definitions.

classRepresentation, setClass, isClass.

Examples

gClass("numeric") ## a built in class

cld <- getClass("thisIsAnUndefinedClass", .Force = TRUE)
cld ## a NULL prototype
## If you are really curious:
getMethod

Get or Test for the Definition of a Method

Description

The function selectMethod() returns the method that would be selected for a call to function f if the arguments had classes as specified by signature. Failing to find a method is an error, unless argument optional = TRUE, in which case NULL is returned.

The function findMethod() returns a list of environments that contain a method for the specified function and signature; by default, these are a subset of the packages in the current search list. See section “Using findMethod()” for details.

The function getMethod() returns the method corresponding to the function and signature supplied similarly to selectMethod, but without using inheritance or group generics.

The functions hasMethod() and existsMethod() test whether selectMethod() or getMethod(), respectively, finds a matching method.

Usage

selectMethod(f, signature, optional = FALSE, useInherited = , mlist = , fdef = , verbose = , doCache = )

findMethod(f, signature, where)

getMethod(f, signature = character(), where, optional = FALSE, mlist, fdef)

existsMethod(f, signature = character(), where)

hasMethod(f, signature = character(), where)

Arguments

f
signature
where
optional
mlist, fdef, useInherited, verbose, doCache

a generic function or the character-string name of one.
the signature of classes to match to the arguments of f. See the details below.
the environment in which to look for the method(s). By default, if the call comes from the command line, the table of methods defined in the generic function itself is used, except for findMethod (see the section below).
if the selection in selectMethod does not find a valid method an error is generated, unless optional is TRUE, in which case the value returned is NULL.
optional arguments to getMethod and selectMethod for internal use. Avoid these: some will work as expected and others will not, and none of them is required for normal use of the functions. But see the section “Methods for as()” for nonstandard inheritance.
Details

The signature argument specifies classes, corresponding to formal arguments of the generic function; to be precise, to the signature slot of the generic function object. The argument may be a vector of strings identifying classes, and may be named or not. Names, if supplied, match the names of those formal arguments included in the signature of the generic. That signature is normally all the arguments except .... However, generic functions can be specified with only a subset of the arguments permitted, or with the signature taking the arguments in a different order.

It’s a good idea to name the arguments in the signature to avoid confusion, if you’re dealing with a generic that does something special with its signature. In any case, the elements of the signature are matched to the formal signature by the same rules used in matching arguments in function calls (see match.call).

The strings in the signature may be class names, "missing" or "ANY". See Methods_Details for the meaning of these in method selection. Arguments not supplied in the signature implicitly correspond to class "ANY"; in particular, giving an empty signature means to look for the default method.

A call to getMethod returns the method for a particular function and signature. The search for the method makes no use of inheritance.

The function selectMethod also looks for a method given the function and signature, but makes full use of the method dispatch mechanism; i.e., inherited methods and group generics are taken into account just as they would be in dispatching a method for the corresponding signature, with the one exception that conditional inheritance is not used. Like getMethod, selectMethod returns NULL or generates an error if the method is not found, depending on the argument optional.

Both selectMethod and getMethod will normally use the current version of the generic function in the R session, which has a table of the methods obtained from all the packages loaded in the session. Optional arguments can cause a search for the generic function from a specified environment, but this is rarely a useful idea. In contrast, findMethod has a different default and the optional where argument may be needed. See the section “Using findMethod()”.

The functions existsMethod and hasMethod return TRUE or FALSE according to whether a method is found, the first corresponding to getMethod (no inheritance) and the second to selectMethod.

Value

The call to selectMethod or getMethod returns the selected method, if one is found. (This class extends function, so you can use the result directly as a function if that is what you want.) Otherwise an error is thrown if optional is FALSE and NULL is returned if optional is TRUE.

The returned method object is a MethodDefinition object, except that the default method for a primitive function is required to be the primitive itself. Note therefore that the only reliable test that the search failed is is.null().

The returned value of findMethod is a list of environments in which a corresponding method was found; that is, a table of methods including the one specified.

Using findMethod()

As its name suggests, this function is intended to behave like find, which produces a list of the packages on the current search list which have, and have exported, the object named. That’s what findMethod does also, by default. The “exported” part in this case means that the package’s namespace has an exportMethods directive for this generic function.

An important distinction is that the absence of such a directive does not prevent methods from the package from being called once the package is loaded. Otherwise, the code in the package could not use un-exported methods.
So, if your question is whether loading package thisPkg will define a method for this function and signature, you need to ask that question about the namespace of the package:

```r
findMethod(f, signature, where = asNamespace("thisPkg"))
```

If the package did not export the method, attaching it and calling `findMethod` with no where argument will not find the method.

Notice also that the length of the signature must be what the corresponding package used. If `thisPkg` had only methods for one argument, only length-1 signatures will match (no trailing "ANY"), even if another currently loaded package had signatures with more arguments.

### Methods for `as()`

The function `setAs` allows packages to define methods for coercing one class of objects to another class. This works internally by defining methods for the generic function `coerce(from, to)`, which cannot be called directly.

The R evaluator selects methods for this purpose using a different form of inheritance. While methods can be inherited for the object being coerced, they cannot inherit for the target class, since the result would not be a valid object from that class. If you want to examine the selection procedure, you must supply the optional argument `useInherited = c(TRUE, FALSE)` to `selectMethod`.

### See Also

`Methods_Details` for the details of method selection; `GenericFunctions` for other functions manipulating methods and generic function objects; `MethodDefinition` for the class that represents method definitions.

### Examples

```r
testFun <- function(x)x
setGeneric("testFun")
setMethod("testFun", "numeric", function(x)x+1)

hasMethod("testFun", "numeric") # TRUE
hasMethod("testFun", "integer") # TRUE, inherited
existsMethod("testFun", "integer") # FALSE
hasMethod("testFun") # TRUE, default method
hasMethod("testFun", "ANY")
```
The Name associated with a Given Package

Description

The functions below produce the package associated with a particular environment or position on the search list, or of the package containing a particular function. They are primarily used to support computations that need to differentiate objects on multiple packages.

Usage

getPackageName(where, create = TRUE)
setPackageName(pkg, env)

packageSlot(object)
packageSlot(object) <- value

Arguments

where the environment or position on the search list associated with the desired package.
object object providing a character string name, plus the package in which this object is to be found.
value the name of the package.
create flag, should a package name be created if none can be inferred? If TRUE and no non-empty package name is found, the current date and time are used as a package name, and a warning is issued. The created name is stored in the environment if that environment is not locked.

pkg, env make the string in pkg the internal package name for all computations that set class and method definitions in environment env.

Details

Package names are normally installed during loading of the package, by the INSTALL script or by the library function. (Currently, the name is stored as the object .packageName but don’t trust this for the future.)

Value

getPackageName returns the character-string name of the package (without the extraneous "package:" found in the search list).
packageSlot returns or sets the package name slot (currently an attribute, not a formal slot, but this may change someday).

setPackageName can be used to establish a package name in an environment that would otherwise not have one. This allows you to create classes and/or methods in an arbitrary environment, but it is usually preferable to create packages by the standard R programming tools (package.skeleton, etc.)
See Also

search, packageName

Examples

## all the following usually return "base"
getPackageName(length(search()))
getPackageName(baseenv())
getPackageName(asNamespace("base"))
getPackageName("package:base")

hasArg

Look for an Argument in the Call

Description

Returns TRUE if name corresponds to an argument in the call, either a formal argument to the function, or a component of . . . , and FALSE otherwise.

Usage

hasArg(name)

Arguments

name

The name of a potential argument, as an unquoted name or character string.

Details

The expression hasArg(x), for example, is similar to !missing(x), with two exceptions. First, hasArg will look for an argument named x in the call if x is not a formal argument to the calling function, but . . . is. Second, hasArg never generates an error if given a name as an argument, whereas missing(x) generates an error if x is not a formal argument.

Value

Always TRUE or FALSE as described above.

See Also

missing

Examples

ftest <- function(x1, ...) c(hasArg(x1), hasArg("y2"))

ftest(1)  ## c(TRUE, FALSE)
ftest(1, 2)  ## c(TRUE, FALSE)
ftest(y2 = 2)  ## c(FALSE, TRUE)
ftest(y = 2)  ## c(FALSE, FALSE) (no partial matching)
ftest(y2 = 2, x = 1)  ## c(TRUE, TRUE) partial match x1
**Manage Implicit Versions of Generic Functions**

**Description**

The implicit generic mechanism stores generic versions of functions in a table in a package. The package does not want the current version of the function to be a generic, however, and retains the non-generic version.

When a call to `setMethod` or `setGeneric` creates a generic version for one of these functions, the object in the table is used. This mechanism is only needed if special arguments were used to create the generic: e.g., the signature or the valueClass options.

Function `implicitGeneric()` returns the implicit generic version, `setGenericImplicit()` turns a generic implicit, `prohibitGeneric()` prevents your function from being made generic, and `registerImplicitGenerics()` saves a set of implicit generic definitions in the cached table of the current session.

**Usage**

```r
implicitGeneric(name, where, generic)
setGenericImplicit(name, where, restore = TRUE)
prohibitGeneric(name, where)
registerImplicitGenerics(what, where)
```

**Arguments**

- `name`: Character string name of the function.
- `where`: Package or environment in which to register the implicit generics. When using the functions from the top level of your own package source, this argument should be omitted.
- `generic`: Obsolete, and likely to be deprecated.
- `restore`: Should the non-generic version of the function be restored?.
- `what`: Optional table of the implicit generics to register, but nearly always omitted, when it defaults to a standard metadata name.

**Details**

Multiple packages may define methods for the same function, to apply to classes defined in that package. Arithmetic and other operators, `plot()` and many other basic computations are typical examples. It’s essential that all such packages write methods for the same definition of the generic function. So long as that generic uses the default choice for signature and other parameters, nothing needs to be done.

If the generic has special properties, these need to be ensured for all packages creating methods for it. The simplest solution is just to make the function generic in the package that originally owned it. If for some reason the owner(s) of that package are unwilling to do this, the alternative is to define the correct generic, save it in a special table and restore the non-generic version by calling `setGenericImplicit`.

Note that the package containing the function can define methods for the implicit generic as well; when the implicit generic is made a real generic, those methods will be included.
The usual reason for having a non-default implicit generic is to provide a non-default signature, and the usual reason for that is to allow lazy evaluation of some arguments. All arguments in the signature of a generic function must be evaluated at the time the function needs to select a method. In the base function `with()` in the example below, evaluation of the argument `expr` must be delayed; therefore, it is excluded from the signature.

If you want to completely prohibit anyone from turning your function into a generic, call `prohibitGeneric()`.

Function `implicitGeneric()` returns the implicit generic version of the named function. If there is no table of these or if this function is not in the table, the result of a simple call `setGeneric(name)` is returned.

**Value**

Function `implicitGeneric()` returns the implicit generic definition (and caches that definition the first time if it has to construct it).

The other functions exist for their side effect and return nothing useful.

**Implicit Generics for Base Functions**

Implicit generic versions exist for some functions in the packages supplied in the distribution of R itself. These are stored in the `methods` package itself and will always be available.

As emphasized repeatedly in the documentation, `setGeneric()` calls for a function in another package should never have non-default settings for arguments such as `signature`. The reasoning applies specially to functions in supplied packages, since methods for these are likely to exist in multiple packages. A call to `implicitGeneric()` will show the generic version.

**See Also**

`setGeneric`

**Examples**

```r
### How we would make the function with() into a generic:

## Since the second argument, 'expr' is used literally, we want
## with() to only have "data" in the signature.

## Not run:
setGeneric("with", signature = "data")
## Now we could predefined methods for "with" if we wanted to.

## When ready, we store the generic as implicit, and restore the original
setGenericImplicit("with")

## End(Not run)
implicitGeneric("with")

# (This implicit generic is stored in the 'methods' package.)
```
inheritedSlotNames  Names of Slots Inherited From a Super Class

Description
For a class (or class definition, see getClass and the description of class classRepresentation), give the names which are inherited from “above”, i.e., super classes, rather than by this class’ definition itself.

Usage
inheritedSlotNames(Class, where = topenv(parent.frame()))

Arguments
Class character string or classRepresentation, i.e., resulting from getClass.
where environment, to be passed further to isClass and getClass.

Value
character vector of slot names, or NULL.

See Also
slotNames, slot, setClass, etc.

Examples
.srch <- search()
library(stats4)
inheritedSlotNames("mle")

if(require("Matrix", quietly = TRUE)) withAutoprint({
inheritedSlotNames("Matrix")  # NULL
## whereas
inheritedSlotNames("sparseMatrix") # --> Dim & Dimnames
## i.e. inherited from "Matrix" class
cl <- getClass("dgCMatrix")    # six slots, etc
inheritedSlotNames(cl) # *all* six slots are inherited
})
## Not run:
## detach package we've attached above:
for(n in rev(which(is.na(match(search(), .srch))))
  try( detach(pos = n) )
## End(Not run)
Methods to Initialize New Objects from a Class

Description

The arguments to function `new` to create an object from a particular class can be interpreted specially for that class, by the definition of a method for function `initialize` for the class. This documentation describes some existing methods, and also outlines how to write new ones.

Methods

`signature(.Object = "ANY")` The default method for `initialize` takes either named or unnamed arguments. Argument names must be the names of slots in this class definition, and the corresponding arguments must be valid objects for the slot (that is, have the same class as specified for the slot, or some superclass of that class). If the object comes from a superclass, it is not coerced strictly, so normally it will retain its current class (specifically, `as(object, Class, strict = FALSE)`).

Unnamed arguments must be objects of this class, or one of its superclasses, or one of its subclasses (from the class, from a class this class extends, or from a class that extends this class). If the object is from a superclass, this normally defines some of the slots in the object.

If the object is from a subclass, the new object is that argument, coerced to the current class. Unnamed arguments are processed first, in the order they appear. Then named arguments are processed. Therefore, explicit values for slots always override any values inferred from superclass or subclass arguments.

`signature(.Object = "traceable")` Objects of a class that extends `traceable` are used to implement debug tracing (see class `traceable` and `trace`).

The `initialize` method for these classes takes special arguments `def, tracer, exit, at, print`. The first of these is the object to use as the original definition (e.g., a function). The others correspond to the arguments to `trace`.

`signature(.Object = "environment"), signature(.Object = ".environment")` The `initialize` method for environments takes a named list of objects to be used to initialize the environment. Subclasses of "environment" inherit an initialize method through ".environment", which has the additional effect of allocating a new environment. If you define your own method for such a subclass, be sure either to call the existing method via `callNextMethod` or allocate an environment in your method, since environments are references and are not duplicated automatically.

`signature(.Object = "signature")` This is a method for internal use only. It takes an optional `functionDef` argument to provide a generic function with a signature slot to define the argument names. See `Methods_Details` for details.

Writing Initialization Methods

Initialization methods provide a general mechanism corresponding to generator functions in other languages.

The arguments to `initialize` are `.Object` and `...`. Nearly always, `initialize` is called from `new`, not directly. The `.Object` argument is then the prototype object from the class.

Two techniques are often appropriate for `initialize` methods: special argument names and `callNextMethod`.
You may want argument names that are more natural to your users than the (default) slot names. These will be the formal arguments to your method definition, in addition to .Object (always) and ...(optionally). For example, the method for class "traceable" documented above would be created by a call to setMethod of the form:

```r
setMethod("initialize", "traceable",
  function(.Object, def, tracer, exit, at, print) { .... })
```

In this example, no other arguments are meaningful, and the resulting method will throw an error if other names are supplied.

When your new class extends another class, you may want to call the initialize method for this superclass (either a special method or the default). For example, suppose you want to define a method for your class, with special argument x, but you also want users to be able to set slots specifically. If you want x to override the slot information, the beginning of your method definition might look something like this:

```r
function(.Object, x, ...) {
  Object <- callNextMethod(.Object, ...)
  if(!missing(x)) { # do something with x
```

You could also choose to have the inherited method override, by first interpreting x, and then calling the next method.

---

**Introduction**

Basic use of S4 Methods and Classes

**Description**

The majority of applications using methods and classes will be in R packages implementing new computations for an application, using new classes of objects that represent the data and results. Computations will be implemented using methods that implement functional computations when one or more of the arguments is an object from these classes.

Calls to the functions `setClass()` define the new classes; calls to `setMethod` define the methods. These, along with ordinary R computations, are sufficient to get started for most applications.

Classes are defined in terms of the data in them and what other classes of data they inherit from. Section ‘Defining Classes’ outlines the basic design of new classes.

Methods are R functions, often implementing basic computations as they apply to the new classes of objects. Section ‘Defining Methods’ discusses basic requirements and special tools for defining methods.

The classes discussed here are the original functional classes. R also supports formal classes and methods similar to those in other languages such as Python, in which methods are part of class definitions and invoked on an object. These are more appropriate when computations expect references to objects that are persistent, making changes to the object over time. See ReferenceClasses and Chapter 9 of the reference for the choice between these and S4 classes.
Defining Classes

All objects in \( R \) belong to a class; ordinary vectors and other basic objects are built-in (\texttt{builtin-class}). A new class is defined in terms of the named \texttt{slots} that it has and/or in terms of existing classes that it inherits from, or \texttt{contains} (discussed in ‘Class Inheritance’ below). A call to \texttt{setClass()} names a new class and uses the corresponding arguments to define it.

For example, suppose we want a class of objects to represent a collection of positions, perhaps from GPS readings. A natural way to think of these in \( R \) would have vectors of numeric values for latitude, longitude and altitude. A class with three corresponding slots could be defined by:

```r
Pos <- setClass("Pos", slots = c(latitude = "numeric", longitude = "numeric", altitude = "numeric"))
```

The value returned is a function, typically assigned as here with the name of the class. Calling this function returns an object from the class; its arguments are named with the slot names. If a function in the class had read the corresponding data, perhaps from a CSV file or from a database, it could return an object from the class by:

```r
Pos(latitude = x, longitude = y, altitude = z)
```

The slots are accessed by the \texttt{@} operator; for example, if \( g \) is an object from the class, \( g@latitude \).

In addition to returning a generator function the call to \texttt{setClass()} assigns a definition of the class in a special metadata object in the package’s namespace. When the package is loaded into an \( R \) session, the class definition is added to a table of known classes.

To make the class and the generating function publicly available, the package should include \texttt{Pos} in \texttt{exportClasses()} and \texttt{export()} directives in its \texttt{NAMESPACE} file:

```r
exportClasses(Pos); export(Pos)
```

Defining Methods

Defining methods for an \( R \) function makes that function \textit{generic}. Instead of a call to the function always being carried out by the same method, there will be several alternatives. These are selected by matching the classes of the arguments in the call to a table in the generic function, indexed by classes for one or more formal arguments to the function, known as the \textit{signatures} for the methods.

A method definition then specifies three things: the name of the function, the signature and the method definition itself. The definition must be a function with the same formal arguments as the generic.

For example, a method to make a plot of an object from class \"Pos\" could be defined by:

```r
setMethod("plot", c("Pos", "missing"), function(x, y, ...) { plotPos(x, y) })
```

This method will match a call to \texttt{plot()} if the first argument is from class \"Pos\" or a subclass of that. The second argument must be missing; only a missing argument matches that class in the signature. Any object will match class \"ANY\" in the corresponding position of the signature.

Class Inheritance

A class may inherit all the slots and methods of one or more existing classes by specifying the names of the inherited classes in the \texttt{contains =} argument to \texttt{setClass()}.

To define a class that extends class \"Pos\" to a class \"GPS\" with a slot for the observation times:

```r
GPS <- setClass("GPS", slots = c(time = "POSIXt"), contains = "Pos")
```

The inherited classes may be \texttt{S4} classes, \texttt{S3} classes or basic data types. \texttt{S3} classes need to be identified as such by a call to \texttt{setOldClass()}; most \texttt{S3} classes in the base package and many in the other built-in packages are already declared, as is \"POSIXt\". If it had not been, the application package should contain:
is

Is an Object from a Class?

Description

Functions to test inheritance relationships between an object and a class or between two classes (extends).

Usage

is(object, class2)

extends(class1, class2, maybe = TRUE, fullInfo = FALSE)

Arguments

object any R object.

class1, class2 character strings giving the names of each of the two classes between which is relations are to be examined, or (more efficiently) the class definition objects for the classes.

fullInfo In a call to extends, with class2 missing, fullInfo is a flag, which if TRUE causes a list of objects of class $\text{SClassExtension}$ to be returned, rather than just the names of the classes. Only the distance slot is likely to be useful in practice; see the ‘Selecting Superclasses’ section;

maybe What to return for conditional inheritance. But such relationships are rarely used and not recommended, so this argument should not be needed.

Selecting Superclasses

A call to $\text{selectSuperClasses}(cl)$ returns a list of superclasses, similarly to extends($cl$). Additional arguments restrict the class names returned to direct superclasses and/or to non-virtual classes.

Either way, programming with the result, particularly using $\text{sapply}$, can be useful.

To find superclasses with more generally defined properties, one can program with the result returned by extends when called with one class as argument. By default, the call returns a character vector including the name of the class itself and of all its superclasses. Alternatively, if
extends is called with fullInfo = TRUE, the return value is a named list, its names being the previous character vector. The elements of the list corresponding to superclasses are objects of class SClassExtension. Of the information in these objects, one piece can be useful: the number of generations between the classes, given by the "distance" slot.

Programming with the result of the call to extends, particularly using sapply, can select superclasses. The programming technique is to define a test function that returns TRUE for superclasses or relationships obeying some requirement. For example, to find only next-to-direct superclasses, use this function with the list of extension objects:

```r
function(what) is(what, "SClassExtension") && what@distance == 2
```
or, to find only superclasses from "myPkg", use this function with the simple vector of names:

```r
function(what) getClassDef(what)@package == "myPkg"
```

Giving such functions as an argument to sapply called on the output of extends allows you to find superclasses with desired properties. See the examples below.

Note
Prior to R 4.2.0 the code used the first elements of class1 and class2, silently. These are now required to be length-one character vectors.

References
Chambers, John M. (2016) Extending R, Chapman & Hall. (Chapters 9 and 10.)

See Also
Although inherits is defined for S3 classes, it has been modified so that the result returned is nearly always equivalent to is, both for S4 and non-S4 objects. Since it is implemented in C, it is somewhat faster. The only non-equivalences arise from use of setIs, which should rarely be encountered.

Examples
```r
## Not run:
## this example can be run if package XRPython from CRAN is installed.
supers <- extends("PythonInterface")
## find all the superclasses from package XR
fromXR <- sapply(supers,
  function(what) getClassDef(what)@package == "XR")
## print them
supers[fromXR]

## find all the superclasses at distance 2
superRelations <- extends("PythonInterface", fullInfo = TRUE)
dist2 <- sapply(superRelations,
  function(what) is(what, "SClassExtension") && what@distance == 2)
## print them
names(superRelations)[dist2]

## End(Not run)
```
isSealedMethod

Check for a Sealed Method or Class

Description

These functions check for either a method or a class that has been sealed when it was defined, and which therefore cannot be re-defined.

Usage

isSealedMethod(f, signature, fdef, where)

isSealedClass(Class, where)

Arguments

f
The quoted name of the generic function.

signature
The class names in the method’s signature, as they would be supplied to setMethod.

fdef
Optional, and usually omitted: the generic function definition for f.

Class
The quoted name of the class.

where
where to search for the method or class definition. By default, searches from the top environment of the call to isSealedMethod or isSealedClass, typically the global environment or the namespace of a package containing a call to one of the functions.

Details

In the R implementation of classes and methods, it is possible to seal the definition of either a class or a method. The basic classes (numeric and other types of vectors, matrix and array data) are sealed. So also are the methods for the primitive functions on those data types. The effect is that programmers cannot re-define the meaning of these basic data types and computations. More precisely, for primitive functions that depend on only one data argument, methods cannot be specified for basic classes. For functions (such as the arithmetic operators) that depend on two arguments, methods can be specified if one of those arguments is a basic class, but not if both are.

Programmers can seal other class and method definitions by using the sealed argument to setClass or setMethod.

Value

The functions return FALSE if the method or class is not sealed (including the case that it is not defined); TRUE if it is.

References

Chambers, John M. (1998) Programming with Data Springer (For the original S4 version.)
Examples

```r
## these are both TRUE
isSealedMethod("+", c("numeric", "character"))
isSealedClass("matrix")

setClass("track", slots = c(x="numeric", y="numeric"))
## but this is FALSE
isSealedClass("track")
## and so is this
isSealedClass("A Name for an undefined Class")
## and so are these, because only one of the two arguments is basic
isSealedMethod("+", c("track", "numeric"))
isSealedMethod("+", c("numeric", "track"))
```

Description

The virtual class "language" and the specific classes that extend it represent unevaluated objects, as produced for example by the parser or by functions such as `quote`.

Usage

```r
### each of these classes corresponds to an unevaluated object
### in the S language.
### The class name can appear in method signatures,
### and in a few other contexts (such as some calls to as()).

"<-
"call"
"for"
"if"
"repeat"
"while"
"name"
"("

### Each of the classes above extends the virtual class "language"
```

Objects from the Class

"language" is a virtual class; no objects may be created from it.

Objects from the other classes can be generated by a call to `new(Class, ...)`, where `Class` is the quoted class name, and the ...arguments are either empty or a single object that is from this class (or an extension).
Methods

coerce signature(from = "ANY", to = "call"). A method exists for as(object, "call"), calling as.call().

Examples

showClass("language")

is( quote(sin(x)) ) # "call" "language"

(ff <- new("if")) ; is(ff) # "if" "language"

(ff <- new("for")) ; is(ff) # "for" "language"

LinearMethodsList-class

Class "LinearMethodsList"

Description

A version of methods lists that has been 'linearized' for producing summary information. The actual objects from class "MethodsList" used for method dispatch are defined recursively over the arguments involved.

Objects from the Class

The function linearizeMlist converts an ordinary methods list object into the linearized form.

Slots

methods: Object of class "list", the method definitions.

arguments: Object of class "list", the corresponding formal arguments, namely as many of the arguments in the signature of the generic function as are active in the relevant method table.

classes: Object of class "list", the corresponding classes in the signatures.

generic: Object of class "genericFunction"; the generic function to which the methods correspond.

Future Note

The current version of linearizeMlist does not take advantage of the MethodDefinition class, and therefore does more work for less effect than it could. In particular, we may move to redefine both the function and the class to take advantage of the stored signatures. Don’t write code depending precisely on the present form, although all the current information will be obtainable in the future.

See Also

Function linearizeMlist for the computation, and class MethodsList for the original, recursive form.
LocalReferenceClasses  

**Description**

Local reference classes are modified ReferenceClasses that isolate the objects to the local frame. Therefore, they do not propagate changes back to the calling environment. At the same time, they use the reference field semantics locally, avoiding the automatic duplication applied to standard R objects.

The current implementation has no special construction. To create a local reference class, call `setRefClass()` with a `contains=` argument that includes "localRefClass". See the example below.

Local reference classes operate essentially as do regular, functional classes in R; that is, changes are made by assignment and take place in the local frame. The essential difference is that replacement operations (like the change to the `twiddle` field in the example) do not cause duplication of the entire object, as would be the case for a formal class or for data with attributes or in a named list. The purpose is to allow large objects in some fields that are not changed along with potentially frequent changes to other fields, but without copying the large fields.

**Usage**

```r
setRefClass(Class, fields = , contains = c("localRefClass",....),
    methods =, where =, ...)
```

**Details**

Localization of objects is only partially automated in the current implementation. Replacement expressions using the `$<-$` operator are safe.

However, if reference methods for the class themselves modify fields, using `<<-`, for example, then one must ensure that the object is local to the relevant frame before any such method is called. Otherwise, standard reference class behavior still prevails.

There are two ways to ensure locality. The direct way is to invoke the special method `x$ensureLocal()` on the object. The other way is to modify a field explicitly by `x$field <- ...` It’s only necessary that one or the other of these happens once for each object, in order to trigger the shallow copy that provides locality for the references. In the example below, we show both mechanisms.

However it’s done, localization must occur before any methods make changes. (Eventaully, some use of code tools should at least largely automate this process, although it may be difficult to guarantee success under arbitrary circumstances.)

**Author(s)**

John Chambers

**Examples**

```r
## class "myIter" has a BigData field for the real (big) data
## and a "twiddle" field for some parameters that it twiddles
## ( for some reason)
```
myIter <- setRefClass("myIter", contains = "localRefClass",
    fields = list(BigData = "numeric", twiddle = "numeric"))

tw <- rnorm(3)
x1 <- myIter(BigData = rnorm(1000), twiddle = tw) # OK, not REALLY big

twiddler <- function(x, n) {
    x$ensureLocal() # see the Details. Not really needed in this example
    for(i in seq_len(n)) {
        x$twiddle <- x$twiddle + rnorm(length(x$twiddle))
        ## then do something ....
        ## Snooping in gdb, etc will show that x$BigData is not copied
    }
    return(x)
}

x2 <- twiddler(x1, 10)

stopifnot(identical(x1$twiddle, tw), !identical(x1$twiddle, x2$twiddle))

makeClassRepresentation

Create a Class Definition

Description

Constructs an object of class classRepresentation to describe a particular class. Mostly a utility function, but you can call it to create a class definition without assigning it, as setClass would do.

Usage

makeClassRepresentation(name, slots=list(), superClasses=character(),
    prototype=NULL, package, validity, access,
    version, sealed, virtual=NA, where)

Arguments

name character string name for the class
slots named list of slot classes as would be supplied to setClass, but without the
    unnamed arguments for superClasses if any.
superClasses what classes does this class extend
prototype an object providing the default data for the class, e.g., the result of a call to
    prototype.
package The character string name for the package in which the class will be stored; see
    getPackageName.
validity Optional validity method. See validObject, and the discussion of validity
    methods in the reference.
access Access information. Not currently used.
version Optional version key for version control. Currently generated, but not used.
sealed  Is the class sealed? See setClass.
virtual Is this known to be a virtual class?
where   The environment from which to look for class definitions needed (e.g., for slots or superclasses). See the discussion of this argument under GenericFunctions.

References
Chambers, John M. (1998) Programming with Data Springer (For the original S4 version.)

See Also
setClass

method.skeleton  Create a Skeleton File for a New Method

Description
This function writes a source file containing a call to setMethod to define a method for the generic function and signature supplied. By default the method definition is in line in the call, but can be made an external (previously assigned) function.

Usage
method.skeleton(generic, signature, file, external = FALSE, where)

Arguments
generic  the character string name of the generic function, or the generic function itself. In the first case, the function need not currently be a generic, as it would not for the resulting call to setMethod.
signature the method signature, as it would be given to setMethod
file     a character string name for the output file, or a writable connection. By default the generic function name and the classes in the signature are concatenated, with separating underscore characters. The file name should normally end in ".R". To write multiple method skeletons to one file, open the file connection first and then pass it to method.skeleton() in multiple calls.
external  flag to control whether the function definition for the method should be a separate external object assigned in the source file, or included in line in the call to setMethod. If supplied as a character string, this will be used as the name for the external function; by default the name concatenates the generic and signature names, with separating underscores.
where    The environment in which to look for the function; by default, the top-level environment of the call to method.skeleton.

Value
The file argument, invisibly, but the function is used for its side effect.

**MethodsList-class**

**Class "MethodsList", Defunct Representation of Methods**

**Description**

This class of objects was used in the original implementation of the package to control method dispatch. Its use is now defunct, but object appear as the default method slot in generic functions. This and any other remaining uses will be removed in the future.

For the modern alternative, see `listOfMethods`.

The details in this documentation are retained to allow analysis of old-style objects.

**Details**

Suppose a function \( f \) has formal arguments \( x \) and \( y \). The methods list object for that function has the object as `name("x")` as its argument slot. An element of the methods named "track" is selected if the actual argument corresponding to \( x \) is an object of class "track". If there is such an element, it can generally be either a function or another methods list object.

In the first case, the function defines the method to use for any call in which \( x \) is of class "track". In the second case, the new methods list object defines the available methods depending on the remaining formal arguments, in this example, \( y \).

Each method corresponds conceptually to a signature; that is a named list of classes, with names corresponding to some or all of the formal arguments. In the previous example, if selecting class "track" for \( x \), finding that the selection was another methods list and then selecting class "numeric" for \( y \) would produce a method associated with the signature \( x = \"track\", y = \"numeric\" \).
Slots

argument: Object of class "name". The name of the argument being used for dispatch at this level.
methods: A named list of the methods (and method lists) defined explicitly for this argument. The names are the names of classes, and the corresponding element defines the method or methods to be used if the corresponding argument has that class. See the details below.
allMethods: A named list, contains all the directly defined methods from the methods slot, plus any inherited methods. Ignored when methods tables are used for dispatch (see Methods_Details).

Extends

Class "OptionalMethods", directly.

General Information on Methods

Description

This documentation covers some general topics on how methods work and how the methods package interacts with the rest of R. The information is usually not needed to get started with methods and classes, but may be helpful for moderately ambitious projects, or when something doesn’t work as expected.

For additional information see documentation for the important steps: (setMethod(), setClass() and setGeneric()). Also Methods_for_Nongenerics on defining formal methods for functions that are not currently generic functions; Methods_for_S3 for the relation to S3 classes and methods; Classes_Details for class definitions and Chapters 9 and 10 of the reference.

How Methods Work

A call to a generic function selects a method matching the actual arguments in the call. The body of the method is evaluated in the frame of the call to the generic function. A generic function is identified by its name and by the package to which it correspond. Unlike ordinary functions, the generic has a slot that specifies its package.

In an R session, there is one version of each such generic, regardless of where the call to that generic originated, and the generic function has a table of all the methods currently available for it; that is, all the methods in packages currently loaded into the session.

Methods are frequently defined for functions that are non-generic in their original package, for example, for function plot() in package graphics. An identical version of the corresponding generic function may exist in several packages. All methods will be dispatched consistently from the R session.

Each R package with a call to setMethod in its source code will include a methods metadata object for that generic. When the package is loaded into an R session, the methods for each generic function are cached, that is, added to the environment of the generic function. This merged table of methods is used to dispatch or select methods from the generic, using class inheritance and possibly group generic functions (see GroupGenericFunctions) to find an applicable method. See the “Method Selection and Dispatch” section below. The caching computations ensure that only one version of each generic function is visible globally; although different attached packages may contain a copy of the generic function, these behave identically with respect to method selection.
Methods_Details

In contrast, it is possible for the same function name to refer to more than one generic function, when these have different package slots. In the latter case, \( \mathbb{R} \) considers the functions unrelated: A generic function is defined by the combination of name and package. See the “Generic Functions” section below.

The methods for a generic are stored according to the corresponding signature in the call to \texttt{setMethod} that defined the method. The signature associates one class name with each of a subset of the formal arguments to the generic function. Which formal arguments are available, and the order in which they appear, are determined by the "signature" slot of the generic function itself. By default, the signature of the generic consists of all the formal arguments except \ldots, in the order they appear in the function definition.

Trailing arguments in the signature of the generic will be inactive if no method has yet been specified that included those arguments in its signature. Inactive arguments are not needed or used in labeling the cached methods. (The distinction does not change which methods are dispatched, but ignoring inactive arguments improves the efficiency of dispatch.)

All arguments in the signature of the generic function will be evaluated when the function is called, rather than using lazy evaluation. Therefore, it’s important to exclude from the signature any arguments that need to be dealt with symbolically (such as the \texttt{expr} argument to function \texttt{with}). Note that only actual arguments are evaluated, not default expressions. A missing argument enters into the method selection as class "missing".

The cached methods are stored in an environment object. The names used for assignment are a concatenation of the class names for the active arguments in the method signature.

\textbf{Method Selection: Details}

When a call to a generic function is evaluated, a method is selected corresponding to the classes of the actual arguments in the signature. First, the cached methods table is searched for an exact match; that is, a method stored under the signature defined by the string value of \texttt{class(x)} for each non-missing argument, and "missing" for each missing argument. If no method is found directly for the actual arguments in a call to a generic function, an attempt is made to match the available methods to the arguments by using the superclass information about the actual classes. A method found by this search is cached in the generic function so that future calls with the same argument classes will not require repeating the search. In any likely application, the search for inherited methods will be a negligible overhead.

Each class definition may include a list of one or more direct superclasses of the new class. The simplest and most common specification is by the \texttt{contains=} argument in the call to \texttt{setClass}. Each class named in this argument is a superclass of the new class. A class will also have as a direct superclass any class union to which it is a member. Class unions are created by a call to \texttt{setClassUnion}. Additional members can be added to the union by a simple call to \texttt{setIs}. Superclasses specified by either mechanism are the direct superclasses.

Inheritance specified in either of these forms is simple in the sense that all the information needed for the superclass is asserted to be directly available from the object. \( \mathbb{R} \) inherited from \( S \) a more general form of inheritance in which inheritance may require some transformation or be conditional on a test. This more general form has not proved to be useful in general practical situations. Since it also adds some computational costs non-simple inheritance is not recommended. See \texttt{setIs} for the general version.

The direct superclasses themselves may have direct superclasses and similarly through further generations. Putting all this information together produces the full list of superclasses for this class. The superclass list is included in the definition of the class that is cached during the \( \mathbb{R} \) session. The distance between the two classes is defined to be the number of generations: 1 for direct superclasses (regardless of which mechanism defined them), then 2 for the direct superclasses of those classes, and so on. To see all the superclasses, with their distance, print the class definition by calling
**Methods_Details**

**getClass.** In addition, any class implicitly has class "ANY" as a superclass. The distance to "ANY" is treated as larger than the distance to any actual class. The special class "missing" corresponding to missing arguments has only "ANY" as a superclass, while "ANY" has no superclasses.

When a method is to be selected by inheritance, a search is made in the table for all methods corresponding to a combination of either the direct class or one of its superclasses, for each argument in the active signature. For an example, suppose there is only one argument in the signature and that the class of the corresponding object was "dgeMatrix" (from the recommended package Matrix). This class has (currently) three direct superclasses and through these additional superclasses at distances 2 through 4. A method that had been defined for any of these classes or for class "ANY" (the default method) would be eligible. Methods for the shortest difference are preferred. If there is only one best method in this sense, method selection is unambiguous.

When there are multiple arguments in the signature, each argument will generate a similar list of inherited classes. The possible matches are now all the combinations of classes from each argument (think of the function outer generating an array of all possible combinations). The search now finds all the methods matching any of this combination of classes. For each argument, the distance to the superclass defines which method(s) are preferred for that argument. A method is considered best for selection if it is among the best (i.e., has the least distance) for each argument.

The end result is that zero, one or more methods may be “best”. If one, this method is selected and cached in the table of methods. If there is only one best match, the selection is ambiguous and a message is printed noting which method was selected (the first method lexicographically in the ordering) and what other methods could have been selected. Since the ambiguity is usually nothing the end user could control, this is not a warning. Package authors should examine their package for possible ambiguous inheritance by calling testInheritedMethods.

Cached inherited selections are not themselves used in future inheritance searches, since that could result in invalid selections. If you want inheritance computations to be done again (for example, because a newly loaded package has a more direct method than one that has already been used in this session), call resetGeneric. Because classes and methods involving them tend to come from the same package, the current implementation does not reset all generics every time a new package is loaded.

Besides being initiated through calls to the generic function, method selection can be done explicitly by calling the function selectMethod. Note that some computations may use this function directly, with optional arguments. The prime example is the use of coerce() methods by function as(). There has been some confusion from comparing coerce methods to a call to selectMethod with other options.

**Method Evaluation: Details**

Once a method has been selected, the evaluator creates a new context in which a call to the method is evaluated. The context is initialized with the arguments from the call to the generic function. These arguments are not rematched. All the arguments in the signature of the generic will have been evaluated (including any that are currently inactive); arguments that are not in the signature will obey the usual lazy evaluation rules of the language. If an argument was missing in the call, its default expression if any will not have been evaluated, since method dispatch always uses class missing for such arguments.

A call to a generic function therefore has two contexts: one for the function and a second for the method. The argument objects will be copied to the second context, but not any local objects created in a nonstandard generic function. The other important distinction is that the parent ("enclosing") environment of the second context is the environment of the method as a function, so that all R programming techniques using such environments apply to method definitions as ordinary functions.

For further discussion of method selection and dispatch, see the references in the sections indicated.
Generic Functions

In principle, a generic function could be any function that evaluates a call to `standardGeneric()`, the internal function that selects a method and evaluates a call to the selected method. In practice, generic functions are special objects that in addition to being from a subclass of class "function" also extend the class `genericFunction`. Such objects have slots to define information needed to deal with their methods. They also have specialized environments, containing the tables used in method selection.

The slots "generic" and "package" in the object are the character string names of the generic function itself and of the package from which the function is defined. As with classes, generic functions are uniquely defined in \( \mathbb{R} \) by the combination of the two names. There can be generic functions of the same name associated with different packages (although inevitably keeping such functions cleanly distinguished is not always easy). On the other hand, \( \mathbb{R} \) will enforce that only one definition of a generic function can be associated with a particular combination of function and package name, in the current session or other active version of \( \mathbb{R} \).

Tables of methods for a particular generic function, in this sense, will often be spread over several other packages. The total set of methods for a given generic function may change during a session, as additional packages are loaded. Each table must be consistent in the signature assumed for the generic function.

\( \mathbb{R} \) distinguishes standard and nonstandard generic functions, with the former having a function body that does nothing but dispatch a method. For the most part, the distinction is just one of simplicity: knowing that a generic function only dispatches a method call allows some efficiencies and also removes some uncertainties.

In most cases, the generic function is the visible function corresponding to that name, in the corresponding package. There are two exceptions, implicit generic functions and the special computations required to deal with \( \mathbb{R} \)'s primitive functions. Packages can contain a table of implicit generic versions of functions in the package, if the package wishes to leave a function non-generic but to constrain what the function would be like if it were generic. Such implicit generic functions are created during the installation of the package, essentially by defining the generic function and possibly methods for it, and then reverting the function to its non-generic form. (See `implicitGeneric` for how this is done.) The mechanism is mainly used for functions in the older packages in \( \mathbb{R} \), which may prefer to ignore S4 methods. Even in this case, the actual mechanism is only needed if something special has to be specified. All functions have a corresponding implicit generic version defined automatically (an implicit, implicit generic function one might say). This function is a standard generic with the same arguments as the non-generic function, with the non-generic version as the default (and only) method, and with the generic signature being all the formal arguments except . . . .

The implicit generic mechanism is needed only to override some aspect of the default definition. One reason to do so would be to remove some arguments from the signature. Arguments that may need to be interpreted literally, or for which the lazy evaluation mechanism of the language is needed, must not be included in the signature of the generic function, since all arguments in the signature will be evaluated in order to select a method. For example, the argument `expr` to the function `with` is treated literally and must therefore be excluded from the signature.

One would also need to define an implicit generic if the existing non-generic function were not suitable as the default method. Perhaps the function only applies to some classes of objects, and the package designer prefers to have no general default method. In the other direction, the package designer might have some ideas about suitable methods for some classes, if the function were generic. With reasonably modern packages, the simple approach in all these cases is just to define the function as a generic. The implicit generic mechanism is mainly attractive for older packages that do not want to require the methods package to be available.
Methods for Non-Generic Functions in Other Packages

Description

In writing methods for an R package, it’s common for these methods to apply to a function (in another package) that is not generic in that package; that is, there are no formal methods for the function in its own package, although it may have S3 methods. The programming in this case involves one extra step, to call `setGeneric()` to declare that the function is generic in your package. Calls to the function in your package will then use all methods defined there or in any other loaded package that creates the same generic function. Similarly, calls to the function in those packages will use your methods.

Method Definitions

All method definitions are stored as objects from the `MethodDefinition` class. Like the class of generic functions, this class extends ordinary R functions with some additional slots: “generic”, containing the name and package of the generic function, and two signature slots, “defined” and “target”, the first being the signature supplied when the method was defined by a call to `setMethod`. The “target” slot starts off equal to the “defined” slot. When an inherited method is cached after being selected, as described above, a copy is made with the appropriate “target” signature. Output from `showMethods`, for example, includes both signatures.

Method definitions are required to have the same formal arguments as the generic function, since the method dispatch mechanism does not rematch arguments, for reasons of both efficiency and consistency.

Methods for Non-Generic Functions in Other Packages
The original version, however, remains non-generic. Calls in that package or in other packages that use that version will not dispatch your methods except for special circumstances:

1. If the function is one of the primitive functions that accept methods, the internal C implementation will dispatch methods if one of the arguments is an S4 object, as should be the case.
2. If the other version of the function dispatches S3 methods and your methods are also registered as S3 methods, the method will usually be dispatched as that S3 method.
3. Otherwise, you will need to ensure that all calls to the function come from a package in which the function is generic, perhaps by copying code to your package.

Details and the underlying reasons are discussed in the following sections.

Generic and Non-Generic Calls

Creating methods for a function (any function) in a package means that calls to the function in that package will select methods according to the actual arguments. However, if the function was originally a non-generic in another package, calls to the function from that package will not dispatch methods. In addition, calls from any third package that imports the non-generic version will also not dispatch methods. This section considers the reason and how one might deal with the consequences.

The reason is simply the R namespace mechanism and its role in evaluating function calls. When a name (such as the name of a function) needs to be evaluated in a call to a function from some package, the evaluator looks first in the frame of the call, then in the namespace of the package and then in the imports to that package.

Defining methods for a function in a package ensures that calls to the function in that package will select the methods, because a generic version of the function is created in the namespace. Similarly, calls from another package that has or imports the generic version will select methods. Because the generic versions are identical, all methods will be available in all these packages.

However, calls from any package that imports the old version or just selects it from the search list will usually not select methods.

A reasonable goal would be to extend the classes of objects that can be included in a data frame by defining methods for \texttt{as.data.frame()} in the base package. This function takes any number of objects as arguments and attempts to combine them as variables into a data frame object. It does this by calling \texttt{as.data.frame()}, also in the base package, for each of the objects.

A reasonable goal would be to extend the classes of objects that can be included in a data frame by defining methods for \texttt{as.data.frame()} in the base package. This function takes any number of objects as arguments and attempts to combine them as variables into a data frame object. It does this by calling \texttt{as.data.frame()}, also in the base package, for each of the objects.

The details of what happens and options for dealing with it depend on the form of the function: a primitive function; a function that dispatches S3 methods; or an ordinary R function.

Primitive functions are not actual R function objects. They go directly to internal C code. Some of them, however, have been implemented to recognize methods. These functions dispatch both S4 and S3 methods from the internal C code. There is no explicit generic function, either S3 or S4. The internal code looks for S4 methods if the first argument, or either of the arguments in the case of a binary operator, is an S4 object. If no S4 method is found, a search is made for an S3 method. So defining methods for these functions works as long as the relevant classes have been defined, which should always be the case.

A function dispatches S3 methods by calling \texttt{UseMethod()}, which does not look for formal methods regardless of whether the first argument is an S4 object or not. This applies to the \texttt{as.data.frame()} example above. To have methods called in this situation, your package must also define the method as an S3 method, if possible. See section ‘S3 “Generic” Functions’.
In the third possibility, the function is defined with no expectation of methods. For example, the base package has a number of functions that compute numerical decompositions of matrix arguments. Some, such as `chol()` and `qr()` are implemented to dispatch S3 methods; others, such as `svd()` are implemented directly as a specific computation. A generic version of the latter functions can be written and called directly to define formal methods, but no code in another package that does not import this generic version will dispatch such methods.

In this case, you need to have the generic version used in all the indirect calls to the function supplying arguments that should dispatch methods. This may require supplying new functions that dispatch methods and then call the function they replace. For example, if S3 methods did not work for `as.data.frame()`, one could call a function that applied the generic version to all its arguments and then called `data.frame()` as a replacement for that function. If all else fails, it might be necessary to copy over the relevant functions so that they would find the generic versions.

### S3 “Generic” Functions

S3 method dispatch looks at the class of the first argument. S3 methods are ordinary functions with the same arguments as the generic function. The “signature” of an S3 method is identified by the name to which the method is assigned, composed of the name of the generic function, followed by “.”, followed by the name of the class. For details, see `UseMethod`.

To implement a method for one of these functions corresponding to S4 classes, there are two possibilities: either an S4 method or an S3 method with the S4 class name. The S3 method is only possible if the intended signature has the first argument and nothing else. In this case, the recommended approach is to define the S3 method and also supply the identical function as the definition of the S4 method. If the S3 generic function was `f3(x, ...)` and the S4 class for the new method was "myClass":

```r
f3.myClass <- function(x, ...) { ..... }
setMethod("f3", "myClass", f3.myClass)
```

Defining both methods usually ensures that all calls to the original function will dispatch the intended method. The S4 method alone would not be called from other packages using the original version of the function. On the other hand, an S3 method alone will not be called if there is any eligible non-default S4 method.

S4 and S3 method selection are designed to follow compatible rules of inheritance, as far as possible. S3 classes can be used for any S4 method selection, provided that the S3 classes have been registered by a call to `setOldClass`, with that call specifying the correct S3 inheritance pattern. S4 classes can be used for any S3 method selection; when an S4 object is detected, S3 method selection uses the contents of `extends(class(x))` as the equivalent of the S3 inheritance (the inheritance is cached after the first call).

An existing S3 method may not behave as desired for an S4 subclass, in which case utilities such as `asS3` and `S3Part` may be useful. If the S3 method fails on the S4 object, `asS3(x)` may be passed instead; if the object returned by the S3 method needs to be incorporated in the S4 object, the replacement function for `S3Part` may be useful.

Examples

```r
## A class that extends a registered S3 class inherits that class' S3 methods.
setClass("myFrame", contains = "data.frame",
slots = c(timestamps = "POSIXt"))
df1 <- data.frame(x = 1:10, y = rnorm(10), z = sample(letters,10))
mydf1 <- new("myFrame", df1, timestamps = Sys.time())

## "myFrame" objects inherit "data.frame" S3 methods; e.g., for `[`
mydf1[1:2, ] # a data frame object (with extra attributes)

## a method explicitly for "myFrame" class
setMethod("[",
signature(x = "myFrame"),
function (x, i, j, ..., drop = TRUE)
{
  S3Part(x) <- callNextMethod()
  x@timestamps <- c(Sys.time(), as.POSIXct(x@timestamps))
  x
}
)
mydf1[1:2, ]

setClass("myDateTime", contains = "POSIXt")

now <- Sys.time() # class(now) is c("POSIXct", "POSIXt")
nowlt <- as.POSIXlt(now)# class(nowLt) is c("POSIXlt", "POSIXt")
mCt <- new("myDateTime", now)
mLt <- new("myDateTime", nowLt)

## S3 methods for an S4 object will be selected using S4 inheritance
## Objects mCt and mLt have different S3Class() values, but this is
## not used.
f3 <- function(x)UseMethod("f3") # an S3 generic to illustrate inheritance

f3.POSIXct <- function(x) "The POSIXct result"
f3.POSIXlt <- function(x) "The POSIXlt result"
f3.POSIXt <- function(x) "The POSIXt result"
stopifnot(identical(f3(mCt), f3.POSIXt(mCt)))
stopifnot(identical(f3(mLt), f3.POSIXt(mLt)))

## An S4 object selects S3 methods according to its S4 "inheritance"
setClass("classA", contains = "numeric",
slots = c(realData = "numeric"))
```
Math.classA <- function(x) { (getFunction(.Generic))(x@realData) }
setMethod("Math", "classA", Math.classA)

x <- new("classA", log(1:10), realData = 1:10)
stopifnot(identical(abs(x), 1:10))

setClass("classB", contains = "classA")

y <- new("classB", x)
stopifnot(identical(abs(y), abs(x))) # (version 2.9.0 or earlier fails here)

## an S3 generic: just for demonstration purposes
f3 <- function(x, ...) UseMethod("f3")

f3.default <- function(x, ...) "Default f3"

## S3 method (only) for classA
f3.classA <- function(x, ...) "Class classA for f3"

## S3 and S4 method for numeric
f3.numeric <- function(x, ...) "Class numeric for f3"
setMethod("f3", "numeric", f3.numeric)

## The S3 method for classA and the closest inherited S3 method for classB
## are not found.

f3(x); f3(y) # both choose "numeric" method

## to obtain the natural inheritance, set identical S3 and S4 methods
setMethod("f3", "classA", f3.classA)

f3(x); f3(y) # now both choose "classA" method

## Need to define an S3 as well as S4 method to use on an S3 object
## or if called from a package without the S4 generic
MathFun <- function(x) { # a smarter "data.frame" method for Math group
  for (i in seq_len(ncol(x))[sapply(x, is.numeric)])
    x[, i] <- (getFunction(.Generic))(x[, i])
  x
}
setMethod("Math", "data.frame", MathFun)

## S4 method works for an S4 class containing data.frame,
## but not for data.frame objects (not S4 objects)

try(logIris <- log(iris)) #gets an error from the old method

## Define an S3 method with the same computation
Math.data.frame <- MathFun

logIris <- log(iris)
The S3 and S4 software in R are two generations implementing functional object-oriented programming. S3 is the original, simpler for initial programming but less general, less formal and less open to validation. The S4 formal methods and classes provide these features but require more programming.

In modern R, the two versions attempt to work together. This documentation outlines how to write methods for both systems by defining an S4 method for a function that dispatches S3 methods. The systems can also be combined by using an S3 class with S4 method dispatch or in S4 class definitions. See setOldClass.

S3 Method Dispatch

The R evaluator will 'dispatch' a method from a function call either when the body of the function calls the special primitive UseMethod or when the call is to one of the builtin primitives such as the math functions or the binary operators.

S3 method dispatch looks at the class of the first argument or the class of either argument in a call to one of the primitive binary operators. In pure S3 situations, 'class' in this context means the class attribute or the implied class for a basic data type such as "numeric". The first S3 method that matches a name in the class is called and the value of that call is the value of the original function call. For details, see S3Methods.

In modern R, a function meth in a package is registered as an S3 method for function fun and class Class by including in the package’s NAMESPACE file the directive

S3method(fun, Class, meth)

By default (and traditionally), the third argument is taken to be the function fun.Class; that is, the name of the generic function, followed by ".", followed by the name of the class.

As with S4 methods, a method that has been registered will be added to a table of methods for this function when the corresponding package is loaded into the session. Older versions of R, copying the mechanism in S, looked for the method in the current search list, but packages should now always register S3 methods rather than requiring the package to be attached.

Methods for S4 Classes

Two possible mechanisms for implementing a method corresponding to an S4 class, there are two possibilities are to register it as an S3 method with the S4 class name or to define and set an S4 method, which will have the side effect of creating an S4 generic version of this function.

For most situations either works, but the recommended approach is to do both: register the S3 method and supply the identical function as the definition of the S4 method. This ensures that the proposed method will be dispatched for any applicable call to the function.
As an example, suppose an S4 class "uncased" is defined, extending "character" and intending to ignore upper- and lower-case. The base function `unique` dispatches S3 methods. To define the class and a method for this function:

```r
setClass("uncased", contains = "character")
unique.uncased <- function(x, incomparables = FALSE, ...) nextMethod(tolower(x))
setMethod("unique", "uncased", unique.uncased)
```

In addition, the `NAMESPACE` for the package should contain:

```r
S3method(unique, uncased)
exportMethods(unique)
```

The result is to define identical S3 and S4 methods and ensure that all calls to `unique` will dispatch that method when appropriate.

**Details**

The reasons for defining both S3 and S4 methods are as follows:

1. An S4 method alone will not be seen if the S3 generic function is called directly. This will be the case, for example, if some function calls `unique()` from a package that does not make that function an S4 generic.

   However, primitive functions and operators are exceptions: The internal C code will look for S4 methods if and only if the object is an S4 object. S4 method dispatch would be used to dispatch any binary operator calls where either of the operands was an S4 object, for example.

2. An S3 method alone will not be called if there is any eligible non-default S4 method.

   So if a package defined an S3 method for `unique` for an S4 class but another package defined an S4 method for a superclass of that class, the superclass method would be chosen, probably not what was intended.

S4 and S3 method selection are designed to follow compatible rules of inheritance, as far as possible. S3 classes can be used for any S4 method selection, provided that the S3 classes have been registered by a call to `setOldClass`, with that call specifying the correct S3 inheritance pattern. S4 classes can be used for any S3 method selection; when an S4 object is detected, S3 method selection uses the contents of `extends(class(x))` as the equivalent of the S3 inheritance (the inheritance is cached after the first call).

For the details of S4 and S3 dispatch see `Methods_Details` and `S3Methods`.

new

Generate an Object from a Class

Description

A call to new returns a newly allocated object from the class identified by the first argument. This call in turn calls the method for the generic function initialize corresponding to the specified class, passing the ... arguments to this method. In the default method for initialize(), named arguments provide values for the corresponding slots and unnamed arguments must be objects from superclasses of this class.

A call to a generating function for a class (see setClass) will pass its ...arguments to a corresponding call to new().

Usage

new(Class, ...)

initialize(.Object, ...)
Arguments

Class either the name of a class, a character string, (the usual case) or the object describing the class (e.g., the value returned by getClass). Note that the character string passed from a generating function includes the package name as an attribute, avoiding ambiguity if two packages have identically named classes.

... arguments to specify properties of the new object, to be passed to initialize().

.Object An object: see the “Initialize Methods” section.

Initialize Methods

The generic function initialize is not called directly. A call to new begins by copying the prototype object from the class definition, and then calls initialize() with this object as the first argument, followed by the ... arguments.

The interpretation of the ... arguments in a call to a generator function or to new() can be specialized to particular classes, by defining an appropriate method for "initialize".

In the default method, unnamed arguments in the ... are interpreted as objects from a superclass, and named arguments are interpreted as objects to be assigned into the correspondingly named slots. Explicitly specified slots override inherited information for the same slot, regardless of the order in which the arguments appear.

The initialize methods do not have to have ... as their second argument (see the examples). Initialize methods are often written when the natural parameters describing the new object are not the names of the slots. If you do define such a method, you should include ... as a formal argument, and your method should pass such arguments along via callNextMethod. This helps the definition of future subclasses of your class. If these have additional slots and your method does not have this argument, it will be difficult for these slots to be included in an initializing call.

See initialize-methods for a discussion of some classes with existing methods.

Methods for initialize can be inherited only by simple inheritance, since it is a requirement that the method return an object from the target class. See the simpleInheritanceOnly argument to setGeneric and the discussion in setIs for the general concept.

Note that the basic vector classes, "numeric", etc. are implicitly defined, so one can use new for these classes. The ... arguments are interpreted as objects of this type and are concatenated into the resulting vector.

Classes_Details for details of class definitions, and setIs for the relation to S3 classes.

Examples

```r
## using the definition of class "track" from \link(setClass)

## a new object with two slots specified
t1 <- new("track", x = seq_along(ydata), y = ydata)
```
# a new object including an object from a superclass, plus a slot
t2 <- new("trackCurve", t1, smooth = ysmooth)

### define a method for initialize, to ensure that new objects have
### equal-length x and y slots. In this version, the slots must still be
### supplied by name.

setMethod("initialize", "track",
  function(.Object, ...) {
    .Object <- callNextMethod()
    if(length(.Object@x) != length(.Object@y))
      stop("specified x and y of different lengths")
    .Object
  })

### An alternative version that allows x and y to be supplied
### unnamed. A still more friendly version would make the default x
### a vector of the same length as y, and vice versa.

setMethod("initialize", "track",
  function(.Object, x = numeric(0), y = numeric(0), ...) {
    .Object <- callNextMethod(.Object, ...)
    if(length(x) != length(y))
      stop("specified x and y of different lengths")
    .Object@x <- x
    .Object@y <- y
    .Object
  })

---

nonStructure-class  A non-structure S4 Class for basic types

Description

S4 classes that are defined to extend one of the basic vector classes should contain the class
structure if they behave like structures; that is, if they should retain their class behavior under
math functions or operators, so long as their length is unchanged. On the other hand, if their class
depends on the values in the object, not just its structure, then they should lose that class under any
such transformations. In the latter case, they should be defined to contain nonStructure.

If neither of these strategies applies, the class likely needs some methods of its own for Ops, Math,
and/or other generic functions. What is not usually a good idea is to allow such computations to
drop down to the default, base code. This is inconsistent with most definitions of such classes.

Methods

Methods are defined for operators and math functions (groups Ops, Math and Math2). In all cases
the result is an ordinary vector of the appropriate type.

ObjectsWithPackage-class

A Vector of Object Names, with associated Package Names

Description

This class of objects is used to represent ordinary character string object names, extended with a package slot naming the package associated with each object.

Objects from the Class

The function getGenerics returns an object of this class.

Slots

.Data: Object of class "character": the object names.

.package: Object of class "character" the package names.

Extends

Class "character", from data part.
Class "vector", by class "character".

See Also

Methods for general background.

Examples

setClass("NumericNotStructure", contains = c("numeric","nonStructure"))
xx <- new("NumericNotStructure", 1:10)
xx + 1 # vector
log(xx) # vector
sample(xx) # vector
Generate a Shell for Documentation of a Formal Class

Description

Assembles all relevant slot and method information for a class, with minimal markup for Rd processing; no QC facilities at present.

Usage

promptClass(clName, filename = NULL, type = "class",
              keywords = "classes", where = topev(parent.frame()),
              generatorName = clName)

Arguments

clName a character string naming the class to be documented.
filename usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is the topic name for the class documentation, followed by ".Rd". Can also be NA (see below).
type the documentation type to be declared in the output file.
keywords the keywords to include in the shell of the documentation. The keyword "classes" should be one of them.
where where to look for the definition of the class and of methods that use it.
generatorName the name for a generator function for this class; only required if a generator function was created and saved under a name different from the class name.

Details

The class definition is found on the search list. Using that definition, information about classes extended and slots is determined.

In addition, the currently available generics with methods for this class are found (using getGenerics). Note that these methods need not be in the same environment as the class definition; in particular, this part of the output may depend on which packages are currently in the search list.

As with other prompt-style functions, unless filename is NA, the documentation shell is written to a file, and a message about this is given. The file will need editing to give information about the meaning of the class. The output of promptClass can only contain information from the metadata about the formal definition and how it is used.

If filename is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to cat(unlist(x), file = filename, sep = "\n"), where x is the list-style representation.

If a generator function is found assigned under the class name or the optional generatorName, skeleton documentation for that function is added to the file.

Value

If filename is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.
promptMethods

Author(s)

VJ Carey <stvjchanning.harvard.edu> and John Chambers

References

Chambers, John M. (1998) Programming with Data Springer (For the original S4 version.)

See Also

prompt for documentation of functions, promptMethods for documentation of method definitions.

For processing of the edited documentation, either use R CMD Rdconv, or include the edited file in the ‘man’ subdirectory of a package.

Examples

## Not run: > promptClass("track")
A shell of class documentation has been written to the file "track-class.Rd".

## End(Not run)

promptMethods Generate a Shell for Documentation of Formal Methods

Description

Generates a shell of documentation for the methods of a generic function.

Usage

promptMethods(f, filename = NULL, methods)

Arguments

f a character string naming the generic function whose methods are to be documented.
filename usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to the coded topic name for these methods (currently, f followed by "-methods.Rd"). Can also be FALSE or NA (see below).
methods optional "listOfMethods" object giving the methods to be documented. By default, the first methods object for this generic is used (for example, if the current global environment has some methods for f, these would be documented).

If this argument is supplied, it is likely to be findMethods(f, where), with where some package containing methods for f.
ReferenceClasses

Details

If `filename` is `FALSE`, the text created is returned, presumably to be inserted some other documentation file, such as the documentation of the generic function itself (see `prompt`).

If `filename` is `NA`, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n"), where x is the list-style representation.

Otherwise, the documentation shell is written to the file specified by `filename`.

Value

If `filename` is `FALSE`, the text generated; if `filename` is `NA`, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

ReferenceClasses

Objects With Fields Treated by Reference (OOP-style)

Description

The software described here allows packages to define reference classes that behave in the style of “OOP” languages such as Java and C++. This model for OOP differs from the functional model implemented by S4 (and S3) classes and methods, in which methods are defined for generic functions. Methods for reference classes are “encapsulated” in the class definition.

Computations with objects from reference classes invoke methods on them and extract or set their fields, using the `$` operator in R. The field and method computations potentially modify the object. All computations referring to the objects see the modifications, in contrast to the usual functional programming model in R.

A call to `setRefClass` in the source code for a package defines the class and returns a generator object. Subsequent calls to the `$methods()` method of the generator will define methods for the class. As with functional classes, if the class is exported from the package, it will be available when the package is loaded.

Methods are R functions. In their usual implementation, they refer to fields and other methods of the class directly by name. See the section on “Writing Reference Methods”.

As with functional classes, reference classes can inherit from other reference classes via a `contains=` argument to `setRefClass`. Fields and methods will be inherited, except where the new class overrides method definitions. See the section on “Inheritance”.
Usage

```r
setRefClass(Class, fields = , contains = , methods = ,
             where = , inheritPackage = , ...)

getRefClass(Class, where = )
```

Arguments

- **Class**: character string name for the class. In the call to `getRefClass()` this argument can also be any object from the relevant class.

- **fields**: either a character vector of field names or a named list of the fields. The resulting fields will be accessed with reference semantics (see the section on “Reference Objects”). If the argument is a list, each element of the list should usually be the character string name of a class, in which case the object in the field must be from that class or a subclass. An alternative, but not generally recommended, is to supply an accessor function; see the section on “Implementation” for accessor functions and the related internal mechanism. Note that fields are distinct from slots. Reference classes should not define class-specific slots. See the note on slots in the “Implementation” section.

- **contains**: optional vector of superclasses for this class. If a superclass is also a reference class, the fields and class-based methods will be inherited.

- **methods**: a named list of function definitions that can be invoked on objects from this class. These can also be created by invoking the `$methods` method on the generator object returned. See the section on “Writing Reference Methods” for details.

- **where**: for `setRefClass`, the environment in which to store the class definition. Should be omitted in calls from a package’s source code. For `getRefClass`, the environment from which to search for the definition. If the package is not loaded or you need to be specific, use `asNamespace` with the package name.

- **inheritPackage**: Should objects from the new class inherit the package environment of a contained superclass? Default `FALSE`. See the Section “Inter-Package Superclasses and External Methods”.

- **...**: other arguments to be passed to `setClass`.

Value

- **setRefClass()**: returns a generator function suitable for creating objects from the class, invisibly. A call to this function takes any number of arguments, which will be passed on to the initialize method. If no initialize method is defined for the class or one of its superclasses, the default method expects named arguments with the name of one of the fields and unnamed arguments, if any, that are objects from one of the superclasses of this class (but only superclasses that are themselves reference classes have any effect).

  The generator function is similar to the S4 generator function returned by `setClass`. In addition to being a generator function, however, it is also a reference class generator object, with reference class methods for various utilities. See the section on reference class generator objects below.

- **getRefClass()**: also returns the generator function for the class. Note that the package slot in the value is the correct package from the class definition, regardless of the `where` argument, which is used only to find the class if necessary.
Reference Objects

Normal objects in \( \mathbb{R} \) are passed as arguments in function calls consistently with functional programming semantics; that is, changes made to an object passed as an argument are local to the function call. The object that supplied the argument is unchanged.

The functional model (sometimes called pass-by-value, although this is inaccurate for \( \mathbb{R} \)) is suitable for many statistical computations and is implicit, for example, in the basic \( \mathbb{R} \) software for fitting statistical models. In some other situations, one would like all the code dealing with an object to see the exact same content, so that changes made in any computation would be reflected everywhere. This is often suitable if the object has some “objective” reality, such as a window in a user interface.

In addition, commonly used languages, including Java, C++ and many others, support a version of classes and methods assuming reference semantics. The corresponding programming mechanism is to invoke a method on an object. In the \( \mathbb{R} \) syntax we use “\$” for this operation; one invokes a method, \( m1 \) say, on an object \( x \) by the expression \( x \$ m1 (...) \).

Methods in this paradigm are associated with the object, or more precisely with the class of the object, as opposed to methods in a function-based class/method system, which are fundamentally associated with the function (in \( \mathbb{R} \), for example, a generic function in an \( \mathbb{R} \) session has a table of all its currently known methods). In this document “methods for a class” as opposed to “methods for a function” will make the distinction.

Objects in this paradigm usually have named fields on which the methods operate. In the \( \mathbb{R} \) implementation, the fields are defined when the class is created. The field itself can optionally have a specified class, meaning that only objects from this class or one of its subclasses can be assigned to the field. By default, fields have class “ANY”.

Fields are accessed by reference. In particular, invoking a method may modify the content of the fields.

Programming for such classes involves writing new methods for a particular class. In the \( \mathbb{R} \) implementation, these methods are \( \mathbb{R} \) functions, with zero or more formal arguments. For standard reference methods, the object itself is not an explicit argument to the method. Instead, fields and methods for the class can be referred to by name in the method definition. The implementation uses \( \mathbb{R} \) environments to make fields and other methods available by name within the method. Specifically, the parent environment of the method is the object itself. See the section on “Writing Reference Methods”. This special use of environments is optional. If a method is defined with an initial formal argument \( \text{.self} \), that will be passed in as the whole object, and the method follows the standard rules for any function in a package. See the section on “External Methods”.

The goal of the software described here is to provide a uniform programming style in \( \mathbb{R} \) for software dealing with reference classes, whether implemented directly in \( \mathbb{R} \) or through an interface to one of the OOP languages.

Writing Reference Methods

Reference methods are functions supplied as elements of a named list, either when invoking \$\text{methods()}\ on a generator object \( g \) or as the argument \text{methods} in a call to \text{setRefClass}. The two mechanisms have the same effect, but the first makes the code more readable.

Methods are written as ordinary \( \mathbb{R} \) functions but have some special features and restrictions in their usual form. In contrast to some other languages (e.g., Python), the object itself does not need to be an argument in the method definition. The body of the function can contain calls to any other reference method, including those inherited from other reference classes and may refer to methods and to fields in the object by name.

Alternatively, a method may be an \text{external} method. This is signalled by \text{.self} being the first formal argument to the method. The body of the method then works like any ordinary function. The
methods are called like other methods (without the .self argument, which is supplied internally and always refers to the object itself). Inside the method, fields and other methods are accessed in the form .self$x. External methods exist so that reference classes can inherit the package environment of superclasses in other packages; see the section on “External Methods”.

Fields may be modified in a method by using the non-local assignment operator, <<- , as in the $edit and $undo methods in the example below. Note that non-local assignment is required: a local assignment with the <- operator just creates a local object in the function call, as it would in any R function. When methods are installed, a heuristic check is made for local assignments to field names and a warning issued if any are detected.

Reference methods should be kept simple; if they need to do some specialized R computation, that computation should use a separate R function that is called from the reference method. Specifically, methods cannot use special features of the enclosing environment mechanism, since the method’s environment is used to access fields and other methods. In particular, methods should not use non-exported entries in the package’s namespace, because the methods may be inherited by a reference class in another package.

Two method names are interpreted specially, initialize and finalize. If an initialize method is defined, it will be invoked when an object is generated from the class. See the discussion of method $new(...) in the section “Initialization Methods”.

If a finalize method is defined, a function will be registered to invoke it before the environment in the object is discarded by the garbage collector; finalizers are registered with atexit=TRUE, and so are also run at the end of R sessions. See the matrix viewer example for both initialize and finalize methods.

Reference methods can not themselves be generic functions; if you want additional function-based method dispatch, write a separate generic function and call that from the method.

Two special object names are available. The entire object can be referred to in a method by the reserved name .self. The object .refClassDef contains the definition of the class of the object. These are accessed as fields but are read-only, with one exception. In principal, the .self field can be modified in the $initialize method, because the object is still being created at this stage. This is not recommended, as it can invalidate the object with respect to its class.

The methods available include methods inherited from superclasses, as discussed in the section “Inheritance”.

Only methods actually used will be included in the environment corresponding to an individual object. To declare that a method requires a particular other method, the first method should include a call to $usingMethods() with the name of the other method as an argument. Declaring the methods this way is essential if the other method is used indirectly (e.g., via sapply() or do.call()). If it is called directly, code analysis will find it. Declaring the method is harmless in any case, however, and may aid readability of the source code.

Documentation for the methods can be obtained by the $help method for the generator object.

Methods for classes are not documented in the Rd format used for R functions. Instead, the $help method prints the calling sequence of the method, followed by self-documentation from the method definition, in the style of Python. If the first element of the body of the method is a literal character string (possibly multi-line), that string is interpreted as documentation. See the method definitions in the example.

**Initialization Methods**

If the class has a method defined for $initialize(), this method will be called once the reference object has been created. You should write such a method for a class that needs to do some special initialization. In particular, a reference method is recommended rather than a method for the S4 generic function initialize(), because some special initialization is required for reference objects
before the initialization of fields. As with S4 classes, methods are written for $initialize()$ and not for $new()$, both for the previous reason and also because $new()$ is invoked on the generator object and would be a method for that class.

The default method for $initialize()$ is equivalent to invoking the method $initFields(...)$. Named arguments assign initial values to the corresponding fields. Unnamed arguments must be objects from this class or a reference superclass of this class. Fields will be initialized to the contents of the fields in such objects, but named arguments override the corresponding inherited fields. Note that fields are simply assigned. If the field is itself a reference object, that object is not copied. The new and previous object will share the reference. Also, a field assigned from an unnamed argument counts as an assignment for locked fields. To override an inherited value for a locked field, the new value must be one of the named arguments in the initializing call. A later assignment of the field will result in an error.

Initialization methods need some care in design. The generator for a reference class will be called with no arguments, for example when copying the object. To ensure that these calls do not fail, the method must have defaults for all arguments or check for missing(). The method should include ... as an argument and pass this on via $callSuper()$ (or $initFields()$ if you know that your superclasses have no initialization methods). This allows future class definitions that subclass this class, with additional fields.

Inheritance

Reference classes inherit from other reference classes by using the standard R inheritance; that is, by including the superclasses in the contains= argument when creating the new class. The names of the reference superclasses are in slot refSuperClasses of the class definition. Reference classes can inherit from ordinary S4 classes also, but this is usually a bad idea if it mixes reference fields and non-reference slots. See the comments in the section on “Implementation”.

Class fields are inherited. A class definition can override a field of the same name in a superclass only if the overriding class is a subclass of the class of the inherited field. This ensures that a valid object in the field remains valid for the superclass as well.

Inherited methods are installed in the same way as directly specified methods. The code in a method can refer to inherited methods in the same way as directly specified methods.

A method may override a method of the same name in a superclass. The overriding method can call the superclass method by $callSuper(...) as described below.

Methods Provided for all Objects

All reference classes inherit from the class "envRefClass". All reference objects can use the following methods.

$callSuper(...) Calls the method inherited from a reference superclass. The call is meaningful only from within another method, and will be resolved to call the inherited method of the same name. The arguments to $callSuper are passed to the superclass version. See the matrix viewer class in the example.

Note that the intended arguments for the superclass method must be supplied explicitly; there is no convention for supplying the arguments automatically, in contrast to the similar mechanism for functional methods.

$copy(shallow = FALSE) Creates a copy of the object. With reference classes, unlike ordinary R objects, merely assigning the object with a different name does not create an independent copy. If shallow is FALSE, any field that is itself a reference object will also be copied, and similarly recursively for its fields. Otherwise, while reassigning a field to a new reference object will have no side effect, modifying such a field will still be reflected in both copies of
the object. The argument has no effect on non-reference objects in fields. When there are
reference objects in some fields but it is asserted that they will not be modified, using shallow
= TRUE will save some memory and time.

$field(name, value) With one argument, returns the field of the object with character string
name. With two arguments, the corresponding field is assigned value. Assignment checks
that name specifies a valid field, but the single-argument version will attempt to get anything
of that name from the object’s environment.

The $field() method replaces the direct use of a field name, when the name of the field must
be calculated, or for looping over several fields.

$export(Class) Returns the result of coercing the object to Class (typically one of the super-
classes of the object’s class). Calling the method has no side effect on the object itself.

$getRefClass(); $getClass() These return respectively the generator object and the formal
class definition for the reference class of this object, efficiently.

$import(value, Class = class(value)) Import the object value into the current object, replac-
ing the corresponding fields in the current object. Object value must come from one of the
superclasses of the current object’s class. If argument Class is supplied, value is first coerced
to that class.

$initFields(...) Initialize the fields of the object from the supplied arguments. This method is
usually only called from a class with a $initialize() method. It corresponds to the default
initialization for reference classes. If there are slots and non-reference superclasses, these may
be supplied in the ... argument as well.

Typically, a specialized $initialize() method carries out its own computations, then in-
vokes $initFields() to perform standard initialization, as shown in the matrixViewer class
in the example below.

$show() This method is called when the object is printed automatically, analogously to the show
function. A general method is defined for class "envRefClass". User-defined reference
classes will often define their own method: see the Example below.

Note two points in the example. As with any show() method, it is a good idea to print the class
effectively to allow for subclasses using the method. Second, to call the function show() from
the method, as opposed to the $show() method itself, refer to methods::show() explicitly.

$trace(what, ...), $untrace(what) Apply the tracing and debugging facilities of the trace
function to the reference method what.

All the arguments of the trace function can be supplied, except for signature, which is not
meaningful.

The reference method can be invoked on either an object or the generator for the class. See
the section on Debugging below for details.

$usingMethods(...) Reference methods used by this method are named as the arguments either
quoted or unquoted. In the code analysis phase of installing the present method, the declared
methods will be included. It is essential to declare any methods used in a nonstandard way
(e.g., via an apply function). Methods called directly do not need to be declared, but it is
harmless to do so. $usingMethods() does nothing at run time.

Objects also inherit two reserved fields:

.self  a reference to the entire object;
.refClassDef  the class definition.

The defined fields should not override these, and in general it is unwise to define a field whose name
begins with ".", since the implementation may use such names for special purposes.
External Methods; Inter-Package Superclasses

The environment of a method in a reference class is the object itself, as an environment. This allows the method to refer directly to fields and other methods, without using the whole object and the "$" operator. The parent of that environment is the namespace of the package in which the reference class is defined. Computations in the method have access to all the objects in the package’s namespace, exported or not.

When defining a class that contains a reference superclass in another package, there is an ambiguity about which package namespace should have that role. The argument `inheritPackage` to `setRefClass()` controls whether the environment of new objects should inherit from an inherited class in another package or continue to inherit from the current package’s namespace.

If the superclass is “lean”, with few methods, or exists primarily to support a family of subclasses, then it may be better to continue to use the new package’s environment. On the other hand, if the superclass was originally written as a standalone, this choice may invalidate existing superclass methods. For the superclass methods to continue to work, they must use only exported functions in their package and the new package must import these.

Either way, some methods may need to be written that do not assume the standard model for reference class methods, but behave essentially as ordinary functions would in dealing with reference class objects.

The mechanism is to recognize external methods. An external method is written as a function in which the first argument, named `.self`, stands for the reference class object. This function is supplied as the definition for a reference class method. The method will be called, automatically, with the first argument being the current object and the other arguments, if any, passed along from the actual call.

Since an external method is an ordinary function in the source code for its package, it has access to all the objects in the namespace. Fields and methods in the reference class must be referred to in the form `.self$name`.

If for some reason you do not want to use `.self` as the first argument, a function `f()` can be converted explicitly as `externalRefMethod(f)`, which returns an object of class "externalRefMethod" that can be supplied as a method for the class. The first argument will still correspond to the whole object.

External methods can be supplied for any reference class, but there is no obvious advantage unless they are needed. They are more work to write, harder to read and (slightly) slower to execute.

**NOTE:** If you are the author of a package whose reference classes are likely to be subclassed in other packages, you can avoid these questions entirely by writing methods that only use exported functions from your package, so that all the methods will work from another package that imports yours.

Reference Class Generators

The call to `setRefClass` defines the specified class and returns a “generator function” object for that class. This object has class "refObjectGenerator"; it inherits from "function" via "classGeneratorFunction" and can be called to generate new objects from the reference class.

The returned object is also a reference class object, although not of the standard construction. It can be used to invoke reference methods and access fields in the usual way, but instead of being implemented directly as an environment it has a subsidiary generator object as a slot, a standard reference object (of class "refGeneratorSlot"). Note that if one wanted to extend the reference class generator capability with a subclass, this should be done by subclassing "refGeneratorSlot", not "refObjectGenerator".
The fields are `def`, the class definition, and `className`, the character string name of the class. Methods generate objects from the class, to access help on reference methods, and to define new reference methods for the class. The currently available methods are:

$\text{new}(\ldots)$ This method is equivalent to calling the generator function returned by `setRefClass`. 

$\text{help}(\text{topic})$ Prints brief help on the topic. The topics recognized are reference method names, quoted or not.

The information printed is the calling sequence for the method, plus self-documentation if any. Reference methods can have an initial character string or vector as the first element in the body of the function defining the method. If so, this string is taken as self-documentation for the method (see the section on “Writing Reference Methods” for details).

If no topic is given or if the topic is not a method name, the definition of the class is printed.

$\text{methods}(\ldots)$ With no arguments, returns the names of the reference methods for this class. With one character string argument, returns the method of that name.

Named arguments are method definitions, which will be installed in the class, as if they had been supplied in the methods argument to `setRefClass()`. Supplying methods in this way, rather than in the call to `setRefClass()`, is recommended for the sake of clearer source code. See the section on “Writing Reference Methods” for details.

All methods for a class should be defined in the source code that defines the class, typically as part of a package. In particular, methods can not be redefined in a class in an attached package with a namespace: The class method checks for a locked binding of the class definition. The new methods can refer to any currently defined method by name (including other methods supplied in this call to `methods()`). Note though that previously defined methods are not re-analyzed meaning that they will not call the new method (unless it redefines an existing method of the same name).

To remove a method, supply `NULL` as its new definition.

$\text{fields}()$ Returns a list of the fields, each with its corresponding class. Fields for which an accessor function was supplied in the definition have class "activeBindingFunction".

$\text{lock}(\ldots)$ The fields named in the arguments are locked; specifically, after the lock method is called, the field may be set once. Any further attempt to set it will generate an error.

If called with no arguments, the method returns the names of the locked fields.

Fields that are defined by an explicit accessor function can not be locked (on the other hand, the accessor function can be defined to generate an error if called with an argument).

All code to lock fields should normally be part of the definition of a class; that is, the read-only nature of the fields is meant to be part of the class definition, not a dynamic property added later. In particular, fields can not be locked in a class in an attached package with a namespace: The class method checks for a locked binding of the class definition. Locked fields can not be subsequently unlocked.

$\text{trace}(\text{what}, \ldots, \text{classMethod} = \text{FALSE})$ Establish a traced version of method `what` for objects generated from this class. The generator object tracing works like the `trace()` method for objects from the class, with two differences. Since it changes the method definition in the class object itself, tracing applies to all objects, not just the one on which the trace method is invoked.

Second, the optional argument `classMethod = TRUE` allows tracing on the methods of the generator object itself. By default, `what` is interpreted as the name of a method in the class for which this object is the generator.

$\text{accessors}(\ldots)$ A number of systems using the OOP programming paradigm recommend or enforce `getter` and `setter` methods corresponding to each field, rather than direct access by name. If you like this style and want to extract a field named `abc` by `x$getAbc()` and assign it by `x$setAbc(value)`, the $\text{accessors}$ method is a convenience function that creates such
getter and setter methods for the specified fields. Otherwise there is no reason to use this mechanism. In particular, it has nothing to do with the general ability to define fields by functions as described in the section on “Reference Objects”.

**Implementation; Reference Classes as S4 Classes**

Reference classes are implemented as S4 classes with a data part of type "environment". Fields correspond to named objects in the environment. A field associated with a function is implemented as an active binding. In particular, fields with a specified class are implemented as a special form of active binding to enforce valid assignment to the field.

As a related feature, the element in the fields= list supplied to setRefClass can be an accessor function, a function of one argument that returns the field if called with no argument or sets it to the value of the argument otherwise. Accessor functions are used internally and for inter-system interface applications, but not generally recommended as they blur the concept of fields as data within the object.

A field, say data, can be accessed generally by an expression of the form x$data for any object from the relevant class. In an internal method for this class, the field can be accessed by the name data. A field that is not locked can be set by an expression of the form x$data <- value. Inside an internal method, a field can be assigned by an expression of the form x <<- value. Note the non-local assignment operator. The standard R interpretation of this operator works to assign it in the environment of the object. If the field has an accessor function defined, getting and setting will call that function.

When a method is invoked on an object, the function defining the method is installed in the object’s environment, with the same environment as the environment of the function.

Reference classes can have validity methods in the same sense as any S4 class (see setValidity). Such methods are often a good idea; they will be called by calling validObject and a validity method, if one is defined, will be called when a reference object is created (from version 3.4 of R on). Just remember that these are S4 methods. The function will be called with the object as its argument. Fields and methods must be accessed using $.

**Note: Slots.** Because of the implementation, new reference classes can inherit from non-reference S4 classes as well as reference classes, and can include class-specific slots in the definition. This is usually a bad idea, if the slots from the non-reference class are thought of as alternatives to fields. Slots will as always be treated functionally. Therefore, changes to the slots and the fields will behave inconsistently, mixing the functional and reference paradigms for properties of the same object, conceptually unclear and prone to errors. In addition, the initialization method for the class will have to sort out fields from slots, with a good chance of creating anomalous behavior for subclasses of this class.

Inheriting from a class union, however, is a reasonable strategy (with all members of the union likely to be reference classes).

**Debugging**

The standard R debugging and tracing facilities can be applied to reference methods. Reference methods can be passed to debug and its relatives from an object to debug further method invocations on that object; for example, debug(xx$edit).

Somewhat more flexible use is available for a reference method version of the trace function. A corresponding $trace() reference method is available for either an object or for the reference class generator (xx$trace() or mEdit$trace() in the example below). Using $trace() on an object sets up a tracing version for future invocations of the specified method for that object. Using $trace() on the generator for the class sets up a tracing version for all future objects from that
class (and sometimes for existing objects from the class if the method is not declared or previously invoked).

In either case, all the arguments to the standard `trace` function are available, except for `signature=` which is meaningless since reference methods can not be S4 generic functions. This includes the typical style `trace(what, browser)` for interactive debugging and `trace(what, edit = TRUE)` to edit the reference method interactively.

Examples

```r
## a simple editor for matrix objects. Method $edit() changes some
## range of values; method $undo() undoes the last edit.
mEdit <- setRefClass("mEdit",
  fields = list( data = "matrix",
          edits = "list"))

## The basic edit, undo methods
mEdit$methods(
  edit = function(i, j, value) {
    ## the following string documents the edit method
    'Replaces the range [i, j] of the
    object by value.'
    backup <-
      list(i, j, data[i,j])
    data[i,j] <<- value
    edits <<- c(edits, list(backup))
    invisible(value)
  },
  undo = function() {
    'Undoes the last edit() operation
    and update the edits field accordingly.'
    prev <- edits
    if(length(prev)) prev <- prev[[length(prev)]]
    else stop("No more edits to undo")
    edit(prev[[1]], prev[[2]], prev[[3]])
    ## trim the edits list
    length(edits) <<- length(edits) - 2
    invisible(prev)
  })

## A method to automatically print objects
mEdit$methods(
  show = function() {
    'Method for automatically printing matrix editors'
    cat("Reference matrix editor object of class",
        classLabel(class(.self)), "\n")
    cat("Data: \\n")
    methods::show(data)
    cat("Undo list is of length", length(edits), "\n")
  }
)
```

xMat <- matrix(1:12,4,3)
xx <- mEdit(data = xMat)
xx$edit(2, 2, 0)
xx
xx$undo()
mEdit$help("undo")
stopifnot(all.equal(xx$data, xMat))
utils::str(xx) # show fields and names of methods

## A method to save the object
mEdit$methods(
  save = function(file) {
    'Save the current object on the file
    in R external object format.'
    base::save(.self, file = file)
  }
)

tf <- tempfile()
xx$save(tf)

## Not run:
## Inheriting a reference class: a matrix viewer
mv <- setRefClass("matrixViewer",
  fields = c("viewerDevice", "viewerFile"),
  contains = "mEdit",
  methods = list( view = function() {
      dd <- dev.cur(); dev.set(viewerDevice)
      devAskNewPage(FALSE)
      matplot(data, main = paste("After",length(edits),"edits"))
      dev.set(dd),
      edit = # invoke previous method, then replot
      function(i, j, value) {
        callSuper(i, j, value)
      view()
    })))

## initialize and finalize methods
mv$methods( initialize =
  function(file = "./matrixView.pdf", ...) {
    viewerFile <<- file
    pdf(viewerFile)
    viewerDevice <<- dev.cur()
    dev.set(dev.prev())
    callSuper("")
  },
  finalize = function() {
    dev.off(viewerDevice)
  })

## debugging an object: call browser() in method $edit()
xx$trace(edit, browser)
removeMethod  Remove a Method

Description
Remove the method for a given function and signature. Obsolete for ordinary applications: Method definitions in a package should never need to remove methods and it’s very bad practice to remove methods that were defined in other packages.

Usage
removeMethod(f, signature, where)

Arguments
f, signature, where
As for setMethod().

Value
TRUE if a method was found to be removed.

representation  Construct a Representation or a Prototype for a Class Definition

Description
These are old utility functions to construct, respectively a list designed to represent the slots and superclasses and a list of prototype specifications. The representation() function is no longer useful, since the arguments slots and contains to setClass are now recommended.

The prototype() function may still be used for the corresponding argument, but a simple list of the same arguments works as well.

Usage
representation(...)
prototype(...)
Arguments

The call to `representation` takes arguments that are single character strings. Unnamed arguments are classes that a newly defined class extends; named arguments name the explicit slots in the new class, and specify what class each slot should have.

In the call to `prototype`, if an unnamed argument is supplied, it unconditionally forms the basis for the prototype object. Remaining arguments are taken to correspond to slots of this object. It is an error to supply more than one unnamed argument.

Details

The `representation` function applies tests for the validity of the arguments. Each must specify the name of a class.

The classes named don’t have to exist when `representation` is called, but if they do, then the function will check for any duplicate slot names introduced by each of the inherited classes.

The arguments to `prototype` are usually named initial values for slots, plus an optional first argument that gives the object itself. The unnamed argument is typically useful if there is a data part to the definition (see the examples below).

Value

The value of `representation` is just the list of arguments, after these have been checked for validity.

The value of `prototype` is the object to be used as the prototype. Slots will have been set consistently with the arguments, but the construction does not use the class definition to test validity of the contents (it hardly can, since the prototype object is usually supplied to create the definition).

### S3Part

**S4 Classes that Contain S3 Classes**

#### Description

A regular (S4) class may contain an S3 class, if that class has been registered (by calling `setOldClass`). The functions described here provide information about contained S3 classes. See the section ‘Functions’.

In modern R, these functions are not usually needed to program with objects from the S4 class. Standard computations work as expected, including method selection for both S4 and S3. To coerce an object to its contained S3 class, use either of the expressions:

```r
as(object, S3Class); as(object, "S3")
```

where `S3Class` evaluates to the name of the contained class. These return slightly different objects, which in rare cases may need to be distinguished. See the section “Contained S3 Objects”.

#### Usage

- `S3Part(object, strictS3 = FALSE, S3Class)`
- `S3Class(object)`
- `isXS3Class(classDef)`
- `slotsFromS3(object)`

#### Arguments

- **object**
  - an object from some class that extends a registered S3 class, or a basic vector, matrix or array object type.
  - For most of the functions, an S3 object can also be supplied, with the interpretation that it is its own S3 part.
strictS3  If TRUE, the value returned by S3Part will be an S3 object, with all the S4 slots removed. Otherwise, an S4 object will always be returned; for example, from the S4 class created by `setOldClass` as a proxy for an S3 class, rather than the underlying S3 object.

S3Class  the character vector to be stored as the S3 class slot in the object. Usually, and by default, retains the slot from `object`, but an S3 superclass is allowed.

classDef  a class definition object, as returned by `getClass`.

The remaining arguments apply only to the replacement versions, which are not recommended.

needClass  Require that the replacement value be this class or a subclass of it.

value  For S3Part<-, the replacement value for the S3 part of the object.
For S3Class<-, the character vector that will be used as a proxy for `class(x)` in S3 method dispatch.

Functions

S3Part: Returns an object from the S3 class that appeared in the contains= argument to `setClass`.
If called with strictS3 = TRUE, S3Part() constructs the underlying S3 object by eliminating all the formally defined slots and turning off the S4 bit of the object. With strictS3 = FALSE the object returned is from the corresponding S4 class. For consistency and generality, S3Part() works also for classes that extend the basic vector, matrix and array classes.
A call to is equivalent coercing the object to class "S3" for the strict case, or to whatever the specific S3 class was, for the non-strict case. The as() calls are usually easier for readers to understand.

S3Class: Returns the character vector of S3 class(es) stored in the object, if the class has the corresponding .S3Class slot. Currently, the function defaults to class otherwise.

isXS3Class: Returns TRUE or FALSE according to whether the class defined by ClassDef extends S3 classes (specifically, whether it has the slot for holding the S3 class).

slotsFromS3: returns a list of the relevant slot classes, or an empty list for any other object.
The function slotsFromS3() is a generic function used internally to access the slots associated with the S3 part of the object. Methods for this function are created automatically when `setOldClass` is called with the S4Class argument. Usually, there is only one S3 slot, containing the S3 class, but the S4Class argument may provide additional slots, in the case that the S3 class has some guaranteed attributes that can be used as formal S4 slots. See the corresponding section in the documentation of `setOldClass`.

Contained S3 Objects

Registering an S3 class defines an S4 class. Objects from this class are essentially identical in content to an object from the S3 class, except for two differences. The value returned by `class()` will always be a single string for the S4 object, and `isS4()` will return TRUE or FALSE in the two cases. See the example below. It is barely possible that some S3 code will not work with the S4 object; if so, use as(x, "S3").

Objects from a class that extends an S3 class will have some basic type and possibly some attributes. For an S3 class that has an equivalent S4 definition (e.g., "data.frame"), an extending S4 class will have a data part and slots. For other S3 classes (e.g., "lm") an object from the extending S4 class will be some sort of basic type, nearly always a vector type (e.g., "list" for "lm"), but the data part will not have a formal definition.

Registering an S3 class by a call to `setOldClass` creates a class of the same name with a slot ".S3Class" to hold the corresponding S3 vector of class strings. New S4 classes that extend such
classes also have the same slot, set to the S3 class of the contained S3 object, which may be an (S3) subclass of the registered class. For example, an S4 class might contain the S3 class "lm", but an object from the class might contain an object from class "mlm", as in the "xlm" example below.

\(R\) is somewhat arbitrary about what it treats as an S3 class: "ts" is, but "matrix" and "array" are not. For classes that extend those, assuming they contain an S3 class is incorrect and will cause some confusion—not usually disastrous, but the better strategy is to stick to the explicit "class". Thus \(\text{as}(x, \text{"matrix"})\) rather than \(\text{as}(x, \text{"S3"})\) or \(\text{S3Part}(x)\).

**S3 and S4 Objects: Conversion Mechanisms**

Objects in \(R\) have an internal bit that indicates whether or not to treat the object as coming from an S4 class. This bit is tested by \(\text{isS4}\) and can be set on or off by \(\text{asS4}\). The latter function, however, does no checking or interpretation; you should only use it if you are very certain every detail has been handled correctly.

As a friendlier alternative, methods have been defined for coercing to the virtual classes "S3" and "S4". The expressions \(\text{as}(\text{object}, \text{"S3"})\) and \(\text{as}(\text{object}, \text{"S4"})\) return S3 and S4 objects, respectively. In addition, they attempt to do conversions in a valid way, and also check validity when coercing to S4.

The expression \(\text{as}(\text{object}, \text{"S3"})\) can be used in two ways. For objects from one of the registered S3 classes, the expression will ensure that the class attribute is the full multi-string S3 class implied by \(\text{class}(\text{object})\). If the registered class has known attribute/slots, these will also be provided. Another use of \(\text{as}(\text{object}, \text{"S3"})\) is to take an S4 object and turn it into an S3 object with corresponding attributes. This is only meaningful with S4 classes that have a data part. If you want to operate on the object without invoking S4 methods, this conversion is usually the safest way.

The expression \(\text{as}(\text{object}, \text{"S4"})\) will use the attributes in the object to create an object from the S4 definition of \(\text{class}(\text{object})\). This is a general mechanism to create partially defined version of S4 objects via S3 computations (not much different from invoking \(\text{new}\) with corresponding arguments, but usable in this form even if the S4 object has an initialize method with different arguments).

\(\text{setOldClass}\)

**Examples**

```r
## an "mlm" object, regressing two variables on two others
sepal <- as.matrix(datasets::iris[, c("Sepal.Width", "Sepal.Length")])
fit <- lm(sepal ~ Petal.Length + Petal.Width + Species, data = datasets::iris)
class(fit) # S3 class: "mlm", "lm"

## a class that contains "mlm"
myReg <- setClass("myReg", slots = c(title = "character"), contains = "mlm")
fit2 <- myReg(fit, title = "Sepal Regression for iris data")

fit2 # shows the inherited "mlm" object and the title
```
identical(S3Part(fit2), as(fit2, "mlm"))

class(as(fit2, "mlm")) # the S4 class, "mlm"

class(as(fit2, "S3")) # the S3 class, c("mlm", "lm")

## An object may contain an S3 class from a subclass of that declared:

xlm <- setClass("xlm", slots = c(eps = "numeric"), contains = "lm")

xfit <- xlm(fit, eps = .Machine$double.eps)

xfit@.S3Class # c("mlm", "lm")

---

**S4 Group Generic Functions**

**Description**

Methods can be defined for group generic functions. Each group generic function has a number of member generic functions associated with it.

Methods defined for a group generic function cause the same method to be defined for each member of the group, but a method explicitly defined for a member of the group takes precedence over a method defined, with the same signature, for the group generic.

The functions shown in this documentation page all reside in the methods package, but the mechanism is available to any programmer, by calling setGroupGeneric (provided package methods is attached).

**Usage**

## S4 group generics:

Arith(e1, e2)
Compare(e1, e2)
Ops(e1, e2)
Logic(e1, e2)
Math(x)
Math2(x, digits)
Summary(x, ..., na.rm = FALSE)
Complex(z)

**Arguments**

x, z, e1, e2 objects.
digits number of digits to be used in round or signif.
... further arguments passed to or from methods.
na.rm logical: should missing values be removed?
Details

Methods can be defined for the group generic functions by calls to `setMethod` in the usual way. Note that the group generic functions should never be called directly – a suitable error message will result if they are. When metadata for a group generic is loaded, the methods defined become methods for the members of the group, but only if no method has been specified directly for the member function for the same signature. The effect is that group generic definitions are selected before inherited methods but after directly specified methods. For more on method selection, see `Methods_Details`.

There are also S3 groups `Math`, `Ops`, `Summary` and `Complex`, see `?S3groupGeneric`, with no corresponding R objects, but these are irrelevant for S4 group generic functions.

The members of the group defined by a particular generic can be obtained by calling `getGroupMembers`. For the group generic functions currently defined in this package the members are as follows:

- **Arith**: `"+", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":`, 
- **Compare**: `"==", ":", ":", ":", ":", ":", ":", ":", ":`, 
- **Logic**: `"&", ":", ":", ":`, 
- **Ops**: `"Arith", ":", ":", ":`, 
- **Math**: `"abs", ":", ":", ":", ":", ":", ":", ":", ":", ":", ":`, 
- **Math2**: `"round", ":", ":`, 
- **Summary**: `"max", ":", ":", ":", ":", ":`, 
- **Complex**: `"Arg", ":", ":", ":`, 

Note that `Ops` merely consists of three sub groups. All the functions in these groups (other than the group generics themselves) are basic functions in R. They are not by default S4 generic functions, and many of them are defined as primitives. However, you can still define formal methods for them, both individually and via the group generics. It all works more or less as you might expect, admittedly via a bit of trickery in the background. See `Methods_Details` for details.

Note that two members of the `Math` group, `log` and `trunc`, have ... as an extra formal argument. Since methods for `Math` will have only one formal argument, you must set a specific method for these functions in order to call them with the extra argument(s).

For further details about group generic functions see section 10.5 of the second reference.

The function `callGeneric` is nearly always relevant when writing a method for a group generic. See the examples below and in section 10.5 of *Software for Data Analysis*.

See `S3groupGeneric` for S3 group generics.
Examples

```
setClass("testComplex", slots = c(zz = "complex"))
## method for whole group "Complex"
setMethod("Complex", "testComplex",
  function(z) c("groupMethod", callGeneric(z@zz)))
## exception for Arg()
setMethod("Arg", "testComplex",
  function(z) c("ArgMethod", Arg(z@zz)))
z1 <- 1+2i
z2 <- new("testComplex", zz = z1)
stopifnot(identical(Mod(z2), c("groupMethod", Mod(z1))))
stopifnot(identical(Arg(z2), c("ArgMethod", Arg(z1))))
```

SClassExtension-class

Class to Represent Inheritance (Extension) Relations

Description

An object from this class represents a single 'is' relationship; lists of these objects are used to represent all the extensions (superclasses) and subclasses for a given class. The object contains information about how the relation is defined and methods to coerce, test, and replace correspondingly.

Objects from the Class

Objects from this class are generated by `setIs`, from direct calls and from the `contains=` information in a call to `setClass`, and from class unions created by `setClassUnion`. In the last case, the information is stored in defining the subclasses of the union class (allowing unions to contain sealed classes).

Slots

- `subClass`, `superClass`: The classes being extended: corresponding to the `from`, and `to` arguments to `setIs`.
- `package`: The package to which that class belongs.
- `coerce`: A function to carry out the `as()` computation implied by the relation. Note that these functions should *not* be used directly. They only deal with the `strict=TRUE` calls to the `as` function, with the full method constructed from this mechanically.
- `test`: The function that would test whether the relation holds. Except for explicitly specified `test` arguments to `setIs`, this function is trivial.
- `replace`: The method used to implement `as(x, Class) <- value`.
- `simple`: A "logical" flag, TRUE if this is a simple relation, either because one class is contained in the definition of another, or because a class has been explicitly stated to extend a virtual class. For simple extensions, the three methods are generated automatically.
- `by`: If this relation has been constructed transitivity, the first intermediate class from the subclass.
- `dataPart`: A "logical" flag, TRUE if the extended class is in fact the data part of the subclass. In this case the extended class is a basic class (i.e., a type).
- `distance`: The distance between the two classes, 1 for directly contained classes, plus the number of generations between otherwise.
Methods

No methods defined with class "SClassExtension" in the signature.

See Also

is, as, and the classRepresentation class.

selectSuperClasses  Super Classes (of Specific Kinds) of a Class

Description

Return superclasses of ClassDef, possibly only non-virtual or direct or simple ones. These functions are designed to be fast, and consequently only work with the contains slot of the corresponding class definitions.

Usage

selectSuperClasses(Class, dropVirtual = FALSE, namesOnly = TRUE, 
  directOnly = TRUE, simpleOnly = directOnly, 
  where = topenv(parent.frame()))

.selectSuperClasses(ext, dropVirtual = FALSE, namesOnly = TRUE, 
  directOnly = TRUE, simpleOnly = directOnly)

Arguments

Class  name of the class or (more efficiently) the class definition object (see getClass).
dropVirtual  logical indicating if only non-virtual superclasses should be returned.
namesOnly  logical indicating if only a vector names instead of a named list class-extensions should be returned.
directOnly  logical indicating if only a direct super classes should be returned.
simpleOnly  logical indicating if only simple class extensions should be returned.
where  (only used when Class is not a class definition) environment where the class definition of Class is found.
ext  for .selectSuperClasses() only, a list of class extensions, typically getClassDef(..)@contains.

Value

a character vector (if namesOnly is true, as per default) or a list of class extensions (as the contains slot in the result of getClass).

Note

The typical user level function is selectSuperClasses() which calls .selectSuperClasses(); i.e., the latter should only be used for efficiency reasons by experienced useRs.
**setAs**

**Methods for Coercing an Object to a Class**

**See Also**

`is`, `getClass`; further, the more technical class `classRepresentation` documentation.

**Examples**

```r
defClass("Root")
setClass("Base", contains = "Root", slots = c(length = "integer"))
setClass("A", contains = "Base", slots = c(x = "numeric"))
setClass("B", contains = "Base", slots = c(y = "character"))
setClass("C", contains = c("A", "B"))

extends("C")  #--> "C" "A" "B" "Base" "Root"
selectSuperClasses("C")  # "A" "B"
selectSuperClasses("C", directOnly=FALSE)  # "A" "B" "Base" "Root"
selectSuperClasses("C", dropVirtual=TRUE, directOnly=FALSE)# ditto w/o "Root"
```

**Description**

A call to `setAs` defines a method for coercing an object of class `from` to class `to`. The methods will then be used by calls to `as` for objects with class `from`, including calls that replace part of the object.

Methods for this purpose work indirectly, by defining methods for function `coerce`. The `coerce` function is not to be called directly, and method selection uses class inheritance only on the first argument.

**Usage**

```r
setAs(from, to, def, replace, where = topenv(parent.frame()))
```

**Arguments**

- `from, to` The classes between which the coerce methods `def` and `replace` perform coercion.
- `def` function of one argument. It will get an object from class `from` and had better return an object of class `to`. The convention is that the name of the argument is `from`; if another argument name is used, `setAs` will attempt to substitute `from`.
- `replace` if supplied, the function to use as a replacement method, when `as` is used on the left of an assignment. Should be a function of two arguments, `from`, `value`, although `setAs` will attempt to substitute if the arguments differ. *The remaining argument will not be used in standard applications.*
- `where` the position or environment in which to store the resulting methods. Do not use this argument when defining a method in a package. Only the default, the namespace of the package, should be used in normal situations.
Inheritance and Coercion

Objects from one class can turn into objects from another class either automatically or by an explicit call to the `as` function. Automatic conversion is special, and comes from the designer of one class of objects asserting that this class extends another class. The most common case is that one or more class names are supplied in the `contains=` argument to `setClass`, in which case the new class extends each of the earlier classes (in the usual terminology, the earlier classes are superclasses of the new class and it is a subclass of each of them).

This form of inheritance is called simple inheritance in R. See `setClass` for details. Inheritance can also be defined explicitly by a call to `setIs`. The two versions have slightly different implications for coerce methods. Simple inheritance implies that inherited slots behave identically in the subclass and the superclass. Whenever two classes are related by simple inheritance, corresponding coerce methods are defined for both direct and replacement use of `as`. In the case of simple inheritance, these methods do the obvious computation: they extract or replace the slots in the object that correspond to those in the superclass definition.

The implicitly defined coerce methods may be overridden by a call to `setAs`; note, however, that the implicit methods are defined for each subclass-superclass pair, so that you must override each of these explicitly, not rely on inheritance.

When inheritance is defined by a call to `setIs`, the coerce methods are provided explicitly, not generated automatically. Inheritance will apply (to the `from` argument, as described in the section below). You could also supply methods via `setAs` for non-inherited relationships, and now these also can be inherited.

For further on the distinction between simple and explicit inheritance, see `setIs`.

How Functions `as` and `setAs` Work

The function `as` turns object into an object of class `Class`. In doing so, it applies a “coerce method”, using S4 classes and methods, but in a somewhat special way. Coerce methods are methods for the function `coerce` or, in the replacement case the function `coerce<->`. These functions have two arguments in method signatures, `from` and `to`, corresponding to the class of the object and the desired coerce class. These functions must not be called directly, but are used to store tables of methods for the use of `as`, directly and for replacements. In this section we will describe the direct case, but except where noted the replacement case works the same way, using `coerce<->` and the `replace` argument to `setAs`, rather than `coerce` and the `def` argument.

Assuming the object is not already of the desired class, `as` first looks for a method in the table of methods for the function `coerce` for the signature `c(from = class(object), to = Class)`, in the same way method selection would do its initial lookup. To be precise, this means the table of both direct and inherited methods, but inheritance is used specially in this case (see below).

If no method is found, `as` looks for an inherited method, but applying, inheritance for the argument `from` only, not for the argument `to` (if you think about it, you’ll probably agree that you wouldn’t want the result to be from some class other than the `Class` specified). Thus, `selectMethod("coerce", sig, useInherited= c(from=TRUE, to= FALSE))` replicates the method selection used by `as()`.

In nearly all cases the method found in this way will be cached in the table of coerce methods (the exception being subclass relationships with a test, which are legal but discouraged). So the detailed calculations should be done only on the first occurrence of a coerce from `class(object)` to `Class`. 

Note that `coerce` is not a standard generic function. It is not intended to be called directly. To prevent accidentally caching an invalid inherited method, calls are routed to an equivalent call to `as`, and a warning is issued. Also, calls to `selectMethod` for this function may not represent the method that `as` will choose. You can only trust the result if the corresponding call to `as` has occurred previously in this session.

With this explanation as background, the function `setAs` does a fairly obvious computation: It constructs and sets a method for the function `coerce` with signature `c(from, to)`, using the `def` argument to define the body of the method. The function supplied as `def` can have one argument (interpreted as an object to be coerced) or two arguments (the `from` object and the `to` class). Either way, `setAs` constructs a function of two arguments, with the second defaulting to the name of the `to` class. The method will be called from `as` with the object as the `from` argument and no `to` argument, with the default for this argument being the name of the intended to class, so the method can use this information in messages.

The direct version of the `as` function also has a `strict=` argument that defaults to `TRUE`. Calls during the evaluation of methods for other functions will set this argument to `FALSE`. The distinction is relevant when the object being coerced is from a simple subclass of the `to` class; if `strict=FALSE` in this case, nothing need be done. For most user-written coerce methods, when the two classes have no subclass/superclass, the `strict=` argument is irrelevant.

The `replace` argument to `setAs` provides a method for `coerce<-`. As with all replacement methods, the last argument of the method must have the name value for the object on the right of the assignment. As with the `coerce` method, the first two arguments are `from`, `to`; there is no `strict=` option for the replace case.

The function `coerce` exists as a repository for such methods, to be selected as described above by the `as` function. Actually dispatching the methods using `standardGeneric` could produce incorrect inherited methods, by using inheritance on the `to` argument; as mentioned, this is not the logic used for `as`. To prevent selecting and caching invalid methods, calls to `coerce` are currently mapped into calls to `as`, with a warning message.

### Basic Coercion Methods

Methods are pre-defined for coercing any object to one of the basic datatypes. For example, `as(x, "numeric")` uses the existing `as.numeric` function. These built-in methods can be listed by `showMethods("coerce")`.

### References

### See Also

If you think of using `try(as(x, cl))`, consider `canCoerce(x, cl)` instead.

### Examples

```r
## using the definition of class "track" from \link{setClass}

setAs("track", "numeric", function(from) from@y)

t1 <- new("track", x=1:20, y=(1:20)^2)
as(t1, "numeric")
```
## The next example shows:
## 1. A virtual class to define setAs for several classes at once.
## 2. as() using inherited information

```r
setClass("ca", slots = c(a = "character", id = "numeric"))
setClass("cb", slots = c(b = "character", id = "numeric"))
setClass("id")
setIs("ca", "id")
setIs("cb", "id")
setAs("id", "numeric", function(from) from@id)
CA <- new("ca", a = "A", id = 1)
CB <- new("cb", b = "B", id = 2)
setAs("cb", "ca", function(from, to) new(to, a=from@b, id = from@id))
as(CB, "numeric")
```

---

**setClass**

*Create a Class Definition*

### Description

Create a class definition and return a generator function to create objects from the class. Typical usage will be of the style:

```r
myClass <- setClass("myClass", slots= ... , contains= ...)
```

where the first argument is the name of the new class and, if supplied, the arguments `slots=` and `contains=` specify the slots in the new class and existing classes from which the new class should inherit. Calls to `setClass()` are normally found in the source of a package: when the package is loaded the class will be defined in the package's namespace. Assigning the generator function with the name of the class is convenient for users, but not a requirement.

### Usage

```r
setClass(Class, representation, prototype, contains=character(),
         validity, access, where, version, sealed, package,
         S3methods = FALSE, slots)
```

### Arguments

- **Class**: character string name for the class.
- **slots**: The names and classes for the slots in the new class. This argument must be supplied by name, `slots=`, in the call, for back compatibility with other arguments no longer recommended.
The argument must be vector with a names attribute, the names being those of
the slots in the new class. Each element of the vector specifies an existing class;
the corresponding slot must be from this class or a subclass of it. Usually, this
is a character vector naming the classes. It's also legal for the elements of
the vector to be class representation objects, as returned by getClass.
As a limiting case, the argument may be an unnamed character vector; the ele-
ments are taken as slot names and all slots have the unrestricted class "ANY".

contains  A vector specifying existing classes from which this class should inherit. The
new class will have all the slots of the superclasses, with the same require-
ments on the classes of these slots. This argument must be supplied by name,
contains=, in the call, for back compatibility with other arguments no longer
recommended.
See the section ‘Virtual Classes’ for the special superclass "VIRTUAL".

prototype, where, validity, sealed, package
  These arguments are currently allowed, but either they are unlikely to be useful
or there are modern alternatives that are preferred.
prototype: supplies an object with the default data for the slots in this class. A
more flexible approach is to write a method for initialize().
where: supplies an environment in which to store the definition. Should not be
used: For calls to setClass() appearing in the source code for a package the
definition will be stored in the namespace of the package.
validity: supplied a validity-checking method for objects from this class. For
clearer code, use a separate call to setValidity().
sealed: if TRUE, the class definition will be sealed, so that another call to
setClass will fail on this class name. But the definition is automatically sealed
after the namespace is loaded, so explicit sealing it is not needed.
package: supplies an optional package name for the class, but the class attribute
should be the package in which the class definition is assigned, as it is by default.

representation, access, version, S3methods
  All these arguments are deprecated from version 3.0.0 of R and should be
avoided.
representation is an argument inherited from S that included both slots and
contains, but the use of the latter two arguments is clearer and recommended.
access and version are included for historical compatibility with S-Plus, but
ignored.
S3methods is a flag indicating that old-style methods will be written involving
this class; ignored now.

Value
A generator function suitable for creating objects from the class is returned, invisibly. A call to this
function generates a call to new for the class. The call takes any number of arguments, which will
be passed on to the initialize method. If no initialize method is defined for the class or one of
its superclasses, the default method expects named arguments with the name of one of the slots and
unnamed arguments that are objects from one of the contained classes.
Typically the generator function is assigned the name of the class, for programming clarity. This is
not a requirement and objects from the class can also be generated directly from new. The advan-
tages of the generator function are a slightly simpler and clearer call, and that the call will contain
the package name of the class (eliminating any ambiguity if two classes from different packages
have the same name).
If the class is virtual, an attempt to generate an object from either the generator or new() will result in an error.

**Basic Use: Slots and Inheritance**

The two essential arguments other than the class name are slots and contains, defining the explicit slots and the inheritance (superclasses). Together, these arguments define all the information in an object from this class; that is, the names of all the slots and the classes required for each of them.

The name of the class determines which methods apply directly to objects from this class. The superclass information specifies which methods apply indirectly, through inheritance. See Methods_Details for inheritance in method selection.

The slots in a class definition will be the union of all the slots specified directly by slots and all the slots in all the contained classes. There can only be one slot with a given name. A class may override the definition of a slot with a given name, but only if the newly specified class is a subclass of the inherited one. For example, if the contained class had a slot a with class "ANY", then a subclass could specify a with class "numeric", but if the original specification for the slot was class "character", the new call to setClass would generate an error.

Slot names "class" and "Class" are not allowed. There are other slot names with a special meaning; these names start with the "." character. To be safe, you should define all of your own slots with names starting with an alphabetic character.

Some inherited classes will be treated specially—object types, S3 classes and a few special cases—whether inherited directly or indirectly. See the next three sections.

**Virtual Classes**

Classes exist for which no actual objects can be created, the virtual classes.

The most common and useful form of virtual class is the class union, a virtual class that is defined in a call to setClassUnion() rather than a call to setClass(). This call lists the members of the union—subclasses that extend the new class. Methods that are written with the class union in the signature are eligible for use with objects from any of the member classes. Class unions can include as members classes whose definition is otherwise sealed, including basic R data types.

Calls to setClass() will also create a virtual class, either when only the Class argument is supplied (no slots or superclasses) or when the contains= argument includes the special class name "VIRTUAL".

In the latter case, a virtual class may include slots to provide some common behavior without fully defining the object—see the class traceable for an example. Note that "VIRTUAL" does not carry over to subclasses; a class that contains a virtual class is not itself automatically virtual.

**Inheriting from Object Types**

In addition to containing other S4 classes, a class definition can contain either an S3 class (see the next section) or a built-in R pseudo-class—one of the R object types or one of the special R pseudo-classes "matrix" and "array". A class can contain at most one of the object types, directly or indirectly. When it does, that contained class determines the “data part” of the class. This appears as a pseudo-slot, ".Data" and can be treated as a slot but actually determines the type of objects from this slot.

Objects from the new class try to inherit the built in behavior of the contained type. In the case of normal R data types, including vectors, functions and expressions, the implementation is relatively straightforward. For any object x from the class, typeof(x) will be the contained basic type; and a special pseudo-slot, .Data, will be shown with the corresponding class. See the "numWithId" example below.
Classes may also inherit from "vector", "matrix" or "array". The data part of these objects can be any vector data type.

For an object from any class that does not contain one of these types or classes, typeof(x) will be "S4".

Some R data types do not behave normally, in the sense that they are non-local references or other objects that are not duplicated. Examples include those corresponding to classes "environment", "externalptr", and "name". These can not be the types for objects with user-defined classes (either S4 or S3) because setting an attribute overwrites the object in all contexts. It is possible to define a class that inherits from such types, through an indirect mechanism that stores the inherited object in a reserved slot, ".xData". See the example for class "stampedEnv" below. An object from such a class does not have a ".Data" pseudo-slot.

For most computations, these classes behave transparently as if they inherited directly from the anomalous type. S3 method dispatch and the relevant as.type() functions should behave correctly, but code that uses the type of the object directly will not. For example, as.environment(e1) would work as expected with the "stampedEnv" class, but typeof(e1) is "S4".

**Inheriting from S3 Classes**

Old-style S3 classes have no formal definition. Objects are “from” the class when their class attribute contains the character string considered to be the class name.

Using such classes with formal classes and methods is necessarily a risky business, since there are no guarantees about the content of the objects or about consistency of inherited methods. Given that, it is still possible to define a class that inherits from an S3 class, providing that class has been registered as an old class (see setOldClass).

Broadly speaking, both S3 and S4 method dispatch try to behave sensibly with respect to inheritance in either system. Given an S4 object, S3 method dispatch and the inherits function should use the S4 inheritance information. Given an S3 object, an S4 generic function will dispatch S4 methods using the S3 inheritance, provided that inheritance has been declared via setOldClass. For details, see setOldClass and Section 10.8 of the reference.

**Classes and Packages**

Class definitions normally belong to packages (but can be defined in the global environment as well, by evaluating the expression on the command line or in a file sourced from the command line). The corresponding package name is part of the class definition; that is, part of the classRepresentation object holding that definition. Thus, two classes with the same name can exist in different packages, for most purposes.

When a class name is supplied for a slot or a superclass in a call to setClass, a corresponding class definition will be found, looking from the namespace of the current package, assuming the call in question appears directly in the source for the package, as it should to avoid ambiguity. The class definition must be already defined in this package, in the imports directives of the package’s DESCRIPTION and NAMESPACE files or in the basic classes defined by the methods package. (The ‘methods’ package must be included in the imports directives for any package that uses S4 methods and classes, to satisfy the "CMD check" utility.)

If a package imports two classes of the same name from separate packages, the packageSlot of the name argument needs to be set to the package name of the particular class. This should be a rare occurrence.

Examples

## A simple class with two slots
track <- setClass("track", slots = c(x="numeric", y="numeric"))
## an object from the class
t1 <- track(x = 1:10, y = 1:10 + rnorm(10))

## A class extending the previous, adding one more slot
trackCurve <- setClass("trackCurve",
    slots = c(smooth = "numeric"),
    contains = "track")
## an object containing a superclass object
t1s <- trackCurve(t1, smooth = 1:10)

## A class similar to "trackCurve", but with different structure
## allowing matrices for the "y" and "smooth" slots
setClass("trackMultiCurve",
    slots = c(x="numeric", y="matrix", smooth="matrix"),
    prototype = list(x=numeric(), y=matrix(0,0,0),
        smooth= matrix(0,0,0)))
## A class that extends the built-in data type "numeric"
numWithId <- setClass("numWithId", slots = c(id = "character"),
    contains = "numeric")
numWithId(1:3, id = "An Example")

## inherit from reference object of type "environment"
stampedEnv <- setClass("stampedEnv", contains = "environment",
    slots = c(update = "POSIXct"))
setMethod("[[<-", c("stampedEnv", "character", "missing"),
    function(x, i, j, ..., value) {
        ev <- as(x, "environment")
        ev[[i]] <- value #update the object in the environment
        x@update <- Sys.time() # and the update time
    }]

e1 <- stampedEnv(update = Sys.time())
e1["noise"] <- rnorm(10)
A class may be defined as the union of other classes; that is, as a virtual class defined as a superclass of several other classes. Class unions are useful in method signatures or as slots in other classes, when we want to allow one of several classes to be supplied.

### Usage

```r
classUnion(name, members, where)
classIs(Class)
```

### Arguments

- **name**: the name for the new union class.
- **members**: the names of the classes that should be members of this union.
- **where**: where to save the new class definition. In calls from a package's source code, should be omitted to save the definition in the package's namespace.
- **Class**: the name or definition of a class.

### Details

The classes in `members` must be defined before creating the union. However, members can be added later on to an existing union, as shown in the example below. Class unions can be members of other class unions.

Class unions are the only way to create a new superclass of a class whose definition is sealed. The namespace of all packages is sealed when the package is loaded, protecting the class and other definitions from being overwritten from another class or from the global environment. A call to `classIs` that tried to define a new superclass for class "numeric", for example, would cause an error.

Class unions are the exception; the class union "maybeNumber" in the examples defines itself as a new superclass of "numeric". Technically, it does not alter the metadata object in the other package's namespace and, of course, the effect of the class union depends on loading the package it belongs to. But, basically, class unions are sufficiently useful to justify the exemption.

The different behavior for class unions is made possible because the class definition object for class unions has itself a special class, "ClassUnionRepresentation", an extension of class `classRepresentation`.

### References

### Examples

```r
## a class for either numeric or logical data
classUnion("maybeNumber", c("numeric", "logical"))

## use the union as the data part of another class
class("withId", contains = "maybeNumber", slots = c(id = "character"))

w1 <- new("withId", 1:10, id = "test 1")
w2 <- new("withId", sqrt(w1)%*%1 < .01, id = "Perfect squares")

## add class "complex" to the union "maybeNumber"
classIs("complex", "maybeNumber")
```
w3 <- new("withId", complex(real = 1:10, imaginary = sqrt(1:10)))

## a class union containing the existing class union "OptionalFunction"
setClassUnion("maybeCode",
c("expression", "language", "OptionalFunction"))

is(quote(sqrt(1:10)), "maybeCode") ## TRUE

---

**setGeneric**  
Create a Generic Version of a Function

**Description**

Create a generic version of the named function so that methods may be defined for it. A call to `setMethod` will call `setGeneric` automatically if applied to a non-generic function.

An explicit call to `setGeneric` is usually not required, but doesn't hurt and makes explicit that methods are being defined for a non-generic function.

Standard calls will be of the form:

```r
setGeneric(name)
```

where `name` specifies an existing function, possibly in another package. An alternative when creating a new generic function in this package is:

```r
setGeneric(name, def)
```

where the function definition `def` specifies the formal arguments and becomes the default method.

**Usage**

```r
setGeneric(name, def= , group=list(), valueClass=character(),
where= , package= , signature= , useAsDefault= ,
genericFunction= , simpleInheritanceOnly = )
```

**Arguments**

- **name**  
The character string name of the generic function.

- **def**  
An optional function object, defining the non-generic version, to become the default method. This is equivalent in effect to assigning `def` as the function and then using the one-argument call to `setGeneric`.

*The following arguments are specialized, optionally used when creating a new generic function with non-standard features. They should not be used when the non-generic is in another package.*

- **group**  
The name of the group generic function to which this function belongs. See `Methods_Details` for details of group generic functions in method selection and `S4groupGeneric` for existing groups.

- **valueClass**  
A character vector specifying one or more class names. The value returned by the generic function must have (or extend) this class, or one of the classes; otherwise, an error is generated.
**signature**  The vector of names from among the formal arguments to the function, that will be allowed in the signature of methods for this function, in calls to `setMethod`. By default and usually, this will be all formal arguments except ... A non-standard signature for the generic function may be used to exclude arguments that take advantage of lazy evaluation; in particular, if the argument may not be evaluated then it cannot be part of the signature.

While ... cannot be used as part of a general signature, it is possible to have this as the only element of the signature. Methods will then be selected if their signature matches all the ... arguments. See the documentation for topic `dotsMethods` for details. It is not possible to mix ... and other arguments in the signature.

It's usually a mistake to omit arguments from the signature in the belief that this improves efficiency. For method selection, the arguments that are used in the signatures for the methods are what counts, and then only seriously on the first call to the function with that combination of classes.

**simpleInheritanceOnly**  Supply this argument as `TRUE` to require that methods selected be inherited through simple inheritance only; that is, from superclasses specified in the `contains=` argument to `setClass`, or by simple inheritance to a class union or other virtual class. Generic functions should require simple inheritance if they need to be assured that they get the complete original object, not one that has been transformed. Examples of functions requiring simple inheritance are `initialize`, because by definition it must return an object from the same class as its argument, and `show`, because it claims to give a full description of the object provided as its argument.

**useAsDefault**  Override the usual default method mechanism. Only relevant when defining a nonstandard generic function. See the section ‘Specialized Local Generics’.

**package**  The name of the package with which this function is associated. Should be determined automatically from the non-generic version.

**where**  Where to store the resulting objects as side effects. The default, to store in the package’s namespace, is the only safe choice.

**genericFunction**  Obsolete.

**Value**

The `setGeneric` function exists for its side effect: saving the generic function to allow methods to be specified later. It returns `name`.

**Basic Use**

The `setGeneric` function is called to initialize a generic function as preparation for defining some methods for that function.

The simplest and most common situation is that `name` specifies an existing function, usually in another package. You now want to define methods for this function. In this case you should supply only `name`, for example:

```r
setGeneric("colSums")
```

There must be an existing function of this name (in this case in package "base"). The non-generic function can be in the same package as the call, typically the case when you are creating a new function plus methods for it. When the function is in another package, it must be available by name,
for example through an `importFrom()` directive in this package’s NAMESPACE file. Not required for functions in "base", which are implicitly imported.

A generic version of the function will be created in the current package. The existing function becomes the default method, and the package slot of the new generic function is set to the location of the original function ("base" in the example).

Two special types of non-generic should be noted. Functions that dispatch S3 methods by calling `UseMethod` are ordinary functions, not objects from the "genericFunction" class. They are made generic like any other function, but some special considerations apply to ensure that S4 and S3 method dispatch is consistent (see Methods_for_S3).

Primitive functions are handled in C code and don’t exist as normal functions. A call to `setGeneric` is allowed in the simple form, but no actual generic function object is created. Method dispatch will take place in the C code. See the section on Primitive Functions for more details.

It’s an important feature that the identical generic function definition is created in every package that uses the same `setGeneric()` call. When any of these packages is loaded into an R session, this function will be added to a table of generic functions, and will contain a methods table of all the available methods for the function.

Calling `setGeneric()` is not strictly necessary before calling `setMethod()`. If the function specified in the call to `setMethod` is not generic, `setMethod` will execute the call to `setGeneric` itself. In the case that the non-generic is in another package, does not dispatch S3 methods and is not a primitive, a message is printed noting the creation of the generic function the first time `setMethod` is called.

The second common use of `setGeneric()` is to create a new generic function, unrelated to any existing function. See the `asRObject()` example below. This case can be handled just like the previous examples, with only the difference that the non-generic function exists in the current package.

Again, the non-generic version becomes the default method. For clarity it’s best for the assignment to immediately precede the call to `setGeneric()` in the source code.

Exactly the same result can be obtained by supplying the default as the `def` argument instead of assigning it. In some applications, there will be no completely general default method. While there is a special mechanism for this (see the ‘Specialized Local Generics’ section), the recommendation is to provide a default method that signals an error, but with a message that explains as clearly as you can why a non-default method is needed.

### Specialized Local Generics

The great majority of calls to `setGeneric()` should either have one argument to ensure that an existing function can have methods, or arguments `name` and `def` to create a new generic function and optionally a default method.

It is possible to create generic functions with nonstandard signatures, or functions that do additional computations besides method dispatch or that belong to a group of generic functions.

None of these mechanisms should be used with a non-generic function from a different package, because the result is to create a generic function that may not be consistent from one package to another. When any such options are used, the new generic function will be assigned with a package slot set to the current package, not the one in which the non-generic version of the function is found.

There is a mechanism to define a specialized generic version of a non-generic function, the `implicitGeneric` construction. This defines the generic version, but then reverts the function to it non-generic form, saving the implicit generic in a table to be activated when methods are defined. However, the mechanism can only legitimately be used either for a non-generic in the same package or by the “methods” package itself. And in the first case, there is no compelling reason not to simply make the function generic, with the non-generic as the default method. See `implicitGeneric` for details.
The body of a generic function usually does nothing except for dispatching methods by a call to `standardGeneric`. Under some circumstances you might just want to do some additional computation in the generic function itself. As long as your function eventually calls `standardGeneric` that is permissible. See the example “authorNames” below.

In this case, the `def` argument will define the nonstandard generic, not the default method. An existing non-generic of the same name and calling sequence should be pre-assigned. It will become the default method, as usual. (An alternative is the `useAsDefault` argument.)

By default, the generic function can return any object. If `valueClass` is supplied, it should be a vector of class names; the value returned by a method is then required to satisfy `is(object, Class)` for one of the specified classes. An empty (i.e., zero length) vector of classes means anything is allowed. Note that more complicated requirements on the result can be specified explicitly, by defining a non-standard generic function.

If the `def` argument calls `standardGeneric` (with or without additional computations) and there is no existing non-generic version of the function, the generic is created without a default method. This is not usually a good idea: better to have a default method that signals an error with a message explaining why the default case is not defined.

A new generic function can be created belonging to an existing group by including the `group` argument. The argument list of the new generic must agree with that of the group. See `setGroupGeneric` for defining a new group generic. For the role of group generics in dispatching methods, see `GroupGenericFunctions` and section 10.5 of the second reference.

**Generic Functions and Primitive Functions**

A number of the basic R functions are specially implemented as primitive functions, to be evaluated directly in the underlying C code rather than by evaluating an R language definition. Most have implicit generics (see `implicitGeneric`), and become generic as soon as methods (including group methods) are defined on them. Others cannot be made generic.

Calling `setGeneric()` for the primitive functions in the base package differs in that it does not, in fact, generate an explicit generic function. Methods for primitives are selected and dispatched from the internal C code, to satisfy concerns for efficiency. The same is true for a few non-primitive functions that dispatch internally. These include `unlist` and `as.vector`.

Note, that the implementation restrict methods for primitive functions to signatures in which at least one of the classes in the signature is a formal S4 class. Otherwise the internal C code will not look for methods. This is a desirable restriction in principle, since optional packages should not be allowed to change the behavior of basic R computations on existing data types.

To see the generic version of a primitive function, use `getGeneric(name)`. The function `isGeneric` will tell you whether methods are defined for the function in the current session.

Note that S4 methods can only be set on those primitives which are ‘internal generic’, plus `%*%`.

Examples

```r
## Specify that this package will define methods for plot()
setGeneric("plot")

## create a new generic function, with a default method
setGeneric("props", function(object) attributes(object))

### A non-standard generic function. It insists that the methods
### return a non-empty character vector (a stronger requirement than
### valueClass = "character" in the call to setGeneric)
setGeneric("authorNames",
  function(text) {
    value <- standardGeneric("authorNames")
    if(!(is(value, "character") && any(nchar(value)>0)))
      stop("authorNames methods must return non-empty strings")
    value
  })

## the asRObject generic function, from package XR
## Its default method just returns object
## See the reference, Chapter 12 for methods
setGeneric("asRObject", function(object, evaluator) {
  object
})
```

Description

The `setGroupGeneric` function behaves like `setGeneric` except that it constructs a group generic function, differing in two ways from an ordinary generic function. First, this function cannot be called directly, and the body of the function created will contain a stop call with this information. Second, the group generic function contains information about the known members of the group, used to keep the members up to date when the group definition changes, through changes in the search list or direct specification of methods, etc.

All members of the group must have the identical argument list.

Usage

```r
setGroupGeneric(name, def= , group=list(), valueClass=character(),
  knownMembers=list(), package= , where= )
```

Arguments

- `name` the character string name of the generic function.
def A function object. There isn’t likely to be an existing nongeneric of this name, so some function needs to be supplied. Any known member or other function with the same argument list will do, because the group generic cannot be called directly.

group, valueClass arguments to pass to \texttt{setGeneric}.

knownMembers the names of functions that are known to be members of this group. This information is used to reset cached definitions of the member generics when information about the group generic is changed.

package, where passed to \texttt{setGeneric}, but obsolete and to be avoided.

Value

The \texttt{setGroupGeneric} function exists for its side effect: saving the generic function to allow methods to be specified later. It returns name.

Examples

```r
## Not run:
## the definition of the "Logic" group generic in the methods package
cat(setGroupGeneric("Logic", function(e1, e2) NULL,
    knownMembers = c("\&", "\|")))
## End(Not run)
```

**setIs** Specify a Superclass Explicitly

Description

\texttt{setIs} is an explicit alternative to the \texttt{contains=} argument to \texttt{setClass}. It is only needed to create relations with explicit test or coercion. These have not proved to be of much practical value, so this function should not likely be needed in applications.

Where the programming goal is to define methods for transforming one class of objects to another, it is usually better practice to call \texttt{setAs()}, which requires the transformations to be done explicitly.

Usage

```r
setIs(class1, class2, test=NULL, coerce=NULL, replace=NULL,
    by = character(), where = toplevel(parent.frame()), classDef =,
    extensionObject = NULL, doComplete = TRUE)
```
Arguments

class1, class2 the names of the classes between which is relations are to be examined defined, or (more efficiently) the class definition objects for the classes.

coerce, replace functions optionally supplied to coerce the object to class2, and to alter the object so that is(object, class2) is identical to value. See the details section below.

test a conditional relationship is defined by supplying this function. Conditional relations are discouraged and are not included in selecting methods. See the details section below.

The remaining arguments are for internal use and/or usually omitted.

extensionObject alternative to the test, coerce, replace, by arguments; an object from class SClassExtension describing the relation. (Used in internal calls.)

doComplete when TRUE, the class definitions will be augmented with indirect relations as well. (Used in internal calls.)

by In a call to setIs, the name of an intermediary class. Coercion will proceed by first coercing to this class and from there to the target class. (The intermediate coercions have to be valid.)

where In a call to setIs, where to store the metadata defining the relationship. Default is the global environment for calls from the top level of the session or a source file evaluated there. When the call occurs in the top level of a file in the source of a package, the default will be the namespace or environment of the package. Other uses are tricky and not usually a good idea, unless you really know what you are doing.

classDef Optional class definition for class, required internally when setIs is called during the initial definition of the class by a call to setClass. Don’t use this argument, unless you really know why you’re doing so.

Details

Arranging for a class to inherit from another class is a key tool in programming. In R, there are three basic techniques, the first two providing what is called “simple” inheritance, the preferred form:

1. By the contains= argument in a call to setClass. This is and should be the most common mechanism. It arranges that the new class contains all the structure of the existing class, and in particular all the slots with the same class specified. The resulting class extension is defined to be simple, with important implications for method definition (see the section on this topic below).

2. Making class1 a subclass of a virtual class either by a call to setClassUnion to make the subclass a member of a new class union, or by a call to setIs to add a class to an existing class union or as a new subclass of an existing virtual class. In either case, the implication should be that methods defined for the class union or other superclass all work correctly for the subclass. This may depend on some similarity in the structure of the subclasses or simply indicate that the superclass methods are defined in terms of generic functions that apply to all the subclasses. These relationships are also generally simple.

3. Supplying coerce and replace arguments to setAs. R allows arbitrary inheritance relationships, using the same mechanism for defining coerce methods by a call to setAs. The difference between the two is simply that setAs will require a call to as for a conversion
to take place, whereas after the call to `setIs`, objects will be automatically converted to the superclass.

The automatic feature is the dangerous part, mainly because it results in the subclass potentially inheriting methods that do not work. See the section on inheritance below. If the two classes involved do not actually inherit a large collection of methods, as in the first example below, the danger may be relatively slight.

If the superclass inherits methods where the subclass has only a default or remotely inherited method, problems are more likely. In this case, a general recommendation is to use the `setAs` mechanism instead, unless there is a strong counter reason. Otherwise, be prepared to override some of the methods inherited.

With this caution given, the rest of this section describes what happens when `coerce=` and `replace=` arguments are supplied to `setIs`.

The `coerce` and `replace` arguments are functions that define how to coerce a `class1` object to `class2`, and how to replace the part of the subclass object that corresponds to `class2`. The first of these is a function of one argument which should be `from`, and the second of two arguments (`from`, `value`). For details, see the section on coerce functions below.

When `by` is specified, the coerce process first coerces to this class and then to `class2`. It’s unlikely you would use the `by` argument directly, but it is used in defining cached information about classes.

The value returned (invisibly) by `setIs` is the revised class definition of `class1`.

**Coerce, replace, and test functions**

The `coerce` argument is a function that turns a `class1` object into a `class2` object. The `replace` argument is a function of two arguments that modifies a `class1` object (the first argument) to replace the part of it that corresponds to `class2` (supplied as `value`, the second argument). It then returns the modified object as the value of the call. In other words, it acts as a replacement method to implement the expression `as(object, class2) <- value`.

The easiest way to think of the `coerce` and `replace` functions is by thinking of the case that `class1` contains `class2` in the usual sense, by including the slots of the second class. (To repeat, in this situation you would not call `setIs`, but the analogy shows what happens when you do.)

The `coerce` function in this case would just make a `class2` object by extracting the corresponding slots from the `class1` object. The `replace` function would replace in the `class1` object the slots corresponding to `class2`, and return the modified object as its value.

For additional discussion of these functions, see the documentation of the `setAs` function. (Unfortunately, argument `def` to that function corresponds to argument `coerce` here.)

The inheritance relationship can also be conditional, if a function is supplied as the test argument. This should be a function of one argument that returns `TRUE` or `FALSE` according to whether the object supplied satisfies the relation `is(object, class2)`. Conditional relations between classes are discouraged in general because they require a per-object calculation to determine their validity. They cannot be applied as efficiently as ordinary relations and tend to make the code that uses them harder to interpret. **NOTE: conditional inheritance is not used to dispatch methods.** Methods for conditional superclasses will not be inherited. Instead, a method for the subclass should be defined that tests the conditional relationship.

**Inherited methods**

A method written for a particular signature (classes matched to one or more formal arguments to the function) naturally assumes that the objects corresponding to the arguments can be treated as coming from the corresponding classes. The objects will have all the slots and available methods for the classes.
The code that selects and dispatches the methods ensures that this assumption is correct. If the inheritance was “simple”, that is, defined by one or more uses of the contains= argument in a call to setClass, no extra work is generally needed. Classes are inherited from the superclass, with the same definition.

When inheritance is defined by a general call to setIs, extra computations are required. This form of inheritance implies that the subclass does not just contain the slots of the superclass, but instead requires the explicit call to the coerce and/or replace method. To ensure correct computation, the inherited method is supplemented by calls to as before the body of the method is evaluated.

The calls to as generated in this case have the argument strict = FALSE, meaning that extra information can be left in the converted object, so long as it has all the appropriate slots. (It’s this option that allows simple subclass objects to be used without any change.) When you are writing your coerce method, you may want to take advantage of that option.

Methods inherited through non-simple extensions can result in ambiguities or unexpected selections. If class2 is a specialized class with just a few applicable methods, creating the inheritance relation may have little effect on the behavior of class1. But if class2 is a class with many methods, you may find that you now inherit some undesirable methods for class1, in some cases, fail to inherit expected methods. In the second example below, the non-simple inheritance from class "factor" might be assumed to inherit S3 methods via that class. But the S3 class is ambiguous, and in fact is "character" rather than "factor".

For some generic functions, methods inherited by non-simple extensions are either known to be invalid or sufficiently likely to be so that the generic function has been defined to exclude such inheritance. For example initialize methods must return an object of the target class; this is straightforward if the extension is simple, because no change is made to the argument object, but is essentially impossible. For this reason, the generic function insists on only simple extensions for inheritance. See the simpleInheritanceOnly argument to setGeneric for the mechanism. You can use this mechanism when defining new generic functions.

If you get into problems with functions that do allow non-simple inheritance, there are two basic choices. Either back off from the setIs call and settle for explicit coercing defined by a call to setAs; or, define explicit methods involving class1 to override the bad inherited methods. The first choice is the safer, when there are serious problems.

Examples
## Two examples of setIs() with coerce= and replace= arguments
## The first one works fairly well, because neither class has many
## inherited methods do be disturbed by the new inheritance

## The second example does NOT work well, because the new superclass,
## "factor", causes methods to be inherited that should not be.

## First example:
## a class definition (see \link{setClass} for class "track")
setClass("trackCurve", contains = "track",
  slots = c( smooth = "numeric"))

## A class similar to "trackCurve", but with different structure
## allowing matrices for the "y" and "smooth" slots
setClass("trackMultiCurve",
  slots = c(x="numeric", y="matrix", smooth="matrix"),
  prototype = structure(list(), x=numeric(), y=matrix(0,0,0),

## Automatically convert an object from class "trackCurve" into
## "trackMultiCurve", by making the y, smooth slots into 1-column matrices

```r
class = function(obj) {
  x = obj@x,
  y = as.matrix(obj@y),
  smooth = as.matrix(obj@smooth))
}
```

## Second Example:
## A class that adds a slot to "character"

```r
setClass("stringsDated", contains = "character",
  slots = c(stamp="POSIXt"))
```

## Convert automatically to a factor by explicit coerce

```r
setIs("stringsDated", "factor",
  coerce = function(from) factor(from@.Data),
  replace = function(from, value) {
    from@.Data <- as.character(value); from })
```

```r
ll <- sample(letters, 10, replace = TRUE)
l1d <- new("stringsDated", ll, stamp = Sys.time())
levels(as(l1d, "factor"))
levels(l1d) # will be NULL--see comment in section on inheritance above.
```

## In contrast, a class that simply extends "factor"
## has no such ambiguities

```r
setClass("factorDated", contains = "factor",
  slots = c(stamp="POSIXt"))
```

```r
fd <- new("factorDated", factor(ll), stamp = Sys.time())
identical(levels(fd), levels(as(fd, "factor")))
```

---

### Description

These functions provide a mechanism for packages to specify computations to be done during the loading of a package namespace. Such actions are a flexible way to provide information only available at load time (such as locations in a dynamically linked library).
A call to `setLoadAction()` or `setLoadActions()` specifies one or more functions to be called when the corresponding namespace is loaded, with the ...argument names being used as identifying names for the actions.

`getLoadActions` reports the currently defined load actions, given a package's namespace as its argument.

`hasLoadAction` returns `TRUE` if a load action corresponding to the given name has previously been set for the `where` namespace.

`evalOnLoad()` and `evalqOnLoad()` schedule a specific expression for evaluation at load time.

**Usage**

```r
setLoadAction(action, aname=, where=)
setLoadActions(..., .where=)
getLoadActions(where=)
hasLoadAction(aname, where=)
evalOnLoad(expr, where=, aname=)
evalqOnLoad(expr, where=, aname=)
```

**Arguments**

- `action, ...` functions of one or more arguments, to be called when this package is loaded. The functions will be called with one argument (the package namespace) so all following arguments must have default values. If the elements of ... are named, these names will be used for the corresponding load metadata.
- `where, .where` the namespace of the package for which the list of load actions are defined. This argument is normally omitted if the call comes from the source code for the package itself, but will be needed if a package supplies load actions for another package.
- `aname` the name for the action. If an action is set without supplying a name, the default uses the position in the sequence of actions specified (".1", etc.).
- `expr` an expression to be evaluated in a load action in environment `where`. In the case of `evalqOnLoad()`, the expression is interpreted literally, in that of `evalOnLoad()` it must be precomputed, typically as an object of type "language".

**Details**

The `evalOnLoad()` and `evalqOnLoad()` functions are for convenience. They construct a function to evaluate the expression and call `setLoadAction()` to schedule a call to that function.

Each of the functions supplied as an argument to `setLoadAction()` or `setLoadActions()` is saved as metadata in the namespace, typically that of the package containing the call to `setLoadActions()`. When this package's namespace is loaded, each of these functions will be called. Action functions are called in the order they are supplied to `setLoadActions()`. The objects assigned have metadata names constructed from the names supplied in the call; unnamed arguments are taken to be named by their position in the list of actions (".1", etc.).
Multiple calls to `setLoadAction()` or `setLoadActions()` can be used in a package’s code; the actions will be scheduled after any previously specified, except if the name given to `setLoadAction()` is that of an existing action. In typical applications, `setLoadActions()` is more convenient when calling from the package’s own code to set several actions. Calls to `setLoadAction()` are more convenient if the action name is to be constructed, which is more typical when one package constructs load actions for another package.

Actions can be revised by assigning with the same name, actual or constructed, in a subsequent call. The replacement must still be a valid function, but can of course do nothing if the intention was to remove a previously specified action.

The functions must have at least one argument. They will be called with one argument, the namespace of the package. The functions will be called at the end of processing of S4 metadata, after dynamically linking any compiled code, the call to `.onLoad()`, if any, and caching method and class definitions, but before the namespace is sealed. (Load actions are only called if methods dispatch is on.)

Functions may therefore assign or modify objects in the namespace supplied as the argument in the call. The mechanism allows packages to save information not available until load time, such as values obtained from a dynamically linked library.

Load actions should be contrasted with user load hooks supplied by `setHook()`. User hooks are generally provided from outside the package and are run after the namespace has been sealed. Load actions are normally part of the package code, and the list of actions is normally established when the package is installed.

Load actions can be supplied directly in the source code for a package. It is also possible and useful to provide facilities in one package to create load actions in another package. The software needs to be careful to assign the action functions in the correct environment, namely the namespace of the target package.

**Value**

`setLoadAction()` and `setLoadActions()` are called for their side effect and return no useful value.

`getLoadActions()` returns a named list of the actions in the supplied namespace.

`hasLoadAction()` returns `TRUE` if the specified action name appears in the actions for this package.

**See Also**

`setHook` for safer (since they are run after the namespace is sealed) and more comprehensive versions in the base package.

**Examples**

```r
## Not run:
## in the code for some package
## ... somewhere else
setLoadActions(function(ns)
  cat("Loaded package", sQuote(getNamespaceName(ns)),
      "at", format(Sys.time()), "\n"),
  setCount = function(ns) assign("myCount", 1, envir = ns),
  function(ns) assign("myPointer", getMyExternalPointer(), envir = ns))
... somewhere later
if(countShouldBe0)
  setLoadAction(function(ns) assign("myCount", 0, envir = ns), "setCount")
```
setMethod

Create and Save a Method

Description

Create a method for a generic function, corresponding to a signature of classes for the arguments. Standard usage will be of the form:

```r
setMethod(f, signature, definition)
```

where `f` is the name of the function, `signature` specifies the argument classes for which the method applies and `definition` is the function definition for the method.

Usage

```r
setMethod(f, signature=character(), definition, 
          where = toopenv(parent.frame()), 
          valueClass = NULL, sealed = FALSE)
```

Arguments

- **f**: The character-string name of the generic function. The unquoted name usually works as well (evaluating to the generic function), except for a few functions in the base package.
- **signature**: The classes required for some of the arguments. Most applications just require one or two character strings matching the first argument(s) in the signature. More complicated cases follow R’s rule for argument matching. See the details below; however, if the signature is not trivial, you should use `method.skeleton` to generate a valid call to `setMethod`.
- **definition**: A function definition, which will become the method called when the arguments in a call to `f` match the classes in `signature`, directly or through inheritance. The definition must be a function with the same formal arguments as the generic; however, `setMethod()` will handle methods that add arguments, if `...` is a formal argument to the generic. See the Details section.
- **where**, **valueClass**, **sealed**: These arguments are allowed but either obsolete or rarely appropriate.
  - where: where to store the definition; should be the default, the namespace for the package.
  - valueClass: obsolete.
  - sealed: prevents the method being redefined, but should never be needed when the method is defined in the source code of a package.

Value

The function exists for its side-effect. The definition will be stored in a special metadata object and incorporated in the generic function when the corresponding package is loaded into an R session.
Method Selection: Avoiding Ambiguity

When defining methods, it’s important to ensure that methods are selected correctly; in particular, packages should be designed to avoid ambiguous method selection.

To describe method selection, consider first the case where only one formal argument is in the active signature; that is, there is only one argument, \( x \) say, for which methods have been defined. The generic function has a table of methods, indexed by the class for the argument in the calls to `setMethod`. If there is a method in the table for the class of \( x \) in the call, this method is selected.

If not, the next best methods would correspond to the direct superclasses of \( \text{class}(x) \)—those appearing in the `contains=` argument when that class was defined. If there is no method for any of these, the next best would correspond to the direct superclasses of the first set of superclasses, and so on.

The first possible source of ambiguity arises if the class has several direct superclasses and methods have been defined for more than one of those; \( \text{R} \) will consider these equally valid and report an ambiguous choice. If your package has the class definition for \( \text{class}(x) \), then you need to define a method explicitly for this combination of generic function and class.

When more than one formal argument appears in the method signature, \( \text{R} \) requires the “best” method to be chosen unambiguously for each argument. Ambiguities arise when one method is specific about one argument while another is specific about a different argument. A call that satisfies both requirements is then ambiguous: The two methods look equally valid, which should be chosen? In such cases the package needs to add a third method requiring both arguments to match.

The most common examples arise with binary operators. Methods may be defined for individual operators, for special groups of operators such as `Arith` or for group `Ops`.

Exporting Methods

If a package defines methods for generic functions, those methods should be exported if any of the classes involved are exported; in other words, if someone using the package might expect these methods to be called. Methods are exported by including an `exportMethods()` directive in the `NAMESPACE` file for the package, with the arguments to the directive being the names of the generic functions for which methods have been defined.

Exporting methods is always desirable in the sense of declaring what you want to happen, in that you do expect users to find such methods. It can be essential in the case that the method was defined for a function that is not originally a generic function in its own package (for example, `plot()` in the `graphics` package). In this case it may be that the version of the function in the \( \text{R} \) session is not generic, and your methods will not be called.

Exporting methods for a function also exports the generic version of the function. Keep in mind that this does not conflict with the function as it was originally defined in another package; on the contrary, it’s designed to ensure that the function in the \( \text{R} \) session dispatches methods correctly for your classes and continues to behave as expected when no specific methods apply. See `Methods_Details` for the actual mechanism.

Details

The call to `setMethod` stores the supplied method definition in the metadata table for this generic function in the environment, typically the global environment or the namespace of a package. In the case of a package, the table object becomes part of the namespace or environment of the package. When the package is loaded into a later session, the methods will be merged into the table of methods in the corresponding generic function object.

Generic functions are referenced by the combination of the function name and the package name; for example, the function "show" from the package "methods". Metadata for methods is identified
by the two strings; in particular, the generic function object itself has slots containing its name and its package name. The package name of a generic is set according to the package from which it originally comes; in particular, and frequently, the package where a non-generic version of the function originated. For example, generic functions for all the functions in package base will have "base" as the package name, although none of them is an S4 generic on that package. These include most of the base functions that are primitives, rather than true functions; see the section on primitive functions in the documentation for setGeneric for details.

Multiple packages can have methods for the same generic function; that is, for the same combination of generic function name and package name. Even though the methods are stored in separate tables in separate environments, loading the corresponding packages adds the methods to the table in the generic function itself, for the duration of the session.

The class names in the signature can be any formal class, including basic classes such as "numeric", "character", and "matrix". Two additional special class names can appear: "ANY", meaning that this argument can have any class at all; and "missing", meaning that this argument must not appear in the call in order to match this signature. Don’t confuse these two: if an argument isn’t mentioned in a signature, it corresponds implicitly to class "ANY", not to "missing". See the example below. Old-style ('S3') classes can also be used, if you need compatibility with these, but you should definitely declare these classes by calling setOldClass if you want S3-style inheritance to work.

Method definitions can have default expressions for arguments, but only if the generic function must have some default expression for the same argument. (This restriction is imposed by the way R manages formal arguments.) If so, and if the corresponding argument is missing in the call to the generic function, the default expression in the method is used. If the method definition has no default for the argument, then the expression supplied in the definition of the generic function itself is used, but note that this expression will be evaluated using the enclosing environment of the method, not of the generic function. Method selection does not evaluate default expressions. All actual (non-missing) arguments in the signature of the generic function will be evaluated when a method is selected—when the call to standardGeneric(f) occurs. Note that specifying class "missing" in the signature does not require any default expressions.

It is possible to have some differences between the formal arguments to a method supplied to setMethod and those of the generic. Roughly, if the generic has ... as one of its arguments, then the method may have extra formal arguments, which will be matched from the arguments matching ... in the call to f. (What actually happens is that a local function is created inside the method, with the modified formal arguments, and the method is re-defined to call that local function.) Method dispatch tries to match the class of the actual arguments in a call to the available methods collected for f. If there is a method defined for the exact same classes as in this call, that method is used. Otherwise, all possible signatures are considered corresponding to the actual classes or to superclasses of the actual classes (including "ANY"). The method having the least distance from the actual classes is chosen; if more than one method has minimal distance, one is chosen (the lexicographically first in terms of superclasses) but a warning is issued. All inherited methods chosen are stored in another table, so that the inheritance calculations only need to be done once per session per sequence of actual classes. See Methods_Details and Section 10.7 of the reference for more details.

Examples

## examples for a simple class with two numeric slots.
## (Run example(setMethod) to see the class and function definitions)

## methods for plotting track objects
##
## First, with only one object as argument, plot the two slots
## y must be included in the signature, it would default to "ANY"
setMethod("plot", signature(x="track", y="missing"),
  function(x, y, ...) plot(x@x, x@y, ...)
)

## plot numeric data on either axis against a track object
## (reducing the track object to the cumulative distance along the track)
## Using a short form for the signature, which matches like formal arguments
setMethod("plot", c("track", "numeric"),
  function(x, y, ...) plot(cumdist(x@x, x@y), y, xlab = "Distance",...)
)

## and similarly for the other axis
setMethod("plot", c("numeric", "track"),
  function(x, y, ...) plot(x, cumdist(y@x, y@y), ylab = "Distance",...)
)

## First, with only one object as argument, plot the two slots
## y must be included in the signature, it would default to "ANY"
setMethod("plot", signature(x="track", y="missing"),
  function(x, y, ...) plot(x@x, x@y, ...)
)

## plot numeric data on either axis against a track object
## (reducing the track object to the cumulative distance along the track)
## Using a short form for the signature, which matches like formal arguments
setMethod("plot", c("track", "numeric"),
  function(x, y, ...) plot(cumdist(x@x, x@y), y, xlab = "Distance",...)
)

## and similarly for the other axis
setMethod("plot", c("numeric", "track"),
  function(x, y, ...) plot(x, cumdist(y@x, y@y), ylab = "Distance",...)
)

t1 <- new("track", x=1:20, y=(1:20)^2)
plot(t1)
plot(qnorm(ppoints(20)), t1)

## Now a class that inherits from "track", with a vector for data at
## the points
setClass("trackData", contains = c("numeric", "track"))
tc1 <- new("trackData", t1, rnorm(20))

## a method for plotting the object
## This method has an extra argument, allowed because ... is an
## argument to the generic function.
setMethod("plot", c("trackData", "missing"),
  function(x, y, maxRadius = max(par("cin")), ...) {
    plot(x@x, x@y, type = "n", ...)
    symbols(x@x, x@y, circles = abs(x), inches = maxRadius)
  }
)
plot(tc1)

## Without other methods for "trackData", methods for "track"
## will be selected by inheritance
plot(qnorm(ppoints(20)), tc1)

## defining methods for primitive function.
## Although "]" and "length" are not ordinary functions
## methods can be defined for them.
setMethod("[", "track",
  function(x, i, j, ..., drop) {
    x@x <- x@x[i]; x@y <- x@y[i]
    x
  })
plot(t1[1:15])

setMethod("length", "track", function(x)length(x@y))
length(t1)

## Methods for binary operators
## A method for the group generic "Ops" will apply to all operators
## unless a method for a more specific operator has been defined.
## For one trackData argument, go on with just the data part
setMethod("Ops", signature(e1 = "trackData"),
  function(e1, e2) callGeneric(e1@.Data, e2))

setMethod("Ops", signature(e2 = "trackData"),
  function(e1, e2) callGeneric(e1, e2@.Data))

## At this point, the choice of a method for a call with BOTH
## arguments from "trackData" is ambiguous. We must define a method.

setMethod("Ops", signature(e1 = "trackData", e2 = "trackData"),
  function(e1, e2) callGeneric(e1@.Data, e2@.Data))

## (well, really we should only do this if the "track" part
## of the two arguments matched)
tc1 +1
1/tc1

all(tc1 == tc1)

---

**setOldClass**

*Register Old-Style (S3) Classes and Inheritance*

### Description

Register an old-style (a.k.a. ‘S3’) class as a formally defined class. Simple usage will be of the form:

```r
setOldClass(Classes)
```

where `Classes` is the character vector that would be the `class` attribute of the S3 object. Calls to `setOldClass()` in the code for a package allow the class to be used as a slot in formal (S4) classes and in signatures for methods (see `Methods_for_S3`). Formal classes can also contain a registered S3 class (see `S3Part` for details).
If the S3 class has a known set of attributes, an equivalent S4 class can be specified by S4Class= in the call to setOldClass(); see the section “Known Attributes”.

Usage

```
setOldClass(Classes, prototype, where, test = FALSE, S4Class)
```

Arguments

- **Classes**: A character vector, giving the names for S3 classes, as they would appear on the right side of an assignment of the class attribute in S3 computations. In addition to S3 classes, an object type or other valid data part can be specified, if the S3 class is known to require its data to be of that form.
- **S4Class**: optionally, the class definition or the class name of an S4 class. The new class will have all the slots and other properties of this class, plus any S3 inheritance implied by multiple names in the Classes argument. See the section on “S3 classes with known attributes” below.
- **prototype**: An optional object to use as the prototype. If the S3 class is not to be VIRTUAL (the default), the use of S4Class= is preferred.
- **where**: Where to store the class definitions. Should be the default (the package namespace) for normal use in an application package.
- **test**: flag, if TRUE, arrange to test inheritance explicitly for each object, needed if the S3 class can have a different set of class strings, with the same first string. Such classes are inherently malformed, are rare, and should be avoided.

Details

The name (or each of the names) in Classes will be defined as an S4 class, extending class oldClass, which is the ‘root’ of all old-style classes. S3 classes with multiple names in their class attribute will have a corresponding inheritance as formal classes. See the “mlm” example.

S3 classes have no formal definition, and therefore no formally defined slots. If no S4 class is supplied as a model, the class created will be a virtual class. If a virtual class (any virtual class) is used for a slot in another class, then the initializing method for the class needs to put something legal in that slot; otherwise it will be set to NULL.

See Methods_for_S3 for the details of method dispatch and inheritance with mixed S3 and S4 methods.

Some S3 classes cannot be represented as an ordinary combination of S4 classes and superclasses, because objects with the same initial string in the class attribute can have different strings following. Such classes are fortunately rare. They violate the basic idea of object-oriented programming and should be avoided. If you must deal with them, it is still possible to register such classes as S4 classes, but now the inheritance has to be verified for each object, and you must call setOldClass with argument test=TRUE.

Pre-Defined Old Classes

Many of the widely used S3 classes in the standard R distribution come pre-defined for use with S4. These don’t need to be explicitly declared in your package (although it does no harm to do so).
The list .OldClassesList contains the old-style classes that are defined by the methods package. Each element of the list is a character vector, with multiple strings if inheritance is included. Each element of the list was passed to setOldClass when creating the methods package; therefore, these classes can be used in setMethod calls, with the inheritance as implied by the list.

**S3 Classes with known attributes**

A further specification of an S3 class can be made if the class is guaranteed to have some attributes of known class (where as with slots, “known” means that the attribute is an object of a specified class, or a subclass of that class).

In this case, the call to setOldClass() can supply an S4 class definition representing the known structure. Since S4 slots are implemented as attributes (largely for just this reason), the known attributes can be specified in the representation of the S4 class. The usual technique will be to create an S4 class with the desired structure, and then supply the class name or definition as the argument S4Class= to setOldClass().

See the definition of class "ts" in the examples below and the data.frame example in Section 10.2 of the reference. The call to setClass to create the S4 class can use the same class name, as here, so long as the call to setOldClass follows in the same package. For clarity it should be the next expression in the same file.

In the example, we define "ts" as a vector structure with a numeric slot for "tsp". The validity of this definition relies on an assertion that all the S3 code for this class is consistent with that definition; specifically, that all "ts" objects will behave as vector structures and will have a numeric "tsp" attribute. We believe this to be true of all the base code in R, but as always with S3 classes, no guarantee is possible.

The S4 class definition can have virtual superclasses (as in the "ts" case) if the S3 class is asserted to behave consistently with these (in the example, time-series objects are asserted to be consistent with the structure class).

Failures of the S3 class to live up to its asserted behavior will usually go uncorrected, since S3 classes inherently have no definition, and the resulting invalid S4 objects can cause all sorts of grief. Many S3 classes are not candidates for known slots, either because the presence or class of the attributes are not guaranteed (e.g., dimnames in arrays, although these are not even S3 classes), or because the class uses named components of a list rather than attributes (e.g., "lm"). An attribute that is sometimes missing cannot be represented as a slot, not even by pretending that it is present with class "NULL", because attributes, unlike slots, can not have value NULL.

One irregularity that is usually tolerated, however, is to optionally add other attributes to those guaranteed to exist (for example, "terms" in "data.frame" objects returned by model.frame). Validity checks by validObject ignore extra attributes; even if this check is tightened in the future, classes extending S3 classes would likely be exempted because extra attributes are so common.

setClass, setMethod

**Examples**

require(stats)
## "lm" and "mlm" are predefined; if they were not this would do it:
## Not run:
setOldClass(c("mlm", "lm"))
## End(Not run)

## Define a new generic function to compute the residual degrees of freedom
setGeneric("dfResidual",
  function(model) stop(gettextf(
      "This function only works for fitted model objects, not class %s",
      class(model))))

setMethod("dfResidual", "lm", function(model)model$df.residual)

## dfResidual will work on mlm objects as well as lm objects
myData <- data.frame(time = 1:10, y = (1:10)^.5)
myLm <- lm(cbind(y, y^3) ~ time, myData)

## two examples extending S3 class "lm": class "xlm" directly
## and "ylm" indirectly
setClass("xlm", slots = c(eps = "numeric"), contains = "lm")
setClass("ylm", slots = c(header = "character"), contains = "xlm")
yml = new("ylm", myLm, header = "Example", eps = 0.)
## for more examples, see ?\link{S3Class}.

## Not run:
## The code in R that defines "ts" as an S4 class
setClass("ts", contains = "structure", slots = c(tsp = "numeric"),
    prototype(NA, tsp = rep(1,3)))
# prototype to be a legal S3 time-series
## and now registers it as an S3 class
setOldClass("ts", S4Class = "ts", where = envir)
## End(Not run)

---

### Description

Display the object, by printing, plotting or whatever suits its class. This function exists to be specialized by methods. The default method calls `showDefault`.

Formal methods for `show` will usually be invoked for automatic printing (see the details).

### Usage

`show(object)`
**Arguments**

object  Any R object

**Details**

Objects from an S4 class (a class defined by a call to `setClass`) will be displayed automatically is if by a call to `show`. S4 objects that occur as attributes of S3 objects will also be displayed in this form; conversely, S3 objects encountered as slots in S4 objects will be printed using the S3 convention, as if by a call to `print`.

Methods defined for `show` will only be inherited by simple inheritance, since otherwise the method would not receive the complete, original object, with misleading results. See the `simpleInheritanceOnly` argument to `setGeneric` and the discussion in `setIs` for the general concept.

**Value**

`show` returns an invisible `NULL`.

**See Also**

`showMethods` prints all the methods for one or more functions.

**Examples**

```
## following the example shown in the setMethod documentation ...
setClass("track", slots = c(x="numeric", y="numeric"))
setClass("trackCurve", contains = "track", slots = c(smooth = "numeric"))
t1 <- new("track", x=1:20, y=(1:20)^2)
tc1 <- new("trackCurve", t1)
setMethod("show", "track", 
  function(object)print(rbind(x = object@x, y=object@y))
)
## The method will now be used for automatic printing of t1

  t1

  x 1  2  3  4  5  6  7  8  9 10 11 12
  y 1  4  9 16 25 36 49 64 81 100 121 144

## End(Not run)
```

```
## and also for tc1, an object of a class that extends "track"
tc1

  x 1  2  3  4  5  6  7  8  9 10 11 12
  y 1  4  9 16 25 36 49 64 81 100 121 144
```

showMethods

Show all the methods for the specified function(s) or class

Description

Show a summary of the methods for one or more generic functions, possibly restricted to those involving specified classes.

Usage

showMethods(f = character(), where = toplevel(parent.frame()),
             classes = NULL, includeDefs = FALSE,
             inherited = !includeDefs,
             showEmpty, printTo = stdout(), fdef)
      .S4methods(generic.function, class)

Arguments

f          one or more function names. If omitted, all functions will be shown that match the other arguments.
            The argument can also be an expression that evaluates to a single generic function, in which case argument fdef is ignored. Providing an expression for the function allows examination of hidden or anonymous functions; see the example for isDiagonal().

where      Where to find the generic function, if not supplied as an argument. When f is missing, or length 0, this also determines which generic functions to examine. If where is supplied, only the generic functions returned by getGenerics(where) are eligible for printing. If where is also missing, all the cached generic functions are considered.

classes    If argument classes is supplied, it is a vector of class names that restricts the displayed results to those methods whose signatures include one or more of those classes.

includeDefs If includeDefs is TRUE, include the definitions of the individual methods in the printout.

inherited  logical indicating if methods that have been found by inheritance, so far in the session, will be included and marked as inherited. Note that an inherited method will not usually appear until it has been used in this session. See selectMethod if you want to know what method would be dispatched for particular classes of arguments.

showEmpty  logical indicating whether methods with no defined methods matching the other criteria should be shown at all. By default, TRUE if and only if argument f is not missing.

printTo    The connection on which the information will be shown; by default, on standard output.
fdef

Optionally, the generic function definition to use; if missing, one is found, looking in where if that is specified. See also comment in ‘Details’. 

generic.function, class

See methods.

Details

See methods for a description of .S4methods.

The name and package of the generic are followed by the list of signatures for which methods are currently defined, according to the criteria determined by the various arguments. Note that the package refers to the source of the generic function. Individual methods for that generic can come from other packages as well.

When more than one generic function is involved, either as specified or because f was missing, the functions are found and showMethods is recalled for each, including the generic as the argument fdef. In complicated situations, this can avoid some anomalous results.

Value

If printTo is FALSE, the character vector that would have been printed is returned; otherwise the value is the connection or filename, via invisible.

See Also

setMethod, and GenericFunctions for other tools involving methods; selectMethod will show you the method dispatched for a particular function and signature of classes for the arguments.

methods provides method discovery tools for light-weight interactive use.

Examples

require(graphics)

## Assuming the methods for plot
## are set up as in the example of help(setMethod),
## print (without definitions) the methods that involve class "track":
showMethods("plot", classes = "track")
## Not run:
## Function "plot":
# x = ANY, y = track
# x = track, y = missing
# x = track, y = ANY

require("Matrix")
showMethods("%*%")# many!
methods(class = "Matrix")# nothing
showMethods(class = "Matrix")# everything
showMethods(Matrix:::isDiagonal) # a non-exported generic

## End(Not run)
signature-class

This class represents the mapping of some of the formal arguments of a function onto the corresponding classes. It is used for two slots in the MethodDefinition class.

Objects from the Class

Objects can be created by calls of the form new("signature", functionDef,...). The functionDef argument, if it is supplied as a function object, defines the formal names. The other arguments define the classes. More typically, the objects are created as side effects of defining methods. Either way, note that the classes are expected to be well defined, usually because the corresponding class definitions exist. See the comment on the package slot.

Slots

-.Data: Object of class "character" the class names.

names: Object of class "character" the corresponding argument names.

package: Object of class "character" the names of the packages corresponding to the class names. The combination of class name and package uniquely defines the class. In principle, the same class name could appear in more than one package, in which case the package information is required for the signature to be well defined.

Extends

Class "character", from data part. Class "vector", by class "character".

Methods

initialize signature(object = "signature"): see the discussion of objects from the class, above.

See Also

class MethodDefinition for the use of this class.
The Slots in an Object from a Formal Class

Description

These functions return or set information about the individual slots in an object.

Usage

\begin{verbatim}
object@name
object@name <- value

slot(object, name)
slot(object, name, check = TRUE) <- value
.hasSlot(object, name)

.slotNames(x)
.getSlots(x)
\end{verbatim}

Arguments

- **object**: An object from a formally defined class.
- **name**: The name of the slot. The operator takes a fixed name, which can be unquoted if it is syntactically a name in the language. A slot name can be any non-empty string, but if the name is not made up of letters, numbers, and ., it needs to be quoted (by backticks or single or double quotes).
- **value**: A new value for the named slot. The value must be valid for this slot in this object’s class.
- **check**: In the replacement version of `slot`, a flag. If `TRUE`, check the assigned value for validity as the value of this slot. User’s code should not set this to `FALSE` in normal use, since the resulting object can be invalid.
- **x**: either the name of a class (as character string), or a class definition. If given an argument that is neither a character string nor a class definition, `.slotNames` (only) uses `class(x)` instead.

Details

The definition of the class specifies all slots directly and indirectly defined for that class. Each slot has a name and an associated class. Extracting a slot returns an object from that class. Setting a slot first coerces the value to the specified slot and then stores it.

Unlike general attributes, slots are not partially matched, and asking for (or trying to set) a slot with an invalid name for that class generates an error.

The `@` extraction operator and `slot` function themselves do no checking against the class definition, simply matching the name in the object itself. The replacement forms do check (except for `slot` in the case check=`FALSE`). So long as slots are set without cheating, the extracted slots will be valid.
Be aware that there are two ways to cheat, both to be avoided but with no guarantees. The obvious way is to assign a slot with `check=FALSE`. Also, slots in R are implemented as attributes, for the sake of some back compatibility. The current implementation does not prevent attributes being assigned, via `attr<-`, and such assignments are not checked for legitimate slot names.

Note that the "@" operators for extraction and replacement are primitive and actually reside in the `base` package.

The replacement versions of "@" and `slot()` differ in the computations done to coerce the right side of the assignment to the declared class of the slot. Both verify that the value provided is from a subclass of the declared slot class. The `slot()` version will go on to call the coerce method if there is one, in effect doing the computation as value, slotClass, strict = FALSE). The "@" version just verifies the relation, leaving any coerce to be done later (e.g., when a relevant method is dispatched).

In most uses the result is equivalent, and the "@" version saves an extra function call, but if empirical evidence shows that a conversion is needed, either call `as()` before the replacement or use the replacement version of `slot()`.

Value

The "@" operator and the `slot` function extract or replace the formally defined slots for the object. Functions `slotNames` and `getSlots` return respectively the names of the slots and the classes associated with the slots in the specified class definition. Except for its extended interpretation of `x` (above), `slotNames(x)` is just `names(getSlots(x))`.

See Also

`@`, `Classes_Details`, `Methods_Details`, `getClass`, `names`.

Examples

```r
setClass("track", slots = c(x="numeric", y="numeric"))
myTrack <- new("track", x = -4:4, y = exp(-4:4))
slot(myTrack, "x")
slot(myTrack, "y") <- log(slot(myTrack, "y"))
utils::str(myTrack) # or
getSlots("track") # or
getSlots(getClass("track"))
slotNames(class(myTrack)) # is the same as
slotNames(myTrack)

## Transform such an S4 object to a list, e.g. to "export" it:
S4toList <- function(obj) {
  sn <- slotNames(obj)
  structure(lapply(sn, slot, object = obj), names = sn)
}
S4toList(myTrack)
```
Description

The virtual class `structure` and classes that extend it are formal classes analogous to S language structures such as arrays and time-series.

Usage

```r
## The following class names can appear in method signatures, 
## as the class in as() and is() expressions, and, except for 
## the classes commented as VIRTUAL, in calls to new()

"matrix"
"array"
"ts"

"structure" ## VIRTUAL
```

Objects from the Classes

Objects can be created by calls of the form `new(Class, ...)`, where `Class` is the quoted name of the specific class (e.g., "matrix"), and the other arguments, if any, are interpreted as arguments to the corresponding function, e.g., `function_matrix()`. There is no particular advantage over calling those functions directly, unless you are writing software designed to work for multiple classes, perhaps with the class name and the arguments passed in.

Objects created from the classes "matrix" and "array" are unusual, to put it mildly, and have been for some time. Although they may appear to be objects from these classes, they do not have the internal structure of either an S3 or S4 class object. In particular, they have no "class" attribute and are not recognized as objects with classes (that is, both `is.object` and `isS4` will return FALSE for such objects). However, methods (both S4 and S3) can be defined for these pseudo-classes and new classes (both S4 and S3) can inherit from them.

That the objects still behave as if they came from the corresponding class (most of the time, anyway) results from special code recognizing such objects being built into the base code of R. For most purposes, treating the classes in the usual way will work, fortunately. One consequence of the special treatment is that these two classes may be used as the data part of an S4 class; for example, you can get away with `contains = "matrix"` in a call to `setGeneric` to create an S4 class that is a subclass of "matrix". There is no guarantee that everything will work perfectly, but a number of classes have been written in this form successfully.

Note that a class containing "matrix" or "array" will have a `.Data` slot with that class. This is the only use of `.Data` other than as a pseudo-class indicating the type of the object. In this case the type of the object will be the type of the contained matrix or array. See `Classes_Details` for a general discussion.

The class "ts" is basically an S3 class that has been registered with S4, using the `setOldClass` mechanism. Versions of R through 2.7.0 treated this class as a pure S4 class, which was in principal a good idea, but in practice did not allow subclasses to be defined and had other intrinsic problems.
(For example, setting the "tsp" parameters as a slot often fails because the built-in implementation does not allow the slot to be temporarily inconsistent with the length of the data. Also, the S4 class prevented the correct specification of the S3 inheritance for class "mts".)

Time-series objects, in contrast to matrices and arrays, have a valid S3 class, "ts", registered using an S4-style definition (see the documentation for setOldClass in the examples section for an abbreviated listing of how this is done). The S3 inheritance of "mts" in package stats is also registered. These classes, as well as "matrix" and "array" should be valid in most examples as superclasses for new S4 class definitions.

All of these classes have special S4 methods for initialize that accept the same arguments as the basic generator functions, matrix, array, and ts, in so far as possible. The limitation is that a class that has more than one non-virtual superclass must accept objects from that superclass in the call to new; therefore, a such a class (what is called a “mixin” in some languages) uses the default method for initialize, with no special arguments.

### Extends

The specific classes all extend class "structure", directly, and class "vector", by class "structure".

### Methods

- **coerce**: Methods are defined to coerce arbitrary objects to these classes, by calling the corresponding basic function, for example, as(x, "matrix") calls as.matrix(x). If strict = TRUE in the call to as(), the method goes on to delete all other slots and attributes other than the dim and dimnames.

- **Ops**: Group methods (see, e.g., S4groupGeneric) are defined for combinations of structures and vectors (including special cases for array and matrix), implementing the concept of vector structures as in the reference. Essentially, structures combined with vectors retain the structure as long as the resulting object has the same length. Structures combined with other structures remove the structure, since there is no automatic way to determine what should happen to the slots defining the structure.

  Note that these methods will be activated when a package is loaded containing a class that inherits from any of the structure classes or class "vector".

### References

Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)

### See Also

Class nonStructure, which enforces the alternative model, in which all slots are dropped if any math transformation or operation is applied to an object from a class extending one of the basic classes.

### Examples

```r
showClass("structure")

## explore a bit
```
testInheritedMethods  Test for and Report about Selection of Inherited Methods

Description

A set of distinct inherited signatures is generated to test inheritance for all the methods of a specified
generic function. If method selection is ambiguous for some of these, a summary of the ambiguities
is attached to the returned object. This test should be performed by package authors before releasing
a package.

Usage

```r
testInheritedMethods(f, signatures, test = TRUE, virtual = FALSE,
                      groupMethods = TRUE, where = .GlobalEnv)
```

Arguments

- **f**
  - a generic function or the character string name of one. By default, all currently
defined subclasses of all the method signatures for this generic will be examined.
The other arguments are mainly options to modify which inheritance patterns
will be examined.

- **signatures**
  - An optional set of subclass signatures to use instead of the relevant subclasses
    computed by testInheritedMethods. See the Details for how this is done.
    This argument might be supplied after a call with test = FALSE, to test selection
    in batches.

- **test**
  - optional flag to control whether method selection is actually tested. If FALSE,
    returns just the list of relevant signatures for subclasses, without calling
    selectMethod for each signature. If there are a very large number of signa-
tures, you may want to collect the full list and then test them in batches.

- **virtual**
  - should virtual classes be included in the relevant subclasses. Normally not, since
    only the classes of actual arguments will trigger the inheritance calculation in a
    call to the generic function. Including virtual classes may be useful if the class
    has no current non-virtual subclasses but you anticipate your users may define
    such classes in the future.

- **groupMethods**
  - should methods for the group generic function be included?

- **where**
  - the environment in which to look for class definitions. Nearly always, use the
default global environment after attaching all the packages with relevant meth-
ods and/or class definitions.
Details

The following description applies when the optional arguments are omitted, the usual case. First, the defining signatures for all methods are computed by calls to `findMethodSignatures`. From these all the known non-virtual subclasses are found for each class that appears in the signature of some method. These subclasses are split into groups according to which class they inherit from, and only one subclass from each group is retained (for each argument in the generic signature). So if a method was defined with class "vector" for some argument, one actual vector class is chosen arbitrarily. The case of "ANY" is dealt with specially, since all classes extend it. A dummy, nonvirtual class, ".Other", is used to correspond to all classes that have no superclasses among those being tested.

All combinations of retained subclasses for the arguments in the generic signature are then computed. Each row of the resulting matrix is a signature to be tested by a call to `selectMethod`. To collect information on ambiguous selections, `testInheritedMethods` establishes a calling handler for the special signal "ambiguousMethodSelection", by setting the corresponding option.

Value

An object of class "methodSelectionReport". The details of this class are currently subject to change. It has slots "target", "selected", "candidates", and "note", all referring to the ambiguous cases (and so of length 0 if there were none). These slots are intended to be examined by the programmer to detect and preferably fix ambiguous method selections. The object contains in addition slots "generic", the name of the generic function, and "allSelections", giving the vector of labels for all the signatures tested.

References

Examples

```r
## if no other attached packages have methods for `+` or its group
## generic functions, this returns a 16 by 2 matrix of selection
## patterns (in R 2.9.0)
testInheritedMethods("+")
```

---

**TraceClasses**

*Classes Used Internally to Control Tracing*

**Description**

The classes described here are used by the R function `trace` to create versions of functions and methods including browser calls, etc., and also to `untrace` the same objects.
Usage

### Objects from the following classes are generated
### by calling trace() on an object from the corresponding
### class without the "WithTrace" in the name.

"functionWithTrace"
"MethodDefinitionWithTrace"
"MethodWithNextWithTrace"
"genericFunctionWithTrace"
"groupGenericFunctionWithTrace"

### the following is a virtual class extended by each of the
### classes above

"traceable"

Objects from the Class

Objects will be created from these classes by calls to trace. (There is an initialize method for
class "traceable", but you are unlikely to need it directly.)

Slots

.Data: The data part, which will be "function" for class "functionWithTrace", and similarly
for the other classes.

original: Object of the original class; e.g., "function" for class "functionWithTrace".

Extends

Each of the classes extends the corresponding untraced class, from the data part; e.g.,
"functionWithTrace" extends "function". Each of the specific classes extends "traceable",
directly, and class "VIRTUAL", by class "traceable".

Methods

The point of the specific classes is that objects generated from them, by function trace(), remain
callable or dispatchable, in addition to their new trace information.

See Also

function trace
validObject

Description

validObject() tests the validity of object related to its class definition; specifically, it checks that all slots specified in the class definition are present and that the object in the slot is from the required class or a subclass of that class.

If the object is valid, TRUE is returned; otherwise, an error is generated, reporting all the validity failures encountered. If argument test is TRUE, the errors are returned as a character vector rather than generating an error.

When an object from a class is initialized, the default method for initialize() calls validObject. A class definition may have a validity method, set by a call to the function setValidity, in the package or environment that defines the class (or via the validity argument to setClass). The method should be a function of one object that returns TRUE or a character-string description of the non-validity. If such a method exists, it will be called from validObject and any strings from failure will be included in the result or the error message. Any validity methods defined for superclasses (from the contains= argument to setClass), will also be called.

Usage

validObject(object, test = FALSE, complete = FALSE)

setValidity(Class, method, where = topenv(parent.frame()) )

getValidity(ClassDef)

Arguments

object any object, but not much will happen unless the object’s class has a formal definition.

test logical; if TRUE and validity fails, the function returns a vector of strings describing the problems. If test is FALSE (the default) validity failure generates an error.

complete logical; if TRUE, validObject is called recursively for each of the slots. The default is FALSE.

Class the name or class definition of the class whose validity method is to be set.

ClassDef a class definition object, as from getClassDef.

method a validity method; that is, either NULL or a function of one argument (object). Like validObject, the function should return TRUE if the object is valid, and one or more descriptive strings if any problems are found. Unlike validObject, it should never generate an error.

where an environment to store the modified class definition. Should be omitted, specifically for calls from a package that defines the class. The definition will be stored in the namespace of the package.

Details

Validity testing takes place ‘bottom up’, checking the slots, then the superclasses, then the object’s own validity method, if there is one.

For each slot and superclass, the existence of the specified class is checked. For each slot, the object in the slot is tested for inheritance from the corresponding class. If complete is TRUE, validObject is called recursively for the object in the slot.
Then, for each of the classes that this class extends (the ‘superclasses’), the explicit validity method of that class is called, if one exists. Finally, the validity method of object’s class is called, if there is one.

**Value**

validObject returns TRUE if the object is valid. Otherwise a vector of strings describing problems found, except that if test is FALSE, validity failure generates an error, with the corresponding strings in the error message.

**Validity methods**

A validity method must be a function of one argument; formally, that argument should be named object. If the argument has a different name, setValidity makes the substitution but in obscure cases that might fail, so it’s wiser to name the argument object.

A good method checks all the possible errors and returns a character vector citing all the exceptions found, rather than returning after the first one. validObject will accumulate these errors in its error message or its return value.

Note that validity methods do not have to check validity of superclasses: validObject calls such methods explicitly.

**References**

setClass; class classRepresentation.

**Examples**

```r
setClass("track",
slots = c(x="numeric", y = "numeric"))
t1 <- new("track", x=1:10, y=sort(stats::rnorm(10)))
## A valid "track" object has the same number of x, y values
validTrackObject <- function(object) {
  if(length(object@x) == length(object@y)) TRUE
  else paste("Unequal x,y lengths: ", length(object@x), ", ",
            length(object@y), sep="")
}
## assign the function as the validity method for the class
setValidity("track", validTrackObject)
## t1 should be a valid "track" object
validObject(t1)
## Now we do something bad
t2 <- t1
t2@x <- 1:20
## This should generate an error
## Not run: try(validObject(t2))

setClass("trackCurve", contains = "track",
slots = c(smooth = "numeric"))

## all superclass validity methods are used when validObject
```
validObject

## is called from initialize() with arguments, so this fails
## Not run: trynew("trackCurve", t2)

setClass("twoTrack", slots = c(tr1 = "track", tr2 = "track"))

## validity tests are not applied recursively by default,
## so this object is created (invalidly)
tT <- new("twoTrack", tr2 = t2)

## A stricter test detects the problem
## Not run: try(validObject(tT, complete = TRUE))
Chapter 8
The parallel package

parallel-package  Support for Parallel Computation

Description
Support for parallel computation, including random-number generation.

Details
This package was first included with R 2.14.0 in 2011.

There is support for multiple RNG streams with the ‘"L'Ecuyer-CMRG”’ RNG: see nextRNGstream.

It contains functionality derived from and pretty much equivalent to that contained in packages multicore (formerly on CRAN, with some low-level functions renamed and not exported) and snow (for socket clusters only, but MPI clusters generated by snow are also supported). There have been many enhancements and bug fixes since 2011.

This package also provides makeForkCluster to create socket clusters by forking (not Windows).

For a complete list of exported functions, use 
l library(help = "parallel").

Author(s)
Brian Ripley, Luke Tierney and Simon Urbanek

Maintainer: R Core Team <R-core@r-project.org>

See Also
Parallel computation involves launching worker processes: functions psnice and pskill in package tools provide means to manage such processes.
clusterApply

Apply Operations using Clusters

Description

These functions provide several ways to parallelize computations using a cluster.

Usage

clusterCall(cl = NULL, fun, ...)
clusterApply(cl = NULL, x, fun, ...)
clusterApplyLB(cl = NULL, x, fun, ...)
clusterEvalQ(cl = NULL, expr)
clusterExport(cl = NULL, varlist, envir = .GlobalEnv)
clusterMap(cl = NULL, Fun, ..., MoreArgs = NULL, RECYCLE = TRUE,
          SIMPLIFY = FALSE, USE.NAMES = TRUE,
          .scheduling = c("static", "dynamic"))
clusterSplit(cl = NULL, seq)
parLapply(cl = NULL, X, fun, ..., chunk.size = NULL)
parSapply(cl = NULL, X, FUN, ..., simplify = TRUE,
          USE.NAMES = TRUE, chunk.size = NULL)
parApply(cl = NULL, X, MARGIN, FUN, ..., chunk.size = NULL)
parCapply(cl = NULL, x, FUN, ..., chunk.size = NULL)
parLapplyLB(cl = NULL, X, fun, ..., chunk.size = NULL)
parSapplyLB(cl = NULL, X, FUN, ..., simplify = TRUE,
            USE.NAMES = TRUE, chunk.size = NULL)

Arguments

cl
fun, FUN
expr
seq
varlist
envir
x
...
MoreArgs
RECYCLE
chunk.size

a cluster object, created by this package or by package snow. If NULL, use the
registered default cluster.
function or character string naming a function.
expression to evaluate.
vector to split.
character vector of names of objects to export.
environment from which to export variables
a vector for clusterApply and clusterApplyLB, a matrix for parRapply and
parCapply.
additional arguments to pass to fun or FUN: beware of partial matching to earlier
arguments.
additional arguments for fun.
logical; if true shorter arguments are recycled.
A vector (atomic or list) for parLapply and parSapply, an array for parApply.
scalar number; number of invocations of fun or FUN in one chunk; a chunk is a
unit for scheduling.
clusterApply 1289

MARGIN vector specifying the dimensions to use.
simplify, USE.NAMES logical; see sapply.
SIMPLIFY logical; see mapply.
.scheduling should tasks be statically allocated to nodes or dynamic load-balancing used?

Details

clusterCall calls a function fun with identical arguments ... on each node.
clusterEvalQ evaluates a literal expression on each cluster node. It is a parallel version of evalq, and is a convenience function invoking clusterCall.
clusterApply calls fun on the first node with arguments x[[1]] and ..., on the second node with x[[2]] and ..., and so on, recycling nodes as needed.
clusterApplyLB is a load balancing version of clusterApply. If the length n of x is not greater than the number of nodes p, then a job is sent to n nodes. Otherwise the first p jobs are placed in order on the p nodes. When the first job completes, the next job is placed on the node that has become free; this continues until all jobs are complete. Using clusterApplyLB can result in better cluster utilization than using clusterApply, but increased communication can reduce performance. Furthermore, the node that executes a particular job is non-deterministic. This means that simulations that assign RNG streams to nodes will not be reproducible.
clusterMap is a multi-argument version of clusterApply, analogous to mapply and Map. If RECYCLE is true shorter arguments are recycled (and either none or all must be of length zero); otherwise, the result length is the length of the shortest argument. Nodes are recycled if the length of the result is greater than the number of nodes. (mapply always uses RECYCLE = TRUE, and has argument SIMPLIFY = TRUE. Map always uses RECYCLE = TRUE.)
clusterExport assigns the values on the master R process of the variables named in varlist to variables of the same names in the global environment (aka 'workspace') of each node. The environment on the master from which variables are exported defaults to the global environment.
clusterSplit splits seq into a consecutive piece for each cluster and returns the result as a list with length equal to the number of nodes. Currently the pieces are chosen to be close to equal in length: the computation is done on the master.

parLapply, parSapply, and parApply are parallel versions of lapply, sapply and apply. Chunks of computation are statically allocated to nodes using clusterApply. By default, the number of chunks is the same as the number of nodes. parLapplyLB, parSapplyLB are load-balancing versions, intended for use when applying FUN to different elements of X takes quite variable amounts of time, and either the function is deterministic or reproducible results are not required. Chunks of computation are allocated dynamically to nodes using clusterApplyLB. From R 3.5.0, the default number of chunks is twice the number of nodes. Before R 3.5.0, the (fixed) number of chunks was the same as the number of nodes. As for clusterApplyLB, with load balancing the node that executes a particular job is non-deterministic and simulations that assign RNG streams to nodes will not be reproducible.

parRapply and parCapply are parallel row and column apply functions for a matrix x; they may be slightly more efficient than parApply but do less post-processing of the result.

A chunk size of 0 with static scheduling uses the default (one chunk per node). With dynamic scheduling, chunk size of 0 has the same effect as 1 (one invocation of FUN/fun per chunk).

Value

For clusterCall, clusterEvalQ and clusterSplit, a list with one element per node.
For `clusterApply` and `clusterApplyLB`, a list the same length as \( x \).

`clusterMap` follows `mapply`.

`clusterExport` returns nothing.

`parLapply` returns a list the length of \( X \).

`parSapply` and `parApply` follow `sapply` and `apply` respectively.

`parRapply` and `parCapply` always return a vector. If `FUN` always returns a scalar result this will be of length the number of rows or columns: otherwise it will be the concatenation of the returned values.

An error is signalled on the master if any of the workers produces an error.

**Note**

These functions are almost identical to those in package *snow*.

Two exceptions: `parLapply` has argument \( X \) not \( x \) for consistency with `lapply`, and `parSapply` has been updated to match `sapply`.

Derived from the *snow* package.

**Examples**

```r
## Use option cl.cores to choose an appropriate cluster size.
cl <- makeCluster(getOption("cl.cores", 2))

clusterApply(cl, 1:2, get("+"), 3)
xx <- 1
clusterExport(cl, "xx")
clusterCall(cl, function(y) xx + y, 2)

## Use clusterMap like an mapply example
clusterMap(cl, function(x, y) seq_len(x) + y,
           c(a = 1, b = 2, c = 3), c(A = 10, B = 0, C = -10))

parSapply(cl, 1:20, get("+"), 3)

## A bootstrapping example, which can be done in many ways:
clusterEvalQ(cl, {
  ## set up each worker. Could also use clusterExport()
  library(boot)
  cd4.rg <- function(data, mle) MASS::mvrnorm(nrow(data), mle$m, mle$v)
  cd4.mle <- list(m = colMeans(cd4), v = var(cd4))
  NULL
})
res <- clusterEvalQ(cl, boot(cd4, corr, R = 100,
           sim = "parametric", ran.gen = cd4.rg, mle = cd4.mle))
library(boot)
boot.cl <- do.call(c, res)
boot.ci(boot.cl, type = c("norm", "basic", "perc"),
        conf = 0.9, h = atanh, hinv = tanh)
stopCluster(cl)
```
## or

```r
library(boot)
run1 <- function(...) {
  library(boot)
  cd4.rg <- function(data, mle) MASS::mvrnorm(nrow(data), mle$m, mle$v)
  cd4.mle <- list(m = colMeans(cd4), v = var(cd4))
  boot(cd4, corr, R = 500, sim = "parametric",
       ran.gen = cd4.rg, mle = cd4.mle)
}
cl <- makeCluster(mc <- getOption("cl.cores", 2))
## to make this reproducible
clusterSetRNGStream(cl, 123)

cl <- detectCores(TRUE)
detectCores(TRUE)
```

### detectCores

**Detect the Number of CPU Cores**

**Description**

Attempt to detect the number of CPU cores on the current host.

**Usage**

```r
detectCores(all.tests = FALSE, logical = TRUE)
```

**Arguments**

- `all.tests` Logical: if true apply all known tests.
- `logical` Logical: if possible, use the number of physical CPUs/cores (if FALSE) or logical CPUs (if TRUE). Currently this is honoured only on macOS, Solaris and Windows.

**Details**

This attempts to detect the number of available CPU cores.

It has methods to do so for Linux, macOS, FreeBSD, OpenBSD, Solaris and Windows. `detectCores(TRUE)` could be tried on other Unix-alike systems.

**Value**

An integer, NA if the answer is unknown.

Exactly what this represents is OS-dependent: where possible by default it counts logical (e.g., hyperthreaded) CPUs and not physical cores or packages.

Under macOS there is a further distinction between ‘available in the current power management mode’ and ‘could be available this boot’, and this function returns the first.

On Sparc Solaris `logical = FALSE` returns the number of physical cores and `logical = TRUE` returns the number of available hardware threads. (Some Sparc CPUs have multiple cores per CPU,
others have multiple threads per core and some have both.) For example, the UltraSparc T2 CPU in the former CRAN check server was a single physical CPU with 8 cores, and each core supports 8 hardware threads. So \( \text{detectCores(logical = FALSE)} \) returns 8, and \( \text{detectCores(logical = TRUE)} \) returns 64.

Where virtual machines are in use, one would hope that the result for \( \text{logical = TRUE} \) represents the number of CPUs available (or potentially available) to that particular VM.

**Note**

This is not suitable for use directly for the \( \text{mc.cores} \) argument of \text{mclapply} nor specifying the number of cores in \text{makeCluster}. First because it may return \text{NA}, second because it does not give the number of \text{allowed} cores, and third because on Sparc Solaris and some Windows boxes it is not reasonable to try to use all the logical CPUs at once.

**Author(s)**

Simon Urbanek and Brian Ripley

**Examples**

\begin{verbatim}
 detectCores()
detectCores(logical = FALSE)
\end{verbatim}

**makeCluster**

Create a Parallel Socket Cluster

**Description**

Creates a set of copies of \text{R} running in parallel and communicating over sockets.

**Usage**

\begin{verbatim}
 makeCluster(spec, type, ...)
 makePSOCKcluster(names, ...)  
 makeForkCluster(nnodes = getOption("mc.cores", 2L), ...)  
 stopCluster(cl = NULL)
 setDefaultCluster(cl = NULL)
 getDefaultCluster()
\end{verbatim}

**Arguments**

- \text{spec} A specification appropriate to the type of cluster.
- \text{names} Either a character vector of host names on which to run the worker copies of \text{R}, or a positive integer (in which case that number of copies is run on \text{localhost}).
- \text{nnodes} The number of nodes to be forked.
- \text{type} One of the supported types: see ‘Details’.
- \text{...} Options to be passed to the function spawning the workers. See ‘Details’.
- \text{cl} an object of class "cluster".
makeCluster creates a cluster of one of the supported types. The default type, "PSOCK", calls makePSOCKcluster. Type "FORK" calls makeForkCluster. Other types are passed to package snow.

makePSOCKcluster is an enhanced version of makeSOCKcluster in package snow. It runs Rscript on the specified host(s) to set up a worker process which listens on a socket for expressions to evaluate, and returns the results (as serialized objects).

makeForkCluster is merely a stub on Windows. On Unix-alike platforms it creates the worker process by forking.

The workers are most often running on the same host as the master, when no options need be set. Several options are supported (mainly for makePSOCKcluster):

master The host name of the master, as known to the workers. This may not be the same as it is known to the master, and on private subnets it may be necessary to specify this as a numeric IP address. For example, macOS is likely to detect a machine as ‘somename.local’, a name known only to itself.

port The port number for the socket connection, default taken from the environment variable R_PARALLEL_PORT, then a randomly chosen port in the range 11000:11999.

timeout The timeout in seconds for that port. This is the maximum time of zero communication between master and worker before failing. Default is 30 days (and the POSIX standard only requires values up to 31 days to be supported).

setup_timeout The maximum number of seconds a worker attempts to connect to master before failing. Default is 2 minutes. The waiting time before the next attempt starts at 0.1 seconds and is incremented 50% after each retry.

outfile Where to direct the stdout and stderr connection output from the workers. "" indicates no redirection (which may only be useful for workers on the local machine). Defaults to ‘/dev/null’ (‘nul:’ on Windows). The other possibility is a file path on the worker’s host. Files will be opened in append mode, as all workers log to the same file.

homogeneous Logical, default true. See ‘Note’.

rscript See ‘Note’.

rscript_args Character vector of additional arguments for Rscript such as ‘--no-environ’.

renice A numerical ‘niceness’ to set for the worker processes, e.g. 15 for a low priority. OS-dependent: see psnice for details.

rshcmd The command to be run on the master to launch a process on another host. Defaults to ssh.

user The user name to be used when communicating with another host.

manual Logical. If true the workers will need to be run manually.

methods Logical. If true (default) the workers will load the methods package: not loading it saves ca 30% of the startup CPU time of the cluster.

useXDR Logical. If true (default) serialization will use XDR: where large amounts of data are to be transferred and all the nodes are little-endian, communication may be substantially faster if this is set to false.

setup_strategy Character. If "parallel" (default) workers will be started in parallel during cluster setup when this is possible, which is now for homogeneous "PSOCK" clusters with all workers started automatically (manual = FALSE) on the local machine. Workers will be started sequentially on other clusters, on all clusters with setup_strategy = "sequential" and on R 3.6.0 and older. This option is for expert use only (e.g. debugging) and may be removed in future versions of R.
Function `makeForkCluster` creates a socket cluster by forking (and hence is not available on Windows). It supports options `port`, `timeout`, and `outfile`, and always uses `useXDR = FALSE`. It is strongly discouraged to use the "FORK" cluster with GUI front-ends or multi-threaded libraries. See `mcfork` for details.

It is good practice to shut down the workers by calling `stopCluster`: however the workers will terminate themselves once the socket on which they are listening for commands becomes unavailable, which it should if the master R session is completed (or its process dies).

Function `setDefaultCluster` registers a cluster as the default one for the current session. Using `setDefaultCluster(NULL)` removes the registered cluster, as does stopping that cluster.

**Value**

For the cluster creators, an object of class `c("SOCKcluster", "cluster")`.

For the default cluster setter and getter, the registered default cluster or `NULL` if there is no such cluster.

**Note**

Option `homogeneous = TRUE` was for years documented as ‘Are all the hosts running identical setups?’, but this was apparently more restrictive than its author intended and not required by the code.

The current interpretation of `homogeneous = TRUE` is that Rscript can be launched using the same path on each worker. That path is given by the option `rscript` and defaults to the full path to Rscript on the master. (The workers are not required to be running the same version of R as the master, nor even as each other.)

For `homogeneous = FALSE`, Rscript on the workers is found on their default shell’s path.

For the very common usage of running both master and worker on a single multi-core host, the default settings are the appropriate ones.

A socket connection is used to communicate from the master to each worker so the maximum number of connections (default 128 but some will be in use) may need to be increased when the master process is started.

Luke Tierney and R Core.

Derived from the `snow` package.

---

**mcaffinity**

*Get or Set CPU Affinity Mask of the Current Process*

**Description**

`mcaffinity` retrieves or sets the CPU affinity mask of the current process, i.e., the set of CPUs the process is allowed to be run on. (CPU here means logical CPU which can be CPU, core or hyperthread unit.)

**Usage**

`mcaffinity(affinity = NULL)`
Arguments

affinity: specification of the CPUs to lock this process to (numeric vector) or NULL if no change is requested.

Details

mcaffinity can be used to obtain (affinity = NULL) or set the CPU affinity mask of the current process. The affinity mask is a list of integer CPU identifiers (starting from 1) that this process is allowed to run on. Not all systems provide user access to the process CPU affinity, in cases where no support is present at all mcaffinity() will return NULL. Some systems may take into account only the number of CPUs present in the mask.

Typically, it is legal to specify larger set than the number of logical CPUs (but at most as many as the OS can handle) and the system will return back the actually present set.

Value

NULL if CPU affinity is not supported by the system or an integer vector with the set of CPUs in the active affinity mask for this process (this may be different than affinity).

Author(s)

Simon Urbanek.

See Also

mccommand, mcparallel

Description

These are low-level support functions for the forking approach.

They are not available on Windows, and not exported from the namespace.

Usage

children(select)
readChild(child)
readChildren(timeout = 0)
selectChildren(children = NULL, timeout = 0)
sendChildStdin(child, what)
sendMaster(what, raw.asis = TRUE)
mckill(process, signal = 2L)
mcchildren

Arguments

select  if omitted, all active children are returned, otherwise select should be a list of processes and only those from the list that are active will be returned.

child  child process (object of the class "childProcess") or a process ID (pid). See also ‘Details’.

timeout  timeout (in seconds, fractions supported) to wait for a response before giving up.

children  list of child processes or a single child process object or a vector of process IDs or NULL. If NULL behaves as if all currently known children were supplied.

what  For sendChildStdin:
      Character or raw vector. In the former case elements are collapsed using the newline character. (But no trailing newline is added at the end!)
      For sendMaster:
      Data to send to the master process. If what is not a raw vector, it will be serialized into a raw vector. Do NOT send an empty raw vector – that is reserved for internal use.

raw.asis  logical, if TRUE and what is a raw vector then it is sent directly as-is to the master (default, suitable for arbitrary payload passing), otherwise raw vectors are serialized before sending just as any other objects (suitable for passing evaluation results).

process  process (object of the class process) or a process ID (pid)

signal  integer: signal to send. Values of 2 (SIGINT), 9 (SIGKILL) and 15 (SIGTERM) are pretty much portable, but for maximal portability use tools::SIGTERM and so on.

Details

children returns currently active children.
readChild reads data (sent by sendMaster) from a given child process.
selectChildren checks children for available data.
readChildren checks all children for available data and reads from the first child that has available data.
sendChildStdin sends a string (or data) to one or more child’s standard input. Note that if the master session was interactive, it will also be echoed on the standard output of the master process (unless disabled). The function is vector-compatible, so you can specify child as a list or a vector of process IDs.
sendMaster sends data from the child to the master process.
mckill sends a signal to a child process: it is equivalent to pskill in package tools.

Value

children returns a (possibly empty) list of objects of class "process", the process ID.
readChild and readChildren return a raw vector with a "pid" attribute if data were available, an integer vector of length one with the process ID if a child terminated or NULL if the child no longer exists (no children at all for readChildren).
selectChildren returns TRUE is the timeout was reached, FALSE if an error occurred (e.g., if the master process was interrupted) or an integer vector of process IDs with children that have data available, or NULL if there are no children.
sendChildStdin returns a vector of TRUE values (one for each member of child) or throws an error.

sendMaster returns TRUE or throws an error.

mckill returns TRUE.

Warning
This is a very low-level interface for expert use only: it not regarded as part of the R API and subject to change without notice.

sendMaster, readChild and sendChildStdin did not support long vectors prior to R 3.4.0 and so were limited to $2^{31} - 1$ bytes (and still are on 32-bit platforms).

Author(s)
Simon Urbanek and R Core.

Derived from the multicore package formerly on CRAN.

mcfork, sendMaster, mcparallel

Examples

## Not run:
p <- mcparallel(scan(n = 1, quiet = TRUE))
sendChildStdin(p, "17.4\n")
mccollect(p)[[1]]
## End(Not run)

mcfork  Fork a Copy of the Current R Process

Description
These are low-level functions, not available on Windows, and not exported from the namespace.
mcfork creates a new child process as a copy of the current R process.
mcexit closes the current child process, informing the master process as necessary.

Usage

mcfork(estranged = FALSE)

mcexit(exit.code = 0L, send = NULL)

Arguments

estranged  logical, if TRUE then the new process has no ties to the parent process, will not show in the list of children and will not be killed on exit.

exit.code  process exit code. By convention 0L signifies a clean exit, 1L an error.

send  if not NULL send this data before exiting (equivalent to using sendMaster).
mcfork

Details

The `mcfork` function provides an interface to the `fork` system call. In addition it sets up a pipe between the master and child process that can be used to send data from the child process to the master (see `sendMaster`) and child’s `stdin` is re-mapped to another pipe held by the master process (see `sendChildStdin`).

If you are not familiar with the `fork` system call, do not use this function directly as it leads to very complex inter-process interactions amongst the R processes involved.

In a nutshell `fork` spawns a copy (child) of the current process, that can work in parallel to the master (parent) process. At the point of forking both processes share exactly the same state including the workspace, global options, loaded packages etc. Forking is relatively cheap in modern operating systems and no real copy of the used memory is created, instead both processes share the same memory and only modified parts are copied. This makes `mcfork` an ideal tool for parallel processing since there is no need to setup the parallel working environment, data and code is shared automatically from the start.

`mcexit` is to be run in the child process. It sends `send` to the master (unless NULL) and then shuts down the child process. The child can also be shut down by sending it the signal `SIGUSR1`, as is done by the unexported function `parallel:::rmChild`.

Value

`mcfork` returns an object of the class "childProcess" to the master and of class "masterProcess" to the child: both the classes inherit from class "process". If `estranged` is set to `TRUE` then the child process will be of the class "estrangedProcess" and cannot communicate with the master process nor will it show up on the list of children. These are lists with components `pid` (the process id of the other process) and a vector `fd` of the two file descriptor numbers for ends in the current process of the inter-process pipes.

`mcexit` never returns.

GUI/embedded environments

It is strongly discouraged to use `mcfork` and the higher-level functions which rely on it (e.g., `mcparallel`, `mclapply` and `pvec`) in GUI or embedded environments, because it leads to several processes sharing the same GUI which will likely cause chaos (and possibly crashes). Child processes should never use on-screen graphics devices. Some precautions have been taken to make this usable in R.app on macOS, but users of third-party front-ends should consult their documentation.

This can also apply to other connections (e.g., to an X server) created before forking, and to files opened by e.g. graphics devices.

Note that `tcltk` counts as a GUI for these purposes since Tcl runs an event loop. That event loop is inhibited in a child process but there could still be problems with Tk graphical connections.

It is strongly discouraged to use `mcfork` and the higher-level functions in any multi-threaded R process (with additional threads created by a third-party library or package). Such use can lead to deadlocks or crashes, because the child process created by `mcfork` may not be able to access resources locked in the parent or may see an inconsistent version of global data (mcfork runs system call fork without exec).

If in doubt, it is safer to use a non-FORK cluster (see `makeCluster`, `clusterApply`).

Warning

This is a very low-level API for expert use only.

**mclapply**

Parallel Versions of `lapply` and `mapply` using Forking

**Description**

`mclapply` is a parallelized version of `lapply`, it returns a list of the same length as `X`, each element of which is the result of applying `FUN` to the corresponding element of `X`.

It relies on forking and hence is not available on Windows unless `mc.cores = 1`.

`mcmapply` is a parallelized version of `mapply`, and `mcMap` corresponds to `Map`.

**Usage**

```r
mclapply(X, FUN, ..., mc.preschedule = TRUE, mc.set.seed = TRUE,
         mc.silent = FALSE, mc.cores = getOption("mc.cores", 2L),
         mc.cleanup = TRUE, mc.allow.recursive = TRUE, affinity.list = NULL)
mcmapply(FUN, ..., MoreArgs = NULL, SIMPLIFY = TRUE, USE.NAMES = TRUE,
         mc.preschedule = TRUE, mc.set.seed = TRUE,
         mc.silent = FALSE, mc.cores = getOption("mc.cores", 2L),
         mc.cleanup = TRUE, affinity.list = NULL)
mcMap(f, ...)
```

**Arguments**

- `X` a vector (atomic or list) or an expressions vector. Other objects (including classed objects) will be coerced by `as.list`.
- `FUN` the function to be applied to (`mclapply`) each element of `X` or (`mcmapply`) in parallel to `...`
the function to be applied in parallel to ...

For `mclapply`, optional arguments to `FUN`. For `mcmapply` and `mcMap`, vector or list inputs: see `mapply`.

**MoreArgs, SIMPLIFY, USE.NAMES**

see `mapply`.

**mc.preschedule**

if set to `TRUE` then the computation is first divided to (at most) as many jobs as there are cores and then the jobs are started, each job possibly covering more than one value. If set to `FALSE` then one job is forked for each value of `X`. The former is better for short computations or large number of values in `X`, the latter is better for jobs that have high variance of completion time and not too many values of `X` compared to `mc.cores`.

**mc.set.seed**

See `mcparallel`.

**mc.silent**

if set to `TRUE` then all output on `stdout` will be suppressed for all parallel processes forked (`stderr` is not affected).

**mc.cores**

The number of cores to use, i.e. at most how many child processes will be run simultaneously. The option is initialized from environment variable `MC_CORES` if set. Must be at least one, and parallelization requires at least two cores.

**mc.cleanup**

if set to `TRUE` then all children that have been forked by this function will be killed (by sending `SIGTERM`) before this function returns. Under normal circumstances `mclapply` waits for the children to deliver results, so this option usually has only effect when `mclapply` is interrupted. If set to `FALSE` then child processes are collected, but not forcefully terminated. As a special case this argument can be set to the number of the signal that should be used to kill the children instead of `SIGTERM`.

**mc.allow.recursive**

Unless true, calling `mclapply` in a child process will use the child and not fork again.

**affinity.list**

a vector (atomic or list) containing the CPU affinity mask for each element of `X`. The CPU affinity mask describes on which CPU (core or hyperthread unit) a given item is allowed to run, see `mcaffinity`. To use this parameter prescheduling has to be deactivated (`mc.preschedule = FALSE`).

### Details

`mclapply` is a parallelized version of `lapply`, provided `mc.cores > 1`: for `mc.cores == 1` (and the `affinity.list` is `NULL`) it simply calls `lapply`.

By default (`mc.preschedule = TRUE`) the input `X` is split into as many parts as there are cores (currently the values are spread across the cores sequentially, i.e. first value to core 1, second to core 2, ...((core + 1)-th value to core 1 etc.) and then one process is forked to each core and the results are collected.

Without prescheduling, a separate job is forked for each value of `X`. To ensure that no more than `mc.cores` jobs are running at once, once that number has been forked the master process waits for a child to complete before the next fork.

Due to the parallel nature of the execution random numbers are not sequential (in the random number sequence) as they would be when using `lapply`. They are sequential for each forked process, but not all jobs as a whole. See `mcparallel` or the package’s vignette for ways to make the results reproducible with `mc.preschedule = TRUE`.

Note: the number of file descriptors (and processes) is usually limited by the operating system, so you may have trouble using more than 100 cores or so (see `ulimit -n` or similar in your OS...
Prior to R 3.4.0 and on a 32-bit platform, the serialized result from each forked process is limited to $2^{31} - 1$ bytes. (Returning very large results via serialization is inefficient and should be avoided.)

affinity.list can be used to run elements of X on specific CPUs. This can be helpful, if elements of X have a high variance of completion time or if the hardware architecture is heterogeneous. It also enables the development of scheduling strategies for optimizing the overall runtime of parallel jobs. If affinity.list is set, the mc.core parameter is replaced with the number of CPU ids used in the affinity masks.

**Value**

For mclapply, a list of the same length as X and named by X.

For mcmapply, a list, vector or array: see mapply.

For mcMap, a list.

Each forked process runs its job inside try(..., silent = TRUE) so if errors occur they will be stored as class "try-error" objects in the return value and a warning will be given. Note that the job will typically involve more than one value of X and hence a "try-error" object will be returned for all the values involved in the failure, even if not all of them failed. If any forked process is killed or fails to deliver a result for any reason, values involved in the failure will be NULL. To allow detection of such errors, FUN should not return NULL. As of R 4.0, the return value of mcmapply is always a list when it needs to contain "try-error" objects (SIMPLIFY is overridden to FALSE).

**Warning**

It is strongly discouraged to use these functions in GUI or embedded environments, because it leads to several processes sharing the same GUI which will likely cause chaos (and possibly crashes). Child processes should never use on-screen graphics devices.

Some precautions have been taken to make this usable in R.app on macOS, but users of third-party front-ends should consult their documentation.

Note that tcltk counts as a GUI for these purposes since Tcl runs an event loop. That event loop is inhibited in a child process but there could still be problems with Tk graphical connections.

It is strongly discouraged to use these functions with multi-threaded libraries or packages (see mcfork for more details). If in doubt, it is safer to use a non-FORK cluster (see makeCluster, clusterApply).

res <- mclapply(seq_len(mc), run1)
res.boot <- do.call(c, res)

## Usage of the affinity.list parameter
A <- runif(2500000,0,100)
B <- runif(2500000,0,100)
C <- runif(5000000,0,100)
first <- function(i) head(sort(i), n = 1)

# Restrict all elements of X to run on CPU 1 and 2
affL <- list(c(1,2), c(1,2), c(1,2))
mclapply(list(A, A, A), first, mc.preschedule = FALSE, affinity.list = affL)

# Completion times are assumed to have a high variance
# To optimize the overall execution time elements of X are scheduled to suitable CPUs
# Assuming that the runtime for C is as long as the runtime of A plus B
# mapping: A to 1 , B to 1, C to 2
X <- list(A, B, C)
affL <- c(1, 1, 2)
mclapply(X, first, mc.preschedule = FALSE, affinity.list = affL)

mclapply

Evaluate an R Expression Asynchronously in a Separate Process

Description

These functions are based on forking and so are not available on Windows.
mclapply starts a parallel R process which evaluates the given expression.
mccollect collects results from one or more parallel processes.
Usage

mcparallel(expr, name, mc.set.seed = TRUE, silent = FALSE,
mc.affinity = NULL, mc.interactive = FALSE,
detached = FALSE)

mccollect(jobs, wait = TRUE, timeout = 0, intermediate = FALSE)

Arguments

expr expression to evaluate (do not use any on-screen devices or GUI elements in this
code, see mcfork for the inadvisability of using mcparallel with GUI front-
ends and multi-threaded libraries). Raw vectors are reserved for internal use
and cannot be returned, but the expression may evaluate e.g. to a list holding
a raw vector. NULL should not be returned because it is used by mccollect to
signal an error.

name an optional name (character vector of length one) that can be associated with the
job.

mc.set.seed logical: see section ‘Random numbers’.

silent if set to TRUE then all output on stdout will be suppressed (stderr is not affected).

mc.affinity either a numeric vector specifying CPUs to restrict the child process to (1-based)
or NULL to not modify the CPU affinity

mc.interactive logical, if TRUE or FALSE then the child process will be set as interactive or non-
interactive respectively. If NA then the child process will inherit the interactive
flag from the parent.

detached logical, if TRUE then the job is detached from the current session and cannot
deliver any results back - it is used for the code side-effect only.

jobs list of jobs (or a single job) to collect results for. Alternatively jobs can also be
an integer vector of process IDs. If omitted collect will wait for all currently
existing children.

wait if set to FALSE it checks for any results that are available within timeout seconds
from now, otherwise it waits for all specified jobs to finish.

timeout timeout (in seconds) to check for job results – applies only if wait is FALSE.

intermediate FALSE or a function which will be called while collect waits for results. The
function will be called with one parameter which is the list of results received
so far.

Details

mcparallel evaluates the expr expression in parallel to the current R process. Everything is shared
read-only (or in fact copy-on-write) between the parallel process and the current process, i.e. no
side-effects of the expression affect the main process. The result of the parallel execution can be
collected using mccollect function.

mccollect function collects any available results from parallel jobs (or in fact any child process).
If wait is TRUE then collect waits for all specified jobs to finish before returning a list containing
the last reported result for each job. If wait is FALSE then mccollect merely checks for any results
available at the moment and will not wait for jobs to finish. If jobs is specified, jobs not listed there
will not be affected or acted upon.

Note: If expr uses low-level multicore functions such as sendMaster a single job can deliver results
multiple times and it is the responsibility of the user to interpret them correctly. mccollect will
return NULL for a terminating job that has sent its results already after which the job is no longer available.

Jobs are identified by process IDs (even when referred to as job objects), which are reused by the operating system. Detached jobs created by mcparallel can thus never be safely referred to by their process IDs nor job objects. Non-detached jobs are guaranteed to exist until collected by mccollect, even if crashed or terminated by a signal. Once collected by mccollect, a job is regarded as detached, and thus no longer need be referred to by its process ID nor its job object. With wait = TRUE, all jobs passed to mccollect are collected. With wait = FALSE, the collected jobs are given as names of the result vector, and thus in subsequent calls to mccollect these jobs must be excluded. Job objects should be used in preference of process IDs whenever accepted by the API.

The mc.affinity parameter can be used to try to restrict the child process to specific CPUs. The availability and the extent of this feature is system-dependent (e.g., some systems will only consider the CPU count, others will ignore it completely).

Value

mcparallel returns an object of the class "parallelJob" which inherits from "childProcess" (see the ‘Value’ section of the help for mcfork). If argument name was supplied this will have an additional component name.

mccollect returns any results that are available in a list. The results will have the same order as the specified jobs. If there are multiple jobs and a job has a name it will be used to name the result, otherwise its process ID will be used. If none of the specified children are still running, it returns NULL.

Random numbers

If mc.set.seed = FALSE, the child process has the same initial random number generator (RNG) state as the current R session. If the RNG has been used (or .Random.seed was restored from a saved workspace), the child will start drawing random numbers at the same point as the current session. If the RNG has not yet been used, the child will set a seed based on the time and process ID when it first uses the RNG: this is pretty much guaranteed to give a different random-number stream from the current session and any other child process.

The behaviour with mc.set.seed = TRUE is different only if RNGkind("L'Ecuyer-CMRG") has been selected. Then each time a child is forked it is given the next stream (see nextRNGStream). So if you select that generator, set a seed and call mc.reset.stream just before the first use of mcparallel the results of simulations will be reproducible provided the same tasks are given to the first, second, …forked process.

Note

Prior to R 3.4.0 and on a 32-bit platform, the serialized result from each forked process is limited to \(2^{31} - 1\) bytes. (Returning very large results via serialization is inefficient and should be avoided.)

Author(s)

Simon Urbanek and R Core.

Derived from the multicore package formerly on CRAN. (but with different handling of the RNG stream).

pvec, mclapply
Examples

```r
p <- mcparallel(1:10)
q <- mcparallel(1:20)
# wait for both jobs to finish and collect all results
res <- mccollect(list(p, q))

p <- mcparallel(1:10)
mccollect(p, wait = FALSE, 10)  # will retrieve the result (since it's fast)
mccollect(p, wait = FALSE)    # will signal the job as terminating
mccollect(p, wait = FALSE)    # there is no longer such a job

# a naive parallel lapply can be created using mcparallel alone:
jobs <- lapply(1:10, function(x) mcparallel(rnorm(x), name = x))
mccollect(jobs)
```

pvec

Parallelize a Vector Map Function using Forking

Description

pvec parallelizes the execution of a function on vector elements by splitting the vector and submitting each part to one core. The function must be a vectorized map, i.e. it takes a vector input and creates a vector output of exactly the same length as the input which doesn’t depend on the partition of the vector.

It relies on forking and hence is not available on Windows unless mc.cores = 1.

Usage

```r
pvec(v, FUN, ..., mc.set.seed = TRUE, mc.silent = FALSE,
     mc.cores = getOption("mc.cores", 2L), mc.cleanup = TRUE)
```

Arguments

- `v` vector to operate on
- `FUN` function to call on each part of the vector
- `...` any further arguments passed to `FUN` after the vector
- `mc.set.seed` See `mcparallel`.
- `mc.silent` if set to TRUE then all output on `stdout` will be suppressed for all parallel processes forked (`stderr` is not affected).
- `mc.cores` The number of cores to use, i.e. at most how many child processes will be run simultaneously. Must be at least one, and at least two for parallel operation. The option is initialized from environment variable `MC_CORES` if set.
- `mc.cleanup` See the description of this argument in `mclapply`. 
Details

pvec parallelizes FUN(x, ...) where FUN is a function that returns a vector of the same length as x. FUN must also be pure (i.e., without side-effects) since side-effects are not collected from the parallel processes. The vector is split into nearly identically sized subvectors on which FUN is run. Although it is in principle possible to use functions that are not necessarily maps, the interpretation would be case-specific as the splitting is in theory arbitrary (a warning is given in such cases).

The major difference between pvec and mclapply is that mclapply will run FUN on each element separately whereas pvec assumes that c(FUN(x[1]), FUN(x[2])) is equivalent to FUN(x[1:2]) and thus will split into as many calls to FUN as there are cores (or elements, if fewer), each handling a subset vector. This makes it more efficient than mclapply but requires the above assumption on FUN.

If mc.cores == 1 this evaluates FUN(v, ...) in the current process.

Value

The result of the computation – in a successful case it should be of the same length as v. If an error occurred or the function was not a map the result may be shorter or longer, and a warning is given.

Note

Due to the nature of the parallelization, error handling does not follow the usual rules since errors will be returned as strings and results from killed child processes will show up simply as nonexistent data. Therefore it is the responsibility of the user to check the length of the result to make sure it is of the correct size. pvec raises a warning if that is the case since it does not know whether such an outcome is intentional or not.

See mcfork for the inadvisability of using this with GUI front-ends and multi-threaded libraries.

Examples

x <- pvec(1:1000, sqrt)
stopifnot(all(x == sqrt(1:1000)))

# One use is to convert date strings to unix time in large datasets
# as that is a relatively slow operation.
# So let's get some random dates first
# (A small test only with 2 cores: set options("mc.cores")
# and increase N for a larger-scale test.)
N <- 1e5
dates <- sprintf('%04d-%02d-%02d', as.integer(2000+rnorm(N)),
                   as.integer(runif(N, 1, 12)), as.integer(runif(N, 1, 28)))

system.time(a <- as.POSIXct(dates))
# But specifying the format is faster
system.time(a <- as.POSIXct(dates, format = "%Y-%m-%d"))

# pvec ought to be faster, but system overhead can be high
system.time(b <- pvec(dates, as.POSIXct, format = "%Y-%m-%d"))
stopifnot(all(a == b))

# using mclapply for this would much slower because each value
# will require a separate call to as.POSIXct()
# as lapply(dates, as.POSIXct) does
system.time(c <- unlist(mclapply(dates, as.POSIXct, format = "%Y-%m-%d")))
stopifnot(all(a == c))
splitInds

clusterSetRNGStream selects the "L'Ecuyer-CMRG" RNG and then distributes streams to the members of a cluster, optionally setting the seed of the streams by set.seed(iseed) (otherwise they are set from the current seed of the master process: after selecting the L’Ecuyer generator).

When not on Windows, Calling mc.reset.stream() after setting the L’Ecuyer random number generator and seed makes runs from mcparallel(mc.set.seed = TRUE) reproducible. This is done internally in mclapply and pvec. (Note that it does not set the seed in the master process, so does not affect the fallback-to-serial versions of these functions.)

Value

For nextRNGStream and nextRNGSubStream, a value which can be assigned to .Random.seed.

Note

Interfaces to L’Ecuyer’s C code are available in CRAN packages rlecuyer and rstream.

splitIndices

Divide Tasks for Distribution in a Cluster

Description

This divides up 1:nx into nc1 lists of approximately equal size, as a way to allocate tasks to nodes in a cluster.

It is mainly for internal use, but some package authors have found it useful.
splitIndices

Usage

splitIndices(nx, ncl)

Arguments

nx Number of tasks.
nc1 Number of cluster nodes.

Value

A list of length ncl, each element being an integer vector.

Examples

splitIndices(20, 3)
Chapter 9

The splines package

splines-package Regression Spline Functions and Classes

Description

Regression spline functions and classes.

Details

This package provides functions for working with regression splines using the B-spline basis, \texttt{bs}, and the natural cubic spline basis, \texttt{ns}.

For a complete list of functions, use \texttt{library(help = "splines")}.

Author(s)

Douglas M. Bates <bates@stat.wisc.edu> and William N. Venables <Bill.Venables@csiro.au>

Maintainer: R Core Team <R-core@r-project.org>

asVector Coerce an Object to a Vector

Description

This is a generic function. Methods for this function coerce objects of given classes to vectors.

Usage

\texttt{asVector(object)}

Arguments

\begin{itemize}
\item \texttt{object} An object.
\end{itemize}
Details

Methods for vector coercion in new classes must be created for the asVector generic instead of as.vector. The as.vector function is internal and not easily extended. Currently the only class with an asVector method is the xyVector class.

Value

a vector

Author(s)

Douglas Bates and Bill Venables

See Also

xyVector

Examples

```r
require(stats)
ispl <- interpSpline( weight ~ height, women )
pred <- predict(ispl)
class(pred)
utils::str(pred)
asVector(pred)
```

backSpline  

Monotone Inverse Spline

Description

Create a monotone inverse of a monotone natural spline.

Usage

backSpline(object)

Arguments

object  
an object that inherits from class nbSpline or npolySpline. That is, the object must represent a natural interpolation spline but it can be either in the B-spline representation or the piecewise polynomial one. The spline is checked to see if it represents a monotone function.

Value

An object of class polySpline that contains the piecewise polynomial representation of a function that has the appropriate values and derivatives at the knot positions to be an inverse of the spline represented by object. Technically this object is not a spline because the second derivative is not constrained to be continuous at the knot positions. However, it is often a much better approximation to the inverse than fitting an interpolation spline to the y/x pairs.
bs

Author(s)
Douglas Bates and Bill Venables

interpSpline

Examples
require(graphics)
ispl <- interpSpline( women$height, women$weight )
bspl <- backSpline( ispl )
plot( bspl )   # plots over the range of the knots
points( women$weight, women$height )

bs

B-Spline Basis for Polynomial Splines

Description
Generate the B-spline basis matrix for a polynomial spline.

Usage
bs(x, df = NULL, knots = NULL, degree = 3, intercept = FALSE,
    Boundary.knots = range(x), warn.outside = TRUE)

Arguments

x
the predictor variable. Missing values are allowed.

df
degrees of freedom; one can specify df rather than knots: bs() then chooses
df-degree (minus one if there is an intercept) knots at suitable quantiles of x
(which will ignore missing values). The default, NULL, takes the number of inner
knots as length(knots). If that is zero as per default, that corresponds to df =
degree - intercept.

knots
the internal breakpoints that define the spline. The default is NULL, which results
in a basis for ordinary polynomial regression. Typical values are the mean or
median for one knot, quantiles for more knots. See also Boundary.knots.

degree
degree of the piecewise polynomial—default is 3 for cubic splines.

intercept
if TRUE, an intercept is included in the basis; default is FALSE.

Boundary.knots
boundary points at which to anchor the B-spline basis (default the range of the
non-NA data). If both knots and Boundary.knots are supplied, the basis pa-
rameters do not depend on x. Data can extend beyond Boundary.knots.

warn.outside
logical indicating if a warning should be signalled in case some x values are
outside the boundary knots.
interpSpline

Details

bs is based on the function `splineDesign`. It generates a basis matrix for representing the family of piecewise polynomials with the specified interior knots and degree, evaluated at the values of \( x \). A primary use is in modeling formulas to directly specify a piecewise polynomial term in a model.

When `Boundary.knots` are set `inside range(x)`, `bs()` now uses a ‘pivot’ inside the respective boundary knot which is important for derivative evaluation. In R versions \( \leq 3.2.2 \), the boundary knot itself had been used as pivot, which lead to somewhat wrong extrapolations.

Value

A matrix of dimension \( c(length(x), df) \), where either `df` was supplied or if `knots` were supplied, \( df = length(knots) + \text{degree} + 1 \) if there is an intercept. Attributes are returned that correspond to the arguments to `bs`, and explicitly give the `knots`, `Boundary.knots` etc for use by `predict.bs()`.

Author(s)

Douglas Bates and Bill Venables. Tweaks by R Core, and a patch fixing extrapolation “outside” `Boundary.knots` by Trevor Hastie.

## example of safe prediction
plot(women, xlab = "Height (in)", ylab = "Weight (lb)")
ht <- seq(57, 73, length.out = 200)
lines(ht, predict(fm1, data.frame(height = ht)))
```

interpSpline

Create an Interpolation Spline

Description

Create an interpolation spline, either from \( x \) and \( y \) vectors (default method), or from a formula / `data.frame` combination (formula method).

Usage

```r
interpSpline(obj1, obj2, bSpline = FALSE, period = NULL,
             ord = 4L,
             na.action = na.fail, sparse = FALSE)
```
interpSpline

Arguments

- **obj1**: either a numeric vector of `x` values or a formula.
- **obj2**: if `obj1` is numeric this should be a numeric vector of the same length. If `obj1` is a formula this can be an optional data frame in which to evaluate the names in the formula.
- **bSpline**: if TRUE the b-spline representation is returned, otherwise the piecewise polynomial representation is returned. Defaults to FALSE.
- **period**: an optional positive numeric value giving a period for a periodic interpolation spline.
- **ord**: an integer specifying the spline order, the number of coefficients per interval. \( ord = d + 1 \) where \( d \) is the degree polynomial degree. Currently, only cubic splines \( (ord = 4) \) are implemented.
- **na.action**: a optional function which indicates what should happen when the data contain NAs. The default action (na.omit) is to omit any incomplete observations. The alternative action na.fail causes interpSpline to print an error message and terminate if there are any incomplete observations.
- **sparse**: logical passed to the underlying splineDesign. If true, saves memory and is faster when there are more than a few hundred points.

Value

An object that inherits from (S3) class spline. The object can be in the B-spline representation, in which case it will be of class nbSpline for natural B-spline, or in the piecewise polynomial representation, in which case it will be of class npolySpline.

isp1 <- interpSpline( women$height, women$weight )
isp12 <- interpSpline( weight ~ height, women )
# ispl and ispl2 should be the same
plot( predict( ispl, seq( 55, 75, length.out = 51 ) ), type = "l" )
points( women$height, women$weight )
plot( ispl )  # plots over the range of the knots
points( women$height, women$weight )
splineKnots( ispl )
```
ns

Generate a Basis Matrix for Natural Cubic Splines

Description

Generate the B-spline basis matrix for a natural cubic spline.

Usage

ns(x, df = NULL, knots = NULL, intercept = FALSE, Boundary.knots = range(x))

Arguments

x the predictor variable. Missing values are allowed.
df degrees of freedom. One can supply df rather than knots; ns() then chooses df - 1 - intercept knots at suitably chosen quantiles of x (which will ignore missing values). The default, df = NULL, sets the number of inner knots as length(knots).
knots breakpoints that define the spline. The default is no knots; together with the natural boundary conditions this results in a basis for linear regression on x. Typical values are the mean or median for one knot, quantiles for more knots. See also Boundary.knots.
intercept if TRUE, an intercept is included in the basis; default is FALSE.
Boundary.knots boundary points at which to impose the natural boundary conditions and anchor the B-spline basis (default the range of the data). If both knots and Boundary.knots are supplied, the basis parameters do not depend on x. Data can extend beyond Boundary.knots.

Details

ns is based on the function splineDesign. It generates a basis matrix for representing the family of piecewise-cubic splines with the specified sequence of interior knots, and the natural boundary conditions. These enforce the constraint that the function is linear beyond the boundary knots, which can either be supplied or default to the extremes of the data.

A primary use is in modeling formula to directly specify a natural spline term in a model: see the examples.

Value

A matrix of dimension length(x) * df where either df was supplied or if knots were supplied, df = length(knots) + 1 + intercept. Attributes are returned that correspond to the arguments to ns, and explicitly give the knots, Boundary.knots etc for use by predict.ns().

References

periodicSpline

Create a Periodic Interpolation Spline

Description

Create a periodic interpolation spline, either from x and y vectors, or from a formula/data.frame combination.

Usage

periodicSpline(obj1, obj2, knots, period = 2*pi, ord = 4L)

Arguments

- **obj1**: either a numeric vector of x values or a formula.
- **obj2**: if obj1 is numeric this should be a numeric vector of the same length. If obj1 is a formula this can be an optional data frame in which to evaluate the names in the formula.
- **knots**: optional numeric vector of knot positions.
- **period**: positive numeric value giving the period for the periodic spline. Defaults to 2 * pi.
- **ord**: integer giving the order of the spline, at least 2. Defaults to 4. See splineOrder for a definition of the order of a spline.

Value

An object that inherits from class spline. The object can be in the B-spline representation, in which case it will be a pbSpline object, or in the piecewise polynomial representation (a ppolySpline object).

See Also

bs, predict.ns, SafePrediction

Examples

```r
require(stats); require(graphics)
ns(women$height, df = 5)
summary(fm1 <- lm(weight ~ ns(height, df = 5), data = women))

## To see what knots were selected
attr(terms(fm1), "predvars")

## example of safe prediction
plot(women, xlab = "Height (in)", ylab = "Weight (lb)")
ht <- seq(57, 73, length.out = 200) ; nD <- data.frame(height = ht)
lines(ht, p1 <- predict(fm1, nD))
stopifnot(all.equal(p1, predict(update(fm1, . ~ splines::ns(height, df=5)), nD)))
# not true in R < 3.5.0
```
polySpline

Piecewise Polynomial Spline Representation

Description

Create the piecewise polynomial representation of a spline object.

Usage

polySpline(object, ...) as.polySpline(object, ...)

Arguments

object An object that inherits from class spline.

... Optional additional arguments. At present no additional arguments are used.

Value

An object that inherits from class polySpline. This is the piecewise polynomial representation of a univariate spline function. It is defined by a set of distinct numeric values called knots. The spline function is a polynomial function between each successive pair of knots. At each interior knot the polynomial segments on each side are constrained to have the same value of the function and some of its derivatives.

Author(s)

Douglas Bates and Bill Venables
**predict.bs**

Evaluate a predefined spline basis at given values.

### Description

Evaluate a predefined spline basis at given values.

### Usage

```r
## S3 method for class 'bs'
predict(object, newx, ...)
## S3 method for class 'ns'
predict(object, newx, ...)
```

### Arguments

- `object`: the result of a call to `bs` or `ns` having attributes describing knots, degree, etc.
- `newx`: the x values at which evaluations are required.
- `...`: Optional additional arguments. At present no additional arguments are used.

### Value

An object just like `object`, except evaluated at the new values of `x`.

These are methods for the generic function `predict` for objects inheriting from classes "bs" or "ns". See `predict` for the general behavior of this function.

### See Also

- `bs`, `ns`, `poly`.

### Examples

```r
require(stats)
basis <- ns(women$height, df = 5)
newX <- seq(58, 72, length.out = 51)
# evaluate the basis at the new data
predict(basis, newX)
```
**predict.bSpline**

*Evaluate a Spline at New Values of x*

**Description**

The `predict` methods for the classes that inherit from the virtual classes `bSpline` and `polySpline` are used to evaluate the spline or its derivatives. The `plot` method for a spline object first evaluates `predict` with the `x` argument missing, then plots the resulting `xyVector` with type = "l".

**Usage**

```r
## S3 method for class 'bSpline'
predict(object, x, nseg = 50, deriv = 0, ...)
## S3 method for class 'nbSpline'
predict(object, x, nseg = 50, deriv = 0, ...)
## S3 method for class 'pbSpline'
predict(object, x, nseg = 50, deriv = 0, ...)
## S3 method for class 'npolySpline'
predict(object, x, nseg = 50, deriv = 0, ...)
## S3 method for class 'ppolySpline'
predict(object, x, nseg = 50, deriv = 0, ...)
```

**Arguments**

- `object` An object that inherits from the `bSpline` or the `polySpline` class.
- `x` A numeric vector of `x` values at which to evaluate the spline. If this argument is missing a suitable set of `x` values is generated as a sequence of `nseg` segments spanning the range of the knots.
- `nseg` A positive integer giving the number of segments in a set of equally-spaced `x` values spanning the range of the knots in `object`. This value is only used if `x` is missing.
- `deriv` An integer between 0 and `splineOrder(object) - 1` specifying the derivative to evaluate.
- `...` further arguments passed to or from other methods.

**Value**

An `xyVector` with components

- `x` the supplied or inferred numeric vector of `x` values
- `y` the value of the spline (or its `deriv`th derivative) at the `x` vector

**Author(s)**

Douglas Bates and Bill Venables

**See Also**

`xyVector`, `interpSpline`, `periodicSpline`
Examples

```r
require(graphics); require(stats)
ispl <- interpSpline( weight ~ height, women )
opar <- par(mfrow = c(2, 2), las = 1)
plot(predict(ispl, nseg = 201),  # plots over the range of the knots
     main = "Original data with interpolating spline", type = "l",
     xlab = "height", ylab = "weight")
points(women$height, women$weight, col = 4)
plot(predict(ispl, nseg = 201, deriv = 1),
     main = "First derivative of interpolating spline", type = "l",
     xlab = "height", ylab = "weight")
plot(predict(ispl, nseg = 201, deriv = 2),
     main = "Second derivative of interpolating spline", type = "l",
     xlab = "height", ylab = "weight")
plot(predict(ispl, nseg = 401, deriv = 3),
     main = "Third derivative of interpolating spline", type = "l",
     xlab = "height", ylab = "weight")
par(opar)
```

### splineDesign

**Design Matrix for B-splines**

**Description**

Evaluate the design matrix for the B-splines defined by knots at the values in x.

**Usage**

```r
splineDesign(knots, x, ord = 4, derivs, outer.ok = FALSE, sparse = FALSE)
spline.des (knots, x, ord = 4, derivs, outer.ok = FALSE, sparse = FALSE)
```

**Arguments**

- **knots**: a numeric vector of knot positions (which will be sorted increasingly if needed).
- **x**: a numeric vector of values at which to evaluate the B-spline functions or derivatives. Unless outer.ok is true, the values in x must be between the “inner” knots knots[ord] and knots[length(knots) - (ord-1)].
- **ord**: a positive integer giving the order of the spline function. This is the number of coefficients in each piecewise polynomial segment, thus a cubic spline has order 4. Defaults to 4.
- **derivs**: an integer vector with values between 0 and ord - 1, conceptually recycled to the length of x. The derivative of the given order is evaluated at the x positions. Defaults to zero (or a vector of zeroes of the same length as x).
- **outer.ok**: logical indicating if x should be allowed outside the inner knots, see the x argument.
- **sparse**: logical indicating if the result should inherit from class "sparseMatrix" (from package Matrix).
A matrix with length(x) rows and length(knots) - ord columns. The i-th row of the matrix contains the coefficients of the B-splines (or the indicated derivative of the B-splines) defined by the knot vector and evaluated at the i-th value of x. Each B-spline is defined by a set of ord successive knots so the total number of B-splines is length(knots) - ord.

Note

The older spline.des function takes the same arguments but returns a list with several components including knots, ord, derivs, and design. The design component is the same as the value of the splineDesign function.

Author(s)

Douglas Bates and Bill Venables

Examples

```r
require(graphics)
splineDesign(knots = 1:10, x = 4:7)
splineDesign(knots = 1:10, x = 4:7, derivs = 1)
## visualize band structure
Matrix::drop0(zapsmall(6*splineDesign(knots = 1:40, x = 4:37, sparse = TRUE)))

knots <- c(1,1.8,3:5,6.5,7,8.1,9.2,10) # 10 => 10-4 = 6 Basis splines
x <- seq(min(knots)-1, max(knots)+1, length.out = 501)
bb <- splineDesign(knots, x = x, outer.ok = TRUE)

plot(range(x), c(0,1), type = "n", xlab = "x", ylab = "",
main = "B-splines - sum to 1 inside inner knots")
mtext(expression(B[j](x) * sum(B[j](x), j == 1, 6)), adj = 0)
abline(v = knots, lty = 3, col = "light gray")
abline(v = knots[c(4,length(knots)-3)], lty = 3, col = "gray10")
lines(x, rowSums(bb), col = "gray", lwd = 2)
matlines(x, bb, ylim = c(0,1), lty = 1)
```

splineKnots

Knot Vector from a Spline

Description

Return the knot vector corresponding to a spline object.

Usage

```r
splineKnots(object)
```

Arguments

object an object that inherits from class "spline".

Value

A non-decreasing numeric vector of knot positions.
**splineOrder**

**Author(s)**
Douglas Bates and Bill Venables

**Examples**

```r
ispl <- interpSpline( weight ~ height, women )
splineKnots( ispl )
```

---

**splineOrder**  
*Determine the Order of a Spline*

**Description**

Return the order of a spline object.

**Usage**

```r
splineOrder(object)
```

**Arguments**

- `object`  
  An object that inherits from class "spline".

**Details**

The order of a spline is the number of coefficients in each piece of the piecewise polynomial representation. Thus a cubic spline has order 4.

**Value**

A positive integer.

**Author(s)**

Douglas Bates and Bill Venables

**See Also**

`splineKnots`, `interpSpline`, `periodicSpline`

**Examples**

```r
splineOrder( interpSpline( weight ~ height, women ) )
```
Construct an \texttt{xyVector} Object

**Description**

Create an object to represent a set of x-y pairs. The resulting object can be treated as a matrix or as a data frame or as a vector. When treated as a vector it reduces to the y component only.

The result of functions such as \texttt{predict.spline} is returned as an \texttt{xyVector} object so the x-values used to generate the y-positions are retained, say for purposes of generating plots.

**Usage**

\texttt{xyVector(x, y)}

**Arguments**

- \texttt{x}: a numeric vector
- \texttt{y}: a numeric vector of the same length as \texttt{x}

**Value**

An object of class \texttt{xyVector} with components

- \texttt{x}: a numeric vector
- \texttt{y}: a numeric vector of the same length as \texttt{x}

**Author(s)**

Douglas Bates and Bill Venables

**Examples**

```r
require(stats); require(graphics)
ispl <- interpSpline( weight ~ height, women )
weights <- predict( ispl, seq( 55, 75, length.out = 51 ) )
class(weights)
plot(weights, type = "l", xlab = "height", ylab = "weight")
points( women$height, women$weight )
weights
```
Chapter 10

.checkMFClasses  Functions to Check the Type of Variables passed to Model Frames

Description

.checkMFClasses checks if the variables used in a predict method agree in type with those used for fitting.
.MFclass categorizes variables for this purpose.
.getXlevels() extracts factor levels from factor or character variables.

Usage

.checkMFClasses(cl, m, ordNotOK = FALSE)
.MFclass(x)
.getXlevels(Terms, m)

1325
Arguments

- cl: a character vector of class descriptions to match.
- m: a model frame (`model.frame()` result).
- x: any R object.
- ordNotOK: logical: are ordered factors different?
- Terms: a terms object (`terms.object`).

Details

For applications involving `model.matrix()` such as linear models we do not need to differentiate between ordered factors and factors as although these affect the coding, the coding used in the fit is already recorded and imposed during prediction. However, other applications may treat ordered factors differently: `rpart` does, for example.

Value

`.checkMFClasses()` checks and either signals an error calling `stop()` or returns `NULL` invisibly.

`.MFclass()` returns a character string, one of "logical", "ordered", "factor", "numeric", "nmatrix.*" (a numeric matrix with a number of columns appended) or "other".

`.getXlevels` returns a named `list` of character vectors, possibly empty, or `NULL`.

Examples

```r
sapply(warpbreaks, .MFclass) # "numeric" plus 2 x "factor"
sapply(iris, .MFclass) # 4 x "numeric" plus "factor"

mf <- model.frame(Sepal.Width ~ Species, iris)
mc <- model.frame(Sepal.Width ~ Sepal.Length, iris)

.checkMFClasses("numeric", mc) # nothing else
.checkMFClasses(c("numeric", "factor"), mf)

## simple .getXlevels() cases :
(xl <- .getXlevels(terms(mf), mf)) # a list with one entry "$ Species" with 3 levels:
stopifnot(exprs = {
  identical(xl$Species, levels(iris$Species))
  identical(.getXlevels(terms(mc), mc), xl[0]) # a empty named list, as no factors
  is.null(.getXlevels(terms(x~x), list(x=1)))
})
```

acf

Auto- and Cross- Covariance and -Correlation Function Estimation

Description

The function `acf` computes (and by default plots) estimates of the autocovariance or autocorrelation function. Function `pacf` is the function used for the partial autocorrelations. Function `ccf` computes the cross-correlation or cross-covariance of two univariate series.
Usage

```r
acf(x, lag.max = NULL,
    type = c("correlation", "covariance", "partial"),
    plot = TRUE, na.action = na.fail, demean = TRUE, ...)
pacf(x, lag.max, plot, na.action, ...)
## Default S3 method:
pacf(x, lag.max = NULL, plot = TRUE, na.action = na.fail,
    ...)  
ccf(x, y, lag.max = NULL, type = c("correlation", "covariance"),
    plot = TRUE, na.action = na.fail, ...)
## S3 method for class 'acf'
x[i, j]
```

Arguments

`x, y` a univariate or multivariate (not ccf) numeric time series object or a numeric vector or matrix, or an \"acf\" object.

`lag.max` maximum lag at which to calculate the acf. Default is \(10 \log_{10}(N/m)\) where \(N\) is the number of observations and \(m\) the number of series. Will be automatically limited to one less than the number of observations in the series.

`type` character string giving the type of acf to be computed. Allowed values are \"correlation\" (the default), \"covariance\" or \"partial\". Will be partially matched.

`plot` logical. If TRUE (the default) the acf is plotted.

`na.action` function to be called to handle missing values. na.pass can be used.

`demean` logical. Should the covariances be about the sample means?

`...` further arguments to be passed to `plot.acf`.

`i` a set of lags (time differences) to retain.

`j` a set of series (names or numbers) to retain.

Details

For type = \"correlation\" and \"covariance\", the estimates are based on the sample covariance. (The lag 0 autocorrelation is fixed at 1 by convention.)

By default, no missing values are allowed. If the `na.action` function passes through missing values (as `na.pass` does), the covariances are computed from the complete cases. This means that the estimate computed may well not be a valid autocorrelation sequence, and may contain missing values. Missing values are not allowed when computing the PACF of a multivariate time series.

The partial correlation coefficient is estimated by fitting autoregressive models of successively higher orders up to `lag.max`.

The generic function `plot` has a method for objects of class \"acf\".

The lag is returned and plotted in units of time, and not numbers of observations.

There are print and subsetting methods for objects of class \"acf\".
Value

An object of class "acf", which is a list with the following elements:

- **lag**: A three dimensional array containing the lags at which the acf is estimated.
- **acf**: An array with the same dimensions as `lag` containing the estimated acf.
- **type**: The type of correlation (same as the `type` argument).
- **n.used**: The number of observations in the time series.
- **series**: The name of the series `x`.
- **snames**: The series names for a multivariate time series.

The lag \( k \) value returned by \( \text{ccf}(x, y) \) estimates the correlation between \( x[t+k] \) and \( y[t] \).

The result is returned invisibly if `plot` is `TRUE`.

`plot.acf`, `ARMAacf` for the exact autocorrelations of a given ARMA process.

Examples

```r
require(graphics)

## Examples from Venables & Ripley
acf(lh)
acf(lh, type = "covariance")
pacf(lh)

acf(ldeaths)
acf(ldeaths, ci.type = "ma")
acf(ts.union(mdeaths, fdeaths))
ccf(mdeaths, fdeaths, ylab = "cross-correlation")
# (just the cross-correlations)

presidents # contains missing values
acf(presidents, na.action = na.pass)
pacf(presidents, na.action = na.pass)
```
acf2AR

**Compute an AR Process Exactly Fitting an ACF**

**Description**
Compute an AR process exactly fitting an autocorrelation function.

**Usage**
acf2AR(acf)

**Arguments**
- **acf**
  An autocorrelation or autocovariance sequence.

**Value**
A matrix, with one row for the computed AR(p) coefficients for 1 <= p <= length(acf).

**See Also**
- `ARMAacf`, `ar.yw` which does this from an empirical ACF.

**Examples**
```r
(Acf <- ARMAacf(c(0.6, 0.3, -0.2)))
acf2AR(Acf)
```

---

add1

**Add or Drop All Possible Single Terms to a Model**

**Description**
Compute all the single terms in the scope argument that can be added to or dropped from the model, fit those models and compute a table of the changes in fit.

**Usage**
add1(object, scope, ...)  
## Default S3 method:  
add1(object, scope, scale = 0, test = c("none", "Chisq"),  
  k = 2, trace = FALSE, ...)

## S3 method for class 'lm'  
add1(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
  x = NULL, k = 2, ...)

## S3 method for class 'glm'  
add1(object, scope, scale = 0, ...)
```
test = c("none", "Rao", "LRT", "Chisq", "F"),
  x = NULL, k = 2, ...)

drop1(object, scope, ...)

## Default S3 method:
drop1(object, scope, scale = 0, test = c("none", "Chisq"),
  k = 2, trace = FALSE, ...)

## S3 method for class 'lm'
drop1(object, scope, scale = 0, all.cols = TRUE,
  test = c("none", "Chisq", "F"), k = 2, ...)

## S3 method for class 'glm'
drop1(object, scope, scale = 0,
  test = c("none", "Rao", "LRT", "Chisq", "F"),
  k = 2, ...)

Arguments

object a fitted model object.
scope a formula giving the terms to be considered for adding or dropping.
scale an estimate of the residual mean square to be used in computing $C_p$. Ignored if 0 or NULL.
test should the results include a test statistic relative to the original model? The F test is only appropriate for lm and aov models or perhaps for glm fits with estimated dispersion. The $\chi^2$ test can be an exact test (lm models with known scale) or a likelihood-ratio test or a test of the reduction in scaled deviance depending on the method. For glm fits, you can also choose "LRT" and "Rao" for likelihood ratio tests and Rao’s efficient score test. The former is synonymous with "Chisq" (although both have an asymptotic chi-square distribution). Values can be abbreviated.
k the penalty constant in AIC / $C_p$.
trace if TRUE, print out progress reports.
x a model matrix containing columns for the fitted model and all terms in the upper scope. Useful if add1 is to be called repeatedly. Warning: no checks are done on its validity.
all.cols (Provided for compatibility with S.) Logical to specify whether all columns of the design matrix should be used. If FALSE then non-estimable columns are dropped, but the result is not usually statistically meaningful.
...

Details

For drop1 methods, a missing scope is taken to be all terms in the model. The hierarchy is respected when considering terms to be added or dropped: all main effects contained in a second-order interaction must remain, and so on.

In a scope formula . means ‘what is already there’.

The methods for lm and glm are more efficient in that they do not recompute the model matrix and call the fit methods directly.
The default output table gives AIC, defined as minus twice log likelihood plus 2p where p is the rank of the model (the number of effective parameters). This is only defined up to an additive constant (like log-likelihoods). For linear Gaussian models with fixed scale, the constant is chosen to give Mallows’ $C_p$, $RSS/scale + 2p - n$. Where $C_p$ is used, the column is labelled as $C_p$ rather than AIC.

The F tests for the "glm" methods are based on analysis of deviance tests, so if the dispersion is estimated it is based on the residual deviance, unlike the F tests of anova.glm.

**Value**

An object of class "anova" summarizing the differences in fit between the models.

**Warning**

The model fitting must apply the models to the same dataset. Most methods will attempt to use a subset of the data with no missing values for any of the variables if na.action = na.omit, but this may give biased results. Only use these functions with data containing missing values with great care.

The default methods make calls to the function nobs to check that the number of observations involved in the fitting process remained unchanged.

**Note**

These are not fully equivalent to the functions in S. There is no keep argument, and the methods used are not quite so computationally efficient.

Their authors’ definitions of Mallows’ $C_p$ and Akaike’s AIC are used, not those of the authors of the models chapter of S.

**Author(s)**

The design was inspired by the S functions of the same names described in Chambers (1992).

**References**

**See Also**

step, aov, lm, extractAIC, anova

**Examples**

```r
require(graphics); require(utils)
## following example(swiss)
lm1 <- lm(Fertility ~ ., data = swiss)
add1(lm1, ~ I(Education^2) + .^2)
drop1(lm1, test = "F") # So called 'type II' anova

## following example(glm)
drop1(glm.D93, test = "Chisq")
drop1(glm.D93, test = "F")
add1(glm.D93, scope = ~outcome*treatment, test = "Rao") ## Pearson Chi-square
```
addmargins

**Puts Arbitrary Margins on Multidimensional Tables or Arrays**

**Description**

For a given table one can specify which of the classifying factors to expand by one or more levels to hold margins to be calculated. One may for example form sums and means over the first dimension and medians over the second. The resulting table will then have two extra levels for the first dimension and one extra level for the second. The default is to sum over all margins in the table. Other possibilities may give results that depend on the order in which the margins are computed. This is flagged in the printed output from the function.

**Usage**

```r
addmargins(A, margin = seq_along(dim(A)), FUN = sum, quiet = FALSE)
```

**Arguments**

- **A**: table or array. The function uses the presence of the "dim" and "dimnames" attributes of `A`.
- **margin**: vector of dimensions over which to form margins. Margins are formed in the order in which dimensions are specified in `margin`.
- **FUN**: list of the same length as `margin`, each element of the list being either a function or a list of functions. In the length-1 case, can be a function instead of a list of one. Names of the list elements will appear as levels in dimnames of the result. Unnamed list elements will have names constructed: the name of a function or a constructed name based on the position in the table.
- **quiet**: logical which suppresses the message telling the order in which the margins were computed.

**Details**

If the functions used to form margins are not commutative, the result depends on the order in which margins are computed. Annotation of margins is done naming the `FUN` list.

**Value**

A table or array with the same number of dimensions as `A`, but with extra levels of the dimensions mentioned in `margin`. The number of levels added to each dimension is the length of the entries in `FUN`. A message with the order of computation of margins is printed.

(A <- table(Aye, Bee, Sea))
(aA <- addmargins(A))

ftable(A)
ftable(aA)

# Non-commutative functions - note differences between resulting tables:
ftable( addmargins(A, c(3, 1),
    FUN = list(list(Min = min, Max = max),
               Sum = sum)))
ftable( addmargins(A, c(1, 3),
    FUN = list(Sum = sum,
               list(Min = min, Max = max))))

# Weird function needed to return the N when computing percentages
sqsm <- function(x) sum(x)^2/100
B <- table(Sea, Bee)
round(sweep(addmargins(B, 1, list(list(All = sum, N = sqsm))), 2,
            apply(B, 2, sum)/100, `/`, 1)
round(sweep(addmargins(B, 2, list(list(All = sum, N = sqsm))), 1,
            apply(B, 1, sum)/100, `/`, 1))

# A total over Bee requires formation of the Bee-margin first:
mB <- addmargins(B, 2, FUN = list(list(Total = sum)))
round(ftable(sweep(addmargins(mB, 1, list(list(All = sum, N = sqsm))), 2,
                      apply(mB, 2, sum)/100, `/`)), 1)

## Zero.Printing table+margins:
set.seed(1)
x <- sample( 1:7, 20, replace = TRUE)
y <- sample( 1:7, 20, replace = TRUE)
(tx <- addmargins( table(x, y) )
print(tx, zero.print = ".")

aggregate

Compute Summary Statistics of Data Subsets

Description

Splits the data into subsets, computes summary statistics for each, and returns the result in a convenient form.

Usage

aggregate(x, ...)

# Default S3 method:
aggregate(x, ...)
aggregate

## S3 method for class 'data.frame'
aggregate(x, by, FUN, ..., simplify = TRUE, drop = TRUE)

## S3 method for class 'formula'
aggregate(x, data, FUN, ...,
          subset, na.action = na.omit)

## S3 method for class 'ts'
aggregate(x, nfrequency = 1, FUN = sum, ndeltat = 1,
          ts.eps = getOption("ts.eps"), ...)

Arguments

- **x**: an R object. For the formula method a formula, such as \( y \sim x \) or \( \text{cbind}(y1, y2) \sim x1 + x2 \), where the \( y \) variables are numeric data to be split into groups according to the grouping \( x \) variables (usually factors).
- **by**: a list of grouping elements, each as long as the variables in the data frame \( x \), or a formula. The elements are coerced to factors before use.
- **FUN**: a function to compute the summary statistics which can be applied to all data subsets.
- **simplify**: a logical indicating whether results should be simplified to a vector or matrix if possible.
- **drop**: a logical indicating whether to drop unused combinations of grouping values. The non-default case drop=FALSE has been amended for R 3.5.0 to drop unused combinations.
- **data**: a data frame (or list) from which the variables in the formula should be taken.
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NA values. The default is to only consider complete cases with respect to the given variables.
- **nfrequency**: new number of observations per unit of time; must be a divisor of the frequency of \( x \).
- **ndeltat**: new fraction of the sampling period between successive observations; must be a divisor of the sampling interval of \( x \).
- **ts.eps**: tolerance used to decide if nfrequency is a sub-multiple of the original frequency.
- **...**: further arguments passed to or used by methods.

Details

aggregate is a generic function with methods for data frames and time series.

The default method, aggregate.default, uses the time series method if \( x \) is a time series, and otherwise coerces \( x \) to a data frame and calls the data frame method.

aggregate.data.frame is the data frame method. If \( x \) is not a data frame, it is coerced to one, which must have a non-zero number of rows. Then, each of the variables (columns) in \( x \) is split into subsets of cases (rows) of identical combinations of the components of \( by \), and \( \text{FUN} \) is applied to each such subset with further arguments in ... passed to it. The result is reformatted into a data frame containing the variables in \( by \) and \( x \). The ones arising from \( by \) contain the unique combinations of grouping values used for determining the subsets, and the ones arising from \( x \)...
the corresponding summaries for the subset of the respective variables in \( x \). If `simplify` is true, summaries are simplified to vectors or matrices if they have a common length of one or greater than one, respectively; otherwise, lists of summary results according to subsets are obtained. Rows with missing values in any of the by variables will be omitted from the result. (Note that versions of \( \mathsf{R} \) prior to 2.11.0 required \( \text{FUN} \) to be a scalar function.)

The formula method provides a standard formula interface to `aggregate.data.frame`. The latter invokes the formula method if by is a formula, in which case `aggregate(x, by, FUN)` is the same as `aggregate(by, x, FUN)` for a data frame \( x \).

`aggregate.ts` is the time series method, and requires \( \text{FUN} \) to be a scalar function. If \( x \) is not a time series, it is coerced to one. Then, the variables in \( x \) are split into appropriate blocks of length \( \text{frequency}(x) / \text{nfrequency} \), and \( \text{FUN} \) is applied to each such block, with further (named) arguments in \( \ldots \) passed to it. The result returned is a time series with frequency \( \text{nfrequency} \) holding the aggregated values. Note that this make most sense for a quarterly or yearly result when the original series covers a whole number of quarters or years: in particular aggregating a monthly series to quarters starting in February does not give a conventional quarterly series.

\( \text{FUN} \) is passed to `match.fun`, and hence it can be a function or a symbol or character string naming a function.

**Value**

For the time series method, a time series of class "ts" or class `c("mts", "ts")`.

For the data frame method, a data frame with columns corresponding to the grouping variables in `by` followed by aggregated columns from \( x \). If the `by` has names, the non-empty times are used to label the columns in the results, with unnamed grouping variables being named `Group.i` for `by[[i]]`.

**Warning**

The first argument of the "formula" method was named `formula` rather than `x` prior to \( \mathsf{R} \) 4.2.0. Portable uses should not name that argument.

**Author(s)**

Kurt Hornik, with contributions by Arni Magnusson.

**References**

**See Also**

`apply`, `lapply`, `tapply`.

**Examples**

```r
## Compute the averages for the variables in \( \text{state.x77} \), grouped
## according to the region (Northeast, South, North Central, West) that
## each state belongs to.
aggregate(state.x77, list(Region = state.region), mean)

## Compute the averages according to region and the occurrence of more
## than 130 days of frost.
aggregate(state.x77,
```
list(Region = state.region, Cold = state.x77[, "Frost"] > 130), mean)

## (Note that no state in 'South' is THAT cold.)

## example with character variables and NAs

testDF <- data.frame(v1 = c(1, 3, 5, 7, 8, 3, 5, NA, 4, 5, 7, 9),
                     v2 = c(11, 33, 55, 77, 88, 33, 55, NA, 44, 55, 77, 99))

by1 <- c("red", "blue", 1, 2, NA, "big", 1, 2, "red", 1, NA, 12)
by2 <- c("wet", "dry", 99, 95, NA, "damp", 95, 99, "red", 99, NA, NA)
aggregate(x = testDF, by = list(by1, by2), FUN = "mean")

# and if you want to treat NAs as a group
fby1 <- factor(by1, exclude = "")
fby2 <- factor(by2, exclude = "")
aggregate(x = testDF, by = list(fby1, fby2), FUN = "mean")

## Formulas, one ~ one, one ~ many, many ~ one, and many ~ many:
aggregate(weight ~ feed, data = chickwts, mean)
aggregate(breaks ~ wool + tension, data = warpbreaks, mean)
aggregate(cbind(Ozone, Temp) ~ Month, data = airquality, mean)
aggregate(cbind(ncases, ncontrols) ~ alcgp + tobgp, data = esoph, sum)

## "complete cases" vs. "available cases"
colSums(is.na(airquality)) # NAs in Ozone but not Temp
## the default is to summarize *complete cases*:
aggregate(cbind(Ozone, Temp) ~ Month, data = airquality, FUN = mean)
## to handle missing values *per variable*:
aggregate(cbind(Ozone, Temp) ~ Month, data = airquality, FUN = mean, 
          na.action = na.pass, na.rm = TRUE)

## Dot notation:
aggregate(. ~ Species, data = iris, mean)
aggregate(len ~ ., data = ToothGrowth, mean)

## Often followed by xtabs():
ag <- aggregate(len ~ ., data = ToothGrowth, mean)
xtabs(len ~ ., data = ag)

## Formula interface via ‘by’ (for pipe operations)
ToothGrowth |> aggregate(len ~ ., FUN = mean)

## Compute the average annual approval ratings for American presidents.
aggregate(presidents, nfrequency = 1, FUN = mean)
## Give the summer less weight.
aggregate(presidents, nfrequency = 1, 
          FUN = weighted.mean, w = c(1, 1, 0.5, 1))
AIC

Description
Generic function calculating Akaike's 'An Information Criterion' for one or several fitted model objects for which a log-likelihood value can be obtained, according to the formula $-2\log\text{likelihood} + kn_{\text{par}}$, where $n_{\text{par}}$ represents the number of parameters in the fitted model, and $k = 2$ for the usual AIC, or $k = \log(n)$ ($n$ being the number of observations) for the so-called BIC or SBC (Schwarz's Bayesian criterion).

Usage
AIC(object, ..., k = 2)
BIC(object, ...)

Arguments
object a fitted model object for which there exists a logLik method to extract the corresponding log-likelihood, or an object inheriting from class logLik.
... optionally more fitted model objects.
k numeric, the penalty per parameter to be used; the default $k = 2$ is the classical AIC.

Details
When comparing models fitted by maximum likelihood to the same data, the smaller the AIC or BIC, the better the fit.

The theory of AIC requires that the log-likelihood has been maximized: whereas AIC can be computed for models not fitted by maximum likelihood, their AIC values should not be compared.

Examples of models not 'fitted to the same data' are where the response is transformed (accelerated-life models are fitted to log-times) and where contingency tables have been used to summarize data.

These are generic functions (with S4 generics defined in package stats4): however methods should be defined for the log-likelihood function logLik rather than these functions: the action of their default methods is to call logLik on all the supplied objects and assemble the results. Note that in several common cases logLik does not return the value at the MLE: see its help page.

The log-likelihood and hence the AIC/BIC is only defined up to an additive constant. Different constants have conventionally been used for different purposes and so extractAIC and AIC may give different values (and do for models of class "lm": see the help for extractAIC). Particular care is needed when comparing fits of different classes (with, for example, a comparison of a Poisson and gamma GLM being meaningless since one has a discrete response, the other continuous).

BIC is defined as $\text{AIC(object, \ldots, k = log(nobs(object)))}$. This needs the number of observations to be known: the default method looks first for a "nobs" attribute on the return value from the logLik method, then tries the nobs generic, and if neither succeed returns BIC as NA.

Value
If just one object is provided, a numeric value with the corresponding AIC (or BIC, or \ldots, depending on $k$).

If multiple objects are provided, a data.frame with rows corresponding to the objects and columns representing the number of parameters in the model (df) and the AIC or BIC.
Author(s)

Originally by José Pinheiro and Douglas Bates, more recent revisions by R-core.

References

See Also

extractAIC, logLik, nobs.

Examples

```r
lm1 <- lm(Fertility ~ ., data = swiss)
AIC(lm1)
stopifnot(all.equal(AIC(lm1),
                   AIC(logLik(lm1))))
BIC(lm1)

lm2 <- update(lm1, . ~ . - Examination)
AIC(lm1, lm2)
BIC(lm1, lm2)
```

Description

Find aliases (linearly dependent terms) in a linear model specified by a formula.

Usage

```r
alias(object, ...)
```

## S3 method for class 'formula'

```r
alias(object, data, ...)
```

## S3 method for class 'lm'

```r
alias(object, complete = TRUE, partial = FALSE, partial.pattern = FALSE, ...)
```

Arguments

- **object**: A fitted model object, for example from `lm` or `aov`, or a formula for `alias.formula`.
- **data**: Optionally, a data frame to search for the objects in the formula.
- **complete**: Should information on complete aliasing be included?
- **partial**: Should information on partial aliasing be included?
Should partial aliasing be presented in a schematic way? If this is done, the results are presented in a more compact way, usually giving the deciles of the coefficients.

... further arguments passed to or from other methods.

Details

Although the main method is for class "lm", alias is most useful for experimental designs and so is used with fits from aov. Complete aliasing refers to effects in linear models that cannot be estimated independently of the terms which occur earlier in the model and so have their coefficients omitted from the fit. Partial aliasing refers to effects that can be estimated less precisely because of correlations induced by the design.

Some parts of the "lm" method require recommended package MASS to be installed.

Value

A list (of class "listof") containing components

Model Description of the model; usually the formula.
Complete A matrix with columns corresponding to effects that are linearly dependent on the rows.
Partial The correlations of the estimable effects, with a zero diagonal. An object of class "mtable" which has its own print method.

Note

The aliasing pattern may depend on the contrasts in use: Helmert contrasts are probably most useful. The defaults are different from those in S.

Author(s)

The design was inspired by the S function of the same name described in Chambers et al. (1992).

References

Examples

```r
op <- options(contrasts = c("contr.helmert", "contr.poly"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
alias(npk.aov)
options(op) # reset
```
Description

Compute analysis of variance (or deviance) tables for one or more fitted model objects.

Usage

anova(object, ...)

Arguments

object an object containing the results returned by a model fitting function (e.g., `lm` or `glm`).
...
additional objects of the same type.

Value

This (generic) function returns an object of class `anova`. These objects represent analysis-of-variance and analysis-of-deviance tables. When given a single argument it produces a table which tests whether the model terms are significant.

When given a sequence of objects, `anova` tests the models against one another in the order specified.

The print method for `anova` objects prints tables in a ‘pretty’ form.

Warning

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R’s default of `na.action = na.omit` is used.

References

See Also

`coefficients`, `effects`, `fitted.values`, `residuals`, `summary`, `drop1`, `add1`.

Description

Compute an analysis of deviance table for one or more generalized linear model fits.

Usage

## S3 method for class 'glm'
anova(object, ..., dispersion = NULL, test = NULL)
Arguments

- `object,...`: objects of class `glm`, typically the result of a call to `glm`, or a list of objects for the "glmlist" method.
- `dispersion`: the dispersion parameter for the fitting family. By default it is obtained from the object(s).
- `test`: a character string, (partially) matching one of "Chisq", "LRT", "Rao", "F" or "Cp". See `stat.anova`. Or logical FALSE, which suppresses any test.

Details

Specifying a single object gives a sequential analysis of deviance table for that fit. That is, the reductions in the residual deviance as each term of the formula is added in turn are given in as the rows of a table, plus the residual deviances themselves.

If more than one object is specified, the table has a row for the residual degrees of freedom and deviance for each model. For all but the first model, the change in degrees of freedom and deviance is also given. (This only makes statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

The table will optionally contain test statistics (and P values) comparing the reduction in deviance for the row to the residuals. For models with known dispersion (e.g., binomial and Poisson fits) the chi-squared test is most appropriate, and for those with dispersion estimated by moments (e.g., `gaussian`, `quasibinomial` and `quasipoisson` fits) the F test is most appropriate. If `anova.glm` can determine which of these cases applies then by default it will use one of the above tests. If the `dispersion` argument is supplied, the dispersion is considered known and the chi-squared test will be used. Argument `test=FALSE` suppresses the test statistics and P values. Mallows' C_p statistic is the residual deviance plus twice the estimate of σ^2 times the residual degrees of freedom, which is closely related to AIC (and a multiple of it if the dispersion is known). You can also choose "LRT" and "Rao" for likelihood ratio tests and Rao's efficient score test. The former is synonymous with "Chisq" (although both have an asymptotic chi-square distribution).

The dispersion estimate will be taken from the largest model, using the value returned by `summary.glm`. As this will in most cases use a Chi-squared-based estimate, the F tests are not based on the residual deviance in the analysis of deviance table shown.

Value

An object of class "anova" inheriting from class "data.frame".

Warning

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R’s default of `na.action = na.omit` is used, and `anova` will detect this with an error.

References

See Also

- `glm`, `anova`.
- `drop1` for so-called ‘type II’ ANOVA where each term is dropped one at a time respecting their hierarchy.
Examples

```r
## --- Continuing the Example from '?glm':

anova(glm.D93, test = FALSE)
anova(glm.D93, test = "Cp")
anova(glm.D93, test = "Chisq")
glm.D93a <-
  update(glm.D93, ~treatment*outcome) # equivalent to Pearson Chi-square
anova(glm.D93, glm.D93a, test = "Rao")
```

---

anova.lm

**ANOVA for Linear Model Fits**

Description

Compute an analysis of variance table for one or more linear model fits.

Usage

```r
## S3 method for class 'lm'
anova(object, ...)

## S3 method for class 'lmlist'
anova(object, ..., scale = 0, test = "F")
```

Arguments

- `object,...` objects of class `lm`, usually, a result of a call to `lm`.
- `test` a character string specifying the test statistic to be used. Can be one of "F", "Chisq" or "Cp", with partial matching allowed, or `NULL` for no test.
- `scale` numeric. An estimate of the noise variance $\sigma^2$. If zero this will be estimated from the largest model considered.

Details

Specifying a single object gives a sequential analysis of variance table for that fit. That is, the reductions in the residual sum of squares as each term of the formula is added in turn are given in as the rows of a table, plus the residual sum of squares.

The table will contain F statistics (and P values) comparing the mean square for the row to the residual mean square.

If more than one object is specified, the table has a row for the residual degrees of freedom and sum of squares for each model. For all but the first model, the change in degrees of freedom and sum of squares is also given. (This only make statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

Optionally the table can include test statistics. Normally the F statistic is most appropriate, which compares the mean square for a row to the residual sum of squares for the largest model considered. If `scale` is specified chi-squared tests can be used. Mallows’ $C_p$ statistic is the residual sum of squares plus twice the estimate of $\sigma^2$ times the residual degrees of freedom.
anova.mlm

Value

An object of class "anova" inheriting from class "data.frame".

Warning

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R's default of na.action = na.omit is used, and anova.lmlist will detect this with an error.

## same effect via separate models
fit0 <- lm(sr ~ 1, data = LifeCycleSavings)
fit1 <- update(fit0, . ~ . + pop15)
fit2 <- update(fit1, . ~ . + pop75)
fit3 <- update(fit2, . ~ . + dpi)
fit4 <- update(fit3, . ~ . + ddpi)
anova(fit0, fit1, fit2, fit3, fit4, test = "F")
anova(fit4, fit2, fit0, test = "F") # unconventional order

Description

Compute a (generalized) analysis of variance table for one or more multivariate linear models.

Usage

## S3 method for class 'mlm'
anova(object, ..., 
  test = c("Pillai", "Wilks", "Hotelling-Lawley", "Roy", "Spherical"),
  Sigma = diag(nrow = p), T = Thin.row(Proj(M) - Proj(X)),
  M = diag(nrow = p), X = ~0,
  idata = data.frame(index = seq_len(p)), tol = 1e-7)
Arguments

- **object**: an object of class "mlm".
- **...**: further objects of class "mlm".
- **test**: choice of test statistic (see below). Can be abbreviated.
- **Sigma**: (only relevant if test == "Spherical"). Covariance matrix assumed proportional to Sigma.
- **T**: transformation matrix. By default computed from M and X.
- **M**: formula or matrix describing the outer projection (see below).
- **X**: formula or matrix describing the inner projection (see below).
- **idata**: data frame describing intra-block design.
- **tol**: tolerance to be used in deciding if the residuals are rank-deficient: see qr.

Details

The `anova.mlm` method uses either a multivariate test statistic for the summary table, or a test based on sphericity assumptions (i.e. that the covariance is proportional to a given matrix).

For the multivariate test, Wilks’ statistic is most popular in the literature, but the default Pillai–Bartlett statistic is recommended by Hand and Taylor (1987). See `summary.manova` for further details.

For the "Spherical" test, proportionality is usually with the identity matrix but a different matrix can be specified using Sigma. Corrections for asphericity known as the Greenhouse–Geisser, respectively Huynh–Feldt, epsilons are given and adjusted F tests are performed.

It is common to transform the observations prior to testing. This typically involves transformation to intra-block differences, but more complicated within-block designs can be encountered, making more elaborate transformations necessary. A transformation matrix T can be given directly or specified as the difference between two projections onto the spaces spanned by M and X, which in turn can be given as matrices or as model formulas with respect to idata (the tests will be invariant to parametrization of the quotient space M/X).

As with `anova.lm`, all test statistics use the SSD matrix from the largest model considered as the (generalized) denominator.

Contrary to other `anova` methods, the intercept is not excluded from the display in the single-model case. When contrast transformations are involved, it often makes good sense to test for a zero intercept.

Value

An object of class "anova" inheriting from class "data.frame"

Note

The Huynh–Feldt epsilon differs from that calculated by SAS (as of v. 8.2) except when the DF is equal to the number of observations minus one. This is believed to be a bug in SAS, not in R.

References

### Examples

```r
require(graphics)
utils::example(SSD)  # Brings in the mlmfit and reacttime objects

mlmfit0 <- update(mlmfit, ~0)

### Traditional tests of intrasubj. contrasts
## Using MANOVA techniques on contrasts:
anova(mlmfit, mlmfit0, X = ~1)

### Assuming sphericity
anova(mlmfit, mlmfit0, X = ~1, test = "Spherical")

### tests using intra-subject 3x2 design
idata <- data.frame(deg = gl(3, 1, 6, labels = c(0, 4, 8)),
                     noise = gl(2, 3, 6, labels = c("A", "P"))
                        )
anova(mlmfit, mlmfit0, X = ~ deg + noise, 
      idata = idata, test = "Spherical")
anova(mlmfit, mlmfit0, M = ~ deg + noise, X = ~ noise, 
      idata = idata, test = "Spherical")
anova(mlmfit, mlmfit0, M = ~ deg + noise, X = ~ deg, 
      idata = idata, test = "Spherical")

f <- factor(rep(1:2, 5))  # bogus, just for illustration
mlmfit2 <- update(mlmfit, ~f)
anova(mlmfit2, mlmfit, mlmfit0, X = ~1, test = "Spherical")
anova(mlmfit2, X = ~1, test = "Spherical")

# one-model form, eqiv. to previous

### There seems to be a strong interaction in these data
plot(colMeans(reacttime))
```

### ansari.test

**Ansari-Bradley Test**

**Description**

Performs the Ansari-Bradley two-sample test for a difference in scale parameters.

**Usage**

```r
ansari.test(x, ...)
```

## Default S3 method:

```r
ansari.test(x, y, 
  alternative = c("two.sided", "less", "greater"),
  exact = NULL, conf.int = FALSE, conf.level = 0.95,
```
### S3 method for class 'formula'

`ansari.test(formula, data, subset, na.action, ...)`

#### Arguments

- `x` numeric vector of data values.
- `y` numeric vector of data values.
- `alternative` indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.
- `exact` a logical indicating whether an exact p-value should be computed.
- `conf.int` a logical, indicating whether a confidence interval should be computed.
- `conf.level` confidence level of the interval.
- `formula` a formula of the form `lhs ~ rhs` where `lhs` is a numeric variable giving the data values and `rhs` a factor with two levels giving the corresponding groups.
- `data` an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- `subset` an optional vector specifying a subset of observations to be used.
- `na.action` a function which indicates what should happen when the data contain `NA` s. Defaults to `getOption("na.action")`.
- `...` further arguments to be passed to or from methods.

#### Details

Suppose that `x` and `y` are independent samples from distributions with densities $f((t - m)/s)/s$ and $f(t - m)$, respectively, where `m` is an unknown nuisance parameter and `s`, the ratio of scales, is the parameter of interest. The Ansari-Bradley test is used for testing the null that `s` equals 1, the two-sided alternative being that `s ≠ 1` (the distributions differ only in variance), and the one-sided alternatives being `s > 1` (the distribution underlying `x` has a larger variance, "greater") or `s < 1` ("less").

By default (if `exact` is not specified), an exact p-value is computed if both samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

Optionally, a nonparametric confidence interval and an estimator for `s` are computed. If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations.

Note that mid-ranks are used in the case of ties rather than average scores as employed in Hollander & Wolfe (1973). See, e.g., Hajek, Sidak and Sen (1999), pages 131ff, for more information.

#### Value

A list with class "htest" containing the following components:

- `statistic` the value of the Ansari-Bradley test statistic.
- `p.value` the p-value of the test.
- `null.value` the ratio of scales `s` under the null, 1.
- `alternative` a character string describing the alternative hypothesis.
method the string "Ansari-Bradley test".
data.name a character string giving the names of the data.
conf.int a confidence interval for the scale parameter. (Only present if argument
conf.int = TRUE.)
estimate an estimate of the ratio of scales. (Only present if argument conf.int = TRUE.)

Note

To compare results of the Ansari-Bradley test to those of the F test to compare two variances (under
the assumption of normality), observe that \( s \) is the ratio of scales and hence \( s^2 \) is the ratio of
variances (provided they exist), whereas for the F test the ratio of variances itself is the parameter
of interest. In particular, confidence intervals are for \( s \) in the Ansari-Bradley test but for \( s^2 \) in the F
test.

```
**aov**

*Fit an Analysis of Variance Model*

**Description**

Fit an analysis of variance model by a call to `lm` (for each stratum if an `Error(.)` is used).

**Usage**

```
aov(formula, data = NULL, projections = FALSE, qr = TRUE,
     contrasts = NULL, ...)
```

**Arguments**

- `formula` A formula specifying the model.
- `data` A data frame in which the variables specified in the formula will be found. If missing, the variables are searched for in the standard way.
- `projections` Logical flag: should the projections be returned?
- `qr` Logical flag: should the QR decomposition be returned?
- `contrasts` A list of contrasts to be used for some of the factors in the formula. These are not used for any `Error` term, and supplying contrasts for factors only in the `Error` term will give a warning.
- `...` Arguments to be passed to `lm`, such as `subset` or `na.action`. See ‘Details’ about `weights`.

**Details**

This provides a wrapper to `lm` for fitting linear models to balanced or unbalanced experimental designs.

The main difference from `lm` is in the way `print`, `summary` and so on handle the fit: this is expressed in the traditional language of the analysis of variance rather than that of linear models.

If the formula contains a single `Error` term, this is used to specify error strata, and appropriate models are fitted within each error stratum.

The formula can specify multiple responses.

Weights can be specified by a `weights` argument, but should not be used with an `Error` term, and are incompletely supported (e.g., not by `model.tables`).

**Value**

An object of class `c("aov", "lm")` or for multiple responses of class `c("maov", "aov", "mlm", "lm")` or for multiple error strata of class `c("aovlist", "listof")`. There are `print` and `summary` methods available for these.
approxfun

Interpolation Functions

Description
Return a list of points which linearly interpolate given data points, or a function performing the linear (or constant) interpolation.

Note
aov is designed for balanced designs, and the results can be hard to interpret without balance: beware that missing values in the response(s) will likely lose the balance. If there are two or more error strata, the methods used are statistically inefficient without balance, and it may be better to use lme in package nlme.

Balance can be checked with the replications function.
The default ‘contrasts’ in R are not orthogonal contrasts, and aov and its helper functions will work better with such contrasts: see the examples for how to select these.

Author(s)
The design was inspired by the S function of the same name described in Chambers et al. (1992).

Examples

```r
## Set orthogonal contrasts.
op <- options(contrasts = c("contr.helmert", "contr.poly"))
( npk.aov <- aov(yield ~ block + N*P*K, npk) )
summary(npk.aov)
coefficients(npk.aov)
## to show the effects of re-ordering terms contrast the two fits
aov(yield ~ block + N * P + K, npk)
aov(terms(yield ~ block + N * P + K, keep.order = TRUE), npk)
```

```r
## as a test, not particularly sensible statistically
npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
npk.aovE
summary(npk.aovE)
options(op) # reset to previous
```
approxfun

Usage

approx (x, y = NULL, xout, method = "linear", n = 50,
       yleft, yright, rule = 1, f = 0, ties = mean, na.rm = TRUE)

approxfun(x, y = NULL, method = "linear",
       yleft, yright, rule = 1, f = 0, ties = mean, na.rm = TRUE)

Arguments

x, y numeric vectors giving the coordinates of the points to be interpolated. Alternatively a single plotting structure can be specified: see xy.coords.
xout an optional set of numeric values specifying where interpolation is to take place.
method specifies the interpolation method to be used. Choices are "linear" or "constant".
n If xout is not specified, interpolation takes place at n equally spaced points spanning the interval \[ \min(x), \max(x) \].
yleft the value to be returned when input x values are less than \( \min(x) \). The default is defined by the value of rule given below.
yright the value to be returned when input x values are greater than \( \max(x) \). The default is defined by the value of rule given below.
rule an integer (of length 1 or 2) describing how interpolation is to take place outside the interval \[ \min(x), \max(x) \]. If rule is 1 then NAs are returned for such points and if it is 2, the value at the closest data extreme is used. Use, e.g., rule = 2:1, if the left and right side extrapolation should differ.
f for method = "constant" a number between 0 and 1 inclusive, indicating a compromise between left- and right-continuous step functions. If y0 and y1 are the values to the left and right of the point then the value is y0 if f = 0, y1 if f = 1, and y0*(1-f)+y1*f for intermediate values. In this way the result is right-continuous for f = 0 and left-continuous for f = 1, even for non-finite y values.
ties handling of tied x values. The string "ordered" or a function (or the name of a function) taking a single vector argument and returning a single number or a list of both, e.g., list("ordered", mean), see 'Details'.
na.rm logical specifying how missing values (NA's) should be handled. Setting na.rm=FALSE will propagate NA's in y to the interpolated values, also depending on the rule set. Note that in this case, NA's in x are invalid, see also the examples.

Details

The inputs can contain missing values which are deleted (if na.rm is true, i.e., by default), so at least two complete \((x, y)\) pairs are required (for method = "linear", one otherwise). If there are duplicated (tied) x values and ties contains a function it is applied to the y values for each distinct x value to produce \((x, y)\) pairs with unique x. Useful functions in this context include mean, min, and max.

If ties = "ordered" the x values are assumed to be already ordered (and unique) and ties are not checked but kept if present. This is the fastest option for large length(x).

If ties is a list of length two, ties[[2]] must be a function to be applied to ties, see above, but if ties[[1]] is identical to "ordered", the x values are assumed to be sorted and are only checked
for ties. Consequently, ties = list("ordered", mean) will be slightly more efficient than the default ties = mean in such a case.

The first y value will be used for interpolation to the left and the last one for interpolation to the right.

Value

approx returns a list with components x and y, containing n coordinates which interpolate the given data points according to the method (and rule) desired.

The function approxfun returns a function performing (linear or constant) interpolation of the given data points. For a given set of x values, this function will return the corresponding interpolated values. It uses data stored in its environment when it was created, the details of which are subject to change.

Warning

The value returned by approxfun contains references to the code in the current version of R: it is not intended to be saved and loaded into a different R session. This is safer for R >= 3.0.0.

## Fit Autoregressive Models to Time Series

### Description

Fit an autoregressive time series model to the data, by default selecting the complexity by AIC.

### Usage

```r
ar(x, aic = TRUE, order.max = NULL,
   method = c("yule-walker", "burg", "ols", "mle", "yw"),
   na.action, series, ...)  
ar.burg(x, ...)  
```

```r
# Default S3 method:
ar.burg(x, aic = TRUE, order.max = NULL,
```
ar

na.action = na.fail, demean = TRUE, series,
var.method = 1, ...

## S3 method for class 'mts'
ar.burg(x, aic = TRUE, order.max = NULL,
na.action = na.fail, demean = TRUE, series,
var.method = 1, ...)

ar.yw(x, ...)

## Default S3 method:
ar.yw(x, aic = TRUE, order.max = NULL,
na.action = na.fail, demean = TRUE, series, ...)

## S3 method for class 'mts'
ar.yw(x, aic = TRUE, order.max = NULL,
na.action = na.fail, demean = TRUE, series,
var.method = 1, ...)

ar.mle(x, aic = TRUE, order.max = NULL, na.action = na.fail,
demean = TRUE, series, ...)

## S3 method for class 'ar'
predict(object, newdata, n.ahead = 1, se.fit = TRUE, ...)

Arguments

x a univariate or multivariate time series.
aic logical. If TRUE then the Akaike Information Criterion is used to choose the
order of the autoregressive model. If FALSE, the model of order order.max is
fitted.
order.max maximum order (or order) of model to fit. Defaults to the smaller of \( N - 1 \)
and \( 10 \log_{10}(N) \) where \( N \) is the number of non-missing observations except for
method = "mle" where it is the minimum of this quantity and 12.
method character string specifying the method to fit the model. Must be one of the
strings in the default argument (the first few characters are sufficient). Defaults
to "yule-walker".
na.action function to be called to handle missing values. Currently, via na.action =
na.pass, only Yule-Walker method can handle missing values which must be
consistent within a time point: either all variables must be missing or none.
demean should a mean be estimated during fitting?
series names for the series. Defaults to deparse1(substitute(x)).
var.method the method to estimate the innovations variance (see ‘Details’).
... additional arguments for specific methods.
object a fit from ar().
newdata data to which to apply the prediction.
n.ahead number of steps ahead at which to predict.
se.fit logical: return estimated standard errors of the prediction error?

Details

For definiteness, note that the AR coefficients have the sign in
\[ x_t - \mu = a_1(x_{t-1} - \mu) + \cdots + a_p(x_{t-p} - \mu) + e_t \]

\(ar\) is just a wrapper for the functions \(ar\cdot yw\), \(ar\cdot burg\), \(ar\cdot ols\) and \(ar\cdot mle\).

Order selection is done by AIC if \(aic\) is true. This is problematic, as of the methods here only \(ar\cdot mle\) performs true maximum likelihood estimation. The AIC is computed as if the variance estimate were the MLE, omitting the determinant term from the likelihood. Note that this is not the same as the Gaussian likelihood evaluated at the estimated parameter values. In \(ar\cdot yw\) the variance matrix of the innovations is computed from the fitted coefficients and the autocovariance of \(x\).

\(ar\cdot burg\) allows two methods to estimate the innovations variance and hence AIC. Method 1 is to use the update given by the Levinson-Durbin recursion (Brockwell and Davis, 1991, (8.2.6) on page 242), and follows S-PLUS. Method 2 is the mean of the sum of squares of the forward and backward prediction errors (as in Brockwell and Davis, 1996, page 145). Percival and Walden (1998) discuss both. In the multivariate case the estimated coefficients will depend (slightly) on the variance estimation method.

Remember that \(ar\) includes by default a constant in the model, by removing the overall mean of \(x\) before fitting the AR model, or (\(ar\cdot mle\)) estimating a constant to subtract.

**Value**

For \(ar\) and its methods a list of class "ar" with the following elements:

- **order**: The order of the fitted model. This is chosen by minimizing the AIC if \(aic\) = TRUE, otherwise it is \(order\cdot max\).
- **ar**: Estimated autoregression coefficients for the fitted model.
- **var.pred**: The prediction variance: an estimate of the portion of the variance of the time series that is not explained by the autoregressive model.
- **x.mean**: The estimated mean of the series used in fitting and for use in prediction.
- **x.intercept**: (\(ar\cdot ols\) only.) The intercept in the model for \(x - x\cdot mean\).
- **aic**: The differences in AIC between each model and the best-fitting model. Note that the latter can have an AIC of \(-Inf\).
- **n.used**: The number of observations in the time series, including missing.
- **n.obs**: The number of non-missing observations in the time series.
- **order.max**: The value of the \(order\cdot max\) argument.
- **partialacf**: The estimate of the partial autocorrelation function up to lag \(order\cdot max\).
- **resid**: residuals from the fitted model, conditioning on the first \(order\) observations. The first \(order\) residuals are set to NA. If \(x\) is a time series, so is \(resid\).
- **method**: The value of the \(method\) argument.
- **series**: The name(s) of the time series.
- **frequency**: The frequency of the time series.
- **call**: The matched call.
- **asy.var.coef**: (univariate case, \(order > 0\)) The asymptotic-theory variance matrix of the coefficient estimates.

For \(predict\cdot ar\), a time series of predictions, or if \(se\cdot fit\) = TRUE, a list with components \(pred\), the predictions, and \(se\), the estimated standard errors. Both components are time series.
Note

Only the univariate case of ar.mle is implemented.
Fitting by method="mle" to long series can be very slow.
If x contains missing values, see NA, also consider using arima(), possibly with method = "ML".

```

---

**ar.ols**

*Fit Autoregressive Models to Time Series by OLS*

**Description**

Fit an autoregressive time series model to the data by ordinary least squares, by default selecting the complexity by AIC.
Usage

ar.ols(x, aic = TRUE, order.max = NULL, na.action = na.fail,
       demean = TRUE, intercept = demean, series, ...)

Arguments

x  A univariate or multivariate time series.

aic  Logical flag. If TRUE then the Akaike Information Criterion is used to choose the order of the autoregressive model. If FALSE, the model of order order.max is fitted.

order.max  Maximum order (or order) of model to fit. Defaults to $10 \log_{10}(N)$ where $N$ is the number of observations.

na.action  function to be called to handle missing values.

demean  should the AR model be for $x$ minus its mean?

intercept  should a separate intercept term be fitted?

series  names for the series. Defaults to deparse1(substitute(x)).

...  further arguments to be passed to or from methods.

Details

ar.ols fits the general AR model to a possibly non-stationary and/or multivariate system of series $x$. The resulting unconstrained least squares estimates are consistent, even if some of the series are non-stationary and/or co-integrated. For definiteness, note that the AR coefficients have the sign in

$$x_t - \mu = a_0 + a_1(x_{t-1} - \mu) + \cdots + a_p(x_{t-p} - \mu) + \epsilon_t$$

where $a_0$ is zero unless intercept is true, and $\mu$ is the sample mean if demean is true, zero otherwise.

Order selection is done by AIC if aic is true. This is problematic, as ar.ols does not perform true maximum likelihood estimation. The AIC is computed as if the variance estimate (computed from the variance matrix of the residuals) were the MLE, omitting the determinant term from the likelihood. Note that this is not the same as the Gaussian likelihood evaluated at the estimated parameter values.

Some care is needed if intercept is true and demean is false. Only use this if the series are roughly centred on zero. Otherwise the computations may be inaccurate or fail entirely.

Value

A list of class "ar" with the following elements:

order  The order of the fitted model. This is chosen by minimizing the AIC if aic = TRUE, otherwise it is order.max.

ar  Estimated autoregression coefficients for the fitted model.

var.pred  The prediction variance: an estimate of the portion of the variance of the time series that is not explained by the autoregressive model.

x.mean  The estimated mean (or zero if demean is false) of the series used in fitting and for use in prediction.

x.intercept  The intercept in the model for $x - x$.mean, or zero if intercept is false.
aic: The differences in AIC between each model and the best-fitting model. Note that the latter can have an AIC of -Inf.

n.used: The number of observations in the time series.

order.max: The value of the order.max argument.

partialacf: NULL. For compatibility with ar.

resid: residuals from the fitted model, conditioning on the first order observations. The first order residuals are set to NA. If x is a time series, so is resid.

method: The character string "Unconstrained LS".

series: The name(s) of the time series.

frequency: The frequency of the time series.

call: The matched call.

asy.se.coef: The asymptotic-theory standard errors of the coefficient estimates.

ar

Examples

ar(lh, method = "burg")
ar.ols(lh)
ar.ols(lh, FALSE, 4) # fit ar(4)
ar.ols(ts.union(BJsales, BJsales.lead))
x <- diff(log(EuStockMarkets))
ar.ols(x, order.max = 6, demean = FALSE, intercept = TRUE)
arima(x, order = c(0L, 0L, 0L),
    seasonal = list(order = c(0L, 0L, 0L), period = NA),
    xreg = NULL, include.mean = TRUE,
    transform.pars = TRUE,
    fixed = NULL, init = NULL,
    method = c("CSS-ML", "ML", "CSS"), n.cond,
    SSinit = c("Gardner1980", "Rossignol2011"),
    optim.method = "BFGS",
    optim.control = list(), kappa = 1e6)

Arguments

x
a univariate time series

order
A specification of the non-seasonal part of the ARIMA model: the three integer components (p, d, q) are the AR order, the degree of differencing, and the MA order.

seasonal
A specification of the seasonal part of the ARIMA model, plus the period (which defaults to frequency(x)). This may be a list with components order and period, or just a numeric vector of length 3 which specifies the seasonal order. In the latter case the default period is used.

xreg
Optionally, a vector or matrix of external regressors, which must have the same number of rows as x.

include.mean
Should the ARMA model include a mean/intercept term? The default is TRUE for undifferenced series, and it is ignored for ARIMA models with differencing.

transform.pars
logical; if true, the AR parameters are transformed to ensure that they remain in the region of stationarity. Not used for method = "CSS". For method = "ML", it has been advantageous to set transform.pars = FALSE in some cases, see also fixed.

fixed
optional numeric vector of the same length as the total number of coefficients to be estimated. It should be of the form

(φ1, ..., φp, θ1, ..., θq, Φ1, ..., ΦP, Θ1, ..., ΘQ, µ),

where φi are the AR coefficients, θi are the MA coefficients, Φi are the seasonal AR coefficients, Θi are the seasonal MA coefficients and µ is the intercept term. Note that the µ entry is required if and only if include.mean is TRUE. In particular it should not be present if the model is an ARIMA model with differencing. The entries of the fixed vector should consist of the values at which the user wishes to “fix” the corresponding coefficient, or NA if that coefficient should not be fixed, but estimated.

The argument transform.pars will be set to FALSE if any AR parameters are fixed. A warning will be given if transform.pars is set to (or left at its default) TRUE. It may be wise to set transform.pars = FALSE even when fixing MA parameters, especially at values that cause the model to be nearly non-invertible.

init
optional numeric vector of initial parameter values. Missing values will be filled in, by zeroes except for regression coefficients. Values already specified in fixed will be ignored.

method
fitting method: maximum likelihood or minimize conditional sum-of-squares. The default (unless there are missing values) is to use conditional-sum-of-squares to find starting values, then maximum likelihood. Can be abbreviated.
n.cond only used if fitting by conditional-sum-of-squares: the number of initial observations to ignore. It will be ignored if less than the maximum lag of an AR term.

SSinit a string specifying the algorithm to compute the state-space initialization of the likelihood; see KalmanLike for details. Can be abbreviated.

optim.method The value passed as the method argument to optim.

optim.control List of control parameters for optim.

kappa the prior variance (as a multiple of the innovations variance) for the past observations in a differenced model. Do not reduce this.

Details

Different definitions of ARMA models have different signs for the AR and/or MA coefficients. The definition used here has

\[ X_t = a_1 X_{t-1} + \cdots + a_p X_{t-p} + e_t + b_1 e_{t-1} + \cdots + b_q e_{t-q} \]

and so the MA coefficients differ in sign from those used in documentation written for S-PLUS. Further, if include.mean is true (the default for an ARMA model), this formula applies to \( X - \mu \) rather than \( X \). For ARIMA models with differencing, the differenced series follows a zero-mean ARMA model. If an xreg term is included, a linear regression (with a constant term if include.mean is true and there is no differencing) is fitted with an ARMA model for the error term.

The variance matrix of the estimates is found from the Hessian of the log-likelihood, and so may only be a rough guide.

Optimization is done by optim. It will work best if the columns in xreg are roughly scaled to zero mean and unit variance, but does attempt to estimate suitable scalings.

Value

A list of class "Arima" with components:

- coef a vector of AR, MA and regression coefficients, which can be extracted by the coef method.
- sigma2 the MLE of the innovations variance.
- var.coef the estimated variance matrix of the coefficients coef, which can be extracted by the vcov method.
- loglik the maximized log-likelihood (of the differenced data), or the approximation to it used.
- arma A compact form of the specification, as a vector giving the number of AR, MA, seasonal AR and seasonal MA coefficients, plus the period and the number of non-seasonal and seasonal differences.
- aic the AIC value corresponding to the log-likelihood. Only valid for method = "ML" fits.
- residuals the fitted innovations.
- call the matched call.
- series the name of the series x.
- code the convergence value returned by optim.
arima

n.cond  the number of initial observations not used in the fitting.
nobs    the number of “used” observations for the fitting, can also be extracted via nobs() and is used by BIC.
model   A list representing the Kalman filter used in the fitting. See KalmanLike.

Fitting methods

The exact likelihood is computed via a state-space representation of the ARIMA process, and the innovations and their variance found by a Kalman filter. The initialization of the differenced ARMA process uses stationarity and is based on Gardner et al. (1980). For a differenced process the non-stationary components are given a diffuse prior (controlled by kappa). Observations which are still controlled by the diffuse prior (determined by having a Kalman gain of at least $1e4$) are excluded from the likelihood calculations. (This gives comparable results to arima0 in the absence of missing values, when the observations excluded are precisely those dropped by the differencing.) Missing values are allowed, and are handled exactly in method "ML".

If transform.pars is true, the optimization is done using an alternative parametrization which is a variation on that suggested by Jones (1980) and ensures that the model is stationary. For an AR(p) model the parametrization is via the inverse tanh of the partial autocorrelations: the same procedure is applied (separately) to the AR and seasonal AR terms. The MA terms are not constrained to be invertible during optimization, but they will be converted to invertible form after optimization if transform.pars is true.

Conditional sum-of-squares is provided mainly for expositional purposes. This computes the sum of squares of the fitted innovations from observation n.cond on, (where n.cond is at least the maximum lag of an AR term), treating all earlier innovations to be zero. Argument n.cond can be used to allow comparability between different fits. The ‘part log-likelihood’ is the first term, half the log of the estimated mean square. Missing values are allowed, but will cause many of the innovations to be missing.

When regressors are specified, they are orthogonalized prior to fitting unless any of the coefficients is fixed. It can be helpful to roughly scale the regressors to zero mean and unit variance.

Note

arima is very similar to arima0 for ARMA models or for differenced models without missing values, but handles differenced models with missing values exactly. It is somewhat slower than arima0, particularly for seasonally differenced models.

References

Simulate from an ARIMA Model

Description

Simulate from an ARIMA model.

Usage

arima.sim(model, n, rand.gen = rnorm, innov = rand.gen(n, ...),
          n.start = NA, start.innov = rand.gen(n.start, ...),
          ...)

Examples

arima(lh, order = c(1,0,0))
arima(lh, order = c(3,0,0))
arima(lh, order = c(1,0,1))

arima(lh, order = c(3,0,0), method = "CSS")

arima(USAccDeaths, order = c(0,1,1), seasonal = list(order = c(0,1,1)))
arima(USAccDeaths, order = c(0,1,1), seasonal = list(order = c(0,1,1)),
       method = "CSS") # drops first 13 observations.
# for a model with as few years as this, we want full ML

arima(LakeHuron, order = c(2,0,0), xreg = time(LakeHuron) - 1920)

## presidents contains NAs
## graphs in example(acf) suggest order 1 or 3
require(graphics)
(fit1 <- arima(presidents, c(1, 0, 0)))
lobs(fit1)
tsdiag(fit1)
(fit3 <- arima(presidents, c(3, 0, 0))) # smaller AIC
tsdiag(fit3)
BIC(fit1, fit3)
## compare a whole set of models; BIC() would choose the smallest
AIC(fit1, arima(presidents, c(2,0,0)),
arima(presidents, c(2,0,1)), # <- chosen (barely) by AIC
fit3, arima(presidents, c(3,0,1)))

## An example of using the 'fixed' argument:
## Note that the period of the seasonal component is taken to be
## frequency(presidents), i.e. 4.
(fitSfx <- arima(presidents, order=c(2,0,1), seasonal=c(1,0,0),
               fixed=c(NA, NA, 0.5, -0.1, 50), transform.pars=FALSE))
## The partly-fixed & smaller model seems better (as we "knew too much"):
AIC(fitSfx, arima(presidents, order=c(2,0,1), seasonal=c(1,0,0)))

## An example of ARIMA forecasting:
predict(fit3, 3)
**Arguments**

- **model**
  A list with component `ar` and/or `ma` giving the AR and MA coefficients respectively. Optionally a component `order` can be used. An empty list gives an ARIMA(0, 0, 0) model, that is white noise.

- **n**
  Length of output series, before un-differencing. A strictly positive integer.

- **rand.gen**
  Optional: a function to generate the innovations.

- **innov**
  An optional times series of innovations. If not provided, `rand.gen` is used.

- **n.start**
  Length of ‘burn-in’ period. If `NA`, the default, a reasonable value is computed.

- **start.innov**
  An optional times series of innovations to be used for the burn-in period. If supplied there must be at least `n.start` values (and `n.start` is by default computed inside the function).

- **...**
  Additional arguments for `rand.gen`. Most usefully, the standard deviation of the innovations generated by `rnorm` can be specified by `sd`.

**Details**

See `arima` for the precise definition of an ARIMA model.

The ARMA model is checked for stationarity.

ARIMA models are specified via the `order` component of `model`, in the same way as for `arima`. Other aspects of the `order` component are ignored, but inconsistent specifications of the MA and AR orders are detected. The un-differencing assumes previous values of zero, and to remind the user of this, those values are returned.

Random inputs for the ‘burn-in’ period are generated by calling `rand.gen`.

**Value**

A time-series object of class "ts".

**See Also**

`arima`

**Examples**

```r
require(graphics)
arima.sim(n = 63, list(ar = c(0.8897, -0.4858), ma = c(-0.2279, 0.2488)),
 sd = sqrt(0.1796))
# mildly long-tailed
arima.sim(n = 63, list(ar = c(0.8897, -0.4858), ma = c(-0.2279, 0.2488)),
 rand.gen = function(n, ...) sqrt(0.1796) * rt(n, df = 5))
# An ARIMA simulation
ts.sim <- arima.sim(list(order = c(1,1,0), ar = 0.7), n = 200)
ts.plot(ts.sim)
```
Description

Fit an ARIMA model to a univariate time series, and forecast from the fitted model.

Usage

```r
arima0(x, order = c(0, 0, 0),
    seasonal = list(order = c(0, 0, 0), period = NA),
    xreg = NULL, include.mean = TRUE, delta = 0.01,
    transform.pars = TRUE, fixed = NULL, init = NULL,
    method = c("ML", "CSS"), n.cond, optim.control = list())
```

Arguments

- `x`: a univariate time series
- `order`: A specification of the non-seasonal part of the ARIMA model: the three components \(p, d, q\) are the AR order, the degree of differencing, and the MA order.
- `seasonal`: A specification of the seasonal part of the ARIMA model, plus the period (which defaults to `frequency(x)`). This should be a list with components `order` and `period`, but a specification of just a numeric vector of length 3 will be turned into a suitable list with the specification as the `order`.
- `xreg`: Optionally, a vector or matrix of external regressors, which must have the same number of rows as `x`.
- `include.mean`: Should the ARIMA model include a mean term? The default is `TRUE` for undifferenced series, `FALSE` for differenced ones (where a mean would not affect the fit nor predictions).
- `delta`: A value to indicate at which point 'fast recursions' should be used. See the 'Details' section.
- `transform.pars`: Logical. If true, the AR parameters are transformed to ensure that they remain in the region of stationarity. Not used for `method = "CSS"`.
- `fixed`: optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in `fixed` will be varied. `transform.pars = TRUE` will be overridden (with a warning) if any ARMA parameters are fixed.
- `init`: optional numeric vector of initial parameter values. Missing values will be filled in, by zeroes except for regression coefficients. Values already specified in `fixed` will be ignored.
- `n.cond`: Only used if fitting by conditional-sum-of-squares: the number of initial observations to ignore. It will be ignored if less than the maximum lag of an AR term.
- `optim.control`: List of control parameters for `optim`.

## S3 method for class 'arima0'

```r
predict(object, n.ahead = 1, newxreg, se.fit = TRUE, ...)
```
The result of an `arima0` fit.

New values of `xreg` to be used for prediction. Must have at least `n.ahead` rows.

The number of steps ahead for which prediction is required.

Logical: should standard errors of prediction be returned?

... arguments passed to or from other methods.

Different definitions of ARMA models have different signs for the AR and/or MA coefficients. The definition here has

\[ X_t = a_1 X_{t-1} + \cdots + a_p X_{t-p} + \epsilon_t + b_1 \epsilon_{t-1} + \cdots + b_q \epsilon_{t-q} \]

and so the MA coefficients differ in sign from those given by S-PLUS. Further, if `include.mean` is true, this formula applies to \( X - m \) rather than \( X \). For ARIMA models with differencing, the differenced series follows a zero-mean ARMA model.

The variance matrix of the estimates is found from the Hessian of the log-likelihood, and so may only be a rough guide, especially for fits close to the boundary of invertibility.

Optimization is done by `optim`. It will work best if the columns in `xreg` are roughly scaled to zero mean and unit variance, but does attempt to estimate suitable scalings.

Finite-history prediction is used. This is only statistically efficient if the MA part of the fit is invertible, so `predict.arima0` will give a warning for non-invertible MA models.

For `arima0`, a list of class "arima0" with components:

- `coef`: a vector of AR, MA and regression coefficients,
- `sigma2`: the MLE of the innovations variance,
- `var.coef`: the estimated variance matrix of the coefficients `coef`.
- `loglik`: the maximized log-likelihood (of the differenced data), or the approximation to it used.
- `arma`: A compact form of the specification, as a vector giving the number of AR, MA, seasonal AR and seasonal MA coefficients, plus the period and the number of non-seasonal and seasonal differences.
- `aic`: the AIC value corresponding to the log-likelihood. Only valid for `method = "ML"` fits.
- `residuals`: the fitted innovations.
- `call`: the matched call.
- `series`: the name of the series \( x \).
- `convergence`: the value returned by `optim`.
- `n.cond`: the number of initial observations not used in the fitting.

For `predict.arima0`, a time series of predictions, or if `se.fit = TRUE`, a list with components `pred`, the predictions, and `se`, the estimated standard errors. Both components are time series.
Fitting methods

The exact likelihood is computed via a state-space representation of the ARMA process, and the
innovations and their variance found by a Kalman filter based on Gardner et al. (1980). This has the
option to switch to ‘fast recursions’ (assume an effectively infinite past) if the innovations variance
is close enough to its asymptotic bound. The argument \(\text{delta}\) sets the tolerance: at its default value
the approximation is normally negligible and the speed-up considerable. Exact computations can
be ensured by setting \(\text{delta}\) to a negative value.

If \(\text{transform.pars}\) is true, the optimization is done using an alternative parametrization which is a
variation on that suggested by Jones (1980) and ensures that the model is stationary. For an AR(p)
model the parametrization is via the inverse tanh of the partial autocorrelations: the same procedure
is applied (separately) to the AR and seasonal AR terms. The MA terms are also constrained to
be invertible during optimization by the same transformation if \(\text{transform.pars}\) is true. Note that
the MLE for MA terms does sometimes occur for MA polynomials with unit roots: such models
can be fitted by using \(\text{transform.pars} = \text{FALSE}\) and specifying a good set of initial values (often
obtainable from a fit with \(\text{transform.pars} = \text{TRUE}\)).

Missing values are allowed, but any missing values will force \(\text{delta}\) to be ignored and full recur-
sions used. Note that missing values will be propagated by differencing, so the procedure used in
this function is not fully efficient in that case.

Conditional sum-of-squares is provided mainly for expositional purposes. This computes the sum
of squares of the fitted innovations from observation \(n.\text{cond}\) on, (where \(n.\text{cond}\) is at least the
maximum lag of an AR term), treating all earlier innovations to be zero. Argument \(n.\text{cond}\) can
be used to allow comparability between different fits. The ‘part log-likelihood’ is the first term,
half the log of the estimated mean square. Missing values are allowed, but will cause many of the
innovations to be missing.

When regressors are specified, they are orthogonalized prior to fitting unless any of the coefficients
is fixed. It can be helpful to roughly scale the regressors to zero mean and unit variance.

Note

This is a preliminary version, and will be replaced by \texttt{arima}.

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and
the regression coefficients.

The results are likely to be different from S-PLUS’s \texttt{arima.mle}, which computes a conditional
likelihood and does not include a mean in the model. Further, the convention used by \texttt{arima.mle}
reverses the signs of the MA coefficients.

ARMAacf

Compute Theoretical ACF for an ARMA Process

Description

Compute the theoretical autocorrelation function or partial autocorrelation function for an ARMA process.

Usage

ARMAacf(ar = numeric(), ma = numeric(), lag.max = r, pacf = FALSE)

Arguments

ar
numeric vector of AR coefficients

ma
numeric vector of MA coefficients

lag.max
integer. Maximum lag required. Defaults to max(p, q+1), where p, q are the numbers of AR and MA terms respectively.

pacf
logical. Should the partial autocorrelations be returned?

Details

The methods used follow Brockwell & Davis (1991, section 3.3). Their equations (3.3.8) are solved for the autocovariances at lags 0, ..., max(p, q + 1), and the remaining autocorrelations are given by a recursive filter.
Value

A vector of (partial) autocorrelations, named by the lags.

References

See Also

`arima, ARMAtoMA, acf2AR` for inverting part of `ARMAacf`; further `filter`.

Examples

```r
ARMAacf(c(1.0, -0.25), 1.0, lag.max = 10)

## Example from Brockwell & Davis (1991, pp.92-4)
## answer: 2^(-n) * (32/3 + 8 * n) / (32/3)

n <- 1:10
a.n <- 2^(-n) * (32/3 + 8 * n) / (32/3)
(A.n <- ARMAacf(c(1.0, -0.25), 1.0, lag.max = 10))
stopifnot(all.equal(unname(A.n), c(1, a.n)))

ARMAacf(c(1.0, -0.25), 1.0, lag.max = 10, pacf = TRUE)
zapsmall(ARMAacf(c(1.0, -0.25), lag.max = 10, pacf = TRUE))

## Cov-Matrix of length-7 sub-sample of AR(1) example:
toeplitz(ARMAacf(0.8, lag.max = 7))
```

---

**ARMAtoMA**

*Convert ARMA Process to Infinite MA Process*

Description

Convert ARMA process to infinite MA process.

Usage

```r
ARMAtoMA(ar = numeric(), ma = numeric(), lag.max)
```

Arguments

- `ar` numeric vector of AR coefficients
- `ma` numeric vector of MA coefficients
- `lag.max` Largest MA(Inf) coefficient required.

Value

A vector of coefficients.
References

arima, ARMAacf.

Examples

ARMAtoMA(c(1.0, -0.25), 1.0, 10)
## Example from Brockwell & Davis (1991, p.92)
## answer (1 + 3*n)*2^(-n)

n <- 1:10; (1 + 3*n)*2^(-n)

---

as.hclust Convert Objects to Class "hclust"

Description

Converts objects from other hierarchical clustering functions to class "hclust".

Usage

as.hclust(x, ...)

Arguments

x Hierarchical clustering object

... further arguments passed to or from other methods.

Details

Currently there is only support for converting objects of class "twins" as produced by the functions diana and agnes from the package cluster. The default method throws an error unless passed an "hclust" object.

Value

An object of class "hclust".

See Also

hclust, and from package cluster, diana and agnes
Examples

```r
x <- matrix(rnorm(30), ncol = 3)
hc <- hclust(dist(x), method = "complete")

if(require("cluster", quietly = TRUE)) {# is a recommended package
  ag <- agnes(x, method = "complete")
hcag <- as.hclust(ag)
  ## The dendrograms order slightly differently:
op <- par(mfrow = c(1,2))
  plot(hc); mtext("hclust", side = 1)
  plot(hcag); mtext("agnes", side = 1)
  detach("package:cluster")
}
```

asOneSidedFormula

Convert to One-Sided Formula

Description

Names, calls, expressions (first element), numeric values, and character strings are converted to one-sided formulae associated with the global environment. If the input is a formula, it must be one-sided, in which case it is returned unaltered.

Usage

```r
asOneSidedFormula(object)
```

Arguments

- `object` a one-sided formula, name, call, expression, numeric value, or character string.

Value

a one-sided formula representing `object`

Author(s)

José Pinheiro and Douglas Bates

See Also

`formula`

Examples

```r
(form <- asOneSidedFormula("age"))
stopifnot(exprs = {
  identical(form, asOneSidedFormula(form))
  identical(form, asOneSidedFormula(as.name("age")))
  identical(form, asOneSidedFormula(expression(age)))
})
asOneSidedFormula(quote(log(age))
asOneSidedFormula(1)
```
ave  

Group Averages Over Level Combinations of Factors

Description

Subsets of x[] are averaged, where each subset consist of those observations with the same factor levels.

Usage

ave(x, ..., FUN = mean)

Arguments

x
A numeric.

...  
Grouping variables, typically factors, all of the same length as x.

FUN
Function to apply for each factor level combination.

Value

A numeric vector, say y of length length(x). If ... is g1, g2, e.g., y[i] is equal to FUN(x[j], for all j with g1[j] == g1[i] and g2[j] == g2[i]).

See Also

mean, median.

Examples

require(graphics)
ave(1:3) # no grouping -> grand mean

attach(warpbreaks)
ave(breaks, wool)
ave(breaks, tension)
ave(breaks, tension, FUN = function(x) mean(x, trim = 0.1))
plot(breaks, main =
    "ave( Warpbreaks ) for wool x tension combinations")
lines(ave(breaks, wool, tension ), type = "s", col = "blue")
lines(ave(breaks, wool, tension, FUN = median), type = "s", col = "green")
legend(40, 70, c("mean", "median"), lty = 1,
    col = c("blue","green"), bg = "gray90")
detach()
Bandwidth Selectors for Kernel Density Estimation

Description

Bandwidth selectors for Gaussian kernels in `density`.

Usage

bw.nrd0(x)

bw.nrd(x)

bw.ucv(x, nb = 1000, lower = 0.1 * hmax, upper = hmax, tol = 0.1 * lower)

bw.bcv(x, nb = 1000, lower = 0.1 * hmax, upper = hmax, tol = 0.1 * lower)

bw.SJ(x, nb = 1000, lower = 0.1 * hmax, upper = hmax, method = c("ste", "dpi"), tol = 0.1 * lower)

Arguments

- **x** numeric vector.
- **nb** number of bins to use.
- **lower, upper** range over which to minimize. The default is almost always satisfactory. hmax is calculated internally from a normal reference bandwidth.
- **method** either "ste" ("solve-the-equation") or "dpi" ("direct plug-in"). Can be abbreviated.
- **tol** for method "ste", the convergence tolerance for `uniroot`. The default leads to bandwidth estimates with only slightly more than one digit accuracy, which is sufficient for practical density estimation, but possibly not for theoretical simulation studies.

Details

`bw.nrd0` implements a rule-of-thumb for choosing the bandwidth of a Gaussian kernel density estimator. It defaults to 0.9 times the minimum of the standard deviation and the interquartile range divided by 1.34 times the sample size to the negative one-fifth power (= Silverman’s ‘rule of thumb’. Silverman (1986, page 48, eqn (3.31))) unless the quartiles coincide when a positive result will be guaranteed.

`bw.nrd` is the more common variation given by Scott (1992), using factor 1.06.

`bw.ucv` and `bw.bcv` implement unbiased and biased cross-validation respectively.

`bw.SJ` implements the methods of Sheather & Jones (1991) to select the bandwidth using pilot estimation of derivatives.

The algorithm for method "ste" solves an equation (via `uniroot`) and because of that, enlarges the interval c(lower, upper) when the boundaries were not user-specified and do not bracket the root.
The last three methods use all pairwise binned distances: they are of complexity $O(n^2)$ up to $n = nb/2$ and $O(n)$ thereafter. Because of the binning, the results differ slightly when $x$ is translated or sign-flipped.

Value

A bandwidth on a scale suitable for the bw argument of density.

Note

Long vectors $x$ are not supported, but neither are they by density and kernel density estimation and for more than a few thousand points a histogram would be preferred.

Author(s)

B. D. Ripley, taken from early versions of package MASS.

References

See Also

density.

bandwidth.nrd, ucv, bcv and width.SJ in package MASS, which are all scaled to the width argument of density and so give answers four times as large.

Examples

```r
require(graphics)
plot(density(precip, n = 1000))
rug(precip)
lines(density(precip, bw = "nrd"), col = 2)
lines(density(precip, bw = "ucv"), col = 3)
lines(density(precip, bw = "bcv"), col = 4)
lines(density(precip, bw = "SJ-ste"), col = 5)
lines(density(precip, bw = "SJ-dpi"), col = 6)
legend(55, 0.035,
  legend = c("nrd","nrd", "ucv", "bcv", "SJ-ste", "SJ-dpi"),
  col = 1:6, lty = 1)
```
Description

 Performs Bartlett’s test of the null that the variances in each of the groups (samples) are the same.

Usage

 bartlett.test(x, ...)

## Default S3 method:
 bartlett.test(x, g, ...)

## S3 method for class 'formula'
 bartlett.test(formula, data, subset, na.action, ...)

Arguments

 x a numeric vector of data values, or a list of numeric data vectors representing the respective samples, or fitted linear model objects (inheriting from class "lm").

g a vector or factor object giving the group for the corresponding elements of x. Ignored if x is a list.

formula a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.

data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").

... further arguments to be passed to or from methods.

Details

 If x is a list, its elements are taken as the samples or fitted linear models to be compared for homogeneity of variances. In this case, the elements must either all be numeric data vectors or fitted linear model objects, g is ignored, and one can simply use bartlett.test(x) to perform the test. If the samples are not yet contained in a list, use bartlett.test(list(x, ...)).

 Otherwise, x must be a numeric data vector, and g must be a vector or factor object of the same length as x giving the group for the corresponding elements of x.

Value

 A list of class "htest" containing the following components:

 statistic Bartlett’s K-squared test statistic.

 parameter the degrees of freedom of the approximate chi-squared distribution of the test statistic.
p.value the p-value of the test.
method the character string "Bartlett test of homogeneity of variances".
data.name a character string giving the names of the data.

References

See Also

var.test for the special case of comparing variances in two samples from normal distributions; fligner.test for a rank-based (nonparametric) k-sample test for homogeneity of variances; ansari.test and mood.test for two rank based two-sample tests for difference in scale.

Examples

require(graphics)

plot(count ~ spray, data = InsectSprays)
bartlett.test(InsectSprays$count, InsectSprays$spray)
bartlett.test(count ~ spray, data = InsectSprays)

Beta

The Beta Distribution

Description

Density, distribution function, quantile function and random generation for the Beta distribution with parameters shape1 and shape2 (and optional non-centrality parameter ncp).

Usage

dbeta(x, shape1, shape2, ncp = 0, log = FALSE)
pbeta(q, shape1, shape2, ncp = 0, lower.tail = TRUE, log.p = FALSE)
qbeta(p, shape1, shape2, ncp = 0, lower.tail = TRUE, log.p = FALSE)
rbeta(n, shape1, shape2, ncp = 0)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
shape1, shape2 non-negative parameters of the Beta distribution.
cp non-centrality parameter.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).
The Beta distribution with parameters \( \text{shape1} = a \) and \( \text{shape2} = b \) has density
\[
f(x) = \frac{\Gamma(a + b)}{\Gamma(a)\Gamma(b)} x^{a-1}(1 - x)^{b-1}
\]
for \( a > 0, b > 0 \) and \( 0 \leq x \leq 1 \) where the boundary values at \( x = 0 \) or \( x = 1 \) are defined as by continuity (as limits).

The mean is \( a/(a + b) \) and the variance is \( ab/((a + b)^2(a + b + 1)) \). If \( a, b > 1 \), (or one of them \( = 1 \)), the mode is \( (a - 1)/(a + b - 2) \). These and all other distributional properties can be defined as limits (leading to point masses at 0, 1/2, or 1) when \( a \) or \( b \) are zero or infinite, and the corresponding \([dpqr]beta()\) functions are defined correspondingly.

\( \text{pbeta} \) is closely related to the incomplete beta function. As defined by Abramowitz and Stegun 6.6.1
\[
B_x(a, b) = \int_0^x t^{a-1}(1 - t)^{b-1}dt,
\]
and 6.6.2 \( I_x(a, b) = B_x(a, b)/B(a, b) \) where \( B(a, b) = B_1(a, b) \) is the Beta function (\( \text{beta} \)).

The noncentral Beta distribution (with \( \text{ncp} = \lambda \)) is defined (Johnson et al., 1995, pp. 502) as the distribution of \( X/(X + Y) \) where \( X \sim \chi^2_n(\lambda) \) and \( Y \sim \chi^2_{2b} \). There, \( \chi^2_n(\lambda) \) is the noncentral chi-squared distribution with \( n \) degrees of freedom and non-centrality parameter \( \lambda \), see Chisquare.

\( \text{dbeta} \) gives the density, \( \text{pbeta} \) the distribution function, \( \text{qbeta} \) the quantile function, and \( \text{rbeta} \) generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by \( n \) for \( \text{rbeta} \), and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

Supplying \( \text{ncp} = 0 \) uses the algorithm for the non-central distribution, which is not the same algorithm as when \( \text{ncp} \) is omitted. This is to give consistent behaviour in extreme cases with values of \( \text{ncp} \) very near zero.

Source

• The central \( \text{dbeta} \) is based on a binomial probability, using code contributed by Catherine Loader (see \( \text{dbinom} \)) if either shape parameter is larger than one, otherwise directly from the definition. The non-central case is based on the derivation as a Poisson mixture of betas (Johnson et al., 1995, pp. 502–3).

We have slightly tweaked the original “TOMS 708” algorithm, and enhanced for \( \log.p = TRUE \). For that (log-scale) case, underflow to \(-\infty\) (i.e., \( P = 0 \)) or \(0\) (i.e., \( P = 1 \)) still happens because the original algorithm was designed without log-scale considerations. Underflow to \(-\infty\) now typically signals a warning.

  This computes the lower tail only, so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant.

### binom.test

**Exact Binomial Test**

**Description**

Performs an exact test of a simple null hypothesis about the probability of success in a Bernoulli experiment.

**Usage**

```
binom.test(x, n, p = 0.5, 
            alternative = c("two.sided", "less", "greater"), 
            conf.level = 0.95)
```

**Arguments**

- `x` number of successes, or a vector of length 2 giving the numbers of successes and failures, respectively.
- `n` number of trials; ignored if `x` has length 2.
- `p` hypothesized probability of success.
- `alternative` indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.
- `conf.level` confidence level for the returned confidence interval.

**Details**

Confidence intervals are obtained by a procedure first given in Clopper and Pearson (1934). This guarantees that the confidence level is at least `conf.level`, but in general does not give the shortest-length confidence intervals.
Binomial

Value

A list with class "htest" containing the following components:

- `statistic` the number of successes.
- `parameter` the number of trials.
- `p.value` the p-value of the test.
- `conf.int` a confidence interval for the probability of success.
- `estimate` the estimated probability of success.
- `null.value` the probability of success under the null, p.
- `alternative` a character string describing the alternative hypothesis.
- `method` the character string "Exact binomial test".
- `data.name` a character string giving the names of the data.

References

See Also

`prop.test` for a general (approximate) test for equal or given proportions.

Examples

```r
## Under (the assumption of) simple Mendelian inheritance, a cross
## between plants of two particular genotypes produces progeny 1/4 of
## which are "dwarf" and 3/4 of which are "giant", respectively.
## In an experiment to determine if this assumption is reasonable, a
## cross results in progeny having 243 dwarf and 682 giant plants.
## If "giant" is taken as success, the null hypothesis is that p =
binom.test(c(682, 243), p = 3/4)  # The same.
binom.test(682, 682 + 243, p = 3/4)  # The same.
## => Data are in agreement with the null hypothesis.
```

---

**The Binomial Distribution**

Description

Density, distribution function, quantile function and random generation for the binomial distribution with parameters `size` and `prob`.

This is conventionally interpreted as the number of 'successes' in `size` trials.
**Usage**

- `dbinom(x, size, prob, log = FALSE)`
- `pbinom(q, size, prob, lower.tail = TRUE, log.p = FALSE)`
- `qbinom(p, size, prob, lower.tail = TRUE, log.p = FALSE)`
- `rbinom(n, size, prob)`

**Arguments**

- `x`, `q` vector of quantiles.
- `p` vector of probabilities.
- `n` number of observations. If `length(n) > 1`, the length is taken to be the number required.
- `size` number of trials (zero or more).
- `prob` probability of success on each trial.
- `log`, `log.p` logical; if TRUE, probabilities `p` are given as log(p).
- `lower.tail` logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.  

**Details**

The binomial distribution with `size = n` and `prob = p` has density

$$p(x) = \binom{n}{x} p^x (1-p)^{n-x}$$

for $x = 0, \ldots, n$. Note that binomial coefficients can be computed by `choose` in R.

If an element of `x` is not integer, the result of `dbinom` is zero, with a warning.

`p(x)` is computed using Loader's algorithm, see the reference below.

The quantile is defined as the smallest value $x$ such that $F(x) \geq p$, where $F$ is the distribution function.

**Value**

- `dbinom` gives the density, `pbinom` gives the distribution function, `qbinom` gives the quantile function and `rbinom` generates random deviates.

  - If `size` is not an integer, NaN is returned.

  - The length of the result is determined by `n` for `rbinom`, and is the maximum of the lengths of the numerical arguments for the other functions.

  - The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Source**

For `dbinom` a saddle-point expansion is used: see

- `pbeta`.

- `qbinom` uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.
rbinom (for size < .Machine$integer.max) is based on

For larger values it uses inversion.

See Also

*Distributions* for other standard distributions, including `dnbinom` for the negative binomial, and `dpois` for the Poisson distribution.

Examples

```r
require(graphics)
# Compute P(45 < X < 55) for X Binomial(100,0.5)
sum(dbinom(46:54, 100, 0.5))
## Using "log = TRUE" for an extended range :
n <- 2000
k <- seq(0, n, by = 20)
plot (k, dbinom(k, n, pi/10, log = TRUE), type = "l", ylab = "log density",
     main = "dbinom(*, log=TRUE) is better than log(dbinom(*))")
lines(k, log(dbinom(k, n, pi/10)), col = "red", lwd = 2)
## extreme points are omitted since dbinom gives 0.
 mtext("dbinom(k, log=TRUE)", adj = 0)
 mtext("extended range", adj = 0, line = -1, font = 4)
 mtext("log(dbinom(k))", col = "red", adj = 1)
```

---

**biplot**

*Biplot of Multivariate Data*

Description

Plot a biplot on the current graphics device.

Usage

```r
biplot(x, ...)
```

## Default S3 method:
```r
biplot(x, y, var.axes = TRUE, col, cex = rep(par("cex"), 2),
       xlabs = NULL, ylabs = NULL, expand = 1,
       xlim = NULL, ylim = NULL, arrow.len = 0.1,
       main = NULL, sub = NULL, xlab = NULL, ylab = NULL, ...)
```

Arguments

- **x**
  The biplot, a fitted object. For `biplot.default`, the first set of points (a two-column matrix), usually associated with observations.

- **y**
  The second set of points (a two-column matrix), usually associated with variables.

- **var.axes**
  If `TRUE` the second set of points have arrows representing them as (unscaled) axes.
biplot

col: A vector of length 2 giving the colours for the first and second set of points respectively (and the corresponding axes). If a single colour is specified it will be used for both sets. If missing the default colour is looked for in the palette: if there it and the next colour as used, otherwise the first two colours of the palette are used.

cex: The character expansion factor used for labelling the points. The labels can be of different sizes for the two sets by supplying a vector of length two.

xlabs: A vector of character strings to label the first set of points: the default is to use the row dimname of x, or 1:n if the dimname is NULL.

ylabs: A vector of character strings to label the second set of points: the default is to use the row dimname of y, or 1:n if the dimname is NULL.

expand: An expansion factor to apply when plotting the second set of points relative to the first. This can be used to tweak the scaling of the two sets to a physically comparable scale.

arrow.len: The length of the arrow heads on the axes plotted in var.axes is true. The arrow head can be suppressed by arrow.len = 0.

xlim, ylim: Limits for the x and y axes in the units of the first set of variables.

main, sub, xlab, ylab, ...: graphical parameters.

Details

A biplot is plot which aims to represent both the observations and variables of a matrix of multivariate data on the same plot. There are many variations on biplots (see the references) and perhaps the most widely used one is implemented by biplot.princomp. The function biplot.default merely provides the underlying code to plot two sets of variables on the same figure.

Graphical parameters can also be given to biplot: the size of xlabs and ylabs is controlled by cex.

Side Effects

A plot is produced on the current graphics device.

References

See Also

biplot.princomp, also for examples.
biplot.princomp

Biplot for Principal Components

Description

Produces a biplot (in the strict sense) from the output of princomp or prcomp.

Usage

```r
## S3 method for class 'prcomp'
biplot(x, choices = 1:2, scale = 1, pc.biplot = FALSE, ...)
## S3 method for class 'princomp'
biplot(x, choices = 1:2, scale = 1, pc.biplot = FALSE, ...)
```

Arguments

- `x` an object of class "princomp".
- `choices` length 2 vector specifying the components to plot. Only the default is a biplot in the strict sense.
- `scale` The variables are scaled by lambda ^ scale and the observations are scaled by lambda ^ (1-scale) where lambda are the singular values as computed by princomp. Normally 0 <= scale <= 1, and a warning will be issued if the specified scale is outside this range.
- `pc.biplot` If true, use what Gabriel (1971) refers to as a "principal component biplot", with lambda = 1 and observations scaled up by sqrt(n) and variables scaled down by sqrt(n). Then inner products between variables approximate covariances and distances between observations approximate Mahalanobis distance.
- `...` optional arguments to be passed to biplot.default.

Details

This is a method for the generic function biplot. There is considerable confusion over the precise definitions: those of the original paper, Gabriel (1971), are followed here. Gabriel and Odoroff (1990) use the same definitions, but their plots actually correspond to pc.biplot = TRUE.

Side Effects

A plot is produced on the current graphics device.

biplot.princomp.
Examples

```r
require(graphics)
biplot(princomp(USArrests))
```

---

<table>
<thead>
<tr>
<th>birthday</th>
<th>Probability of coincidences</th>
</tr>
</thead>
</table>

Description

Computes answers to a generalised *birthday paradox* problem. `pbirthday` computes the probability of a coincidence and `qbirthday` computes the smallest number of observations needed to have at least a specified probability of coincidence.

Usage

```r
qbirthday(prob = 0.5, classes = 365, coincident = 2)
pbirthday(n, classes = 365, coincident = 2)
```

Arguments

- `classes`: How many distinct categories the people could fall into
- `prob`: The desired probability of coincidence
- `n`: The number of people
- `coincident`: The number of people to fall in the same category

Details

The birthday paradox is that a very small number of people, 23, suffices to have a 50–50 chance that two or more of them have the same birthday. This function generalises the calculation to probabilities other than 0.5, numbers of coincident events other than 2, and numbers of classes other than 365.

The formula used is approximate for `coincident > 2`. The approximation is very good for moderate values of `prob` but less good for very small probabilities.

Value

- `qbirthday`: Minimum number of people needed for a probability of at least `prob` that `k` or more of them have the same one out of `classes` equiprobable labels.
- `pbirthday`: Probability of the specified coincidence.

References

Examples

require(graphics)

## the standard version
qbirthday() # 23
## probability of > 2 people with the same birthday
pbirthday(23, coincident = 3)

## examples from Diaconis & Mosteller p. 858.
## 'coincidence' is that husband, wife, daughter all born on the 16th
qbirthday(classes = 30, coincident = 3) # approximately 18
qbirthday(coincident = 4) # exact value 187
qbirthday(coincident = 10) # exact value 1181

## same 4-digit PIN number
qbirthday(classes = 10^4)

## 0.9 probability of three or more coincident birthdays
qbirthday(coincident = 3, prob = 0.9)

## Chance of 4 or more coincident birthdays in 150 people
pbirthday(150, coincident = 4)

## 100 or more coincident birthdays in 1000 people: very rare
pbirthday(1000, coincident = 100)

Box.test

Box-Pierce and Ljung-Box Tests

Description

Compute the Box–Pierce or Ljung–Box test statistic for examining the null hypothesis of independence in a given time series. These are sometimes known as 'portmanteau' tests.

Usage

Box.test(x, lag = 1, type = c("Box-Pierce", "Ljung-Box"), fitdf = 0)

Arguments

x a numeric vector or univariate time series.
lag the statistic will be based on lag autocorrelation coefficients.
type test to be performed: partial matching is used.
fitdf number of degrees of freedom to be subtracted if x is a series of residuals.

Details

These tests are sometimes applied to the residuals from an ARMA(p, q) fit, in which case the references suggest a better approximation to the null-hypothesis distribution is obtained by setting fitdf = p+q, provided of course that lag > fitdf.
Value

A list with class "htest" containing the following components:

- statistic: the value of the test statistic.
- parameter: the degrees of freedom of the approximate chi-squared distribution of the test statistic (taking fitdf into account).
- p.value: the p-value of the test.
- method: a character string indicating which type of test was performed.
- data.name: a character string giving the name of the data.

Note

Missing values are not handled.

Author(s)

A. Trapletti

References

Examples

```r
x <- rnorm(100)
Box.test(x, lag = 1)
Box.test(x, lag = 1, type = "Ljung")
```

---

Sets Contrasts for a Factor

Description

Sets the "contrasts" attribute for the factor.

Usage

`C(object, contr, how.many, ...)`

Arguments

- `object`: a factor or ordered factor
- `contr`: which contrasts to use. Can be a matrix with one row for each level of the factor or a suitable function like `contr.poly` or a character string giving the name of the function
- `how.many`: the number of contrasts to set, by default one less than `nlevels(object)`. Additional arguments for the function `contr`.
Details

For compatibility with S, contr can be treatment, helmert, sum or poly (without quotes) as shorthand for contr.treatment and so on.

Value

The factor object with the "contrasts" attribute set.

References

See Also

contrasts, contr.sum, etc.

Examples

## reset contrasts to defaults
options(contrasts = c("contr.treatment", "contr.poly"))
tens <- with(warpbreaks, C(tension, poly, 1))
attributes(tens)
## tension SHOULD be an ordered factor, but as it is not we can use
aov(breaks ~ wool + tens + tension, data = warpbreaks)
## show the use of ... The default contrast is contr.treatment here
summary(lm(breaks ~ wool + C(tension, base = 2), data = warpbreaks))

# following on from help(esoph)
model3 <- glm(cbind(ncases, ncontrols) ~ agegp + C(tobgp, , 1) +
              C(alcgp, , 1), data = esoph, family = binomial())
summary(model3)

---

cancor

Canonical Correlations

Description

Compute the canonical correlations between two data matrices.

Usage

cancor(x, y, xcenter = TRUE, ycenter = TRUE)

Arguments

x numeric matrix \((n \times p_1)\), containing the x coordinates.
y numeric matrix \((n \times p_2)\), containing the y coordinates.
xcenter logical or numeric vector of length $p_1$, describing any centering to be done on the x values before the analysis. If TRUE (default), subtract the column means. If FALSE, do not adjust the columns. Otherwise, a vector of values to be subtracted from the columns.

ycenter analogous to xcenter, but for the y values.

Details

The canonical correlation analysis seeks linear combinations of the y variables which are well explained by linear combinations of the x variables. The relationship is symmetric as ‘well explained’ is measured by correlations.

Value

A list containing the following components:

- cor correlations.
- xcoef estimated coefficients for the x variables.
- ycoef estimated coefficients for the y variables.
- xcenter the values used to adjust the x variables.
- ycenter the values used to adjust the x variables.

References

See Also

qr, svd.

Examples

```r
## signs of results are random
pop <- LifeCycleSavings[, 2:3]
oec <- LifeCycleSavings[, -(2:3)]
cancor(pop, oec)

x <- matrix(rnorm(150), 50, 3)
y <- matrix(rnorm(250), 50, 5)
(cxy <- cancor(x, y))
all(abs(cor(x %*% cxy$xcoef, 
y %*% cxy$ycoef[,1:3] - diag(cxy$cor)) < 1e-15)
all(abs(cor(x %*% cxy$xcoef) - diag(3)) < 1e-15)
all(abs(cor(y %*% cxy$ycoef) - diag(5)) < 1e-15)
```
Case and Variable Names of Fitted Models

Description

Simple utilities returning (non-missing) case names, and (non-eliminated) variable names.

Usage

```r
case.names(object, ...)
## S3 method for class 'lm'
case.names(object, full = FALSE, ...)

variable.names(object, ...)
## S3 method for class 'lm'
variable.names(object, full = FALSE, ...)
```

Arguments

- `object` an R object, typically a fitted model.
- `full` logical; if TRUE, all names (including zero weights, ...) are returned.
- `...` further arguments passed to or from other methods.

Value

A character vector.

See Also

`lm`; further, `all.names`, `all.vars` for functions with a similar name but only slightly related purpose.

Examples

```r
x <- 1:20
y <- setNames(x + (x/4 - 2)^3 + rnorm(20, sd = 3),
   paste("O", x, sep = "."))
ww <- rep(1, 20); ww[13] <- 0
summary(lmxy <- lm(y ~ x + I(x^2)+I(x^3) + I((x-10)^2), weights = ww),
   correlation = TRUE)
variable.names(lmxy)
variable.names(lmxy, full = TRUE) # includes the last
case.names(lmxy)
case.names(lmxy, full = TRUE) # includes the 0-weight case
```
Description

Density, distribution function, quantile function and random generation for the Cauchy distribution with location parameter location and scale parameter scale.

Usage

dcauchy(x, location = 0, scale = 1, log = FALSE)
pcauchy(q, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
qcauchy(p, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
rcauchy(n, location = 0, scale = 1)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
location, scale location and scale parameters.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

If location or scale are not specified, they assume the default values of 0 and 1 respectively.

The Cauchy distribution with location \( l \) and scale \( s \) has density

\[
f(x) = \frac{1}{\pi s} \left( 1 + \left( \frac{x - l}{s} \right)^2 \right)^{-1}
\]

for all \( x \).

Value

dcauchy, pcauchy, and qcauchy are respectively the density, distribution function and quantile function of the Cauchy distribution. rcauchy generates random deviates from the Cauchy.

The length of the result is determined by n for rcauchy, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Source

dcauchy, pcauchy and qcauchy are all calculated from numerically stable versions of the definitions.
rcauchy uses inversion.
chisq.test

Examples

dcauchy(-1:4)

chisq.test           Pearson’s Chi-squared Test for Count Data

Description

chisq.test performs chi-squared contingency table tests and goodness-of-fit tests.

Usage

chisq.test(x, y = NULL, correct = TRUE, 
p = rep(1/length(x), length(x)), rescale.p = FALSE, 
simulate.p.value = FALSE, B = 2000)

Arguments

x a numeric vector or matrix. x and y can also both be factors.
y a numeric vector; ignored if x is a matrix. If x is a factor, y should be a factor of the same length.
correct a logical indicating whether to apply continuity correction when computing the test statistic for 2 by 2 tables: one half is subtracted from all |O - E| differences; however, the correction will not be bigger than the differences themselves. No correction is done if simulate.p.value = TRUE.
p a vector of probabilities of the same length as x. An error is given if any entry of p is negative.
rescale.p a logical scalar; if TRUE then p is rescaled (if necessary) to sum to 1. If rescale.p is FALSE, and p does not sum to 1, an error is given.
simulate.p.value a logical indicating whether to compute p-values by Monte Carlo simulation.
B an integer specifying the number of replicates used in the Monte Carlo test.
Details

If \(x\) is a matrix with one row or column, or if \(x\) is a vector and \(y\) is not given, then a goodness-of-fit test is performed (\(x\) is treated as a one-dimensional contingency table). The entries of \(x\) must be non-negative integers. In this case, the hypothesis tested is whether the population probabilities equal those in \(p\), or are all equal if \(p\) is not given.

If \(x\) is a matrix with at least two rows and columns, it is taken as a two-dimensional contingency table: the entries of \(x\) must be non-negative integers. Otherwise, \(x\) and \(y\) must be vectors or factors of the same length; cases with missing values are removed, the objects are coerced to factors, and the contingency table is computed from these. Then Pearson’s chi-squared test is performed of the null hypothesis that the joint distribution of the cell counts in a 2-dimensional contingency table is the product of the row and column marginals.

If simulate.p.value is FALSE, the p-value is computed from the asymptotic chi-squared distribution of the test statistic; continuity correction is only used in the 2-by-2 case (if correct is TRUE, the default). Otherwise the p-value is computed for a Monte Carlo test (Hope, 1968) with \(B\) replicates. The default \(B = 2000\) implies a minimum p-value of about \(0.0005\) (\(1/(B+1)\)).

In the contingency table case, simulation is done by random sampling from the set of all contingency tables with given marginals, and works only if the marginals are strictly positive. Continuity correction is never used, and the statistic is quoted without it. Note that this is not the usual sampling situation assumed for the chi-squared test but rather that for Fisher’s exact test.

In the goodness-of-fit case simulation is done by random sampling from the discrete distribution specified by \(p\), each sample being of size \(n = \text{sum}(x)\). This simulation is done in \(R\) and may be slow.

Value

A list with class "htest" containing the following components:

- **statistic** the value the chi-squared test statistic.
- **parameter** the degrees of freedom of the approximate chi-squared distribution of the test statistic, NA if the p-value is computed by Monte Carlo simulation.
- **p.value** the p-value for the test.
- **method** a character string indicating the type of test performed, and whether Monte Carlo simulation or continuity correction was used.
- **data.name** a character string giving the name(s) of the data.
- **observed** the observed counts.
- **expected** the expected counts under the null hypothesis.
- **residuals** the Pearson residuals, \((\text{observed} - \text{expected}) / \sqrt{\text{expected}}\).
- **stdres** standardized residuals, \((\text{observed} - \text{expected}) / \sqrt{V}\), where \(V\) is the residual cell variance (Agresti, 2007, section 2.4.5 for the case where \(x\) is a matrix, \(n \times p \times (1 - p)\) otherwise).

Source

The code for Monte Carlo simulation is a C translation of the Fortran algorithm of Patefield (1981).

Examples

```r
## From Agresti(2007) p.39
M <- as.table(rbind(c(762, 327, 468), c(484, 239, 477)))
dimnames(M) <- list(gender = c("F", "M"),
                     party = c("Democrat","Independent", "Republican"))
Xsq <- chisq.test(M)  # Prints test summary
Xsq$observed  # observed counts (same as M)
Xsq$expected  # expected counts under the null
Xsq$residuals # Pearson residuals
Xsq$stdres   # standardized residuals

## Effect of simulating p-values
x <- matrix(c(12, 5, 7, 7), ncol = 2)
chisq.test(x)$p.value # 0.4233
chisq.test(x, simulate.p.value = TRUE, B = 10000)$p.value # around 0.29!

## Testing for population probabilities
## Case A. Tabulated data
x <- c(A = 20, B = 15, C = 25)
chisq.test(x)
chisq.test(as.table(x))  # the same
x <- c(89,37,30,28,2)
p <- c(40,20,20,15,5)
try(
  chisq.test(x, p = p)  # gives an error
)
chisq.test(x, p = p, rescale.p = TRUE)  # works
  # Expected count in category 5
  # is 1.86 < 5 ==> chi square approx.
chisq.test(x, p = p)  # maybe doubtful, but is ok!
chisq.test(x, p = p, simulate.p.value = TRUE)

## Case B. Raw data
x <- trunc(5 * runif(100))
chisq.test(table(x))  # NOT 'chisq.test(x)'!
```
Description

Density, distribution function, quantile function and random generation for the chi-squared ($\chi^2$) distribution with df degrees of freedom and optional non-centrality parameter ncp.

Usage

dchisq(x, df, ncp = 0, log = FALSE)
pchisq(q, df, ncp = 0, lower.tail = TRUE, log.p = FALSE)
qchisq(p, df, ncp = 0, lower.tail = TRUE, log.p = FALSE)
rchisq(n, df, ncp = 0)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
df degrees of freedom (non-negative, but can be non-integer).
ncp non-centrality parameter (non-negative).
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

The chi-squared distribution with df = $n \geq 0$ degrees of freedom has density

$$f_n(x) = \frac{1}{2^{n/2} \Gamma(n/2)} x^{n/2-1} e^{-x/2}$$

for $x > 0$, where $f_0(x) := \lim_{n \to 0} f_n(x) = \delta_0(x)$, a point mass at zero, is not a density function proper, but a "$\delta$ distribution". The mean and variance are $n$ and $2n$.

The non-central chi-squared distribution with df = $n$ degrees of freedom and non-centrality parameter $\lambda$ has density

$$f(x) = f_{n, \lambda}(x) = e^{-\lambda/2} \sum_{r=0}^{\infty} \frac{(\lambda/2)^r}{r!} f_{n+2r}(x)$$

for $x \geq 0$. For integer $n$, this is the distribution of the sum of squares of $n$ normals each with variance one, $\lambda$ being the sum of squares of the normal means; further, $E(X) = n + \lambda$, $\text{Var}(X) = 2(n + 2 \cdot \lambda)$, and $E((X - E(X))^3) = 8(n + 3 \cdot \lambda)$.

Note that the degrees of freedom df = $n$, can be non-integer, and also $n = 0$ which is relevant for non-centrality $\lambda > 0$, see Johnson et al. (1995, chapter 29). In that (noncentral, zero df) case, the distribution is a mixture of a point mass at $x = 0$ (of size pchisq(0, df=0, ncp=ncp)) and a continuous part, and dchisq() is not a density with respect to that mixture measure but rather the limit of the density for df $\to 0$.

Note that ncp values larger than about 1e5 (and even smaller) may give inaccurate results with many warnings for pchisq and qchisq.
dchisq gives the density, pchisq gives the distribution function, qchisq gives the quantile function, and rchisq generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rchisq, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

Supplying ncp = 0 uses the algorithm for the non-central distribution, which is not the same algorithm used if ncp is omitted. This is to give consistent behaviour in extreme cases with values of ncp very near zero.

The code for non-zero ncp is principally intended to be used for moderate values of ncp: it will not be highly accurate, especially in the tails, for large values.

Source

The central cases are computed via the gamma distribution.

The non-central dchisq and rchisq are computed as a Poisson mixture of central chi-squares (Johnson et al., 1995, p.436).

The non-central pchisq is for ncp < 80 computed from the Poisson mixture of central chi-squares and for larger ncp via a C translation of

which computes the lower tail only (so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant).

The non-central qchisq is based on inversion of pchisq.

References

See Also

Distributions for other standard distributions.

A central chi-squared distribution with n degrees of freedom is the same as a Gamma distribution with shape $\alpha = n/2$ and scale $\sigma = 2$. Hence, see dgamma for the Gamma distribution.

The central chi-squared distribution with 2 d.f. is identical to the exponential distribution with rate 1/2: $\chi^2_2 = Exp(1/2)$, see dexp.

stopifnot(all.equal(pp00, exp(-lam/2)),
          all.equal(pp.0, exp(-lam/2)))

---

**cmdscale**

*Classical (Metric) Multidimensional Scaling*

**Description**

Classical multidimensional scaling (MDS) of a data matrix. Also known as principal coordinates analysis (Gower, 1966).

**Usage**

`cmdscale(d, k = 2, eig = FALSE, add = FALSE, x.ret = FALSE, list. = eig || add || x.ret)`
cmdscale

Arguments

d  a distance structure such as that returned by dist or a full symmetric matrix containing the dissimilarities.

k  the maximum dimension of the space which the data are to be represented in; must be in \{1, 2, \ldots, n - 1\}.

eig  indicates whether eigenvalues should be returned.

add  logical indicating if an additive constant \(c^*\) should be computed, and added to the non-diagonal dissimilarities such that the modified dissimilarities are Euclidean.

x.ret  indicates whether the doubly centred symmetric distance matrix should be returned.

list.  logical indicating if a list should be returned or just the \(n \times k\) matrix, see ‘Value’.

Details

Multidimensional scaling takes a set of dissimilarities and returns a set of points such that the distances between the points are approximately equal to the dissimilarities. (It is a major part of what ecologists call ‘ordination’.)

A set of Euclidean distances on \(n\) points can be represented exactly in at most \(n - 1\) dimensions. cmdscale follows the analysis of Mardia (1978), and returns the best-fitting \(k\)-dimensional representation, where \(k\) may be less than the argument \(k\).

The representation is only determined up to location (cmdscale takes the column means of the configuration to be at the origin), rotations and reflections. The configuration returned is given in principal-component axes, so the reflection chosen may differ between R platforms (see prcomp).

When add = TRUE, a minimal additive constant \(c^*\) is computed such that the dissimilarities \(d_{ij} + c^*\) are Euclidean and hence can be represented in \(n - 1\) dimensions. Whereas S (Becker et al., 1988) computes this constant using an approximation suggested by Torgerson, \(R\) uses the analytical solution of Cailliez (1983), see also Cox and Cox (2001). Note that because of numerical errors the computed eigenvalues need not all be non-negative, and even theoretically the representation could be in fewer than \(n - 1\) dimensions.

Value

If .list is false (as per default), a matrix with \(k\) columns whose rows give the coordinates of the points chosen to represent the dissimilarities.

Otherwise, a list containing the following components.

points  a matrix with up to \(k\) columns whose rows give the coordinates of the points chosen to represent the dissimilarities.

eig  the \(n\) eigenvalues computed during the scaling process if eig is true. NB: versions of \(R\) before 2.12.1 returned only \(k\) but were documented to return \(n - 1\).

x  the doubly centered distance matrix if x.ret is true.

ac  the additive constant \(c^*, 0\) if add = FALSE.

GOF  a numeric vector of length 2, equal to say \((g_1, g_2)\), where \(g_i = (\sum_{j=1}^{k} \lambda_j)/(\sum_{j=1}^{n} T_i(\lambda_j))\), where \(\lambda_j\) are the eigenvalues (sorted in decreasing order), \(T_1(v) = |v|\), and \(T_2(v) = max(v, 0)\).

Examples
require(graphics)
loc <- cmdscale(eurodist)
x <- loc[, 1]
y <- -loc[, 2] # reflect so North is at the top
# note asp = 1, to ensure Euclidean distances are represented correctly
plot(x, y, type = "n", xlab = "", ylab = "", asp = 1, axes = FALSE,
main = "cmdscale(eurodist)")
text(x, y, rownames(loc), cex = 0.6)

table

coef

Extract Model Coefficients

Description
coef is a generic function which extracts model coefficients from objects returned by modeling functions. coefficients is an alias for it.

Usage
coef(object, ...)
coefficients(object, ...)
## Default S3 method:
coef(object, complete = TRUE, ...)
## S3 method for class 'aov'
coef(object, complete = FALSE, ...)
complete.cases

Arguments

object
an object for which the extraction of model coefficients is meaningful.

complete
for the default (used for lm, etc) and aov methods: logical indicating if the full coefficient vector should be returned also in case of an over-determined system where some coefficients will be set to NA, see also alias. Note that the default differs for lm() and aov() results.

... other arguments.

Details

All object classes which are returned by model fitting functions should provide a coef method or use the default one. (Note that the method is for coef and not coefficients.)
The "aov" method does not report aliased coefficients (see alias) by default where complete = FALSE.
The complete argument also exists for compatibility with vcov methods, and coef and aov methods for other classes should typically also keep the complete = * behavior in sync. By that, with p <- length(coef(obj, complete = TF)).dim(vcov(obj, complete = TF)) == c(p,p) will be fulfilled for both complete settings and the default.

Value

Coefficients extracted from the model object object.
For standard model fitting classes this will be a named numeric vector. For "maov" objects (produced by aov) it will be a matrix.

References

See Also

fitted.values and residuals for related methods; glm, lm for model fitting.

Examples

x <- 1:5; coef(lm(c(1:3, 7, 6) ~ x))

---

complete.cases Find Complete Cases

description

Return a logical vector indicating which cases are complete, i.e., have no missing values.

Usage

complete.cases(...)

Arguments

... a sequence of vectors, matrices and data frames.
confint

Confidence Intervals for Model Parameters

Description

Computes confidence intervals for one or more parameters in a fitted model. There is a default and a method for objects inheriting from class "lm".

Usage

confint(object, parm, level = 0.95, ...)  
## Default S3 method:  
confint(object, parm, level = 0.95, ...)  
## S3 method for class 'lm'  
confint(object, parm, level = 0.95, ...)  
## S3 method for class 'glm'  
confint(object, parm, level = 0.95, trace = FALSE, test=c("LRT", "Rao"), ...)  
## S3 method for class 'nls'  
confint(object, parm, level = 0.95, ...)

Arguments

object a fitted model object.
parm a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.

Value

A logical vector specifying which observations/rows have no missing values across the entire sequence.

Note

A current limitation of this function is that it uses low level functions to determine lengths and missingness, ignoring the class. This will lead to spurious errors when some columns have classes with length or is.na methods, for example "POSIXlt", as described in PR#16648.

See Also

is.na, na.omit, na.fail.

Examples

x <- airquality[, -1]  # x is a regression design matrix
y <- airquality[, 1]  # y is the corresponding response

stopifnot(complete.cases(y) != is.na(y))
ok <- complete.cases(x, y)
sum(!ok)  # how many are not "ok" ?
x <- x[ok,]
y <- y[ok]
level

the confidence level required.

trace

logical. Should profiling be traced?

test

use Likelihood Ratio or Rao Score test in profiling.

... additional argument(s) for methods.

Details

confint is a generic function. The default method assumes normality, and needs suitable coef and vcov methods to be available. The default method can be called directly for comparison with other methods.

For objects of class "lm" the direct formulae based on t values are used.

Methods for classes "glm" and "nls" call the appropriate profile method, then find the confidence intervals by interpolation in the profile traces. If the profile object is already available it can be used as the main argument rather than the fitted model object itself.

Value

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1-level)/2 and 1 - (1-level)/2 in % (by default 2.5% and 97.5%).

References

confint(fit)
confint(fit, "wt")

## from example(glm)
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3, 1, 9); treatment <- gl(3, 3)
glm.D93 <- glm(counts ~ outcome + treatment, family = poisson())
confint(glm.D93)
confint.default(glm.D93) # based on asymptotic normality

constrOptim

Linearly Constrained Optimization

Description

Minimise a function subject to linear inequality constraints using an adaptive barrier algorithm.
constrOptim

Usage

constrOptim(theta, f, grad, ui, ci, mu = 1e-04, control = list(),
  method = if(is.null(grad)) "Nelder-Mead" else "BFGS",
  outer.iterations = 100, outer.eps = 1e-05, ...,
  hessian = FALSE)

Arguments

theta numeric (vector) starting value (of length p): must be in the feasible region.

f function to minimise (see below).

grad gradient of f (a function as well), or NULL (see below).

ui constraint matrix (k x p), see below.

ci constraint vector of length k (see below).

mu (Small) tuning parameter.

control, method, hessian passed to optim.

outer.iterations iterations of the barrier algorithm.

outer.eps non-negative number; the relative convergence tolerance of the barrier algorithm.

... Other named arguments to be passed to f and grad: needs to be passed through optim so should not match its argument names.

Details

The feasible region is defined by ui %*% theta - ci >= 0. The starting value must be in the interior of the feasible region, but the minimum may be on the boundary.

A logarithmic barrier is added to enforce the constraints and then optim is called. The barrier function is chosen so that the objective function should decrease at each outer iteration. Minima in the interior of the feasible region are typically found quite quickly, but a substantial number of outer iterations may be needed for a minimum on the boundary.

The tuning parameter mu multiplies the barrier term. Its precise value is often relatively unimportant. As mu increases the augmented objective function becomes closer to the original objective function but also less smooth near the boundary of the feasible region.

Any optim method that permits infinite values for the objective function may be used (currently all but "L-BFGS-B").

The objective function f takes as first argument the vector of parameters over which minimisation is to take place. It should return a scalar result. Optional arguments ... will be passed to optim and then (if not used by optim) to f. As with optim, the default is to minimise, but maximisation can be performed by setting control$fnscale to a negative value.

The gradient function grad must be supplied except with method = "Nelder-Mead". It should take arguments matching those of f and return a vector containing the gradient.

Value

As for optim, but with two extra components: barrier.value giving the value of the barrier function at the optimum and outer.iterations gives the number of outer iterations (calls to optim). The counts component contains the sum of all optim$counts.
contrast

(Possibly Sparse) Contrast Matrices

Description

Return a matrix of contrasts.
Usage

contr.helmert(n, contrasts = TRUE, sparse = FALSE)
contr.poly(n, scores = 1:n, contrasts = TRUE, sparse = FALSE)
contr.sum(n, contrasts = TRUE, sparse = FALSE)
contr.treatment(n, base = 1, contrasts = TRUE, sparse = FALSE)
contr.SAS(n, contrasts = TRUE, sparse = FALSE)

Arguments

n a vector of levels for a factor, or the number of levels.
contrasts a logical indicating whether contrasts should be computed.
sparse logical indicating if the result should be sparse (of class dgCMatrix), using package Matrix.
scores the set of values over which orthogonal polynomials are to be computed.
base an integer specifying which group is considered the baseline group. Ignored if contrasts is FALSE.

Details

These functions are used for creating contrast matrices for use in fitting analysis of variance and regression models. The columns of the resulting matrices contain contrasts which can be used for coding a factor with n levels. The returned value contains the computed contrasts. If the argument contrasts is FALSE a square indicator matrix (the dummy coding) is returned except for contr.poly (which includes the 0-degree, i.e. constant, polynomial when contrasts = FALSE).

contr.helmert returns Helmert contrasts, which contrast the second level with the first, the third with the average of the first two, and so on. contr.poly returns contrasts based on orthogonal polynomials. contr.sum uses ‘sum to zero contrasts’.

contr.treatment contrasts each level with the baseline level (specified by base): the baseline level is omitted. Note that this does not produce ‘contrasts’ as defined in the standard theory for linear models as they are not orthogonal to the intercept.

contr.SAS is a wrapper for contr.treatment that sets the base level to be the last level of the factor. The coefficients produced when using these contrasts should be equivalent to those produced by many (but not all) SAS procedures.

For consistency, sparse is an argument to all these contrast functions, however sparse = TRUE for contr.poly is typically pointless and is rarely useful for contr.helmert.

Value

A matrix with n rows and k columns, with k=n-1 if contrasts is TRUE and k=n if contrasts is FALSE.

References

\[
\text{zapsmall} \left(\text{crossprod}(cP), \text{digits} = 15\right) \ # \text{orthonormal up to fuzz}
\]

corresponding

Description

Set and view the contrasts associated with a factor.

Usage

contrasts(x, contrasts = TRUE, sparse = FALSE)
contrasts(x, how.many = NULL) <- value

Arguments

x a factor or a logical variable.
contrasts logical. See ‘Details’.
sparse logical indicating if the result should be sparse (of class \text{dgCMatrix}), using package \text{Matrix}.
how.many integer number indicating how many contrasts should be made. Defaults to one less than the number of levels of \text{x}. This need not be the same as the number of columns of value.
value either a numeric matrix (or a sparse or dense matrix of a class extending \text{dMatrix} from package \text{Matrix}) whose columns give coefficients for contrasts in the levels of \text{x}, or (the quoted name of) a function which computes such matrices.

Details

If contrasts are not set for a factor the default functions from \text{options("contrasts")} are used.
A logical vector \text{x} is converted into a two-level factor with levels \text{c(FALSE, TRUE)} (regardless of which levels occur in the variable).
The argument \text{contrasts} is ignored if \text{x} has a matrix \text{contrasts} attribute set. Otherwise if \text{contrasts} = \text{TRUE} it is passed to a contrasts function such as \text{contr.treatment} and if \text{contrasts} = \text{FALSE} an identity matrix is returned. Suitable functions have a first argument which is the character vector of levels, a named argument \text{contrasts} (always called with \text{contrasts} = \text{TRUE}) and optionally a logical argument \text{sparse}. 

contrasts

Get and Set Contrast Matrices
If value supplies more than how many contrasts, the first how many are used. If too few are supplied, a suitable contrast matrix is created by extending value after ensuring its columns are contrasts (orthogonal to the constant term) and not collinear.

convolve

Convolution of Sequences via FFT

Description

Use the Fast Fourier Transform to compute the several kinds of convolutions of two sequences.

Usage

convolve(x, y, conj = TRUE, type = c("circular", "open", "filter"))

Arguments

x, y numeric sequences of the same length to be convolved.
conj logical; if TRUE, take the complex conjugate before back-transforming (default, and used for usual convolution).
type character; partially matched to "circular", "open", "filter". For "circular", the two sequences are treated as circular, i.e., periodic. For "open" and "filter", the sequences are padded with 0s (from left and right) first; "filter" returns the middle sub-vector of "open", namely, the result of running a weighted mean of x with weights y.
convolve

Details

The Fast Fourier Transform, fft, is used for efficiency.

The input sequences x and y must have the same length if circular is true.

Note that the usual definition of convolution of two sequences x and y is given by convolve(x, rev(y), type = "o").

Value

If r <- convolve(x, y, type = "open") and n <- length(x), m <- length(y), then

\[ r_k = \sum_i x_{k-i} y_i \]

where the sum is over all valid indices i, for \( k = 1, \ldots, n + m - 1 \).

If type == "circular", \( n = m \) is required, and the above is true for \( i, k = 1, \ldots, n \) when \( x_j := x_{n+j} \) for \( j < 1 \).

References

zapsmall(convolve(x, y[3:5], type = "f")) # rather
x <- rnorm(50)
y <- rnorm(50)
# Circular convolution *has* this symmetry:
all.equal(convolve(x, y, conj = FALSE), rev(convolve(rev(y),x)))

n <- length(x <- -20:24)
y <- (x-10)^2/1000 + rnorm(x)/8
Han <- function(y) # Hanning
  convolve(y, c(1,2,1)/4, type = "filter")
plot(x, y, main = "Using convolve(.) for Hanning filters")
lines(x[-c(1 , n) ], Han(y), col = "red")
lines(x[-c(1:2, (n-1):n)], Han(Han(y)), lwd = 2, col = "dark blue")
cophenetic

Cophenetic Distances for a Hierarchical Clustering

Description

Computes the cophenetic distances for a hierarchical clustering.

Usage

cophenetic(x)
## Default S3 method:
cophenetic(x)
## S3 method for class 'dendrogram'
cophenetic(x)

Arguments

x an R object representing a hierarchical clustering. For the default method, an object of class "hclust" or with a method for as.hclust() such as "agnes" in package cluster.

Details

The cophenetic distance between two observations that have been clustered is defined to be the intergroup dissimilarity at which the two observations are first combined into a single cluster. Note that this distance has many ties and restrictions.

It can be argued that a dendrogram is an appropriate summary of some data if the correlation between the original distances and the cophenetic distances is high. Otherwise, it should simply be viewed as the description of the output of the clustering algorithm.

cophenetic is a generic function. Support for classes which represent hierarchical clusterings (total indexed hierarchies) can be added by providing an as.hclust() or, more directly, a cophenetic() method for such a class.

The method for objects of class "dendrogram" requires that all leaves of the dendrogram object have non-null labels.

Value

An object of class "dist".

cor(d0, d.coph) # 0.9911

cor

Correlation, Variance and Covariance (Matrices)

Description

var, cov and cor compute the variance of x and the covariance or correlation of x and y if these are vectors. If x and y are matrices then the covariances (or correlations) between the columns of x and the columns of y are computed.

cov2cor scales a covariance matrix into the corresponding correlation matrix efficiently.

Usage

var(x, y = NULL, na.rm = FALSE, use)
cov(x, y = NULL, use = "everything", method = c("pearson", "kendall", "spearman"))
cor(x, y = NULL, use = "everything", method = c("pearson", "kendall", "spearman"))
cov2cor(V)

Arguments

x a numeric vector, matrix or data frame.
y NULL (default) or a vector, matrix or data frame with compatible dimensions to x. The default is equivalent to y = x (but more efficient).
na.rm logical. Should missing values be removed?
use an optional character string giving a method for computing covariances in the presence of missing values. This must be (an abbreviation of) one of the strings "everything", "all.obs", "complete.obs", "na.or.complete", or "pairwise.complete.obs".
method a character string indicating which correlation coefficient (or covariance) is to be computed. One of "pearson" (default), "kendall", or "spearman": can be abbreviated.

V symmetric numeric matrix, usually positive definite such as a covariance matrix.

Details

For cov and cor one must either give a matrix or data frame for x or give both x and y.

The inputs must be numeric (as determined by is.numeric: logical values are also allowed for historical compatibility): the "kendall" and "spearman" methods make sense for ordered inputs but xtfrm can be used to find a suitable prior transformation to numbers.

var is just another interface to cov, where na.rm is used to determine the default for use when that is unspecified. If na.rm is TRUE then the complete observations (rows) are used (use = "na.or.complete") to compute the variance. Otherwise, by default use = "everything".

If use is "everything", NAs will propagate conceptually, i.e., a resulting value will be NA whenever one of its contributing observations is NA.

If use is "all.obs", then the presence of missing observations will produce an error. If use is "complete.obs" then missing values are handled by casewise deletion (and if there are no complete cases, that gives an error).

"na.or.complete" is the same unless there are no complete cases, that gives NA. Finally, if use has the value "pairwise.complete.obs" then the correlation or covariance between each pair of variables is computed using all complete pairs of observations on those variables. This can result in covariance or correlation matrices which are not positive semi-definite, as well as NA entries if there are no complete pairs for that pair of variables. For cov and var, "pairwise.complete.obs" only works with the "pearson" method. Note that (the equivalent of) var(double(0), use = *) gives NA for use = "everything" and "na.or.complete". and gives an error in the other cases.

The denominator \(n - 1\) is used which gives an unbiased estimator of the (co)variance for i.i.d. observations. These functions return NA when there is only one observation.

For cor(), if method is "kendall" or "spearman", Kendall’s \(\tau\) or Spearman’s \(\rho\) statistic is used to estimate a rank-based measure of association. These are more robust and have been recommended if the data do not necessarily come from a bivariate normal distribution.

For cov(), a non-Pearson method is unusual but available for the sake of completeness. Note that "spearman" basically computes \(\text{cor}(R(x), R(y))\) (or \(\text{cov}(\ldots)\)) where \(R(u) := \text{rank}(u, \text{na.last = "keep"})\). In the case of missing values, the ranks are calculated depending on the value of use, either based on complete observations, or based on pairwise completeness with reranking for each pair.

When there are ties, Kendall’s \(\tau_b\) is computed, as proposed by Kendall (1945).

Scaling a covariance matrix into a correlation one can be achieved in many ways, mathematically most appealing by multiplication with a diagonal matrix from left and right, or more efficiently by using sweep(..., FUN = "/") twice. The cov2cor function is even a bit more efficient, and provided mostly for didactical reasons.

Value

For \(r \leftarrow \text{cor}(\ldots, \text{use = "all.obs"})\), it is now guaranteed that all(abs(r) <= 1).

Note

Some people have noted that the code for Kendall’s tau is slow for very large datasets (many more than 1000 cases). It rarely makes sense to do such a computation, but see function cor.fk in package pcaPP.
References

cor.test for confidence intervals (and tests).
cov.wt for weighted covariance computation.
sd for standard deviation (vectors).

Examples

```r
var(1:10) # 9.166667

var(1:5, 1:5) # 2.5

## Two simple vectors
cor(1:10, 2:11) # == 1

## Correlation Matrix of Multivariate sample:
(C1 <- cor(longley))

## Graphical Correlation Matrix:
symnum(C1) # highly correlated

## Spearman's rho and Kendall's tau
symnum(clS <- cor(longley, method = "spearman"))
symnum(clK <- cor(longley, method = "kendall"))

## How much do they differ?
i <- lower.tri(C1)
cor(cbind(P = C1[i], S = clS[i], K = clK[i]))

## cov2cor() scales a covariance matrix by its diagonal
## to become the correlation matrix.
cov2cor # see the function definition (and learn ..)
stopifnot(all.equal(C1, cov2cor(cov(longley))));
  all.equal(cor(longley, method = "kendall"),
            cov2cor(cov(longley, method = "kendall")))

##--- Missing value treatment:
C1 <- cov(swiss)
range(eigen(C1, only.values = TRUE)$values) # 6.19 1921

## swM := "swiss" with 3 "missing"s:
swM <- swiss
colnames(swM) <- abbreviate(colnames(swiss), minlength=6)
swM[1,2] <- swM[7,3] <- swM[25,5] <- NA # create 3 "missing"

## Consider all 5 "use" cases:
(C. <- cov(swM)) # use="everything" quite a few NA's in cov.matrix
```
cor.test

```r
try(cov(swM, use = "all")) # Error: missing obs...
C2 <- cov(swM, use = "complete")
stopifnot(identical(C2, cov(swM, use = "na.or.complete")))
rangen(eigen(C2, only.values = TRUE)$values) # 6.46 1930
C3 <- cov(swM, use = "pairwise")
rangen(eigen(C3, only.values = TRUE)$values) # 6.19 1938
## Kendall's tau doesn't change much:
symnum(Rc <- cor(swM, method = "kendall", use = "complete"))
symnum(Rp <- cor(swM, method = "kendall", use = "pairwise"))
symnum(R. <- cor(swiss, method = "kendall"))
## "pairwise" is closer componentwise,
summary(abs(c(1 - Rp/R.)))
summary(abs(c(1 - Rc/R.)))
## but "complete" is closer in Eigen space:
EV <- function(m) eigen(m, only.values=TRUE)$values
summary(abs(1 - EV(Rp)/EV(R.)) / abs(1 - EV(Rc)/EV(R.)))
```

---

cor.test

**Test for Association/Correlation Between Paired Samples**

**Description**

Test for association between paired samples, using one of Pearson’s product moment correlation coefficient, Kendall’s τ or Spearman’s ρ.

**Usage**

```r
cor.test(x, ...)
```

### Default S3 method:

```r
cor.test(x, y,
  alternative = c("two.sided", "less", "greater"),
  method = c("pearson", "kendall", "spearman"),
  exact = NULL, conf.level = 0.95, continuity = FALSE, ...)
```

### S3 method for class ‘formula’

```r
cor.test(formula, data, subset, na.action, ...)
```

**Arguments**

- **x, y**: numeric vectors of data values. x and y must have the same length.
- **alternative**: indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. "greater" corresponds to positive association, "less" to negative association.
- **method**: a character string indicating which correlation coefficient is to be used for the test. One of "pearson", "kendall", or "spearman", can be abbreviated.
- **exact**: a logical indicating whether an exact p-value should be computed. Used for Kendall’s τ and Spearman’s ρ. See ‘Details’ for the meaning of NULL (the default).
conf.level: confidence level for the returned confidence interval. Currently only used for the Pearson product moment correlation coefficient if there are at least 4 complete pairs of observations.

continuity: logical: if true, a continuity correction is used for Kendall’s τ and Spearman’s ρ when not computed exactly.

formula: a formula of the form ~ u + v, where each of u and v are numeric variables giving the data values for one sample. The samples must be of the same length.

data: an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset: an optional vector specifying a subset of observations to be used.

na.action: a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").

Details

The three methods each estimate the association between paired samples and compute a test of the value being zero. They use different measures of association, all in the range [−1, 1] with 0 indicating no association. These are sometimes referred to as tests of no correlation, but that term is often confined to the default method.

If method is "pearson", the test statistic is based on Pearson’s product moment correlation coefficient cor(x, y) and follows a t distribution with length(x)−2 degrees of freedom if the samples follow independent normal distributions. If there are at least 4 complete pairs of observation, an asymptotic confidence interval is given based on Fisher’s Z transform.

If method is "kendall" or "spearman", Kendall’s τ or Spearman’s ρ statistic is used to estimate a rank-based measure of association. These tests may be used if the data do not necessarily come from a bivariate normal distribution.

For Kendall’s test, by default (if exact is NULL), an exact p-value is computed if there are less than 50 paired samples containing finite values and there are no ties. Otherwise, the test statistic is the estimate scaled to zero mean and unit variance, and is approximately normally distributed.

For Spearman’s test, p-values are computed using algorithm AS 89 for n < 1290 and exact = TRUE, otherwise via the asymptotic t approximation. Note that these are ‘exact’ for n < 10, and use an Edgeworth series approximation for larger sample sizes (the cutoff has been changed from the original paper).

Value

A list with class "htest" containing the following components:

- statistic: the value of the test statistic.
- parameter: the degrees of freedom of the test statistic in the case that it follows a t distribution.
- p.value: the p-value of the test.
- estimate: the estimated measure of association, with name "cor", "tau", or "rho" corresponding to the method employed.
- null.value: the value of the association measure under the null hypothesis, always 0.
- alternative: a character string describing the alternative hypothesis.
method  a character string indicating how the association was measured.
data.name  a character string giving the names of the data.
conf.int  a confidence interval for the measure of association. Currently only given for
Pearson’s product moment correlation coefficient in case of at least 4 complete
pairs of observations.

supply different (and often more accurate) approximations.

Examples

```r
## Assessment of tuna quality. We compare the Hunter L measure of
## lightness to the averages of consumer panel scores (recoded as
## integer values from 1 to 6 and averaged over 80 such values) in
## 9 lots of canned tuna.
x <- c(44.4, 45.9, 41.9, 53.3, 44.7, 44.1, 50.7, 45.2, 60.1)
y <- c(2.6, 3.1, 2.5, 5.0, 3.6, 4.0, 5.2, 2.8, 3.8)

## The alternative hypothesis of interest is that the
## Hunter L value is positively associated with the panel score.
cor.test(x, y, method = "kendall", alternative = "greater")
## => p=0.05972
cor.test(x, y, method = "kendall", alternative = "greater",
             exact = FALSE) # using large sample approximation
## => p=0.04765

## Compare this to
cor.test(x, y, method = "spearm", alternative = "g")
cor.test(x, y, alternative = "g")

## Formula interface.
require(graphics)
pairs(USJudgeRatings)
cor.test(~ CONT + INTG, data = USJudgeRatings)
```
Weighted Covariance Matrices

**Description**

Returns a list containing estimates of the weighted covariance matrix and the mean of the data, and optionally of the (weighted) correlation matrix.

**Usage**

```r
cov.wt(x, wt = rep(1/nrow(x), nrow(x)), cor = FALSE, center = TRUE,
method = c("unbiased", "ML"))
```

**Arguments**

- `x` a matrix or data frame. As usual, rows are observations and columns are variables.
- `wt` a non-negative and non-zero vector of weights for each observation. Its length must equal the number of rows of `x`.
- `cor` a logical indicating whether the estimated correlation weighted matrix will be returned as well.
- `center` either a logical or a numeric vector specifying the centers to be used when computing covariances. If `TRUE`, the (weighted) mean of each variable is used, if `FALSE`, zero is used. If `center` is numeric, its length must equal the number of columns of `x`.
- `method` string specifying how the result is scaled, see ‘Details’ below. Can be abbreviated.

**Details**

By default, `method = "unbiased"`. The covariance matrix is divided by one minus the sum of squares of the weights, so if the weights are the default `(1/n)` the conventional unbiased estimate of the covariance matrix with divisor `(n - 1)` is obtained.

**Value**

A list containing the following named components:

- `cov` the estimated (weighted) covariance matrix
- `center` an estimate for the center (mean) of the data.
- `n.obs` the number of observations (rows) in `x`.
- `wt` the weights used in the estimation. Only returned if given as an argument.
- `cor` the estimated correlation matrix. Only returned if `cor` is `TRUE`.

**See Also**

`cov` and `var`. 
Examples

```r
(xy <- cbind(x = 1:10, y = c(1:3, 8:5, 8:10)))
w1 <- c(0,0,0,1,1,1,1,1,0,0)
cov.wt(xy, wt = w1) # i.e. method = "unbiased"
cov.wt(xy, wt = w1, method = "ML", cor = TRUE)
```

Description

Plots a cumulative periodogram.

Usage

```r
cpgram(ts, taper = 0.1,
       main = paste("Series: ", deparse1(substitute(ts))),
       ci.col = "blue")
```

Arguments

- `ts`  
  a univariate time series

- `taper`  
  proportion tapered in forming the periodogram

- `main`  
  main title

- `ci.col`  
  colour for confidence band.

Value

None.

Side Effects

Plots the cumulative periodogram in a square plot.

Note

From package MASS.

Author(s)

B.D. Ripley

Examples

```r
require(graphics)
par(pty = "s", mfrow = c(1,2))
cpgram(lh)
lh.ar <- ar(lh, order.max = 9)
cpgram(lh.ar$resid, main = "AR(3) fit to lh")
cpgram(ldeaths)
```
cutree

Cut a Tree into Groups of Data

Description

Cuts a tree, e.g., as resulting from `hclust`, into several groups either by specifying the desired number(s) of groups or the cut height(s).

Usage

`cutree(tree, k = NULL, h = NULL)`

Arguments

- `tree` a tree as produced by `hclust`. `cutree()` only expects a list with components `merge`, `height`, and `labels`, of appropriate content each.
- `k` an integer scalar or vector with the desired number of groups
- `h` numeric scalar or vector with heights where the tree should be cut.

At least one of `k` or `h` must be specified, `k` overrides `h` if both are given.

Details

Cutting trees at a given height is only possible for ultrametric trees (with monotone clustering heights).

Value

`cutree` returns a vector with group memberships if `k` or `h` are scalar, otherwise a matrix with group memberships is returned where each column corresponds to the elements of `k` or `h`, respectively (which are also used as column names).

References

See Also

`hclust`, `dendrogram` for cutting trees themselves.

Examples

```r
hc <- hclust(dist(USArrests))
cutree(hc, k = 1:5)  # k = 1 is trivial
cutree(hc, h = 250)

## Compare the 2 and 4 grouping:
g24 <- cutree(hc, k = c(2,4))
table(grp2 = g24[, "2"], grp4 = g24[, "4"])
```
Description

Decompose a time series into seasonal, trend and irregular components using moving averages. Deals with additive or multiplicative seasonal component.

Usage

decompose(x, type = c("additive", "multiplicative"), filter = NULL)

Arguments

x
A time series.

type
The type of seasonal component. Can be abbreviated.

filter
A vector of filter coefficients in reverse time order (as for AR or MA coefficients), used for filtering out the seasonal component. If NULL, a moving average with symmetric window is performed.

Details

The additive model used is:

\[ Y_t = T_t + S_t + e_t \]

The multiplicative model used is:

\[ Y_t = T_t S_t e_t \]

The function first determines the trend component using a moving average (if filter is NULL, a symmetric window with equal weights is used), and removes it from the time series. Then, the seasonal figure is computed by averaging, for each time unit, over all periods. The seasonal figure is then centered. Finally, the error component is determined by removing trend and seasonal figure (recycled as needed) from the original time series.

This only works well if x covers an integer number of complete periods.

Value

An object of class "decomposed.ts" with following components:

x
The original series.

seasonal
The seasonal component (i.e., the repeated seasonal figure).

figure
The estimated seasonal figure only.

trend
The trend component.

random
The remainder part.

type
The value of type.

Note

The function stl provides a much more sophisticated decomposition.

Examples

require(graphics)

m <- decompose(co2)
m$figure
plot(m)

## example taken from Kendall/Stuart
x <- c(-50, 175, 149, 214, 247, 237, 225, 329, 729, 809,
     530, 489, 540, 457, 195, 176, 337, 239, 128, 102, 232, 429, 3,
     98, 43, -141, -77, -13, 125, 361, -45, 184)
x <- ts(x, start = c(1951, 1), end = c(1958, 4), frequency = 4)
m <- decompose(x)

## seasonal figure: 6.25, 8.62, -8.84, -6.03
round(decompose(x)$figure / 10, 2)

Description

delete.response returns a terms object for the same model but with no response variable.
drop.terms removes variables from the right-hand side of the model. There is also a "[.terms" method to perform the same function (with keep.response = TRUE).
reformulate creates a formula from a character vector. If length(termlabels) > 1, its elements are concatenated with +. Non-syntactic names (e.g. containing spaces or special characters; see make.names) must be protected with backticks (see examples). A non-parseable response still works for now, back compatibly, with a deprecation warning.

Usage

delete.response(termobj)
reformulate(termlabels, response = NULL, intercept = TRUE, env = parent.frame())
drop.terms(termobj, dropx = NULL, keep.response = FALSE)
Arguments

- **termobj**: A terms object
- **termlabels**: character vector giving the right-hand side of a model formula. Cannot be zero-length.
- **response**: character string, symbol or call giving the left-hand side of a model formula, or NULL.
- **intercept**: logical: should the formula have an intercept?
- **env**: the environment of the formula returned.
- **dropx**: vector of positions of variables to drop from the right-hand side of the model.
- **keep.response**: Keep the response in the resulting object?

Value

delete.response and drop.terms return a terms object.
reformulate returns a formula.

See Also

- **terms**

Examples

```r
ff <- y ~ z + x + w
tt <- terms(ff)
tt
delete.response(tt)
drop.terms(tt, 2:3, keep.response = TRUE)
tt[-1]
tt[2:3]
reformulate(attr(tt, "term.labels"))
```

```r
## keep LHS:
reformulate("x\*w", ff[[2]])
```

```r
fS <- surv(ft, case) ~ a + b
reformulate(c("a", "b*f"), fS[[2]])
```

```r
## using non-syntactic names:
reformulate(c("P/E", "% Growth"), response = as.name("+-"))
```

```r
x <- c("a name", "another name")
tryCatch( reformulate(x), error = function(e) "Syntax error."
)
```

```r
## rather backquote the strings in x:
reformulate(sprintf("\`%s\`", x))
```

```r
stopifnot(identical(~ var, reformulate("var")),
               identical(~ a + b + c, reformulate(letters[1:3])),
               identical( y ~ a + b, reformulate(letters[1:2], "y"))
)
```
**dendrapply**

Apply a Function to All Nodes of a Dendrogram

**Description**

Apply function **FUN** to each node of a **dendrogram** recursively. When \( y \leftarrow \text{dendrapply}(x, \text{fn}) \), then \( y \) is a dendrogram of the same graph structure as \( x \) and for each node, \( y.\text{node}[j] \leftarrow \text{FUN}(x.\text{node}[j], \ldots) \) (where \( y.\text{node}[j] \) is an (invalid!) notation for the \( j \)-th node of \( y \)).

**Usage**

\[
\text{dendrapply}(X, \text{FUN}, \ldots)
\]

**Arguments**

- **X**: an object of class "**dendrogram**".
- **FUN**: an R function to be applied to each dendrogram node, typically working on its **attributes** alone, returning an altered version of the same node.
- \( \ldots \)**: potential further arguments passed to **FUN**.

**Value**

Usually a dendrogram of the same (graph) structure as \( X \). For that, the function must be conceptually of the form **FUN** <- \{ **attributes**(X) <- \ldots; X \}, i.e., returning the node with some attributes added or changed.

**Note**

The implementation is somewhat experimental and suggestions for enhancements (or nice examples of usage) are very welcome. The current implementation is **recursive** and inefficient for dendrograms with many non-leaves. See the ‘Warning’ in **dendrogram**.

**Author(s)**

Martin Maechler

**See Also**

- **as.dendrogram**, **lapply** for applying a function to each component of a list. **rapply** for doing so to each non-list component of a nested list.

**Examples**

```r
require(graphics)

## a smallish simple dendrogram
dhc <- as.dendrogram(hc <- hclust(dist(USArrests), "ave"))
(dhc21 <- dhc[[2]][[1]])

## too simple:
dendrapply(dhc21, function(n) utils::str(attributes(n)))
```
dendrogram

## toy example to set colored leaf labels:
local({
  colLab <- function(n) {
    if(is.leaf(n)) {
      a <- attributes(n)
      i <<- i+1
      attr(n, "nodePar") <-
        c(a$nodePar, list(lab.col = mycols[i], lab.font = i%%3))
    }
    n
  }
  mycols <- grDevices::rainbow(attr(dhc21,"members"))
  i <<- 0
})
dL <- dendrapply(dhc21, colLab)
op <- par(mfrow = 2:1)
plot(dhc21)
plot(dL) ## --> colored labels!
par(op)

dendrogram

General Tree Structures

### Description

Class "dendrogram" provides general functions for handling tree-like structures. It is intended as a replacement for similar functions in hierarchical clustering and classification/regression trees, such that all of these can use the same engine for plotting or cutting trees.

#### Usage

as.dendrogram(object, ...)
## S3 method for class 'hclust'
as.dendrogram(object, hang = -1, check = TRUE, ...)

## S3 method for class 'dendrogram'
as.hclust(x, ...)

## S3 method for class 'dendrogram'
plot(x, type = c("rectangle", "triangle"),
    center = FALSE,
    edge.root = is.leaf(x) || !is.null(attr(x, "edgetext")),
    nodePar = NULL, edgePar = list(),
    leaflab = c("perpendicular", "textlike", "none"),
    dLeaf = NULL, xlab = ",", ylab = "", xaxt = "n", yaxt = "s",
    horiz = FALSE, frame.plot = FALSE, xlim, ylim, ...)

## S3 method for class 'dendrogram'
cut(x, h, ...)

## S3 method for class 'dendrogram'
merge(x, y, ..., height,
adjust = c("auto", "add.max", "none")

## S3 method for class 'dendrogram'
nobs(object, ...)

## S3 method for class 'dendrogram'
print(x, digits, ...)

## S3 method for class 'dendrogram'
rev(x)

## S3 method for class 'dendrogram'
str(object, max.level = NA, digits.d = 3, 
give.attr = FALSE, wid = getOption("width"), 
nest.lev = 0, indent.str = "", 
last.str = getOption("str.dendrogram.last"), stem = "--", 
...)

is.leaf(object)

Arguments

object any R object that can be made into one of class "dendrogram".

x, y object(s) of class "dendrogram".

hang numeric scalar indicating how the height of leaves should be computed from the heights of their parents; see plot.hclust.

check logical indicating if object should be checked for validity. This check is not necessary when x is known to be valid such as when it is the direct result of hclust(). The default is check=TRUE, e.g. for protecting against memory explosion with invalid inputs.

type type of plot.

center logical; if TRUE, nodes are plotted centered with respect to the leaves in the branch. Otherwise (default), plot them in the middle of all direct child nodes.

edge.root logical; if true, draw an edge to the root node.

nodePar a list of plotting parameters to use for the nodes (see points) or NULL by default which does not draw symbols at the nodes. The list may contain components named pch, cex, col, xpd, and/or bg each of which can have length two for specifying separate attributes for inner nodes and leaves. Note that the default of pch is 1:2, so you may want to use pch = NA if you specify nodePar.

edgePar a list of plotting parameters to use for the edge segments and labels (if there's an edgetext). The list may contain components named col, lty and lwd (for the segments), p.col, p.lwd, and p.lty (for the polygon around the text) and t.col for the text color. As with nodePar, each can have length two for differentiating leaves and inner nodes.

leaflab a string specifying how leaves are labeled. The default "perpendicular" write text vertically (by default). "textlike" writes text horizontally (in a rectangle), and "none" suppresses leaf labels.

dLeaf a number specifying the distance in user coordinates between the tip of a leaf and its label. If NULL as per default, 3/4 of a letter width or height is used.
The dendrogram is directly represented as a nested list where each component corresponds to a branch of the tree. Hence, the first branch of tree \( z \) is \( z[[1]] \), the second branch of the corresponding subtree is \( z[[1]][[2]] \), or shorter \( z[[c(1,2)]] \), etc.. Each node of the tree carries some information needed for efficient plotting or cutting as attributes, of which only members, height and leaf for leaves are compulsory:

- **members**: total number of leaves in the branch
- **height**: numeric non-negative height at which the node is plotted.
- **midpoint**: numeric horizontal distance of the node from the left border (the leftmost leaf) of the branch (unit 1 between all leaves). This is used for plot(*, center = FALSE).
- **label**: character; the label of the node
- **x.member** for cut()$upper, the number of *former* members; more generally a substitute for the members component used for ‘horizontal’ (when horiz = FALSE, else ‘vertical’) alignment.
- **edgetext**: character; the label for the edge leading to the node
- **nodePar**: a named list (of length-1 components) specifying node-specific attributes for points plotting, see the nodePar argument above.
- **edgePar**: a named list (of length-1 components) specifying attributes for segments plotting of the edge leading to the node, and drawing of the edgetext if available, see the edgePar argument above.
- **leaf**: logical, if TRUE, the node is a leaf of the tree.
cut.dendrogram() returns a list with components \$upper and \$lower, the first is a truncated version of the original tree, also of class dendrogram, the latter a list with the branches obtained from cutting the tree, each a dendrogram.

There are \([,\) print, and str methods for "dendrogram" objects where the first one (extraction) ensures that selecting sub-branches keeps the class, i.e., returns a dendrogram even if only a leaf. On the other hand, \([\) (single bracket) extraction returns the underlying list structure.

Objects of class "hclust" can be converted to class "dendrogram" using method as.dendrogram(), and since R 2.13.0, there is also a as.hclust() method as an inverse.

rev.dendrogram simply returns the dendrogram \(x\) with reversed nodes, see also reorder.dendrogram.

The merge\((x, y, \ldots)\) method merges two or more dendrograms into a new one which has \(x\) and \(y\) (and optional further arguments) as branches. Note that before R 3.1.2, adjust = "none" was used implicitly, which is invalid when, e.g., the dendrograms are from as.dendrogram(hclust(\(\ldots\))).

nobs(object) returns the total number of leaves (the members attribute, see above).

is.leaf(object) returns logical indicating if \(object\) is a leaf (the most simple dendrogram).

plotNode() and plotNodeLimit() are helper functions.

**Warning**

Some operations on dendrograms such as merge() make use of recursion. For deep trees it may be necessary to increase options("expressions"): if you do, you are likely to need to set the C stack size (Cstack_info())[["size"]] larger than the default where possible.

**Note**

plot(): When using type = "triangle", center = TRUE often looks better.

str(d): If you really want to see the internal structure, use str(unclass(d)) instead.

**See Also**

dendrapply for applying a function to each node. order.dendrogram and reorder.dendrogram; further, the labels method.

**Examples**

```r
require(graphics); require(utils)

hc <- hclust(dist(USArrests), "ave")
(dend1 <- as.dendrogram(hc)) # "print()" method
str(dend1) # "str()" method
str(dend1, max.level = 2, last.str = "") # only the first two sub-levels
oo <- options(str.dendrogram.last = \\) # yet another possibility
str(dend1, max.level = 2) # only the first two sub-levels
options(oo) # .. resetting them

op <- par(mfrow = c(2,2), mar = c(5,2,1,4))
plot(dend1)
## "triangle" type and show inner nodes:
plot(dend1, nodePar = list(pch = c(1,NA), cex = 0.8, lab.cex = 0.8),
     type = "t", center = TRUE)
plot(dend1, edgePar = list(col = 1:2, lty = 2:3),
     dLeaf = 1, edge.root = TRUE)
```
plot(dend1, nodePar = list(pch = 2:1, cex = .4*2:1, col = 2:3),
     horiz = TRUE)

## simple test for as.hclust() as the inverse of as.dendrogram():
stopifnot(identical(as.hclust(dend1)[1:4], hc[1:4]))

dend2 <- cut(dend1, h = 70)
## leaves are wrong horizontally in R 4.0 and earlier:
pplot(dend2$upper)

## dend2$lower is *NOT* a dendrogram, but a list of ..:
pplot(dend2$lower[[3]], nodePar = list(col = 4), horiz = TRUE, type = "tr")

## "inner" and "leaf" edges in different type & color:
pplot(dend2$lower[[2]], nodePar = list(col = 1),
       edgePar = list(ly = 1:2, col = 2:1), edge.root = TRUE)
par(op)
d2 <- dend2$lower[[2]][[2]][[1]]
stopifnot(identical(d3, dend2$lower[[2]][[c(2,1)]]))
str(d3, last.str = "")

## to peek at the inner structure "if you must", use '[...]' indexing :
str(d3[[2]][[1]]) ## or the full
str(d3[])

## merge() to join dendrograms:
(d13 <- merge(dend2$lower[[1]], dend2$lower[[3]]))
## merge() all parts back (using default 'height' instead of original one):
den.1 <- Reduce(merge, dend2$lower)
## or merge() all four parts at same height --> 4 branches (!)
d. <- merge(dend2$lower[[1]], dend2$lower[[2]], dend2$lower[[3]],
            dend2$lower[[4]])
## (with a warning) or the same using do.call :
stopifnot(identical(d., do.call(merge, dend2$lower)))
plot(d., main = "merge(d1, d2, d3, d4) |-> dendrogram with a 4-split")

## "Zoom" in to the first dendrogram :
pplot(dend1, xlim = c(1,20), ylim = c(1,50))
nP <- list(col = 3:2, cex = c(2.0, 0.75), pch = 21:22,
bg = c("light blue", "pink"),
         lab.cex = 0.75, lab.col = "tomato")
plot(d3, nodePar = nP, edgePar = list(col = "gray", lwd = 2), horiz = TRUE)
addE <- function(n) {
  if(is.leaf(n)) {
    attr(n, "edgePar") <- list(p.col = "plum")
    attr(n, "edgetext") <- paste(attr(n,"members"),"members")
  } n
}
d3e <- dendrapply(d3, addE)
plot(d3e, nodePar = nP)
plot(d3e, nodePar = nP, leaflab = "textlike")

---

density

---

**Kernel Density Estimation**
Description

The (S3) generic function density computes kernel density estimates. Its default method does so with the given kernel and bandwidth for univariate observations.

Usage

density(x, ...)

## Default S3 method:
density(x, bw = "nrd0", adjust = 1,
   kernel = c("gaussian", "epanechnikov", "rectangular",
               "triangular", "biweight",
               "cosine", "optcosine"),
   weights = NULL, window = kernel, width,
   give.Rkern = FALSE, subdensity = FALSE,
   warnWbw = var(weights) > 0,
   n = 512, from, to, cut = 3, ext = 4,
   old.coords = FALSE,
   na.rm = FALSE, ...)

Arguments

x the data from which the estimate is to be computed. For the default method a numeric vector: long vectors are not supported.

bw the smoothing bandwidth to be used. The kernels are scaled such that this is the standard deviation of the smoothing kernel. (Note this differs from the reference books cited below.)

bw can also be a character string giving a rule to choose the bandwidth. See bw.nrd. The default, "nrd0", has remained the default for historical and compatibility reasons, rather than as a general recommendation, where e.g., "SJ" would rather fit, see also Venables and Ripley (2002).

The specified (or computed) value of bw is multiplied by adjust.

adjust the bandwidth used is actually adjust*bw. This makes it easy to specify values like 'half the default’ bandwidth.

kernel, window a character string giving the smoothing kernel to be used. This must partially match one of "gaussian", "rectangular", "triangular", "epanechnikov", "biweight", "cosine" or "optcosine", with default "gaussian", and may be abbreviated to a unique prefix (single letter).

"cosine" is smoother than "optcosine", which is the usual 'cosine' kernel in the literature and almost MSE-efficient. However, "cosine" is the version used by S.

weights numeric vector of non-negative observation weights, hence of same length as x. The default NULL is equivalent to weights = rep(1/nx, nx) where nx is the length of (the finite entries of) x[]. If na.rm = TRUE and there are NA’s in x, they and the corresponding weights are removed before computations. In that case, when the original weights have summed to one, they are re-scaled to keep doing so.

Note that weights are not taken into account for automatic bandwidth rules, i.e., when bw is a string. When the weights are proportional to true counts cn, density(x = rep(x, cn)) may be used instead of weights.
width

this exists for compatibility with S; if given, and bw is not, will set bw to width
if this is a character string, or to a kernel-dependent multiple of width if this is
numeric.
give.Rkern

logical; if true, no density is estimated, and the ‘canonical bandwidth’ of the
chosen kernel is returned instead.
subdensity

used only when weights are specified which do not sum to one. When true, it
indicates that a “sub-density” is desired and no warning should be signalled. By
default, when false, a warning is signalled when the weights do not sum to one.
warnWbw

logical, used only when weights are specified and bw is character, i.e., automatic
bandwidth selection is chosen (as by default). When true (as by default), a warning is signalled to alert the user that automatic bandwidth selection will
not take the weights into account and hence may be suboptimal.
n
the number of equally spaced points at which the density is to be estimated.
When n > 512, it is rounded up to a power of 2 during the calculations (as fft is
used) and the final result is interpolated by approx. So it almost always makes
sense to specify n as a power of two.
from, to

the left and right-most points of the grid at which the density is to be estimated;
the defaults are cut * bw outside of range(x).
cut

by default, the values of from and to are cut bandwidths beyond the extremes
of the data. This allows the estimated density to drop to approximately zero at
the extremes.
inf

a positive extension factor, 4 by default. The values from and to are further extended on both sides to
lo <- from - ext * bw and up <- to + ext * bw which are then used to build the grid used for the FFT and interpolation, see n above.
Do not change unless you know what you are doing!
old.coords

logical to require pre-R 4.4.0 behaviour which gives too large values by a
factor of about $1 + 1/(2n - 2)$.
na.rm

logical; if TRUE, missing values are removed from x. If FALSE any missing values
cause an error.
... further arguments for (non-default) methods.

Details

The algorithm used in density.default disperses the mass of the empirical distribution function
over a regular grid of at least 512 points and then uses the fast Fourier transform to convolve this
approximation with a discretized version of the kernel and then uses linear approximation to evaluate
the density at the specified points.
The statistical properties of a kernel are determined by

$$\sigma_K^2 = \int t^2 K(t) dt$$

which is always

1 for our kernels (and hence the bandwidth bw is the standard deviation of the kernel) and

$$R(K) = \int K(t) dt.$$ MSE-equivalent bandwidths (for different kernels) are proportional to $\sigma_K R(K)$ which is scale invariant and for our kernels equal to $R(K)$. This value is returned when give.Rkern = TRUE. See the examples for using exact equivalent bandwidths.
Infinite values in x are assumed to correspond to a point mass at +/-Inf and the density estimate is
of the sub-density on (-Inf, +Inf).

Value

If give.Rkern is true, the number $R(K)$, otherwise an object with class "density" whose under-
lying structure is a list containing the following components.
density

x
the n coordinates of the points where the density is estimated.
y
the estimated density values. These will be non-negative, but can be zero.
bw
the bandwidth used.
n
the sample size after elimination of missing values.
call
the call which produced the result.
data.name
the deparsed name of the x argument.
has.na
logical, for compatibility (always FALSE).

The print method reports summary values on the x and y components.

### deriv

**Symbolic and Algorithmic Derivatives of Simple Expressions**

**Description**

Compute derivatives of simple expressions, symbolically and algorithmically.

**Usage**

\[ \text{D (expr, name)} \]

\[ \text{deriv(expr, \ldots)} \]

\[ \text{deriv3(expr, \ldots)} \]

**Arguments**

| expr | a expression or call or (except D) a formula with no lhs. |
| name, namevec | character vector, giving the variable names (only one for D()) with respect to which derivatives will be computed. |
| function.arg | if specified and non-NULL, a character vector of arguments for a function return, or a function (with empty body) or TRUE, the latter indicating that a function with argument names namevec should be used. |
| tag | character; the prefix to be used for the locally created variables in result. Must be no longer than 60 bytes when translated to the native encoding. |
| hessian | a logical value indicating whether the second derivatives should be calculated and incorporated in the return value. |
| ... | arguments to be passed to or from methods. |
Details

D is modeled after its S namesake for taking simple symbolic derivatives.

deriv is a generic function with a default and a formula method. It returns a call for computing the expr and its (partial) derivatives, simultaneously. It uses so-called algorithmic derivatives. If function.arg is a function, its arguments can have default values, see the fx example below.

Currently, deriv.formula just calls deriv.default after extracting the expression to the right of ~.

deriv3 and its methods are equivalent to deriv and its methods except that hessian defaults to TRUE for deriv3.

The internal code knows about the arithmetic operators +, -, *, / and ^, and the single-variable functions exp, log, sin, cos, tan, sinh, cosh, sqrt, pnorm, dnorm, asin, acos, atan, gamma, lgamma, digamma and trigamma, as well as psigamma for one or two arguments (but derivative only with respect to the first). (Note that only the standard normal distribution is considered.) Since R 3.4.0, the single-variable functions log1p, expm1, log2, log10, cospi, sinpi, tanpi, factorial, and 1factorial are supported as well.

Value

D returns a call and therefore can easily be iterated for higher derivatives.

deriv and deriv3 normally return an expression object whose evaluation returns the function values with a "gradient" attribute containing the gradient matrix. If hessian is TRUE the evaluation also returns a "hessian" attribute containing the Hessian array.

If function.arg is not NULL, deriv and deriv3 return a function with those arguments rather than an expression.

References

See Also

nlm and optim for numeric minimization which could make use of derivatives.

Examples

### formula argument :

```r
dx2x <- deriv(~ x^2, "x") ; dx2x
```

### Not run: expression{

```r
 .value <- x^2
 .grad <- array(0, c(length(.value), 1), list(NULL, c("x")))
 .grad[,"x"] <- 2 * x
 attr(.value, "gradient") <- .grad
 .value
}
```

### End(Not run)

```r
mode(dx2x)
x <- -1:2
eval(dx2x)
```
## Something 'tougher':
trig.exp <- expression(sin(cos(x + y^2)))
(D.sc <- D(trig.exp, "x"))
all.equal(D(trig.exp[[1]], "x"), D.sc)

(dxy <- deriv(trig.exp, c("x", "y")))
y <- 1
eval(dxy)
eval(D.sc)

## function returned:
deriv(y ~ sin(cos(x) * y)), c("x","y"), function.arg = TRUE)

## function with defaulted arguments:
(fx <- deriv(y ~ b0 + b1 * 2^(-x/th), c("b0", "b1", "th"),
          function(b0, b1, th, x = 1:7()) ) )
fx(2, 3, 4)

## First derivative
D(expression(x^2), "x")
stopifnot(D(as.name("x"), "x") == 1)

## Higher derivatives
deriv3(y ~ b0 + b1 * 2^(-x/th), c("b0", "b1", "th"),
       c("b0", "b1", "th", "x" ) )

## Higher derivatives:
DD <- function(expr, name, order = 1) {
  if(order < 1) stop("order' must be >= 1")
  if(order == 1) D(expr, name)
  else DD(D(expr, name), name, order - 1)
}
DD(expression(sin(x^2)), "x", 3)

## New (R 3.4.0, 2017):
D(quote(log1p(x^2)), "x")
stopifnot(identical(D(quote(log1p(x^2)), "x"),
                      D(quote(log(1+x^2)), "x")))
D(quote(expm1(x^2)), "x")
stopifnot(identical(D(quote(expm1(x^2)), "x"),
                      quote(exp(x^2) * (2 * x))))
D(quote(sinpi(x^2)), "x")
D(quote(cospi(x^2)), "x")
D(quote(tanpi(x^2)), "x")
stopifnot(identical(D(quote(log2 (x^2)), "x"),...
deviance

\[
\text{quote}(2 \times x/(x^2 \times \log(2)))
\]

\[
\text{identical}(D(\text{quote}(\log_{10}(x^2)), "x"),
\text{quote}(2 \times x/(x^2 \times \log(10))))
\]

---

**deviance**

*Model Deviance*

**Description**

Returns the deviance of a fitted model object.

**Usage**

\[
\text{deviance}(\text{object, ...})
\]

**Arguments**

- `object` - an object for which the deviance is desired.
- `...` - additional optional argument.

**Details**

This is a generic function which can be used to extract deviances for fitted models. Consult the individual modeling functions for details on how to use this function.

**Value**

The value of the deviance extracted from the object `object`.

**References**

**See Also**

- `df.residual`, `extractAIC`, `glm`, `lm`.

---

**df.residual**

*Residual Degrees-of-Freedom*

**Description**

Returns the residual degrees-of-freedom extracted from a fitted model object.

**Usage**

\[
\text{df.residual}(\text{object, ...})
\]
Arguments

object an object for which the degrees-of-freedom are desired.
...
additional optional arguments.

Details

This is a generic function which can be used to extract residual degrees-of-freedom for fitted models. Consult the individual modeling functions for details on how to use this function.

The default method just extracts the df.residual component.

Value

The value of the residual degrees-of-freedom extracted from the object x.

See Also

deviance, glm, lm.

---

diffinv Discrete Integration: Inverse of Differencing

Description

Computes the inverse function of the lagged differences function diff.

Usage

diffinv(x, ...)

## Default S3 method:
diffinv(x, lag = 1, differences = 1, xi, ...)
## S3 method for class 'ts'
diffinv(x, lag = 1, differences = 1, xi, ...)  

Arguments

x a numeric vector, matrix, or time series.
lag a scalar lag parameter.
differences an integer representing the order of the difference.
xi a numeric vector, matrix, or time series containing the initial values for the integrals. If missing, zeros are used.
... arguments passed to or from other methods.

Details

diffinv is a generic function with methods for class "ts" and default for vectors and matrices. Missing values are not handled.
**Value**

A numeric vector, matrix, or time series (the latter for the "ts" method) representing the discrete integral of \(x\).

**Author(s)**

A. Trapletti

**See Also**

diff

**Examples**

```r
s <- 1:10
d <- diff(s)
diffinv(d, xi = 1)
```

---

**dist**

*Distance Matrix Computation*

**Description**

This function computes and returns the distance matrix computed by using the specified distance measure to compute the distances between the rows of a data matrix.

**Usage**

```r
dist(x, method = "euclidean", diag = FALSE, upper = FALSE, p = 2)
as.dist(m, diag = FALSE, upper = FALSE)
## Default S3 method:
as.dist(m, diag = FALSE, upper = FALSE)
## S3 method for class 'dist'
print(x, diag = NULL, upper = NULL,
digits = getOption("digits"), justify = "none",
right = TRUE, ...)
## S3 method for class 'dist'
as.matrix(x, ...)
```

**Arguments**

- **x**: a numeric matrix, data frame or "dist" object.
- **method**: the distance measure to be used. This must be one of "euclidean", "maximum", "manhattan", "canberra", "binary" or "minkowski". Any unambiguous substring can be given.
- **diag**: logical value indicating whether the diagonal of the distance matrix should be printed by `print.dist`. 

---
logical value indicating whether the upper triangle of the distance matrix should be printed by `print.dist`.

- `m`: The power of the Minkowski distance.

An object with distance information to be converted to a "dist" object. For the default method, a "dist" object, or a matrix (of distances) or an object which can be coerced to such a matrix using `as.matrix()`. (Only the lower triangle of the matrix is used, the rest is ignored).

digits, justify passed to `format` inside of `print()`.

Additional arguments, passed to other methods.

Details

Available distance measures are (written for two vectors `x` and `y`):

- **euclidean**: Usual distance between the two vectors (2 norm aka $L_2$), $\sqrt{\sum_i (x_i - y_i)^2}$.
- **maximum**: Maximum distance between two components of `x` and `y` (supremum norm)
- **manhattan**: Absolute distance between the two vectors (1 norm aka $L_1$).
- **canberra**: $\sum_i |x_i - y_i|/(|x_i| + |y_i|)$. Terms with zero numerator and denominator are omitted from the sum and treated as if the values were missing.

This is intended for non-negative values (e.g., counts), in which case the denominator can be written in various equivalent ways; Originally, R used $x_i + y_i$, then from 1998 to 2017, $|x_i| + |y_i|$, and then the correct $|x_i| + |y_i|.

- **binary**: (aka asymmetric binary): The vectors are regarded as binary bits, so non-zero elements are ‘on’ and zero elements are ‘off’. The distance is the proportion of bits in which only one is on amongst those in which at least one is on. This also called “Jaccard” distance in some contexts. Here, two all-zero observations have distance 0, whereas in traditional Jaccard definitions, the distance would be undefined for that case and give NaN numerically.

- **minkowski**: The $p$ norm, the $p$-th root of the sum of the $p$-th powers of the differences of the components.

Missing values are allowed, and are excluded from all computations involving the rows within which they occur. Further, when Inf values are involved, all pairs of values are excluded when their contribution to the distance gave NaN or NA. If some columns are excluded in calculating a Euclidean, Manhattan, Canberra or Minkowski distance, the sum is scaled up proportionally to the number of columns used. If all pairs are excluded when calculating a particular distance, the value is NA.

The "dist" method of `as.matrix()` and `as.dist()` can be used for conversion between objects of class "dist" and conventional distance matrices.

`as.dist()` is a generic function. Its default method handles objects inheriting from class "dist", or coercible to matrices using `as.matrix()`. Support for classes representing distances (also known as dissimilarities) can be added by providing an `as.matrix()` or, more directly, an `as.dist` method for such a class.

Value

`dist` returns an object of class "dist".

The lower triangle of the distance matrix stored by columns in a vector, say do. If `n` is the number of observations, i.e., `n <- attr(do, "Size")`, then for $i < j \leq n$, the dissimilarity between (row) $i$ and $j$ is $d_0[n * (i - 1) - i * (i - 1)/2 + j - 1]$. The length of the vector is $n * (n - 1)/2$, i.e., of order $n^2$.

The object has the following attributes (besides "class" equal to "dist"): 
**dist**

Size: integer, the number of observations in the dataset.

Labels: optionally, contains the labels, if any, of the observations of the dataset.

Diag, Upper: logicals corresponding to the arguments diag and upper above, specifying how the object should be printed.

call: optionally, the call used to create the object.

method: optionally, the distance method used; resulting from `dist()`, the `(match.arg())ed` method argument.

daisy in the cluster package with more possibilities in the case of mixed (continuous / categorical) variables. hclust.

---

**Examples**

```r
require(graphics)

x <- matrix(rnorm(100), nrow = 5)
dist(x)
dist(x, diag = TRUE)
dist(x, upper = TRUE)
m <- as.matrix(dist(x))
d <- as.dist(m)
stopifnot(d == dist(x))

## Use correlations between variables "as distance"

dd <- as.dist((1 - cor(USJudgeRatings))/2)
round(1000 * dd) # (prints more nicely)
plot(hclust(dd)) # to see a dendrogram of clustered variables

## example of binary and canberra distances.

x <- c(0, 0, 1, 1, 1, 1)
y <- c(1, 0, 1, 1, 0, 1)
dist(rbind(x, y), method = "binary")
## answer 0.4 = 2/5
dist(rbind(x, y), method = "canberra")
## answer 2 * (6/5)

## To find the names
labels(eurodist)

## Examples involving "Inf":
## 1)
x[6] <- Inf
(m2 <- rbind(x, y))
dist(m2, method = "binary") # warning, answer 0.5 = 2/4
```

---
## These all give "Inf":

```r
testifnot(Inf == dist(m2, method = "euclidean"),
          Inf == dist(m2, method = "maximum"),
          Inf == dist(m2, method = "manhattan"))
```

## "Inf" is same as very large number:

```r
x1 <- x; x1[6] <- 1e100
stopifnot(dist(cbind(x, y), method = "canberra") ==
          print(dist(cbind(x1, y), method = "canberra")))
```

## 2)

```r
y[6] <- Inf #-> 6-th pair is excluded
dist(rbind(x, y), method = "binary" )  # warning; 0.5
dist(rbind(x, y), method = "canberra" )  # 3
dist(rbind(x, y), method = "maximum")  # 1
dist(rbind(x, y), method = "manhattan") # 2.4
```

---

### Distributions in the stats package

#### Description

Density, cumulative distribution function, quantile function and random variate generation for many standard probability distributions are available in the `stats` package.

#### Details

The functions for the density/mass function, cumulative distribution function, quantile function and random variate generation are named in the form `dxxx`, `pxxx`, `qxxx` and `rxxx` respectively.

- For the beta distribution see `dbeta`.
- For the binomial (including Bernoulli) distribution see `dbinom`.
- For the Cauchy distribution see `dcauchy`.
- For the chi-squared distribution see `dchisq`.
- For the exponential distribution see `dexp`.
- For the F distribution see `df`.
- For the gamma distribution see `dgamma`.
- For the geometric distribution see `dgeom`. (This is also a special case of the negative binomial.)
- For the hypergeometric distribution see `dhyper`.
- For the log-normal distribution see `dlnorm`.
- For the multinomial distribution see `dmultinom`.
- For the normal distribution see `dnorm`.
- For the negative binomial distribution see `dnbinom`.
- For the normal distribution see `dnorm`.
- For the Poisson distribution see `dpois`.
- For the Student’s t distribution see `dt`.
- For the uniform distribution see `dunif`.
- For the Weibull distribution see `dweibull`.
- For less common distributions of test statistics see `pbirthday`, `dsignrank`, `ptukey` and `dwilcox` (and see the ‘See Also’ section of `cor.test`).
Description

This extracts coefficients in terms of the original levels of the coefficients rather than the coded variables.

Usage

```r
dummy.coef(object, ...)
```

```r
## S3 method for class 'lm'
dummy.coef(object, use.na = FALSE, ...)
```

```r
## S3 method for class 'aovlist'
dummy.coef(object, use.na = FALSE, ...)
```

Arguments

- **object**: a linear model fit.
- **use.na**: logical flag for coefficients in a singular model. If `use.na` is true, undetermined coefficients will be missing; if false they will get one possible value.
- **...**: arguments passed to or from other methods.

Details

A fitted linear model has coefficients for the contrasts of the factor terms, usually one less in number than the number of levels. This function re-expresses the coefficients in the original coding; as the coefficients will have been fitted in the reduced basis, any implied constraints (e.g., zero sum for `contr helmert` or `contr.sum`) will be respected. There will be little point in using `dummy.coef` for `contr.treatment` contrasts, as the missing coefficients are by definition zero.

The method used has some limitations, and will give incomplete results for terms such as `poly(x, 2)`. However, it is adequate for its main purpose, `aov` models.

Value

A list giving for each term the values of the coefficients. For a multistratum `aov` model, such a list for each stratum.

Warning

This function is intended for human inspection of the output: it should not be used for calculations. Use coded variables for all calculations.

The results differ from S for singular values, where S can be incorrect.

See Also

ecdf

Empirical Cumulative Distribution Function

Description

Compute an empirical cumulative distribution function, with several methods for plotting, printing and computing with such an “ecdf” object.

Usage

eecdf(x)

## S3 method for class 'ecdf'
plot(x, ..., ylab="Fn(x)", verticals = FALSE,
    col.01line = "gray70", pch = 19)

## S3 method for class 'ecdf'
print(x, digits = getOption("digits") - 2, ...)

## S3 method for class 'ecdf'
summary(object, ...)

## S3 method for class 'ecdf'
quantile(x, ...)

Arguments

x, object  numeric vector of the observations for ecdf; for the methods, an object inheriting from class "ecdf".

...  arguments to be passed to subsequent methods, e.g., plot.stepfun for the plot method.

ylab  label for the y-axis.

verticals  see plot.stepfun.

col.01line  numeric or character specifying the color of the horizontal lines at y = 0 and 1, see colors.

pch  plotting character.

digits  number of significant digits to use, see print.
The e.c.d.f. (empirical cumulative distribution function) $F_n$ is a step function with jumps $i/n$ at observation values, where $i$ is the number of tied observations at that value. Missing values are ignored.

For observations $x = (x_1, x_2, \ldots, x_n)$, $F_n$ is the fraction of observations less or equal to $t$, i.e.,

$$F_n(t) = \frac{\# \{x_i \leq t\}}{n} = \frac{1}{n} \sum_{i=1}^{n} 1[x_i \leq t].$$

The function `plot.ecdf` which implements the `plot` method for ecdf objects, is implemented via a call to `plot.stepfun`; see its documentation.

For `ecdf`, a function of class "ecdf", inheriting from the "stepfun" class, and hence inheriting a `knots()` method.

For the summary method, a summary of the knots of object with a "header" attribute.

The `quantile(obj, ...)` method computes the same quantiles as `quantile(x, ...)` would where $x$ is the original sample.

The objects of class "ecdf" are not intended to be used for permanent storage and may change structure between versions of R (and did at R 3.0.0). They can usually be re-created by

```r
eval(attr(old_obj, "call"), environment(old_obj))
```

since the data used is stored as part of the object’s environment.

Author(s)
Martin Maechler; fixes and new features by other R-core members.

See Also
`stepfun`, the more general class of step functions, `approxfun` and `splinefun`.

Examples
```r
### Simple didactical ecdf example :
x <- rnorm(12)
Fn <- ecdf(x)
Fn  # a *function*
Fn(x) # returns the percentiles for x
tt <- seq(-2, 2, by = 0.1)
12 * Fn(tt) # Fn is a 'simple' function (with values k/12)
summary(Fn)
## see below for graphics
knots(Fn)  # the unique data values (12 of them if there were no ties)

y <- round(rnorm(12), 1); y[3] <- y[1]
Fn12 <- ecdf(y)
Fn12
```
knots(Fn12) # unique values (always less than 12!)
summary(Fn12)
summary.stepfun(Fn12)

## Advanced: What's inside the function closure?
ls(environment(Fn12))
## "f" "method" "na.rm" "nobs" "x" "y" "yleft" "yright"
utils::ls.str(environment(Fn12))
stopifnot(all.equal(quantile(Fn12), quantile(y)))

###----------------- Plotting --------------------------
require(graphics)
op <- par(mfrow = c(3, 1), mgp = c(1.5, 0.8, 0), mar = .1+c(3,3,2,1))
F10 <- ecdf(rnorm(10))
plot(F10)
plot(Fn12, lwd = 2) ; mtext("lwd = 2", adj = 1)
xx <- unique(sort(c(seq(-3, 2, length.out = 201), knots(Fn12))))
lines(xx, Fn12(xx), col = "blue")
abline(v = knots(Fn12), lty = 2, col = "gray70")

## luxury plot
plot(Fn12, verticals = TRUE, col.hor = "red", col.vert = "bisque")

##-- this works too (automatic call to ecdf(.)):
plot.ecdf(rnorm(24))
title("via simple plot.ecdf(x)", adj = 1)
par(op)

---

**eff.aovlist**

*Compute Efficiencies of Multistratum Analysis of Variance*

**Description**

Computes the efficiencies of fixed-effect terms in an analysis of variance model with multiple strata.

**Usage**

`eff.aovlist(aovlist)`

**Arguments**

- `aovlist` The result of a call to `aov` with an `Error` term.
Details

Fixed-effect terms in an analysis of variance model with multiple strata may be estimable in more than one stratum, in which case there is less than complete information in each. The efficiency for a term is the fraction of the maximum possible precision (inverse variance) obtainable by estimating in just that stratum. Under the assumption of balance, this is the same for all contrasts involving that term.

This function is used to pick strata in which to estimate terms in `model.tables.aovlist` and `se.contrast.aovlist`.

In many cases terms will only occur in one stratum, when all the efficiencies will be one: this is detected and no further calculations are done.

The calculation used requires orthogonal contrasts for each term, and will throw an error if non-orthogonal contrasts (e.g., treatment contrasts or an unbalanced design) are detected.

Value

A matrix giving for each non-pure-error stratum (row) the efficiencies for each fixed-effect term in the model.

Examples

```r
## An example from Yates (1932),
## a 2*3 design in 2 blocks replicated 4 times

Block <- gl(8, 4)
A <- factor(c(0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,
            0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1))
B <- factor(c(0,0,1,1,0,0,1,1,0,1,0,1,0,1,0,1,0,1,0,1,
            0,0,1,1,0,0,1,1,0,1,0,1,0,1,0,1,0,1,0,1))
C <- factor(c(0,1,1,0,1,0,0,1,0,0,1,1,0,0,1,1,0,0,1,1,
            1,0,1,0,0,1,1,1,1,1,0,0))
Yield <- c(101, 373, 398, 291, 312, 106, 265, 450, 106, 306, 324, 449,
          272, 89, 407, 338, 87, 324, 279, 471, 323, 128, 423, 334,
          131, 103, 445, 437, 324, 361, 302, 272)
aovdat <- data.frame(Block, A, B, C, Yield)

old <- getOption("contrasts")
options(contrasts = c("contr.helmert", "contr.poly"))

(fit <- aov(Yield ~ A*B*C + Error(Block), data = aovdat))

eff.aovlist(fit)
options(contrasts = old)
```
effects

Effects from Fitted Model

Description

Returns (orthogonal) effects from a fitted model, usually a linear model. This is a generic function, but currently only has a methods for objects inheriting from classes "lm" and "glm".

Usage

```r
effects(object, ...)  
## S3 method for class 'lm'
effects(object, set.sign = FALSE, ...)
```

Arguments

- `object` an R object; typically, the result of a model fitting function such as `lm`.
- `set.sign` logical. If `TRUE`, the sign of the effects corresponding to coefficients in the model will be set to agree with the signs of the corresponding coefficients, otherwise the sign is arbitrary.
- `...` arguments passed to or from other methods.

Details

For a linear model fitted by `lm` or `aov`, the effects are the uncorrelated single-degree-of-freedom values obtained by projecting the data onto the successive orthogonal subspaces generated by the QR decomposition during the fitting process. The first \( r \) (the rank of the model) are associated with coefficients and the remainder span the space of residuals (but are not associated with particular residuals).

Empty models do not have effects.

Value

A (named) numeric vector of the same length as `residuals`, or a matrix if there were multiple responses in the fitted model, in either case of class "coef".

The first \( r \) rows are labelled by the corresponding coefficients, and the remaining rows are unlabelled. Note that in rank-deficient models the corresponding coefficients will be in a different order if pivoting occurred.

References

See Also

`coef`
Examples

```r
y <- c(1:3, 7, 5)
x <- c(1:3, 6:7)
( ee <- effects(lm(y ~ x)) )
c( round(ee - effects(lm(y+10 ~ I(x-3.8))), 3) )
# just the first is different
```

embed

Embedding a Time Series

Description

Embeds the time series `x` into a low-dimensional Euclidean space.

Usage

```r
embed (x, dimension = 1)
```

Arguments

- `x`: a numeric vector, matrix, or time series.
- `dimension`: a scalar representing the embedding dimension.

Details

Each row of the resulting matrix consists of sequences `x[t]`, `x[t-1]`, ..., `x[t-dimension+1]`, where `t` is the original index of `x`. If `x` is a matrix, i.e., `x` contains more than one variable, then `x[t]` consists of the `t`-th observation on each variable.

Value

A matrix containing the embedded time series `x`.

Author(s)

A. Trapletti, B.D. Ripley

Examples

```r
x <- 1:10
embed (x, 3)
```
expand.model.frame  

Add new variables to a model frame

Description

Evaluates new variables as if they had been part of the formula of the specified model. This ensures that the same na.action and subset arguments are applied and allows, for example, $x$ to be recovered for a model using $\sin(x)$ as a predictor.

Usage

```r
expand.model.frame(model, extras, 
                   envir = environment(formula(model)), 
                   na.expand = FALSE)
```

Arguments

- **model**: a fitted model
- **extras**: one-sided formula or vector of character strings describing new variables to be added
- **envir**: an environment to evaluate things in
- **na.expand**: logical; see below

Details

If `na.expand = FALSE` then NA values in the extra variables will be passed to the `na.action` function used in `model`. This may result in a shorter data frame (with `na.omit`) or an error (with `na.fail`). If `na.expand = TRUE` the returned data frame will have precisely the same rows as `model.frame(model)`, but the columns corresponding to the extra variables may contain NA.

Value

A data frame.

See Also

`model.frame`, `predict`

Examples

```r
model <- lm(log(Volume) ~ log(Girth) + log(Height), data = trees)
expand.model.frame(model, ~ Girth) # prints data.frame like

dd <- data.frame(x = 1:5, y = rnorm(5), z = c(1,2,NA,4,5))
model <- glm(y ~ x, data = dd, subset = 1:4, na.action = na.omit)
expand.model.frame(model, "z", na.expand = FALSE) # = default
expand.model.frame(model, "z", na.expand = TRUE)
```
The Exponential Distribution

Description

Density, distribution function, quantile function and random generation for the exponential distribution with rate rate (i.e., mean 1/rate).

Usage

dexp(x, rate = 1, log = FALSE)
pexp(q, rate = 1, lower.tail = TRUE, log.p = FALSE)
qexp(p, rate = 1, lower.tail = TRUE, log.p = FALSE)
rexp(n, rate = 1)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
rate vector of rates.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[ X \leq x ] \), otherwise, \( P[ X > x ] \).

Details

If rate is not specified, it assumes the default value of 1.
The exponential distribution with rate \( \lambda \) has density

\[
f(x) = \lambda e^{-\lambda x}
\]

for \( x \geq 0 \).

Value

dexp gives the density, pexp gives the distribution function, qexp gives the quantile function, and rexp generates random deviates.
The length of the result is determined by n for rexp, and is the maximum of the lengths of the numerical arguments for the other functions.
The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

The cumulative hazard \( H(t) = -\log(1 - F(t)) \) is \(-\text{pexp}(t, r, \text{lower} = \text{FALSE}, \log = \text{TRUE})\).
dexp, pexp and qexp are all calculated from numerically stable versions of the definitions.

rexp uses

**References**

**See Also**

exp for the exponential function.

Distributions for other standard distributions, including dgamma for the gamma distribution and dweibull for the Weibull distribution, both of which generalize the exponential.

**Examples**

dexp(1) - exp(-1) # ~ 0

```r
rsunif <- function(n) { n1 <- n+1
cE <- cumsum(rexp(n1)); cE[seq_len(n)]/cE[n1] } 
plot(rsunif(1000), ylim=0:1, pch=".")
abline(0,1/(1000+1), col=adjustcolor(1, 0.5))
```

---

**extractAIC**

*Extract AIC from a Fitted Model*

**Description**

Computes the (generalized) Akaike An Information Criterion for a fitted parametric model.

**Usage**

```r
extractAIC(fit, scale, k = 2, ...)
```

**Arguments**

- `fit` fitted model, usually the result of a fitter like `lm`.
- `scale` optional numeric specifying the scale parameter of the model, see `scale` in `step`. Currently only used in the "lm" method, where `scale` specifies the estimate of the error variance, and `scale = 0` indicates that it is to be estimated by maximum likelihood.
- `k` numeric specifying the ‘weight’ of the equivalent degrees of freedom (≡ edf) part in the AIC formula.
- `...` further arguments (currently unused in base R).
Details

This is a generic function, with methods in base R for classes "aov", "glm" and "lm" as well as for "negbin" (package MASS) and "coxph" and "survreg" (package survival).

The criterion used is

\[
AIC = -2 \log L + k \times \text{edf},
\]

where \( L \) is the likelihood and edf the equivalent degrees of freedom (i.e., the number of free parameters for usual parametric models) of fit.

For linear models with unknown scale (i.e., for \( \text{lm} \) and \( \text{aov} \)), \(-2 \log L\) is computed from the deviance and uses a different additive constant to \( \logL \) and hence AIC. If \( RSS \) denotes the (weighted) residual sum of squares then extractAIC uses for \(-2 \log L\) the formulae \( RSS/s - n \) (corresponding to Mallows’ \( C_p \)) in the case of known scale \( s \) and \( n \log(RSS/n) \) for unknown scale. AIC only handles unknown scale and uses the formula \( n \log(RSS/n) + n + n \log 2\pi - \sum \log w \) where \( w \) are the weights. Further AIC counts the scale estimation as a parameter in the edf and extractAIC does not.

For \( \text{glm} \) fits the family’s \( \text{aic}() \) function is used to compute the AIC: see the note under \( \logL \) about the assumptions this makes.

\( k = 2 \) corresponds to the traditional AIC, using \( k = \log(n) \) provides the BIC (Bayesian IC) instead.

Note that the methods for this function may differ in their assumptions from those of methods for AIC (usually via a method for \( \logL \)). We have already mentioned the case of "lm" models with estimated scale, and there are similar issues in the "glm" and "negbin" methods where the dispersion parameter may or may not be taken as ‘free’. This is immaterial as extractAIC is only used to compare models of the same class (where only differences in AIC values are considered).

Value

A numeric vector of length 2, with first and second elements giving

- edf: the ‘equivalent degrees of freedom’ for the fitted model \( \text{fit} \).
- AIC: the (generalized) Akaike Information Criterion for \( \text{fit} \).

Note

This function is used in \text{add1}, \text{drop1} and \text{step} and the similar functions in package 	ext{MASS} from which it was adopted.

Examples

utils::example(glm)
extractAIC(glm.D93) #>> 5 15.129
factanal  

Factor Analysis

Description

Perform maximum-likelihood factor analysis on a covariance matrix or data matrix.

Usage

factanal(x, factors, data = NULL, covmat = NULL, n.obs = NA,
        subset, na.action, start = NULL,
        scores = c("none", "regression", "Bartlett"),
        rotation = "varimax", control = NULL, ...)

Arguments

x  A formula or a numeric matrix or an object that can be coerced to a numeric matrix.
factors  The number of factors to be fitted.
data  An optional data frame (or similar: see model.frame), used only if x is a formula. By default the variables are taken from environment(formula).
covmat  A covariance matrix, or a covariance list as returned by cov.wt. Of course, correlation matrices are covariance matrices.
n.obs  The number of observations, used if covmat is a covariance matrix.
subset  A specification of the cases to be used, if x is used as a matrix or formula.
na.action  The na.action to be used if x is used as a matrix or formula.
start  NULL or a matrix of starting values, each column giving an initial set of uniquenesses.
scores  Type of scores to produce, if any. The default is none, "regression" gives Thompson's scores, "Bartlett" given Bartlett's weighted least-squares scores. Partial matching allows these names to be abbreviated.
rotation  character. "none" or the name of a function to be used to rotate the factors: it will be called with first argument the loadings matrix, and should return a list with component loadings giving the rotated loadings, or just the rotated loadings.
control  A list of control values,

  nstart  The number of starting values to be tried if start = NULL. Default 1.
  trace  logical. Output tracing information? Default FALSE.
  lower  The lower bound for uniquenesses during optimization. Should be > 0. Default 0.005.
  opt  A list of control values to be passed to optim's control argument.
  rotate  a list of additional arguments for the rotation function.

...  Components of control can also be supplied as named arguments to factanal.
The factor analysis model is

\[ x = \Lambda f + e \]

for a \( p \)-element vector \( x \), a \( p \times k \) matrix \( \Lambda \) of loadings, a \( k \)-element vector \( f \) of scores and a \( p \)-element vector \( e \) of errors. None of the components other than \( x \) is observed, but the major restriction is that the scores be uncorrelated and of unit variance, and that the errors be independent with variances \( \Psi \), the uniquenesses. It is also common to scale the observed variables to unit variance, and done in this function.

Thus factor analysis is in essence a model for the correlation matrix of \( x \),

\[ \Sigma = \Lambda \Lambda' + \Psi \]

There is still some indeterminacy in the model for it is unchanged if \( \Lambda \) is replaced by \( GA \) for any orthogonal matrix \( G \). Such matrices \( G \) are known as rotations (although the term is applied also to non-orthogonal invertible matrices).

If \( \text{covmat} \) is supplied it is used. Otherwise \( x \) is used if it is a matrix, or a formula \( x \) is used with \( \text{data} \) to construct a model matrix, and that is used to construct a covariance matrix. (It makes no sense for the formula to have a response, and all the variables must be numeric.) Once a covariance matrix is found or calculated from \( x \), it is converted to a correlation matrix for analysis. The correlation matrix is returned as component \( \text{correlation} \) of the result.

The fit is done by optimizing the log likelihood assuming multivariate normality over the uniquenesses. (The maximizing loadings for given uniquenesses can be found analytically: Lawley & Maxwell (1971, p. 27).) All the starting values supplied in \( \text{start} \) are tried in turn and the best fit obtained is used. If \( \text{start} = \text{NULL} \) then the first fit is started at the value suggested by Jöreskog (1963) and given by Lawley & Maxwell (1971, p. 31), and then \( \text{control}$\text{nstart} - 1 \) other values are tried, randomly selected as equal values of the uniquenesses.

The uniquenesses are technically constrained to lie in \([0, 1]\), but near-zero values are problematical, and the optimization is done with a lower bound of \( \text{control}$\text{lower} \), default 0.005 (Lawley & Maxwell, 1971, p. 32).

Scores can only be produced if a data matrix is supplied and used. The first method is the regression method of Thomson (1951), the second the weighted least squares method of Bartlett (1937, 8). Both are estimates of the unobserved scores \( f \). Thomson’s method regresses (in the population) the unknown \( f \) on \( x \) to yield

\[ \hat{f} = \Lambda \Sigma^{-1} x \]

and then substitutes the sample estimates of the quantities on the right-hand side. Bartlett’s method minimizes the sum of squares of standardized errors over the choice of \( f \), given (the fitted) \( \Lambda \).

If \( x \) is a formula then the standard \( \text{NA} \)-handling is applied to the scores (if requested): see \( \text{napredict} \).

The \text{print} method (documented under \text{loadings}) follows the factor analysis convention of drawing attention to the patterns of the results, so the default precision is three decimal places, and small loadings are suppressed.

Value

An object of class “factanal” with components

- \text{loadings}: A matrix of loadings, one column for each factor. The factors are ordered in decreasing order of sums of squares of loadings, and given the sign that will make the sum of the loadings positive. This is of class “loadings”: see \text{loadings} for its \text{print} method.
- \text{uniquenesses}: The uniquenesses computed.
correlation  The correlation matrix used.
criteria    The results of the optimization: the value of the criterion (a linear function of
             the negative log-likelihood) and information on the iterations used.
factors     The argument factors.
dof         The number of degrees of freedom of the factor analysis model.
method      The method: always "mle".
rotmat      The rotation matrix if relevant.
scores      If requested, a matrix of scores. napredict is applied to handle the treatment
             of values omitted by the na.action.
n.obs       The number of observations if available, or NA.
call        The matched call.
na.action   If relevant.
STATISTIC, PVAL The significance-test statistic and P value, if it can be computed.

Note

There are so many variations on factor analysis that it is hard to compare output from different
programs. Further, the optimization in maximum likelihood factor analysis is hard, and many other
examples we compared had less good fits than produced by this function. In particular, solutions
which are ‘Heywood cases’ (with one or more uniquenesses essentially zero) are much more com-
mon than most texts and some other programs would lead one to believe.

---

**factor.scope**

*Compute Allowed Changes in Adding to or Dropping from a Formula*

**Description**

add.scope and drop.scope compute those terms that can be individually added to or dropped from a model while respecting the hierarchy of terms.

**Usage**

add.scope(terms1, terms2)

drop.scope(terms1, terms2)

factor.scope(factor, scope)

**Arguments**

- **terms1**
  - the terms or formula for the base model.

- **terms2**
  - the terms or formula for the upper (add.scope) or lower (drop.scope) scope. If missing for drop.scope it is taken to be the null formula, so all terms (except any intercept) are candidates to be dropped.

- **factor**
  - the "factor" attribute of the terms of the base object.

- **scope**
  - a list with one or both components drop and add giving the "factor" attribute of the lower and upper scopes respectively.

**Details**

factor.scope is not intended to be called directly by users.

**Value**

For add.scope and drop.scope a character vector of terms labels. For factor.scope, a list with components drop and add, character vectors of terms labels.
See Also

add1, drop1, aov, lm

Examples

add.scope(~ a + b + c + a:b, ~ (a + b + c)^3)
# [1] "a:c"  "b:c"
drop.scope(~ a + b + c + a:b)
# [1] "c"    "a:b"

family

Family Objects for Models

Description

Family objects provide a convenient way to specify the details of the models used by functions such as glm. See the documentation for glm for the details on how such model fitting takes place.

Usage

family(object, ...)

binomial(link = "logit")
gaussian(link = "identity")
Gamma(link = "inverse")
inverse.gaussian(link = "1/mu^2")
poisson(link = "log")
quasi(link = "identity", variance = "constant")
quasibinomial(link = "logit")
quasipoisson(link = "log")

Arguments

link

a specification for the model link function. This can be a name/expression, a literal character string, a length-one character vector, or an object of class "link-glm" (such as generated by make.link) provided it is not specified via one of the standard names given next.

The gaussian family accepts the links (as names) identity, log and inverse; the binomial family the links logit, probit, cauchit, (corresponding to logistic, normal and Cauchy CDFs respectively) log and cloglog (complementary log-log); the Gamma family the links inverse, identity and log; the poisson family the links log, identity, and sqrt; and the inverse.gaussian family the links 1/mu^2, inverse, identity and log.

The quasi family accepts the links logit, probit, cloglog, identity, inverse, log, 1/mu^2 and sqrt, and the function power can be used to create a power link function.

for all families other than quasi, the variance function is determined by the family. The quasi family will accept the literal character string (or unquoted as a name/expression) specifications "constant", "mu(1-mu)", "mu", "mu^2" and "mu^3", a length-one character vector taking one of those values, or a list containing components varfun, validmu, dev.resids, initialize and name.
family object the function family accesses the family objects which are stored within objects created by modelling functions (e.g., glm).

... further arguments passed to methods.

Details

family is a generic function with methods for classes "glm" and "lm" (the latter returning gaussian()).

For the binomial and quasibinomial families the response can be specified in one of three ways:

1. As a factor: 'success' is interpreted as the factor not having the first level (and hence usually of having the second level).
2. As a numerical vector with values between 0 and 1, interpreted as the proportion of successful cases (with the total number of cases given by the weights).
3. As a two-column integer matrix: the first column gives the number of successes and the second the number of failures.

The quasibinomial and quasipoisson families differ from the binomial and poisson families only in that the dispersion parameter is not fixed at one, so they can model over-dispersion. For the binomial case see McCullagh and Nelder (1989, pp. 124–8). Although they show that there is (under some restrictions) a model with variance proportional to mean as in the quasi-binomial model, note that glm does not compute maximum-likelihood estimates in that model. The behaviour of S is closer to the quasi- variants.

Value

An object of class "family" (which has a concise print method). This is a list with elements

- family character: the family name.
- link character: the link name.
- linkfun function: the link.
- linkinv function: the inverse of the link function.
- variance function: the variance as a function of the mean.
- dev.resids function giving the deviance for each observation as a function of (y, mu, wt), used by the residuals method when computing deviance residuals.
- aic function giving the AIC value if appropriate (but NA for the quasi- families). More precisely, this function returns $-2\ell + 2s$, where $\ell$ is the log-likelihood and $s$ is the number of estimated scale parameters. Note that the penalty term for the location parameters (typically the "regression coefficients") is added elsewhere, e.g., in glm.fit() or AIC(), see the AIC example in glm. See logLik for the assumptions made about the dispersion parameter.
- mu.eta function: derivative of the inverse-link function with respect to the linear predictor. If the inverse-link function is $\mu = g^{-1}(\eta)$ where $\eta$ is the value of the linear predictor, then this function returns $d(g^{-1})/d\eta = d\mu/d\eta$.
- initialize expression. This needs to set up whatever data objects are needed for the family as well as n (needed for AIC in the binomial family) and mustart (see glm).
- validmu logical function. Returns TRUE if a mean vector mu is within the domain of variance.
- valideta logical function. Returns TRUE if a linear predictor eta is within the domain of linkinv.
simulate (optional) function `simulate(object, nsim)` to be called by the "lm" method of `simulate`. It will normally return a matrix with `nsim` columns and one row for each fitted value, but it can also return a list of length `nsim`. Clearly this will be missing for 'quasi-' families.

dispersion (optional since R version 4.0.0) numeric: value of the dispersion parameter, if fixed, or NA_real if free.

**Note**

The link and variance arguments have rather awkward semantics for back-compatibility. The recommended way is to supply them as quoted character strings, but they can also be supplied unquoted (as names or expressions). Additionally, they can be supplied as a length-one character vector giving the name of one of the options, or as a list (for `link`, of class "link-glm"). The restrictions apply only to links given as names: when given as a character string all the links known to `make.link` are accepted.

This is potentially ambiguous: supplying `link = logit` could mean the unquoted name of a link or the value of object `logit`. It is interpreted if possible as the name of an allowed link, then as an object. (You can force the interpretation to always be the value of an object via `logit[1]`.)

**Author(s)**

The design was inspired by S functions of the same names described in Hastie & Pregibon (1992) (except quasibinomial and quasipoisson).

**References**

**See Also**

`glm`, `power`, `make.link`.

For binomial coefficients, `choose`; the binomial and negative binomial distributions, `Binomial`, and `NegBinomial`.

**Examples**

```r
require(utils) # for str

nf <- gaussian() # Normal family
nf
str(nf)

gf <- Gamma()
gf
str(gf)
gf$linkinv
gf$variance(-3:4) #== (.5)^2
```
## Binomial with default 'logit' link: Check some properties visually:

```r
bi <- binomial()
et <- seq(-10, 10, by=1/8)
plot(et, bi$mu.eta(et), type="l")
```

## show that mu.eta() is derivative of linkinv():

```r
lines((et[-1]+et[-length(et)])/2, col=adjustcolor("red", 1/4),
diff(bi$linkinv(et))/diff(et), type="l", lwd=4)
```

## which here is the logistic density:

```r
lines(et, dlogis(et), lwd=3, col=adjustcolor("blue", 1/4))
```

```r
stopifnot(exprs = {
  all.equal(bi$mu.eta(et), dlogis(et))
  all.equal(bi$linkinv(et), plogis(et) -> m)
  all.equal(bi$linkfun(m), qlogis(m)) # logit(.)  ==  qlogis(.) !
})
```

## Data from example(glm):

```r
d.AD <- data.frame(treatment = gl(3,3),
  outcome = gl(3,1,9),
  counts = c(18,17,15, 20,10,20, 25,13,12))
glm.D93 <- glm(counts ~ outcome + treatment, d.AD, family = poisson())
```

## Quasipoisson: compare with above / example(glm):

```r
glm.qD93 <- glm(counts ~ outcome + treatment, d.AD, family = quasipoisson())
```

```r
glm.qD93
anova (glm.qD93, test = "F")
summary(glm.qD93)
```

## for Poisson results (same as from 'glm.D93' !) use

```r
anova (glm.qD93, dispersion = 1, test = "Chisq")
summary(glm.qD93, dispersion = 1)
```

## Example of user-specified link, a logit model for p^days

**See Shaffer, T. 2004. Auk 121(2): 526-540.**

```r
logexp <- function(days = 1)
{
  linkfun <- function(mu) qlogis(mu^(1/days))
  linkinv <- function(eta) plogis(eta)^(eta -> m) * 
    binomial()$mu.eta(eta)
  valideta <- function(eta) TRUE
  link <- paste0("logexp(", days, ")")
  structure(list(linkfun = linkfun, linkinv = linkinv,
    mu.eta = mu.eta, valideta = valideta, name = link),
    class = "link-glm")
}
(bil3 <- binomial(logexp(3)))
```

## in practice this would be used with a vector of 'days', in
## which case use an offset of 0 in the corresponding formula
## to get the null deviance right.

## Binomial with identity link: often not a good idea, as both
## computationally and conceptually difficult:

```r
binomial(link = "identity")  ## is exactly the same as
binomial(link = make.link("identity"))
```
## tests of quasi

```r
x <- rnorm(100)
y <- rpois(100, exp(1+x))
glm(y ~ x, family = quasi(variance = "mu", link = "log"))
# which is the same as
glm(y ~ x, family = poisson)
glm(y ~ x, family = quasi(variance = "mu^2", link = "log"))
## Not run: glm(y ~ x, family = quasi(variance = "mu^3", link = "log")) # fails
y <- rbinom(100, 1, plogis(x))
# need to set a starting value for the next fit
glm(y ~ x, family = quasi(variance = "mu(1-mu)", link = "logit"), start = c(0,1))
```

---

### FDist

#### The F Distribution

**Description**

Density, distribution function, quantile function and random generation for the F distribution with `df1` and `df2` degrees of freedom (and optional non-centrality parameter `ncp`).

**Usage**

```r
df(x, df1, df2, ncp, log = FALSE)
pf(q, df1, df2, ncp, lower.tail = TRUE, log.p = FALSE)
qf(p, df1, df2, ncp, lower.tail = TRUE, log.p = FALSE)
rf(n, df1, df2, ncp)
```

**Arguments**

- `x`, `q` vector of quantiles.
- `p` vector of probabilities.
- `n` number of observations. If `length(n) > 1`, the length is taken to be the number required.
- `df1, df2` degrees of freedom. `Inf` is allowed.
- `ncp` non-centrality parameter. If omitted the central F is assumed.
- `log, log.p` logical; if TRUE, probabilities `p` are given as log(`p`).
- `lower.tail` logical; if TRUE (default), probabilities are `P[X ≤ x]`, otherwise, `P[X > x]`.

**Details**

The F distribution with `df1 = ν1` and `df2 = ν2` degrees of freedom has density

\[
f(x) = \frac{Γ(ν1/2 + ν2/2)}{Γ(ν1/2)Γ(ν2/2)} \left( \frac{ν1}{ν2} \right)^{ν1/2} x^{ν1/2-1} \left( 1 + \frac{ν1 x}{ν2} \right)^{-(ν1+ν2)/2}
\]

for `x > 0`.

The F distribution’s cumulative distribution function (cdf), \( F_{ν1, ν2} \), fulfills (Abramowitz & Stegun 26.6.2, p.946) \( F_{ν1, ν2}(qF) = 1 - I_x(ν2/2, ν1/2) = I_{1-x}(ν1/2, ν2/2) \), where \( x := \frac{ν2}{ν2 + ν1 qF} \), and \( I_x(a, b) \) is the incomplete beta function; in R, \( \text{pbeta}(x, a, b) \).
It is the distribution of the ratio of the mean squares of $\nu_1$ and $\nu_2$ independent standard normals, and hence of the ratio of two independent chi-squared variates each divided by its degrees of freedom. Since the ratio of a normal and the root mean-square of $m$ independent normals has a Student’s $t_m$ distribution, the square of a $t_m$ variate has a $F$ distribution on $1$ and $m$ degrees of freedom.

The non-central $F$ distribution is again the ratio of mean squares of independent normals of unit variance, but those in the numerator are allowed to have non-zero means and ncp is the sum of squares of the means. See Chisquare for further details on non-central distributions.

**Value**

$df$ gives the density, $pf$ gives the distribution function $qf$ gives the quantile function, and $rf$ generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by $n$ for $rf$, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than $n$ are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Note**

Supplying ncp = 0 uses the algorithm for the non-central distribution, which is not the same algorithm used if ncp is omitted. This is to give consistent behaviour in extreme cases with values of ncp very near zero.

The code for non-zero ncp is principally intended to be used for moderate values of ncp: it will not be highly accurate, especially in the tails, for large values.

**Source**

For the central case of $df$, computed via a binomial probability, code contributed by Catherine Loader (see dbinom); for the non-central case computed via dbeta, code contributed by Peter Ruckdeschel.

For $pf$, via pbeta (or for large df2, via pchisq).

For $qf$, via qchisq for large df2, else via qbeta.

**References**

**See Also**

Distributions for other standard distributions, including dchisq for chi-squared and dt for Student’s $t$ distributions.
Examples

```r
## Equivalence of pt(., nu) with pf(.^2, 1, nu):
x <- seq(0.001, 5, length.out = 100)
nu <- 4
stopifnot(all.equal(2*pt(x, nu) - 1, pf(x^2, 1, nu)),
  ## upper tails:
  all.equal(2*pt(x, nu, lower.tail=FALSE),
  pf(x^2, 1, nu, lower.tail=FALSE)))
## the density of the square of a t_m is 2*dt(x, m)/(2*x)
all.equal(df(x^2, 1, 5), dt(x, 5)/x)
## Identity (F <-> t): qf(2*p - 1, 1, df) == qt(p, df)^2 for p >= 1/2
p <- seq(1/2, .99, length.out = 50); df <- 10
rel.err <- function(x, y) ifelse(x == y, 0, abs(x-y)/mean(abs(c(x,y))))
stopifnot(all.equal(qf(2*p - 1, df1 = 1, df2 = df),
  qt(p, df)^2))
## Identity (F <-> Beta <-> incompl.beta):
n1 <- 7; n2 <- 12; qF <- c((0:4)/4, 1.5, 2:16)
x <- n2/(n2 + n1*qF)
stopifnot(all.equal(pf(qF, n1, n2, lower.tail=FALSE),
  pbeta(x, n2/2, n1/2)))
```

fft

Fast Discrete Fourier Transform (FFT)

Description

Computes the Discrete Fourier Transform (DFT) of an array with a fast algorithm, the “Fast Fourier Transform” (FFT).

Usage

```r
fft(z, inverse = FALSE)
mvfft(z, inverse = FALSE)
```

Arguments

- `z`: a real or complex array containing the values to be transformed. Long vectors are not supported.
- `inverse`: if TRUE, the unnormalized inverse transform is computed (the inverse has a \( + \) in the exponent of \( e \), but here, we do not divide by \( 1/\text{length}(x) \)).

Value

When `z` is a vector, the value computed and returned by `fft` is the unnormalized univariate discrete Fourier transform of the sequence of values in `z`. Specifically, \( y[\ell] = \sum_{k=1}^{n} z[k] \exp(-2\pi i (k-1)(\ell-1)/n) \)
for \( h = 1, \ldots, n \) where \( n = \text{length}(y) \). If \texttt{inverse} is TRUE, \( \exp(-2\pi \ldots) \) is replaced with \( \exp(2\pi \ldots) \).

When \( z \) contains an array, \texttt{fft} computes and returns the multivariate (spatial) transform. If \texttt{inverse} is TRUE, the (unnormalized) inverse Fourier transform is returned, i.e., if \( y \leftarrow \text{fft}(z) \), then \( z \) is \( \text{fft}(y, \text{inverse} = \text{TRUE}) / \text{length}(y) \).

By contrast, \texttt{mvfft} takes a real or complex matrix as argument, and returns a similar shaped matrix, but with each column replaced by its discrete Fourier transform. This is useful for analyzing vector-valued series.

The FFT is fastest when the length of the series being transformed is highly composite (i.e., has many factors). If this is not the case, the transform may take a long time to compute and will use a large amount of memory.

**Source**

**References**

**See Also**

\texttt{convolve, nextn}.

**Examples**

```r
x <- 1:4
fft(x)
fft(fft(x), inverse = TRUE)/length(x)
```

```r
## Slow Discrete Fourier Transform (DFT) - e.g., for checking the formula
fft0 <- function(z, inverse=FALSE) {
  n <- length(z)
  if(n == 0) return(z)
  k <- 0:(n-1)
  ff <- (if(inverse) 1 else -1) * 2*pi * 1i * k/n
  vapply(1:n, function(h) sum(z * exp(ff*(h-1))), complex(1))
}

relD <- function(x,y) 2* abs(x - y) / abs(x + y)
n <- 2^8
z <- complex(n, rnorm(n), rnorm(n))
## relative differences in the order of 4*10^{-14} :
summary(relD(fft(z), fft0(z)))
summary(relD(fft(z, inverse=TRUE), fft0(z, inverse=TRUE)))
```
Description

Applies linear filtering to a univariate time series or to each series separately of a multivariate time series.

Usage

filter(x, filter, method = c("convolution", "recursive"),
       sides = 2, circular = FALSE, init)

Arguments

- **x**: a univariate or multivariate time series.
- **filter**: a vector of filter coefficients in reverse time order (as for AR or MA coefficients).
- **method**: Either "convolution" or "recursive" (and can be abbreviated). If "convolution" a moving average is used: if "recursive" an autoregression is used.
- **sides**: for convolution filters only. If sides = 1 the filter coefficients are for past values only; if sides = 2 they are centred around lag 0. In this case the length of the filter should be odd, but if it is even, more of the filter is forward in time than backward.
- **circular**: for convolution filters only. If TRUE, wrap the filter around the ends of the series, otherwise assume external values are missing (NA).
- **init**: for recursive filters only. Specifies the initial values of the time series just prior to the start value, in reverse time order. The default is a set of zeros.

Details

Missing values are allowed in x but not in filter (where they would lead to missing values everywhere in the output).

Note that there is an implied coefficient 1 at lag 0 in the recursive filter, which gives

\[ y_t = x_t + f_1 y_{t-1} + \cdots + f_p y_{t-p} \]

No check is made to see if recursive filter is invertible: the output may diverge if it is not.

The convolution filter is

\[ y_t = f_1 x_{t+o} + \cdots + f_p x_{t+o-(p-1)} \]

where o is the offset: see sides for how it is determined.

Value

A time series object.
f 

Note

convolve(), type = "filter") uses the FFT for computations and so may be faster for long filters on univariate series, but it does not return a time series (and so the time alignment is unclear), nor does it handle missing values. filter is faster for a filter of length 100 on a series of length 1000, for example.

See Also

convolve, arima.sim

Examples

x <- 1:100
filter(x, rep(1, 3))
filter(x, rep(1, 3), sides = 1)
filter(x, rep(1, 3), sides = 1, circular = TRUE)

filter(presidents, rep(1, 3))

fisher.test

Fisher's Exact Test for Count Data

Description

Performs Fisher's exact test for testing the null of independence of rows and columns in a continuity table with fixed marginals.

Usage

fisher.test(x, y = NULL, workspace = 200000, hybrid = FALSE,
            hybridPars = c(expect = 5, percent = 80, Emin = 1),
            control = list(), or = 1, alternative = "two.sided",
            conf.int = TRUE, conf.level = 0.95,
            simulate.p.value = FALSE, B = 2000)

Arguments

x
a two-dimensional contingency table in matrix form, or a factor object.

y
a factor object; ignored if x is a matrix.

workspace
an integer specifying the size of the workspace used in the network algorithm. In units of 4 bytes. Only used for non-simulated p-values larger than 2 x 2 tables. Since R version 3.5.0. this also increases the internal stack size which allows larger problems to be solved, however sometimes needing hours. In such cases, simulate.p.value=TRUE may be more reasonable.

hybrid
a logical. Only used for larger than 2 x 2 tables, in which cases it indicates whether the exact probabilities (default) or a hybrid approximation thereof should be computed.

hybridPars
a numeric vector of length 3, by default describing ‘Cochran’s conditions’ for the validity of the chi-squared approximation, see ‘Details’.
control a list with named components for low level algorithm control. At present the only one used is "mult", a positive integer \( \geq 2 \) with default 30 used only for larger than \( 2 \times 2 \) tables. This says how many times as much space should be allocated to paths as to keys: see file ‘fexact.c’ in the sources of this package.

or the hypothesized odds ratio. Only used in the \( 2 \times 2 \) case.

alternative indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. Only used in the \( 2 \times 2 \) case.

conf.int logical indicating if a confidence interval for the odds ratio in a \( 2 \times 2 \) table should be computed (and returned).

conf.level confidence level for the returned confidence interval. Only used in the \( 2 \times 2 \) case

simulate.p.value a logical indicating whether to compute p-values by Monte Carlo simulation, in larger than \( 2 \times 2 \) tables.

\( B \) an integer specifying the number of replicates used in the Monte Carlo test.

Details

If \( x \) is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both \( x \) and \( y \) must be vectors or factors of the same length. Incomplete cases are removed, vectors are coerced into factor objects, and the contingency table is computed from these.

For \( 2 \times 2 \) cases, p-values are obtained directly using the (central or non-central) hypergeometric distribution. Otherwise, computations are based on a C version of the FORTRAN subroutine FEXACT which implements the network developed by Mehta and Patel (1983, 1986) and improved by Clarkson, Fan and Joe (1993). The FORTRAN code can be obtained from https://netlib.org/toms/643. Note this fails (with an error message) when the entries of the table are too large. (It transposes the table if necessary so it has no more rows than columns. One constraint is that the product of the row marginals be less than \( 2^{31} - 1 \).)

For \( 2 \times 2 \) tables, the null of conditional independence is equivalent to the hypothesis that the odds ratio equals one. ‘Exact’ inference can be based on observing that in general, given all marginal totals fixed, the first element of the contingency table has a non-central hypergeometric distribution with non-centrality parameter given by the odds ratio (Fisher, 1935). The alternative for a one-sided test is based on the odds ratio, so \( \text{alternative} = \text{"greater"} \) is a test of the odds ratio being bigger than or.

Two-sided tests are based on the odds ratio, so \( \text{alternative} = \text{"greater"} \) is a test of the odds ratio being bigger than or.

For larger than \( 2 \times 2 \) tables and \( \text{hybrid} = \text{TRUE} \), asymptotic chi-squared probabilities are only used if the ‘Cochran conditions’ (or modified version thereof) specified by \( \text{hybridPars} = \text{c(expect = 5, percent = 80, Emin = 1)} \) are satisfied, that is if no cell has expected counts less than 1 (= Emin) and more than 80% (= percent) of the cells have expected counts at least 5 (= expect), otherwise the exact calculation is used. A corresponding if() decision is made for all sub-tables considered. Accidentally, \( R \) has used 180 instead of 80 as percent, i.e., \( \text{hybridPars}[2] \) in \( R \) versions between 3.0.0 and 3.4.1 (inclusive), i.e., the 2nd of the \( \text{hybridPars} \) (all of which used to be hard-coded previous to \( R \) 3.5.0). Consequently, in these versions of \( R \), \( \text{hybrid=TRUE} \) never made a difference.

In the \( r \times c \) case with \( r > 2 \) or \( c > 2 \), internal tables can get too large for the exact test in which case an error is signalled. Apart from increasing workspace sufficiently, which then may lead to
very long running times, using `simulate.p.value = TRUE` may then often be sufficient and hence advisable.

Simulation is done conditional on the row and column marginals, and works only if the marginals are strictly positive. (A C translation of the algorithm of Patefield (1981) is used.) Note that the default number of replicates (`B = 2000`) implies a minimum p-value of about 0.0005 (`1/(B + 1)`).

**Value**

A list with class "htest" containing the following components:

- `p.value` the p-value of the test.
- `conf.int` a confidence interval for the odds ratio. Only present in the `2 x 2` case and if argument `conf.int = TRUE`.
- `estimate` an estimate of the odds ratio. Note that the conditional Maximum Likelihood Estimate (MLE) rather than the unconditional MLE (the sample odds ratio) is used. Only present in the `2 x 2` case.
- `null.value` the odds ratio under the null, or. Only present in the `2 x 2` case.
- `alternative` a character string describing the alternative hypothesis.
- `method` the character string "Fisher's Exact Test for Count Data".
- `data.name` a character string giving the name(s) of the data.

**References**

**See Also**

- `chisq.test`
- `fisher.exact` in package `exact2x2` for alternative interpretations of two-sided tests and confidence intervals for `2 x 2` tables.
Examples

## A British woman claimed to be able to distinguish whether milk or tea was added to the cup first. To test, she was given 8 cups of tea, in four of which milk was added first. The null hypothesis is that there is no association between the true order of pouring and the woman's guess, the alternative that there is a positive association (that the odds ratio is greater than 1).

```r
TeaTasting <- matrix(c(3, 1, 1, 3), nrow = 2, 
dimnames = list(Guess = c("Milk", "Tea"), 
Truth = c("Milk", "Tea")))
fisher.test(TeaTasting, alternative = "greater")
## => p = 0.2429, association could not be established
```

## Fisher (1962, 1970), Criminal convictions of like-sex twins
Convictions <- matrix(c(2, 10, 15, 3), nrow = 2, 
dimnames = list(c("Dizygotic", "Monozygotic"), 
c("Convicted", "Not convicted")))

```r
Convictions
fisher.test(Convictions, alternative = "less")
fisher.test(Convictions, conf.int = FALSE)
fisher.test(Convictions, conf.level = 0.95)$conf.int
fisher.test(Convictions, conf.level = 0.99)$conf.int
```

## A r x c table Agresti (2002, p. 57) Job Satisfaction
Job <- matrix(c(1, 2, 1, 0, 3, 3, 6, 1, 10, 10, 14, 9, 6, 7, 12, 11), 4, 4, 
dimnames = list(income = c("< 15k", "15-25k", "25-40k", "> 40k"), 
satisfaction = c("VeryD", "LittleD", "ModerateS", "VeryS")))

```r
fisher.test(Job) # 0.7827
fisher.test(Job, simulate.p.value = TRUE, B = 1e5) # also close to 0.78
```

## 6th example in Mehta & Patel's JASA paper
MP6 <- rbind(
c(1, 2, 1, 0, 1), 
c(2, 0, 2, 3, 0), 
c(0, 1, 1, 2, 7, 3), 
c(1, 1, 2, 0, 0, 1), 
c(0, 1, 1, 1, 0, 0))

```r
fisher.test(MP6)
# Exactly the same p-value, as Cochran's conditions are never met:
fisher.test(MP6, hybrid=TRUE)
```

fitted

Extract Model Fitted Values

fitted is a generic function which extracts fitted values from objects returned by modeling functions. fitted.values is an alias for it.

All object classes which are returned by model fitting functions should provide a fitted method. (Note that the generic is fitted and not fitted.values.)
Methods can make use of \texttt{napredict} methods to compensate for the omission of missing values. The default and \texttt{nls} methods do.

\textbf{Usage}

\begin{verbatim}
fitted(object, ...)  
fitted.values(object, ...)
\end{verbatim}

\textbf{Arguments}

- \texttt{object} an object for which the extraction of model fitted values is meaningful.
- \texttt{...} other arguments.

\textbf{Value}

Fitted values extracted from the object \texttt{object}.

\textbf{References}

\textbf{See Also}

\texttt{coefficients, glm, lm, residuals}.

\begin{verbatim}
fivenum(x, na.rm = TRUE)
\end{verbatim}

\textbf{Arguments}

- \texttt{x} numeric, maybe including NAs and ±Inf.s.
- \texttt{na.rm} logical; if TRUE, all NA and NaNs are dropped, before the statistics are computed.

\textbf{Value}

A numeric vector of length 5 containing the summary information. See \texttt{boxplot.stats} for more details.

\textbf{See Also}

\texttt{IQR, boxplot.stats, median, quantile, range}.

\textbf{Examples}

\begin{verbatim}
fivenum(c(rnorm(100), -1:1/0))
\end{verbatim}
fligner.test  

Fligner-Killeen Test of Homogeneity of Variances

Description

Performs a Fligner-Killeen (median) test of the null that the variances in each of the groups (samples) are the same.

Usage

fligner.test(x, ...)

## Default S3 method:
fligner.test(x, g, ...)

## S3 method for class 'formula'
fligner.test(formula, data, subset, na.action, ...)

Arguments

x  
a numeric vector of data values, or a list of numeric data vectors.

g  
a vector or factor object giving the group for the corresponding elements of x. Ignored if x is a list.

formula  
a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.

data  
an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset  
an optional vector specifying a subset of observations to be used.

na.action  
a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").

...  
further arguments to be passed to or from methods.

Details

If x is a list, its elements are taken as the samples to be compared for homogeneity of variances, and hence have to be numeric data vectors. In this case, g is ignored, and one can simply use fligner.test(x) to perform the test. If the samples are not yet contained in a list, use fligner.test(list(x, ...)).

Otherwise, x must be a numeric data vector, and g must be a vector or factor object of the same length as x giving the group for the corresponding elements of x.

The Fligner-Killeen (median) test has been determined in a simulation study as one of the many tests for homogeneity of variances which is most robust against departures from normality, see Conover, Johnson & Johnson (1981). It is a k-sample simple linear rank which uses the ranks of the absolute values of the centered samples and weights \( a(i) = \text{qnorm}(1+i/(n+1))/2 \). The version implemented here uses median centering in each of the samples (F-K:med \( X^2 \) in the reference).
A list of class "htest" containing the following components:

- **statistic**: the Fligner-Killeen:med $X^2$ test statistic.
- **parameter**: the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- **p.value**: the p-value of the test.
- **method**: the character string “Fligner-Killeen test of homogeneity of variances”.
- **data.name**: a character string giving the names of the data.

**References**

**See Also**

- `ansari.test` and `mood.test` for rank-based two-sample test for a difference in scale parameters;
- `var.test` and `bartlett.test` for parametric tests for the homogeneity of variances.

**Examples**

```r
require(graphics)
plot(count ~ spray, data = InsectSprays)
fligner.test(InsectSprays$count, InsectSprays$spray)
fligner.test(count ~ spray, data = InsectSprays)
## Compare this to bartlett.test()
```

**Description**

The generic function `formula` and its specific methods provide a way of extracting formulae which have been included in other objects.

`as.formula` is almost identical, additionally preserving attributes when object already inherits from "formula".

**Usage**

```r
formula(x, ...) DF2formula(x, env = parent.frame()) as.formula(object, env = parent.frame())
## S3 method for class 'formula'
print(x, showEnv = !identical(e, .GlobalEnv), ...)
```
Arguments

x, object  
R object, for DF2formula() a data.frame.

... further arguments passed to or from other methods.

env  
the environment to associate with the result, if not already a formula.

showEnv  
logical indicating if the environment should be printed as well.

Details

The models fitted by, e.g., the \texttt{lm} and \texttt{glm} functions are specified in a compact symbolic form. The \texttt{~} operator is basic in the formation of such models. An expression of the form \textit{y} \texttt{~} \texttt{model} is interpreted as a specification that the response \textit{y} is modelled by a linear predictor specified symbolically by \texttt{model}. Such a model consists of a series of terms separated by + operators. The terms themselves consist of variable and factor names separated by : operators. Such a term is interpreted as the interaction of all the variables and factors appearing in the term.

In addition to + and :, a number of other operators are useful in model formulae.

- The \* operator denotes factor crossing: \texttt{a*b} is interpreted as \texttt{a + b + a:b}.
- The \* operator indicates crossing to the specified degree. For example \texttt{(a+b+c)^2} is identical to \texttt{(a+b+c)*(a+b+c)} which in turn expands to a formula containing the main effects for \texttt{a}, \texttt{b} and \texttt{c} together with their second-order interactions.
- The \%in\% operator indicates that the terms on its left are nested within those on the right. For example \texttt{a + b \%in\% a} expands to the formula \texttt{a + a:b}.
- The / operator provides a shorthand, so that \texttt{a / b} is equivalent to \texttt{a + b \%in\% a}.
- The \- operator removes the specified terms, hence \texttt{(a+b+c)^2 - a:b} is identical to \texttt{a + b + c + b:c + a:c}. It can also used to remove the intercept term: when fitting a linear model \textit{y} \texttt{~ x - 1} specifies a line through the origin. A model with no intercept can be also specified as \texttt{y \sim x + 0} or \texttt{y \sim 0 + x}.

While formulae usually involve just variable and factor names, they can also involve arithmetic expressions. The formula \texttt{log(y) ~ a + log(x)} is quite legal. When such arithmetic expressions involve operators which are also used symbolically in model formulae, there can be confusion between arithmetic and symbolic operator use.

To avoid this confusion, the function \texttt{I()} can be used to bracket those portions of a model formula where the operators are used in their arithmetic sense. For example, in the formula \texttt{y ~ a + I(b+c)}, the term \texttt{b+c} is to be interpreted as the sum of \texttt{b} and \texttt{c}.

Variable names can be quoted by backticks `like this` in formulae, although there is no guarantee that all code using formulae will accept such non-syntactic names.

Most model-fitting functions accept formulae with right-hand-side including the function \texttt{offset} to indicate terms with a fixed coefficient of one. Some functions accept other 'specials' such as \texttt{strata} or \texttt{cluster} (see the specials argument of \texttt{terms.formula}).

There are two special interpretations of . in a formula. The usual one is in the context of a data argument of model fitting functions and means 'all columns not otherwise in the formula': see \texttt{terms.formula}. In the context of \texttt{update.formula}, only, it means 'what was previously in this part of the formula'.

When \texttt{formula} is called on a fitted model object, either a specific method is used (such as that for class "nls") or the default method. The default first looks for a "formula" component of the object (and evaluates it), then a "terms" component, then a \texttt{formula} parameter of the call (and evaluates its value) and finally a "formula" attribute.
There is a formula method for data frames. When there's "terms" attribute with a formula, e.g., for a `model.frame()`, that formula is returned. If you'd like the previous (R \leq 3.5.x) behavior, use the auxiliary `DF2formula()` which does not consider a "terms" attribute. Otherwise, if there is only one column this forms the RHS with an empty LHS. For more columns, the first column is the LHS of the formula and the remaining columns separated by + form the RHS.

**Value**

All the functions above produce an object of class "formula" which contains a symbolic model formula.

**Environments**

A formula object has an associated environment, and this environment (rather than the parent environment) is used by `model.frame` to evaluate variables that are not found in the supplied data argument.

Formulas created with the \texttt{\sim} operator use the environment in which they were created. Formulas created with \texttt{as.formula} will use the \texttt{env} argument for their environment.

**Note**

In R versions up to 3.6.0, character \texttt{x} of length more than one were parsed as separate lines of R code and the first complete expression was evaluated into a formula when possible. This silently truncates such vectors of characters inefficiently and to some extent inconsistently as this behaviour had been undocumented. For this reason, such use has been deprecated. If you must work via character \texttt{x}, do use a string, i.e., a character vector of length one.

E.g., \texttt{eval(call("~", quote(foo + bar)))} has been an order of magnitude more efficient than \texttt{formula(c("~", "foo + bar"))}.

Further, character "expressions" needing an \texttt{eval()} to return a formula are now deprecated.

**References**

**See Also**

\texttt{\sim}, \texttt{I}, \texttt{offset}.

For formula manipulation: \texttt{update.formula}, \texttt{terms.formula}, and \texttt{all.vars}. For typical use: \texttt{lm}, \texttt{glm}, and \texttt{coplot}. For formula construction: \texttt{reformulate}.

**Examples**

```r
class(fo <- y ~ x1*x2) # "formula"
fo
typeof(fo) # R internal: "language"
terms(fo)

environment(fo)
environment(as.formula("y ~ x"))
environment(as.formula("y ~ x", env = new.env()))
```
## Create a formula for a model with a large number of variables:
```
xnam <- paste0("x", 1:25)
(fmla <- as.formula(paste("y ~ ", paste(xnam, collapse= "+"), "\n)))
```
## Equivalent with reformulate():
```
 fmla2 <- reformulate(xnam, response = "y")
 stopifnot(identical(fmla, fmla2))
```

---

### formula.nls

**Extract Model Formula from nls Object**

#### Description

Returns the model used to fit object.

#### Usage

```
## S3 method for class 'nls'
formula(x, ...)
```

#### Arguments

- `x` an object inheriting from class "nls", representing a nonlinear least squares fit.
- `...` further arguments passed to or from other methods.

#### Value

A formula representing the model used to obtain object.

#### Author(s)

José Pinheiro and Douglas Bates

#### See Also

- `nls`, `formula`

#### Examples

```
fml <- nls(circumference ~ A/(1+exp((B-age)/C)), Orange,
            start = list(A = 160, B = 700, C = 350))
formula(fml)
```
friedman.test

friedman.test

Description

Performs a Friedman rank sum test with unreplicated blocked data.

Usage

friedman.test(y, ...)

## Default S3 method:
friedman.test(y, groups, blocks, ...)

## S3 method for class 'formula'
friedman.test(formula, data, subset, na.action, ...)

Arguments

y either a numeric vector of data values, or a data matrix.

groups a vector giving the group for the corresponding elements of y if this is a vector; ignored if y is a matrix. If not a factor object, it is coerced to one.

blocks a vector giving the block for the corresponding elements of y if this is a vector; ignored if y is a matrix. If not a factor object, it is coerced to one.

formula a formula of the form a ~ b | c, where a, b and c give the data values and corresponding groups and blocks, respectively.

data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").

... further arguments to be passed to or from methods.

Details

friedman.test can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in y for each combination of levels of groups and blocks) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of blocks, the location parameter of y is the same in each of the groups.

If y is a matrix, groups and blocks are obtained from the column and row indices, respectively. NA’s are not allowed in groups or blocks; if y contains NA’s, corresponding blocks are removed.
Value

A list with class "htest" containing the following components:

- **statistic**: the value of Friedman's chi-squared statistic.
- **parameter**: the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- **p.value**: the p-value of the test.
- **method**: the character string "Friedman rank sum test".
- **data.name**: a character string giving the names of the data.

friedman.test(x ~ w | t, data = wb)
```

---

### ftable

#### Flat Contingency Tables

**Description**

Create ‘flat’ contingency tables.

**Usage**

```r
ftable(x, ...)
```

#### Default S3 method:

```r
ftable(..., exclude = c(NA, NaN), row.vars = NULL,
       col.vars = NULL)
```

**Arguments**

- `x, ...`: R objects which can be interpreted as factors (including character strings), or a list (or data frame) whose components can be so interpreted, or a contingency table object of class "table" or "ftable".
- `exclude`: values to use in the exclude argument of `factor` when interpreting non-factor objects.
- `row.vars`: a vector of integers giving the numbers of the variables, or a character vector giving the names of the variables to be used for the rows of the flat contingency table.
- `col.vars`: a vector of integers giving the numbers of the variables, or a character vector giving the names of the variables to be used for the columns of the flat contingency table.

**Details**

`ftable` creates ‘flat’ contingency tables. Similar to the usual contingency tables, these contain the counts of each combination of the levels of the variables (factors) involved. This information is then re-arranged as a matrix whose rows and columns correspond to unique combinations of the levels of the row and column variables (as specified by `row.vars` and `col.vars`, respectively). The combinations are created by looping over the variables in reverse order (so that the levels of the left-most variable vary the slowest). Displaying a contingency table in this flat matrix form (via `print.ftable`, the print method for objects of class "ftable") is often preferable to showing it as a higher-dimensional array.
ftable is a generic function. Its default method, ftable.default, first creates a contingency table in array form from all arguments except row.vars and col.vars. If the first argument is of class "table", it represents a contingency table and is used as is; if it is a flat table of class "ftable", the information it contains is converted to the usual array representation using as.table. Otherwise, the arguments should be R objects which can be interpreted as factors (including character strings), or a list (or data frame) whose components can be so interpreted, which are cross-tabulated using table. Then, the arguments row.vars and col.vars are used to collapse the contingency table into flat form. If neither of these two is given, the last variable is used for the columns. If both are given and their union is a proper subset of all variables involved, the other variables are summed out.

When the arguments are R expressions interpreted as factors, additional arguments will be passed to table to control how the variable names are displayed; see the last example below.

Function ftable.formula provides a formula method for creating flat contingency tables.

There are methods for as.table, as.matrix and as.data.frame.

Value

ftable returns an object of class "ftable", which is a matrix with counts of each combination of the levels of variables with information on the names and levels of the (row and columns) variables stored as attributes "row.vars" and "col.vars".

See Also

ftable.formula for the formula interface (which allows a data = . argument); read.ftable for information on reading, writing and coercing flat contingency tables; table for ordinary cross-tabulation; xtabs for formula-based cross-tabulation.

Examples

## Start with a contingency table.
ftable(Titanic, row.vars = 1:3)
ftable(Titanic, row.vars = 1:2, col.vars = "Survived")
ftable(Titanic, row.vars = 2:1, col.vars = "Survived")

## Start with a data frame.
x <- ftable(mtcars[,c("cyl", "vs", "am", "gear")])
x
ftable(x, row.vars = c(2, 4))

## Start with expressions, use table()'s "dnn" to change labels
ftable(mtcars$cyl, mtcars$v$vs, mtcars$am, mtcars$gear, row.vars = c(2, 4),
       dnn = c("Cylinders", "V/S", "Transmission", "Gears"))
Usage

## S3 method for class 'formula'
ftable(formula, data = NULL, subset, na.action, ...)

Arguments

- **formula**: a formula object with both left and right hand sides specifying the column and row variables of the flat table.
- **data**: a data frame, list or environment (or similar: see `model.frame`) containing the variables to be cross-tabulated, or a contingency table (see below).
- **subset**: an optional vector specifying a subset of observations to be used. Ignored if `data` is a contingency table.
- **na.action**: a function which indicates what should happen when the data contain NAs. Ignored if `data` is a contingency table.
- **...**: further arguments to the default `ftable` method may also be passed as arguments, see `ftable.default`.

Details

This is a method of the generic function `ftable`. The left and right hand side of `formula` specify the column and row variables, respectively, of the flat contingency table to be created. Only the `+` operator is allowed for combining the variables. A `.` may be used once in the formula to indicate inclusion of all the remaining variables.

If `data` is an object of class "table" or an array with more than 2 dimensions, it is taken as a contingency table, and hence all entries should be nonnegative. Otherwise, if it is not a flat contingency table (i.e., an object of class "ftable"), it should be a data frame or matrix, list or environment containing the variables to be cross-tabulated. In this case, `na.action` is applied to the data to handle missing values, and, after possibly selecting a subset of the data as specified by the `subset` argument, a contingency table is computed from the variables.

The contingency table is then collapsed to a flat table, according to the row and column variables specified by `formula`.

Value

A flat contingency table which contains the counts of each combination of the levels of the variables, collapsed into a matrix for suitably displaying the counts.

x <- ftable(Survived ~ ., data = Titanic)
x
ftable(Sex ~ Class + Age, data = x)
```
The Gamma Distribution

Description

Density, distribution function, quantile function and random generation for the Gamma distribution with parameters shape and scale.

Usage

dgamma(x, shape, rate = 1, scale = 1/rate, log = FALSE)
pgamma(q, shape, rate = 1, scale = 1/rate, lower.tail = TRUE, log.p = FALSE)
qgamma(p, shape, rate = 1, scale = 1/rate, lower.tail = TRUE, log.p = FALSE)
rgamma(n, shape, rate = 1, scale = 1/rate)

Arguments

x, q  vector of quantiles.
p  vector of probabilities.
n  number of observations. If length(n) > 1, the length is taken to be the number required.
rate  an alternative way to specify the scale.
shape, scale  shape and scale parameters. Must be positive, scale strictly.
log, log.p  logical; if TRUE, probabilities/densities p are returned as log(p).
lower.tail  logical; if TRUE (default), probabilities are P[X ≤ x], otherwise, P[X > x].

Details

If scale is omitted, it assumes the default value of 1.

The Gamma distribution with parameters shape = α and scale = σ has density

\[ f(x) = \frac{1}{\sigma^\alpha \Gamma(\alpha)} x^{\alpha-1} e^{-x/\sigma} \]

for \( x \geq 0, \alpha > 0 \) and \( \sigma > 0 \). (Here \( \Gamma(\alpha) \) is the function implemented by R’s \texttt{gamma()} and defined in its help. Note that \( \alpha = 0 \) corresponds to the trivial distribution with all mass at point 0.)

The mean and variance are \( E(X) = \alpha \sigma \) and \( Var(X) = \alpha \sigma^2 \).

The cumulative hazard \( H(t) = -\log(1 - F(t)) \) is

\[ -\text{pgamma}(t, \ldots, \text{lower} = \text{FALSE}, \text{log} = \text{TRUE}) \]

Note that for smallish values of shape (and moderate scale) a large parts of the mass of the Gamma distribution is on values of \( x \) so near zero that they will be represented as zero in computer arithmetic. So \texttt{rgamma} may well return values which will be represented as zero. (This will also happen for very large values of scale since the actual generation is done for scale = 1.)
GammaDist

Value
dgamma gives the density, pgamma gives the distribution function, qgamma gives the quantile function, and rgamma generates random deviates.
Invalid arguments will result in return value NaN, with a warning.
The length of the result is determined by n for rgamma, and is the maximum of the lengths of the numerical arguments for the other functions.
The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note
The S (Becker et al., 1988) parametrization was via shape and rate: S had no scale parameter. It is an error to supply both scale and rate.
pgamma is closely related to the incomplete gamma function. As defined by Abramowitz and Stegun 6.5.1 (and by ‘Numerical Recipes’) this is

\[ P(a, x) = \frac{1}{\Gamma(a)} \int_0^x t^{a-1}e^{-t}dt \]

\( P(a, x) \) is pgamma(x, a). Other authors (for example Karl Pearson in his 1922 tables) omit the normalizing factor, defining the incomplete gamma function \( \gamma(a, x) \) as \( \gamma(a, x) = \int_0^x t^{a-1}e^{-t}dt \), i.e., pgamma(x, a) * gamma(a). Yet other use the ‘upper’ incomplete gamma function,

\[ \Gamma(a, x) = \int_x^\infty t^{a-1}e^{-t}dt, \]

which can be computed by pgamma(x, a, lower = FALSE) * gamma(a).
Note however that pgamma(x, a, ..) currently requires \( a > 0 \), whereas the incomplete gamma function is also defined for negative \( a \). In that case, you can use gamma_inc(a,x) (for \( \Gamma(a, x) \)) from package gsl.

See also https://en.wikipedia.org/wiki/Incomplete_gamma_function, or https://dlmf.nist.gov/8.2#i.

Source
dgamma is computed via the Poisson density, using code contributed by Catherine Loader (see dbinom).
pgamma uses an unpublished (and not otherwise documented) algorithm ‘mainly by Morten Welinder’.
qgamma is based on a C translation of
plus a final Newton step to improve the approximation.
rgamma for shape >= 1 uses
and for 0 < shape < 1 uses

                      # representable non-zero number

table(rgamma(1e4, 0.001) == 0)/1e4

Geometric

The Geometric Distribution

Description

Density, distribution function, quantile function and random generation for the geometric distribution with parameter prob.

Usage

dgeom(x, \text{prob}, \log = \text{FALSE})
pgeom(q, \text{prob}, \text{lower.tail} = \text{TRUE}, \log.p = \text{FALSE})
qgeom(p, \text{prob}, \text{lower.tail} = \text{TRUE}, \log.p = \text{FALSE})
rgeom(n, \text{prob})

Arguments

x, q

vector of quantiles representing the number of failures in a sequence of Bernoulli trials before success occurs.

p

vector of probabilities.
Geometric

\[ p(x) = p(1 - p)^x \]

for \( x = 0, 1, 2, \ldots, 0 < p \leq 1 \).

If an element of \( x \) is not integer, the result of \( \text{dgeom} \) is zero, with a warning.

The quantile is defined as the smallest value \( x \) such that \( F(x) \geq p \), where \( F \) is the distribution function.

Details

The geometric distribution with \( \text{prob} = p \) has density

\[ p(x) = p(1 - p)^x \]

for \( x = 0, 1, 2, \ldots, 0 < p \leq 1 \).

Value

\( \text{dgeom} \) gives the density, \( \text{pgeom} \) gives the distribution function, \( \text{qgeom} \) gives the quantile function, and \( \text{rgeom} \) generates random deviates.

Invalid \( \text{prob} \) will result in return value \( \text{NaN} \), with a warning.

The length of the result is determined by \( n \) for \( \text{rgeom} \), and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

\( \text{rgeom} \) returns a vector of type \text{integer} unless generated values exceed the maximum representable integer when \text{double} values are returned.

Source

\( \text{dgeom} \) computes via \( \text{dbinom} \), using code contributed by Catherine Loader (see \text{dbinom}).
\( \text{pgeom} \) and \( \text{qgeom} \) are based on the closed-form formulae.
\( \text{rgeom} \) uses the derivation as an exponential mixture of Poisson distributions, see

See Also

\text{Distributions} for other standard distributions, including \text{dnbinom} for the negative binomial which generalizes the geometric distribution.

Examples

\[ \text{qgeom}(\{1:9\}/10, \text{prob} = .2) \]
\[ \text{Ni} <- \text{rgeom}(20, \text{prob} = 1/4); \text{table(factor(Ni, 0:max(Ni)))} \]
Get Initial Parameter Estimates

Description

This function evaluates initial parameter estimates for a nonlinear regression model. If data is a parameterized data frame or pframe object, its parameters attribute is returned. Otherwise the object is examined to see if it contains a call to a selfStart object whose initial attribute can be evaluated.

Usage

getInitial(object, data, ...)

Arguments

- **object**: a formula or a selfStart model that defines a nonlinear regression model
- **data**: a data frame in which the expressions in the formula or arguments to the selfStart model can be evaluated
- **...**: optional additional arguments

Value

A named numeric vector or list of starting estimates for the parameters. The construction of many selfStart models is such that these "starting" estimates are, in fact, the converged parameter estimates.

Author(s)

José Pinheiro and Douglas Bates

PurTrt <- Puromycin[ Puromycin$state == "treated", ]
print(getInitial( rate ~ SSmicmen( conc, Vm, K ), PurTrt ), digits = 3)
```
glm

Fitting Generalized Linear Models

Description

glm is used to fit generalized linear models, specified by giving a symbolic description of the linear predictor and a description of the error distribution.

Usage

glm(formula, family = gaussian, data, weights, subset, 
    na.action, start = NULL, etastart, mustart, offset, 
    control = list(...), model = TRUE, method = "glm.fit", 
    x = FALSE, y = TRUE, singular.ok = TRUE, contrasts = NULL, ...)

glm.fit(x, y, weights = rep.int(1, nobs), 
    start = NULL, etastart = NULL, mustart = NULL, 
    offset = rep.int(0, nobs), family = gaussian(), 
    control = list(), intercept = TRUE, singular.ok = TRUE)

## S3 method for class 'glm'
weights(object, type = c("prior", "working"), ...)

Arguments

formula an object of class "formula" (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under 'Details'.

family a description of the error distribution and link function to be used in the model. For glm this can be a character string naming a family function, a family function or the result of a call to a family function. For glm.fit only the third option is supported. (See family for details of family functions.)

data an optional data frame, list or environment (or object coercible by as.data.frame) to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula). Typically the environment from which glm is called.

weights an optional vector of 'prior weights' to be used in the fitting process. Should be NULL or a numeric vector.

subset an optional vector specifying a subset of observations to be used in the fitting process.

na.action a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The 'factory-fresh' default is na.omit. Another possible value is NULL, no action. Value na.exclude can be useful.

start starting values for the parameters in the linear predictor.

etastart starting values for the linear predictor.

mustart starting values for the vector of means.
offset  
 this can be used to specify an *a priori* known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases. One or more offset terms can be included in the formula instead or as well, and if more than one is specified their sum is used. See `model.offset`.

control  
a list of parameters for controlling the fitting process. For `glm.fit` this is passed to `glm.control`.

model  
a logical value indicating whether `model.frame` should be included as a component of the returned value.

method  
the method to be used in fitting the model. The default method "glm.fit" uses iteratively reweighted least squares (IWLS): the alternative "model.frame" returns the model frame and does no fitting.

User-supplied fitting functions can be supplied either as a function or a character string naming a function, with a function which takes the same arguments as `glm.fit`. If specified as a character string it is looked up from within the `stats` namespace.

x, y  
For `glm`: logical values indicating whether the response vector and model matrix used in the fitting process should be returned as components of the returned value.

For `glm.fit`: x is a design matrix of dimension n * p, and y is a vector of observations of length n.

singular.ok  
logical; if FALSE a singular fit is an error.

contrasts  
an optional list. See the `contrasts.arg` of `model.matrix.default`.

intercept  
logical. Should an intercept be included in the null model?

object  
an object inheriting from class "glm".

type  
character, partial matching allowed. Type of weights to extract from the fitted model object. Can be abbreviated.

...  
For `glm`: arguments to be used to form the default `control` argument if it is not supplied directly.

For `weights`: further arguments passed to or from other methods.

**Details**

A typical predictor has the form `response ~ terms` where `response` is the (numeric) response vector and `terms` is a series of terms which specifies a linear predictor for `response`. For binomial and quasibinomial families the response can also be specified as a `factor` (when the first level denotes failure and all others success) or as a two-column matrix with the columns giving the numbers of successes and failures. A terms specification of the form `first + second` indicates all the terms in `first` together with all the terms in `second` with any duplicates removed.

A specification of the form `first:second` indicates the set of terms obtained by taking the interactions of all terms in `first` with all terms in `second`. The specification `first*second` indicates the cross of `first` and `second`. This is the same as `first + second + first:second`.

The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on: to avoid this pass a `terms` object as the formula. Non-NULL weights can be used to indicate that different observations have different dispersions (with the values in `weights` being inversely proportional to the dispersions); or equivalently, when the elements of `weights` are positive integers w_i, that each response y_i is the mean of w_i unit-weight observations. For a binomial GLM prior weights are used to give the number of trials when the response is the proportion of successes: they would rarely be used for a Poisson GLM.
glm.fit is the workhorse function: it is not normally called directly but can be more efficient where the response vector, design matrix and family have already been calculated.

If more than one of etastart, start and mustart is specified, the first in the list will be used. It is often advisable to supply starting values for a quasi family, and also for families with unusual links such as gaussian("log").

All of weights, subset, offset, etastart and mustart are evaluated in the same way as variables in formula, that is first in data and then in the environment of formula.

For the background to warning messages about ‘fitted probabilities numerically 0 or 1 occurred’ for binomial GLMs, see Venables & Ripley (2002, pp. 197–8).

Value

glm returns an object of class inheriting from "glm" which inherits from the class "lm". See later in this section. If a non-standard method is used, the object will also inherit from the class (if any) returned by that function.

The function summary (i.e., summary.glm) can be used to obtain or print a summary of the results and the function anova (i.e., anova.glm) to produce an analysis of variance table.

The generic accessor functions coefficients, effects, fitted.values and residuals can be used to extract various useful features of the value returned by glm.

weights extracts a vector of weights, one for each case in the fit (after subsetting and na.action).

An object of class "glm" is a list containing at least the following components:

coefficients a named vector of coefficients
residuals the working residuals, that is the residuals in the final iteration of the IWLS fit. Since cases with zero weights are omitted, their working residuals are NA.
fitted.values the fitted mean values, obtained by transforming the linear predictors by the inverse of the link function.
rank the numeric rank of the fitted linear model.
family the family object used.
linear.predictors the linear fit on link scale.
deviance up to a constant, minus twice the maximized log-likelihood. Where sensible, the constant is chosen so that a saturated model has deviance zero.
aic A version of Akaike’s An Information Criterion, minus twice the maximized log-likelihood plus twice the number of parameters, computed via the aic component of the family. For binomial and Poison families the dispersion is fixed at one and the number of parameters is the number of coefficients. For gaussian, Gamma and inverse gaussian families the dispersion is estimated from the residual deviance, and the number of parameters is the number of coefficients plus one. For a gaussian family the MLE of the dispersion is used so this is a valid value of AIC, but for Gamma and inverse gaussian families it is not. For families fitted by quasi-likelihood the value is NA.
null.deviance The deviance for the null model, comparable with deviance. The null model will include the offset, and an intercept if there is one in the model. Note that this will be incorrect if the link function depends on the data other than through the fitted mean: specify a zero offset to force a correct calculation.
iter the number of iterations of IWLS used.
weights the working weights, that is the weights in the final iteration of the IWLS fit.
prior.weights  the weights initially supplied, a vector of 1s if none were.
df.residual   the residual degrees of freedom.
df.null       the residual degrees of freedom for the null model.
y            if requested (the default) the y vector used. (It is a vector even for a binomial model.)
x            if requested, the model matrix.
model        if requested (the default), the model frame.
converged    logical. Was the IWLS algorithm judged to have converged?
boundary     logical. Is the fitted value on the boundary of the attainable values?
call         the matched call.
formula      the formula supplied.
terms        the terms object used.
data         the data argument.
offset       the offset vector used.
control      the value of the control argument used.
method       the name of the fitter function used (when provided as a character string to glm() or the fitter function (when provided as that).
contrasts    (where relevant) the contrasts used.
xlevels      (where relevant) a record of the levels of the factors used in fitting.
na.action    (where relevant) information returned by model.frame on the special handling of NAs.

In addition, non-empty fits will have components qr, R and effects relating to the final weighted linear fit.

Objects of class "glm" are normally of class c("glm", "lm"), that is inherit from class "lm", and well-designed methods for class "lm" will be applied to the weighted linear model at the final iteration of IWLS. However, care is needed, as extractor functions for class "glm" such as residuals and weights do not just pick out the component of the fit with the same name.

If a binomial glm model was specified by giving a two-column response, the weights returned by prior.weights are the total numbers of cases (factored by the supplied case weights) and the component y of the result is the proportion of successes.

Fitting functions

The argument method serves two purposes. One is to allow the model frame to be recreated with no fitting. The other is to allow the default fitting function glm.fit to be replaced by a function which takes the same arguments and uses a different fitting algorithm. If glm.fit is supplied as a character string it is used to search for a function of that name, starting in the stats namespace.

The class of the object return by the fitter (if any) will be prepended to the class returned by glm.

Author(s)

The original R implementation of glm was written by Simon Davies working for Ross Ihaka at the University of Auckland, but has since been extensively re-written by members of the R Core team. The design was inspired by the S function of the same name described in Hastie & Pregibon (1992).

summary(glm.D93)

## Computing AIC [in many ways]:
(A0 <- AIC(glm.D93))
(l1 <- logLik(glm.D93))
A1 <- -2*c(l1) + 2*attr(l1, "df")
A2 <- glm.D93$sfamily$logLik(counts, mu=fitted(glm.D93), wt=1) +
2 * length(coef(glm.D93))
stopifnot(exprs = {
  all.equal(A0, A1)
  all.equal(A1, A2)
  all.equal(A1, glm.D93$slogLik)
})

## an example with offsets from Venables & Ripley (2002, p.189)
utils::data(anorexia, package = "MASS")
anorex.1 <- glm(Postwt ~ Prewt + Treat + offset(Prewt),
              family = gaussian, data = anorexia)
summary(anorex.1)

# A Gamma example, from McCullagh & Nelder (1989, pp. 300-2)
clotting <- data.frame(
  u = c(5,10,15,20,30,40,60,80,100),
  lot1 = c(118,58,42,35,27,25,21,19,18),
  lot2 = c(58,39,30,20,15,20,15,9,7),
  lot3 = c(49,11,19,17,16,16,14,12,10))
glm clotting ~ u + lot1 + lot2 + lot3, family = Gamma())
glm.control

Auxiliary for Controlling GLM Fitting

Description

Auxiliary function for glm fitting. Typically only used internally by glm.fit, but may be used to construct a control argument to either function.

Usage

glm.control(epsilon = 1e-8, maxit = 25, trace = FALSE)

Arguments

epsilon positive convergence tolerance \( \epsilon \); the iterations converge when \(|\text{dev} - \text{dev}_{\text{old}}|/(|\text{dev}| + 0.1) < \epsilon\).

maxit integer giving the maximal number of IWLS iterations.

trace logical indicating if output should be produced for each iteration.

Details

The control argument of glm is by default passed to the control argument of glm.fit, which uses its elements as arguments to glm.control: the latter provides defaults and sanity checking.

If epsilon is small (less than \(10^{-10}\)) it is also used as the tolerance for the detection of collinearity in the least squares solution.

When trace is true, calls to cat produce the output for each IWLS iteration. Hence, options(digits = *) can be used to increase the precision, see the example.

Value

A list with components named as the arguments.

References

### Description
These functions are all methods for class glm or summary.glm objects.

### Usage
```r
### S3 method for class 'glm'
family(object, ...)

### S3 method for class 'glm'
residuals(object, type = c("deviance", "pearson", "working", "response", "partial"), ...)
```

### Arguments
- **object**: an object of class glm, typically the result of a call to glm.
- **type**: the type of residuals which should be returned. The alternatives are: "deviance" (default), "pearson", "working", "response", and "partial". Can be abbreviated.
- **...**: further arguments passed to or from other methods.

### Details
The references define the types of residuals: Davison & Snell is a good reference for the usages of each.

The partial residuals are a matrix of working residuals, with each column formed by omitting a term from the model.

How residuals treats cases with missing values in the original fit is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the residuals, whereas if na.action = na.exclude they will appear, with residual value NA. See also naresid.

For fits done with y = FALSE the response values are computed from other components.
References

See Also

`glm` for computing `glm.obj`, `anova.glm`; the corresponding generic functions, `summary.glm`, `coef`, `deviance`, `df.residual`, `effects`, `fitted`, `residuals`.

`influence.measures` for deletion diagnostics, including standardized (`rstandard`) and studentized (`rstudent`) residuals.

---

### hclust

#### Hierarchical Clustering

**Description**

Hierarchical cluster analysis on a set of dissimilarities and methods for analyzing it.

**Usage**

```r
hclust(d, method = "complete", members = NULL)
```

### S3 method for class 'hclust'

```r
plot(x, labels = NULL, hang = 0.1, check = TRUE, axes = TRUE, frame.plot = FALSE, ann = TRUE, main = "Cluster Dendrogram", sub = NULL, xlab = NULL, ylab = "Height", ...)
```

**Arguments**

- **d**: a dissimilarity structure as produced by `dist`.
- **method**: the agglomeration method to be used. This should be (an unambiguous abbreviation of) one of "ward.D", "ward.D2", "single", "complete", "average" (= UPGMA), "mcquitty" (= WPGMA), "median" (= WPGMC) or "centroid" (= UPGMC).
- **members**: `NULL` or a vector with length size of `d`. See the ‘Details’ section.
- **x**: an object of the type produced by `hclust`.
- **hang**: The fraction of the plot height by which labels should hang below the rest of the plot. A negative value will cause the labels to hang down from 0.
- **check**: logical indicating if the `x` object should be checked for validity. This check is not necessary when `x` is known to be valid such as when it is the direct result of `hclust()`. The default is `check=TRUE`, as invalid inputs may crash R due to memory violation in the internal C plotting code.
This function performs a hierarchical cluster analysis using a set of dissimilarities for the \( n \) objects being clustered. Initially, each object is assigned to its own cluster and then the algorithm proceeds iteratively, at each stage joining the two most similar clusters, continuing until there is just a single cluster. At each stage distances between clusters are recomputed by the Lance–Williams dissimilarity update formula according to the particular clustering method being used.

A number of different clustering methods are provided. Ward’s minimum variance method aims at finding compact, spherical clusters. The complete linkage method finds similar clusters. The single linkage method (which is closely related to the minimal spanning tree) adopts a ‘friends of friends’ clustering strategy. The other methods can be regarded as aiming for clusters with characteristics somewhere between the single and complete link methods. Note however, that methods “median” and “centroid” are not leading to a monotone distance measure, or equivalently the resulting dendrograms can have so called inversions or reversals which are hard to interpret, but note the trichotomies in Legendre and Legendre (2012).

Two different algorithms are found in the literature for Ward clustering. The one used by option "ward.D" (equivalent to the only Ward option "ward" in R versions \( \leq 3.0.3 \)) does not implement Ward’s (1963) clustering criterion, whereas option "ward.D2" implements that criterion (Murtagh and Legendre 2014). With the latter, the dissimilarities are squared before cluster updating. Note that \texttt{agnes}(\*, method="ward") corresponds to \texttt{hclust}(\*, "ward.D2").

If \texttt{members} ! = \texttt{NULL}, then \( d \) is taken to be a dissimilarity matrix between clusters instead of dissimilarities between singletons and \texttt{members} gives the number of observations per cluster. This way the hierarchical cluster algorithm can be ‘started in the middle of the dendrogram’, e.g., in order to reconstruct the part of the tree above a cut (see examples). Dissimilarities between clusters can be efficiently computed (i.e., without \texttt{hclust} itself) only for a limited number of distance/linkage combinations, the simplest one being squared Euclidean distance and centroid linkage. In this case the dissimilarities between the clusters are the squared Euclidean distances between cluster means.

In hierarchical cluster displays, a decision is needed at each merge to specify which subtree should go on the left and which on the right. Since, for \( n \) observations there are \( n - 1 \) merges, there are \( 2^{(n-1)} \) possible orderings for the leaves in a cluster tree, or dendrogram. The algorithm used in \texttt{hclust} is to order the subtree so that the tighter cluster is on the left (the last, i.e., most recent, merge of the left subtree is at a lower value than the last merge of the right subtree). Single observations are the tightest clusters possible, and merges involving two observations place them in order by their observation sequence number.

**Value**

An object of class "\texttt{hclust}" which describes the tree produced by the clustering process. The object is a list with components:
merge

an \( n - 1 \) by 2 matrix. Row \( i \) of \texttt{merge} describes the merging of clusters at step \( i \) of the clustering. If an element \( j \) in the row is negative, then observation \( -j \) was merged at this stage. If \( j \) is positive then the merge was with the cluster formed at the (earlier) stage \( j \) of the algorithm. Thus negative entries in \texttt{merge} indicate agglomerations of singletons, and positive entries indicate agglomerations of non-singletons.

height

a set of \( n - 1 \) real values (non-decreasing for ultrametric trees). The clustering height: that is, the value of the criterion associated with the clustering method for the particular agglomeration.

order

a vector giving the permutation of the original observations suitable for plotting, in the sense that a cluster plot using this ordering and matrix \texttt{merge} will not have crossings of the branches.

labels

labels for each of the objects being clustered.

call

the call which produced the result.

method

the cluster method that has been used.

dist.method

the distance that has been used to create \( d \) (only returned if the distance object has a "method" attribute).

There are \texttt{print}, \texttt{plot} and \texttt{identify} (see \texttt{identify.hclust}) methods and the \texttt{rect.hclust()} function for \texttt{hclust} objects.

Note

Method "centroid" is typically meant to be used with squared Euclidean distances.

Author(s)

The \texttt{hclust} function is based on Fortran code contributed to STATLIB by F. Murtagh.

Examples

require(graphics)

### Example 1: Violent crime rates by US state
hc <- hclust(dist(USArrests), "ave")
plot(hc)
plot(hc, hang = -1)

## Do the same with centroid clustering and squared Euclidean distance,
## cut the tree into ten clusters and reconstruct the upper part of the
## tree from the cluster centers.
hc <- hclust(dist(USArrests)^2, "cen")
memb <- cutree(hc, k = 10)
cent <- NULL
for(k in 1:10){
  cent <- rbind(cent, colMeans(USArrests[memb == k, , drop = FALSE]))
}
hc1 <- hclust(dist(cent)^2, method = "cen", members = table(memb))
par(par)

### Example 2: Straight-line distances among 10 US cities
## Compare the results of algorithms "ward.D" and "ward.D2"
mds2 <- -cmdscale(UScitiesD)
plot(mds2, type="n", axes=FALSE, ann=FALSE)
text(mds2, labels=rownames(mds2), xpd = NA)

hcity.D <- hclust(UScitiesD, "ward.D") # "wrong"
hcity.D2 <- hclust(UScitiesD, "ward.D2")
par(par)
plot(hcity.D, hang=-1)
plot(hcity.D2, hang=-1)
par(par)

heatmap

**Draw a Heat Map**

**Description**

A heat map is a false color image (basically image(t(x))) with a dendrogram added to the left side and to the top. Typically, reordering of the rows and columns according to some set of values (row or column means) within the restrictions imposed by the dendrogram is carried out.
**Usage**

```r
heatmap(x, Rowv = NULL, Colv = if(symm)"Rowv" else NULL,
distfun = dist, hclustfun = hclust,
reorderfun = function(d, w) reorder(d, w),
add.expr, symm = FALSE, revC = identical(Colv, "Rowv"),
scale = c("row", "column", "none"), na.rm = TRUE,
margins = c(5, 5), ColSideColors, RowSideColors,
cexRow = 0.2 + 1/log10(nr), cexCol = 0.2 + 1/log10(nc),
labRow = NULL, labCol = NULL, main = NULL,
xlab = NULL, ylab = NULL,
keep.dendro = FALSE, verbose = getOption("verbose"), ...)
```

**Arguments**

- **x**: numeric matrix of the values to be plotted.
- **Rowv**: determines if and how the row dendrogram should be computed and reordered. Either a dendrogram or a vector of values used to reorder the row dendrogram or NA to suppress any row dendrogram (and reordering) or by default, NULL, see 'Details' below.
- **Colv**: determines if and how the column dendrogram should be reordered. Has the same options as the Rowv argument above and additionally when x is a square matrix, Colv = "Rowv" means that columns should be treated identically to the rows (and so if there is to be no row dendrogram there will not be a column one either).
- **distfun**: function used to compute the distance (dissimilarity) between both rows and columns. Defaults to dist.
- **hclustfun**: function used to compute the hierarchical clustering when Rowv or Colv are not dendrograms. Defaults to hclust. Should take as argument a result of distfun and return an object to which as.dendrogram can be applied.
- **reorderfun**: function(d, w) of dendrogram and weights for reordering the row and column dendrograms. The default uses reorder.dendrogram.
- **add.expr**: expression that will be evaluated after the call to image. Can be used to add components to the plot.
- **symm**: logical indicating if x should be treated symmetrically; can only be true when x is a square matrix.
- **revC**: logical indicating if the column order should be reversed for plotting, such that e.g., for the symmetric case, the symmetry axis is as usual.
- **scale**: character indicating if the values should be centered and scaled in either the row direction or the column direction, or none. The default is "row" if symm false, and "none" otherwise.
- **na.rm**: logical indicating whether NA’s should be removed.
- **margins**: numeric vector of length 2 containing the margins (see par(mar = *)) for column and row names, respectively.
- **ColSideColors**: (optional) character vector of length ncol(x) containing the color names for a horizontal side bar that may be used to annotate the columns of x.
- **RowSideColors**: (optional) character vector of length nrow(x) containing the color names for a vertical side bar that may be used to annotate the rows of x.
cexRow, cexCol positive numbers, used as cex.axis in for the row or column axis labeling. The defaults currently only use number of rows or columns, respectively.

labRow, labCol character vectors with row and column labels to use; these default to rrownames(x) or colnames(x), respectively.

main, xlab, ylab main, x- and y-axis titles; defaults to none.

keep.dendro logical indicating if the dendrogram(s) should be kept as part of the result (when Rowv and/or Colv are not NA).

verbose logical indicating if information should be printed.

... additional arguments passed on to image, e.g., col specifying the colors.

Details

If either Rowv or Colv are dendrograms they are honored (and not reordered). Otherwise, dendrograms are computed as dd <- as.dendrogram(hclustfun(distfun(X))) where X is either x or t(x).

If either is a vector (of ‘weights’) then the appropriate dendrogram is reordered according to the supplied values subject to the constraints imposed by the dendrogram, by reorder(dd, Rowv), in the row case. If either is missing, as by default, then the ordering of the corresponding dendrogram is by the mean value of the rows/columns, i.e., in the case of rows, Rowv <- rowMeans(x, na.rm = na.rm). If either is NA, no reordering will be done for the corresponding side.

By default (scale = "row") the rows are scaled to have mean zero and standard deviation one. There is some empirical evidence from genomic plotting that this is useful.

Value

Invisibly, a list with components

rowInd row index permutation vector as returned by order.dendrogram.

colInd column index permutation vector.

Rowv the row dendrogram; only if input Rowv was not NA and keep.dendro is true.

Colv the column dendrogram; only if input Colv was not NA and keep.dendro is true.

Note

Unless Rowv = NA (or Colv = NA), the original rows and columns are reordered in any case to match the dendrogram, e.g., the rows by order.dendrogram(Rowv) where Rowv is the (possibly reorder()ed) row dendrogram.

heatmap() uses layout and draws the image in the lower right corner of a 2x2 layout. Consequentially, it can not be used in a multi column/row layout, i.e., when par(mfrow = *) or (mfcol = *) has been called.

```

**HoltWinters**  

**Holt-Winters Filtering**

**Description**

Computes Holt-Winters Filtering of a given time series. Unknown parameters are determined by minimizing the squared prediction error.

**Usage**

```r
HoltWinters(x, alpha = NULL, beta = NULL, gamma = NULL,
seasonal = c("additive", "multiplicative"),
```
start.periods = 2, l.start = NULL, b.start = NULL, 
s.start = NULL, 
optim.start = c(alpha = 0.3, beta = 0.1, gamma = 0.1), 
optim.control = list())

Arguments

x An object of class ts
alpha alpha parameter of Holt-Winters Filter.
beta beta parameter of Holt-Winters Filter. If set to FALSE, the function will do exponential smoothing.
gamma gamma parameter used for the seasonal component. If set to FALSE, an non-seasonal model is fitted.
seasonal Character string to select an "additive" (the default) or “multiplicative” seasonal model. The first few characters are sufficient. (Only takes effect if gamma is non-zero).
start.periods Start periods used in the autodetection of start values. Must be at least 2.
l.start Start value for level (a[0]).
b.start Start value for trend (b[0]).
s.start Vector of start values for the seasonal component (s_1[0], ..., s_p[0]).
optim.start Vector with named components alpha, beta, and gamma containing the starting values for the optimizer. Only the values needed must be specified. Ignored in the one-parameter case.
optim.control Optional list with additional control parameters passed to optim if this is used. Ignored in the one-parameter case.

Details

The additive Holt-Winters prediction function (for time series with period length p) is

\[ \hat{Y}[t + h] = a[t] + hb[t] + s[t - p + 1 + (h - 1) \mod p], \]

where \(a[t], b[t]\) and \(s[t]\) are given by

\[
\begin{align*}
a[t] &= \alpha(Y[t] - s[t - p]) + (1 - \alpha)(a[t - 1] + b[t - 1]) \\
b[t] &= \beta(a[t] - a[t - 1]) + (1 - \beta)b[t - 1] \\
s[t] &= \gamma(Y[t] - a[t]) + (1 - \gamma)s[t - p]
\end{align*}
\]

The multiplicative Holt-Winters prediction function (for time series with period length p) is

\[ \hat{Y}[t + h] = (a[t] + hb[t]) \times s[t - p + 1 + (h - 1) \mod p]. \]

where \(a[t], b[t]\) and \(s[t]\) are given by

\[
\begin{align*}
a[t] &= \alpha(Y[t]/s[t - p]) + (1 - \alpha)(a[t - 1] + b[t - 1]) \\
b[t] &= \beta(a[t] - a[t - 1]) + (1 - \beta)b[t - 1] \\
s[t] &= \gamma(Y[t]/a[t]) + (1 - \gamma)s[t - p]
\end{align*}
\]

The data in \(x\) are required to be non-zero for a multiplicative model, but it makes most sense if they are all positive.
The function tries to find the optimal values of \( \alpha \) and/or \( \beta \) and/or \( \gamma \) by minimizing the squared one-step prediction error if they are NULL (the default). optimize will be used for the single-parameter case, and optim otherwise.

For seasonal models, start values for \( a \), \( b \) and \( s \) are inferred by performing a simple decomposition in trend and seasonal component using moving averages (see function decompose) on the start.periods first periods (a simple linear regression on the trend component is used for starting level and trend). For level/trend-models (no seasonal component), start values for \( a \) and \( b \) are \( x[2] \) and \( x[2] - x[1] \), respectively. For level-only models (ordinary exponential smoothing), the start value for \( a \) is \( x[1] \).

Value

An object of class "HoltWinters", a list with components:

- **fitted**: A multiple time series with one column for the filtered series as well as for the level, trend and seasonal components, estimated contemporaneously (that is at time \( t \) and not at the end of the series).
- **x**: The original series
- **alpha**: alpha used for filtering
- **beta**: beta used for filtering
- **gamma**: gamma used for filtering
- **coefficients**: A vector with named components \( a \), \( b \), \( s1 \), \( s2 \), \( sp \) containing the estimated values for the level, trend and seasonal components
- **seasonal**: The specified seasonal parameter
- **SSE**: The final sum of squared errors achieved in optimizing
- **call**: The call used

---

**Hypergeometric Distribution**

The Hypergeometric Distribution

**Description**

Density, distribution function, quantile function and random generation for the hypergeometric distribution.

**Usage**

dhyper(x, m, n, k, log = FALSE)
phyper(q, m, n, k, lower.tail = TRUE, log.p = FALSE)
qhyper(p, m, n, k, lower.tail = TRUE, log.p = FALSE)
rhyper(nn, m, n, k)

**Arguments**

- `x, q` vector of quantiles representing the number of white balls drawn without replacement from an urn which contains both black and white balls.
- `m` the number of white balls in the urn.
- `n` the number of black balls in the urn.
- `k` the number of balls drawn from the urn, hence must be in $0, 1, \ldots, m + n$.
- `p` probability, it must be between 0 and 1.
- `nn` number of observations. If `length(nn) > 1`, the length is taken to be the number required.
- `log, log.p` logical; if TRUE, probabilities p are given as log(p).
- `lower.tail` logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

**Details**

The hypergeometric distribution is used for sampling without replacement. The density of this distribution with parameters $m, n$ and $k$ (named $Np$, $N - Np$, and $n$, respectively in the reference below, where $N := m + n$ is also used in other references) is given by

$$p(x) = \binom{m}{x} \binom{n}{k-x} / \binom{m+n}{k}$$
Hypergeometric

for \( x = 0, \ldots, k \).

Note that \( p(x) \) is non-zero only for \( \max(0, k - n) \leq x \leq \min(k, m) \).

With \( p := m/(m + n) \) (hence \( Np = N \times p \) in the reference’s notation), the first two moments are mean

\[
E[X] = \mu = kp
\]

and variance

\[
\text{Var}(X) = kp(1 - p) \frac{m + n - k}{m + n - 1},
\]

which shows the closeness to the Binomial\((k, p)\) (where the hypergeometric has smaller variance unless \( k = 1 \)).

The quantile is defined as the smallest value \( x \) such that \( F(x) \geq p \), where \( F \) is the distribution function.

In \texttt{rhyper()}, if one of \( m, n, k \) exceeds \texttt{Machine$integer.max}, currently the equivalent of \texttt{qhyper(runif(nn), m,n,k)} is used which is comparably slow while instead a binomial approximation may be considerably more efficient.

Value
d\text{hyper} gives the density, \text{phyper} gives the distribution function, \text{qhyper} gives the quantile function, and \text{rhyper} generates random deviates.

Invalid arguments will result in return value \texttt{NaN}, with a warning.

The length of the result is determined by \( n \) for \text{rhyper}, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

Source
d\text{hyper} computes via binomial probabilities, using code contributed by Catherine Loader (see \texttt{dbinom}).

\text{phyper} is based on calculating \text{dhyper} and \text{phyper}(\ldots)/\text{dhyper}(\ldots) (as a summation), based on ideas of Ian Smith and Morten Welinder.

\text{qhyper} is based on inversion (of an earlier \text{phyper}() algorithm).

\text{rhyper} is based on a corrected version of

References

See Also

\texttt{Distributions} for other standard distributions.
Examples

```r
m <- 10; n <- 7; k <- 8
x <- 0:(k+1)
rbind(phyper(x, m, n, k), dhyper(x, m, n, k))
all(phyper(x, m, n, k) == cumsum(dhyper(x, m, n, k))) # FALSE
## but errors are very small:
signif(phyper(x, m, n, k) - cumsum(dhyper(x, m, n, k)), digits = 3)
stopifnot(abs(phyper(x, m, n, k) - cumsum(dhyper(x, m, n, k))) < 5e-16)
```

Description

`identify.hclust` reads the position of the graphics pointer when the (first) mouse button is pressed. It then cuts the tree at the vertical position of the pointer and highlights the cluster containing the horizontal position of the pointer. Optionally a function is applied to the index of data points contained in the cluster.

Usage

```r
## S3 method for class 'hclust'
identify(x, FUN = NULL, N = 20, MAXCLUSTER = 20, DEV.FUN = NULL, ...)  
```

Arguments

- `x`: an object of the type produced by `hclust`.
- `FUN`: (optional) function to be applied to the index numbers of the data points in a cluster (see ‘Details’ below).
- `N`: the maximum number of clusters to be identified.
- `MAXCLUSTER`: the maximum number of clusters that can be produced by a cut (limits the effective vertical range of the pointer).
- `DEV.FUN`: (optional) integer scalar. If specified, the corresponding graphics device is made active before `FUN` is applied.
- `...`: further arguments to `FUN`.

Details

By default clusters can be identified using the mouse and an invisible list of indices of the respective data points is returned.

If `FUN` is not NULL, then the index vector of data points is passed to this function as first argument, see the examples below. The active graphics device for `FUN` can be specified using `DEV.FUN`.

The identification process is terminated by pressing any mouse button other than the first, see also `identify`.

Value

Either a list of data point index vectors or a list of return values of `FUN`.

influence.measures

Regression Deletion Diagnostics

Description

This suite of functions can be used to compute some of the regression (leave-one-out deletion) diagnostics for linear and generalized linear models discussed in Belsley, Kuh and Welsch (1980), Cook and Weisberg (1982), etc.

Usage

influence.measures(model, infl = influence(model))

rstandard(model, ...)

## S3 method for class 'lm'

rstandard(model, infl = lm.influence(model, do.coef = FALSE),
    sd = sqrt(deviance(model)/df.residual(model)),
    type = c("sd.1", "predictive"), ...)

## S3 method for class 'glm'

rstandard(model, infl = influence(model, do.coef = FALSE),
    type = c("deviance", "pearson"), ...)

rstudent(model, ...)

## S3 method for class 'lm'

rstudent(model, infl = lm.influence(model, do.coef = FALSE),
```r
res = infl$wt.res, ...)
## S3 method for class 'glm'
rstudent(model, infl = influence(model, do.coef = FALSE), ...)

dffits(model, infl = , res = )

## S3 method for class 'lm'
dfbeta(model, ...)

## S3 method for class 'lm'
dfbetas(model, ...)

dfbetas(model, infl = lm.influence(model, do.coef = TRUE), ...)

covratio(model, infl = lm.influence(model, do.coef = FALSE),
res = weighted.residuals(model))

cooks.distance(model, ...)

## S3 method for class 'lm'
cooks.distance(model, infl = lm.influence(model, do.coef = FALSE),
res = weighted.residuals(model),
sd = sqrt(deviance(model)/df.residual(model)),
hat = infl$hat, ...)

## S3 method for class 'glm'
cooks.distance(model, infl = influence(model, do.coef = FALSE),
res = infl$pear.res,
dispersion = summary(model)$dispersion,
hat = infl$hat, ...)

hatvalues(model, ...)

## S3 method for class 'lm'
hatvalues(model, infl = lm.influence(model, do.coef = FALSE), ...)

hat(x, intercept = TRUE)
```

**Arguments**

- **model**: an \texttt{R} object, typically returned by \texttt{lm} or \texttt{glm}.
- **infl**: influence structure as returned by \texttt{lm.influence} or \texttt{influence} (the latter only for the \texttt{glm} method of \texttt{rstudent} and \texttt{cooks.distance}).
- **res**: (possibly weighted) residuals, with proper default.
- **sd**: standard deviation to use, see default.
- **dispersion**: dispersion (for \texttt{glm} objects) to use, see default.
- **hat**: hat values \(H_{ii}\), see default.
- **type**: type of residuals for \texttt{rstandard}, with different options and meanings for \texttt{lm} and \texttt{glm}. Can be abbreviated.
- **x**: the \(X\) or design matrix.
- **intercept**: should an intercept column be prepended to \(x\)?
- **...**: further arguments passed to or from other methods.
Details

The primary high-level function is `influence.measures` which produces a class "infl" object
tabular display showing the DFBETAs for each model variable, DFFITs, covariance ratios, Cook’s
distances and the diagonal elements of the hat matrix. Cases which are influential with respect to
any of these measures are marked with an asterisk.

The functions `dfbetas`, `dffits`, `covratio` and `cooks.distance` provide direct access to the
to the corresponding diagnostic quantities. Functions `rstandard` and `rstudent` give the standardized and
Studentized residuals respectively. (These re-normalize the residuals to have unit variance, using
an overall and leave-one-out measure of the error variance respectively.)

Note that for multivariate `lm()` models (of class "mlm"), these functions return 3d arrays instead of
matrices, or matrices instead of vectors.

Values for generalized linear models are approximations, as described in Williams (1987) (except
that Cook’s distances are scaled as $F$ rather than as chi-square values). The approximations can be
poor when some cases have large influence.

The optional `infl`, `res` and `sd` arguments are there to encourage the use of these direct access
functions, in situations where, e.g., the underlying basic influence measures (from `lm.influence`
or the generic `influence`) are already available.

Note that cases with weights == 0 are dropped from all these functions, but that if a linear model
has been fitted with `na.action = na.exclude`, suitable values are filled in for the cases excluded
during fitting.

For linear models, `rstandard(*, type = "predictive")` provides leave-one-out cross validation
residuals, and the “PRESS” statistic (PREdictive Sum of Squares, the same as the CV score) of
model model is

$$\text{PRESS} <- \text{sum}(\text{rstandard(model, type=\"pred\")}^2)$$

The function `hat()` exists mainly for S (version 2) compatibility; we recommend using `hatvalues()` instead.

Note

For `hatvalues`, `dfbeta`, and `dfbetas`, the method for linear models also works for generalized
linear models.

cooks.distance(glmI)))

---

**integrate**

*Integration of One-Dimensional Functions*

**Description**

Adaptive quadrature of functions of one variable over a finite or infinite interval.

**Usage**

```r
integrate(f, lower, upper, ..., subdivisions = 100L,
rel.tol = .Machine$double.eps^0.25, abs.tol = rel.tol,
stop.on.error = TRUE, keep.xy = FALSE, aux = NULL)
```

**Arguments**

- `f` an \texttt{R} function taking a numeric first argument and returning a numeric vector of the same length. Returning a non-finite element will generate an error.
- `lower, upper` the limits of integration. Can be infinite.
- `...` additional arguments to be passed to \texttt{f}.
- `subdivisions` the maximum number of subintervals.
- `rel.tol` relative accuracy requested.
- `abs.tol` absolute accuracy requested.
- `stop.on.error` logical. If true (the default) an error stops the function. If false some errors will give a result with a warning in the message component.
- `keep.xy` unused. For compatibility with S.
- `aux` unused. For compatibility with S.

**Details**

Note that arguments after \ldots must be matched exactly.

If one or both limits are infinite, the infinite range is mapped onto a finite interval.

For a finite interval, globally adaptive interval subdivision is used in connection with extrapolation by Wynn’s Epsilon algorithm, with the basic step being Gauss–Kronrod quadrature.

`rel.tol` cannot be less than `\max(50* .Machine$double.eps, 0.5e-28)` if `abs.tol <= 0`.

Note that the comments in the \texttt{C} source code in `R/src/appl/integrate.c` give more details, particularly about reasons for failure (internal error code \texttt{ier >= 1}).

In \texttt{R} versions ≤ 3.2.x, the first entries of `lower` and `upper` were used whereas an error is signalled now if they are not of length one.
Value

A list of class "integrate" with components

- **value**: the final estimate of the integral.
- **abs.error**: estimate of the modulus of the absolute error.
- **subdivisions**: the number of subintervals produced in the subdivision process.
- **message**: "OK" or a character string giving the error message.
- **call**: the matched call.

Note

Like all numerical integration routines, these evaluate the function on a finite set of points. If the function is approximately constant (in particular, zero) over nearly all its range it is possible that the result and error estimate may be seriously wrong.

When integrating over infinite intervals do so explicitly, rather than just using a large number as the endpoint. This increases the chance of a correct answer – any function whose integral over an infinite interval is finite must be near zero for most of that interval.

For values at a finite set of points to be a fair reflection of the behaviour of the function elsewhere, the function needs to be well-behaved, for example differentiable except perhaps for a small number of jumps or integrable singularities.

f must accept a vector of inputs and produce a vector of function evaluations at those points. The Vectorize function may be helpful to convert f to this form.

Source

Based on QUADPACK routines dqags and dqagi by R. Piessens and E. deDoncker–Kapenga, available from Netlib.

Examples

```r
integrate(dnorm, -1.96, 1.96)
integrate(dnorm, -Inf, Inf)
## a slowly-convergent integral
integrand <- function(x) {1/((x+1)*sqrt(x))}
integrate(integrand, lower = 0, upper = Inf)
## don't do this if you really want the integral from 0 to Inf
integrate(integrand, lower = 0, upper = 10)
integrate(integrand, lower = 0, upper = 100000)
integrate(integrand, lower = 0, upper = 1000000, stop.on.error = FALSE)
## some functions do not handle vector input properly
f <- function(x) 2.0
try(integrate(f, 0, 1))
integrate(Vectorize(f), 0, 1) ## correct
integrate(function(x) rep(2.0, length(x)), 0, 1) ## correct
```
## integrate can fail if misused
integrate(dnorm, 0, 2)
integrate(dnorm, 0, 20)
integrate(dnorm, 0, 200)
integrate(dnorm, 0, 2000)
integrate(dnorm, 0, 20000) ## fails on many systems
integrate(dnorm, 0, Inf) ## works

integrate(dnorm, 0:1, 20) #-> error!
## "silently" gave integrate(dnorm, 0, 20) in earlier versions of R

---

**interaction.plot**  
**Two-way Interaction Plot**

### Description
Plots the mean (or other summary) of the response for two-way combinations of factors, thereby illustrating possible interactions.

### Usage

```r
interaction.plot(x.factor, trace.factor, response, fun = mean,
                 type = c("l", "p", "b", "o", "c"), legend = TRUE,
                 trace.label = deparse1(substitute(trace.factor)),
                 fixed = FALSE,
                 xlab = deparse1(substitute(x.factor)),
                 ylab = ylabel,
                 ylim = range(cells, na.rm = TRUE),
                 lty = nc:1, col = 1, pch = c(1:9, 0, letters),
                 xpd = NULL, leg.bg = par("bg"), leg.bty = "n",
                 xtick = FALSE, xaxt = par("xaxt"), axes = TRUE,
                 ...)  
```

### Arguments

- **x.factor**  
a factor whose levels will form the x axis.

- **trace.factor**  
another factor whose levels will form the traces.

- **response**  
a numeric variable giving the response.

- **fun**  
the function to compute the summary. Should return a single real value.

- **type**  
the type of plot (see `plot.default`): lines or points or both.

- **legend**  
logical. Should a legend be included?

- **trace.label**  
overall label for the legend.

- **fixed**  
logical. Should the legend be in the order of the levels of `trace.factor` (TRUE) or in the order of the traces at their right-hand ends (FALSE, the default)?

- **xlab, ylab**  
the x and y label of the plot each with a sensible default.

- **ylim**  
numeric of length 2 giving the y limits for the plot.

- **lty**  
line type for the lines drawn, with sensible default.
interaction.plot

col the color to be used for plotting.
pch a vector of plotting symbols or characters, with sensible default.
xpd determines clipping behaviour for the legend used, see par(xpd). Per default, the legend is not clipped at the figure border.
leg.bg, leg.bty arguments passed to legend().
xtick logical. Should tick marks be used on the x axis?
xaxt, axes, ... graphics parameters to be passed to the plotting routines.

Details

By default the levels of x.factor are plotted on the x axis in their given order, with extra space on the right for the legend (if specified). If x.factor is an ordered factor and the levels are numeric, these numeric values are used for the x axis.

The response and hence its summary can contain missing values. If so, the missing values and the line segments joining them are omitted from the plot (and this can be somewhat disconcerting).

The graphics parameters xlab, ylab, ylim, lty, col and pch are given suitable defaults (and xlim and xaxs are set and cannot be overridden). The defaults are to cycle through the line types, use the foreground colour, and to use the symbols 1:9, 0, and the small letters to plot the traces.

Note

Some of the argument names and the precise behaviour are chosen for S-compatibility.

References

Examples

require(graphics)

with(ToothGrowth, {
  interaction.plot(dose, supp, len, fixed = TRUE)
  dose <- ordered(dose)
  interaction.plot(dose, supp, len, fixed = TRUE,
                   col = 2:3, leg.bty = "o", xtick = TRUE)
  interaction.plot(dose, supp, len, fixed = TRUE, col = 2:3, type = "p")
})

with(OrchardSprays, {
  interaction.plot(treatment, rowpos, decrease)
  interaction.plot(rowpos, treatment, decrease, cex.axis = 0.8)
  ## order the rows by their mean effect
  rowpos <- factor(rowpos,
                   levels = sort.list(tapply(decrease, rowpos, mean)))
  interaction.plot(rowpos, treatment, decrease, col = 2:9, lty = 1)
})
IQR

The Interquartile Range

Description

computes interquartile range of the x values.

Usage

IQR(x, na.rm = FALSE, type = 7)

Arguments

x a numeric vector.
na.rm logical. Should missing values be removed?
type an integer selecting one of the many quantile algorithms, see quantile.

Details

Note that this function computes the quartiles using the quantile function rather than following Tukey’s recommendations, i.e., $\text{IQR}(x) = \text{quantile}(x, 3/4) - \text{quantile}(x, 1/4)$.

For normally $N(m, 1)$ distributed $X$, the expected value of $\text{IQR}(X)$ is $2\times\text{qnorm}(3/4) = 1.3490$, i.e., for a normal-consistent estimate of the standard deviation, use $\text{IQR}(x) / 1.349$.

IQR(rivers)

---

is.empty.model

Test if a Model’s Formula is Empty

Description

R’s formula notation allows models with no intercept and no predictors. These require special handling internally. is.empty.model() checks whether an object describes an empty model.

Usage

is.empty.model(x)
**isoreg**

Arguments

- `x` A `terms` object or an object with a `terms` method.

Value

- TRUE if the model is empty

See Also

- `lm`, `glm`

Examples

```r
y <- rnorm(20)
is.empty.model(y ~ 0)
is.empty.model(y ~ -1)
is.empty.model(lm(y ~ 0))
```

---

**isoreg**  
**Isotonic / Monotone Regression**

Description

Compute the isotonic (monotonically increasing nonparametric) least squares regression which is piecewise constant.

Usage

```r
isoreg(x, y = NULL)
```

Arguments

- `x`, `y` coordinate vectors of the regression points. Alternatively a single plotting structure can be specified: see `xy.coords`. The `y` values, and even `sum(y)` must be finite, currently.

Details

The algorithm determines the convex minorant \( m(x) \) of the cumulative data (i.e., \( \text{cumsum}(y) \)) which is piecewise linear and the result is \( m'(x) \), a step function with level changes at locations where the convex \( m(x) \) touches the cumulative data polygon and changes slope.  

- `as.stepfun()` returns a `stepfun` object which can be more parsimonious.

Value

- `isoreg()` returns an object of class `isoreg` which is basically a list with components
  - `x` original (constructed) abscissa values `x`.
  - `y` corresponding `y` values.
  - `yf` fitted values corresponding to ordered `x` values.
  - `yc` cumulative `y` values corresponding to ordered `x` values.
iKnots integer vector giving indices where the fitted curve jumps, i.e., where the convex minorant has kinks.

isOrd logical indicating if original x values were ordered increasingly already.

ord if(!isOrd)
: integer permutation order(x) of original x.

call the call to isoreg() used.

Note

The inputs can be long vectors, but iKnots will wrap around at $2^{31}$.

The code should be improved to accept weights additionally and solve the corresponding weighted least squares problem.

‘Patches are welcome!’

References

See Also

the plotting method plot.isoreg with more examples; isoMDS() from the MASS package internally uses isotonic regression.

Examples

```r
require(graphics)

(ir <- isoreg(c(1,0,4,3,3,5,4,2,0)))
plot(ir, plot.type = "row")

(ir3 <- isoreg(y3 <- c(1,0,4,3,3,5,4,2, 3))) # last "3", not "0"
(f13 <- as.stepfun(ir3))
(ir4 <- isoreg(1:10, y4 <- c(5, 9, 1:2, 5:8, 3, 8)))
cat(sprintf("R^2 = %.2f\n",
1 - sum(residuals(ir4)^2) / ((10-1)*var(y4))))

## If you are interested in the knots alone :
with(ir4, cbind(iKnots, yf[iKnots]))

## Example of unordered x[] with ties:
x <- sample((0:30)/8)
y <- exp(x)
x. <- round(x) # ties!
plot(m <- isoreg(x., y))
stopifnot(all.equal(with(m, yf[iKnots]),
as.vector(tapply(y, x., mean))))
```
KalmanLike

Description

Use Kalman Filtering to find the (Gaussian) log-likelihood, or for forecasting or smoothing.

Usage

KalmanLike(y, mod, nit = 0L, update = FALSE)
KalmanRun(y, mod, nit = 0L, update = FALSE)
KalmanSmooth(y, mod, nit = 0L)
KalmanForecast(n.ahead = 10L, mod, update = FALSE)
makeARIMA(phi, theta, Delta, kappa = 1e6,
           SSinit = c("Gardner1980", "Rossignol2011"),
           tol = .Machine$double.eps)

Arguments

y
  a univariate time series.
mod
  a list describing the state-space model: see ‘Details’.
nit
  the time at which the initialization is computed. nit = 0L implies that the initialization is for a one-step prediction, so \( P_n \) should not be computed at the first step.
update
  if TRUE the update mod object will be returned as attribute "mod" of the result.
n.ahead
  the number of steps ahead for which prediction is required.
phi, theta
  numeric vectors of length \( \geq 0 \) giving AR and MA parameters.
Delta
  vector of differencing coefficients, so an ARMA model is fitted to \( y[t] - \Delta[1]*y[t-1] - \ldots \).
kappa
  the prior variance (as a multiple of the innovations variance) for the past observations in a differenced model.
SSinit
  a string specifying the algorithm to compute the \( P_n \) part of the state-space initialization; see ‘Details’.
tol
  tolerance eventually passed to solve.default when SSinit = "Rossignol2011".

Details

These functions work with a general univariate state-space model with state vector ‘a’, transitions ‘a \( \leftarrow T a + R e \), \( e \sim N(0, \kappa Q) \) and observation equation ‘y = Z'a + eta’, (eta \( \equiv \eta \), \( \eta \sim N(0, \kappa h) \). The likelihood is a profile likelihood after estimation of \( \kappa \).

The model is specified as a list with at least components

- \( T \) the transition matrix
- \( Z \) the observation coefficients
- \( h \) the observation variance
KalmanLike

V 'RQR'

a the current state estimate
P the current estimate of the state uncertainty matrix Q
Pn the estimate at time $t-1$ of the state uncertainty matrix Q (not updated by KalmanForecast).

KalmanSmooth is the workhorse function for tsSmooth.

makeARIMA constructs the state-space model for an ARIMA model, see also arima.

The state-space initialization has used Gardner et al.’s method (SSinit = "Gardner1980"), as only method for years. However, that suffers sometimes from deficiencies when close to non-stationarity. For this reason, it may be replaced as default in the future and only kept for reproducibility reasons. Explicit specification of SSinit is therefore recommended, notably also in arima(). The "Rossignol2011" method has been proposed and partly documented by Raphael Rossignol, Univ. Grenoble, on 2011-09-20 (see PR#14682, below), and later been ported to C by Matwey V. Kornilov. It computes the covariance matrix of $(X_{t-1}, ..., X_{t-p}, Z_t, ..., Z_{t-q})$ by the method of difference equations (page 93 of Brockwell and Davis (1991)), apparently suggested by a referee of Gardner et al. (see p.314 of their paper).

Value

For KalmanLike, a list with components Lik (the log-likelihood less some constants) and s2, the estimate of $\kappa$.

For KalmanRun, a list with components values, a vector of length 2 giving the output of KalmanLike, resid (the residuals) and states, the contemporaneous state estimates, a matrix with one row for each observation time.

For KalmanSmooth, a list with two components. Component smooth is a $n$ by $p$ matrix of state estimates based on all the observations, with one row for each time. Component var is a $n$ by $p$ by $p$ array of variance matrices.

For KalmanForecast, a list with components pred, the predictions, and var, the unscaled variances of the prediction errors (to be multiplied by s2).

For makeARIMA, a model list including components for its arguments.

Warning

These functions are designed to be called from other functions which check the validity of the arguments passed, so very little checking is done.

           se = sqrt(pr$var * fit3$sigma2)))
  mod <- attr(pr, "mod")
}
```

kernapply

**Apply Smoothing Kernel**

**Description**

kernapply computes the convolution between an input sequence and a specific kernel.

**Usage**

```r
kernapply(x, ...)
```

## Default S3 method:
```r
kernapply(x, k, circular = FALSE, ...)
```

## S3 method for class 'ts'
```r
kernapply(x, k, circular = FALSE, ...)
```

## S3 method for class 'vector'
```r
kernapply(x, k, circular = FALSE, ...)
```

## S3 method for class 'tskernel'
```r
kernapply(x, k, circular = FALSE, ...)
```

**Arguments**

- `x`: an input vector, matrix, time series or kernel to be smoothed.
- `k`: smoothing "tskernel" object.
- `circular`: a logical indicating whether the input sequence to be smoothed is treated as circular, i.e., periodic.
- `...`: arguments passed to or from other methods.

**Value**

A smoothed version of the input sequence.
Note

This uses \texttt{fft} to perform the convolution, so is fastest when \texttt{NROW(x)} is a power of 2 or some other highly composite integer.

---

kernel  

\textit{Smoothing Kernel Objects}

Description

The "tskernel" class is designed to represent discrete symmetric normalized smoothing kernels. These kernels can be used to smooth vectors, matrices, or time series objects.

There are \texttt{print, plot} and \texttt{[]} methods for these kernel objects.

Usage

\begin{verbatim}
kernel(coef, m = 2, r, name)

df.kernel(k)
bandwidth.kernel(k)
is.tskernel(k)

## S3 method for class 'tskernel'
plot(x, type = "h", xlab = "k", ylab = "W[k]",
     main = attr(x,"name"), \ldots)
\end{verbatim}

Arguments

\begin{itemize}
\item \texttt{coef} the upper half of the smoothing kernel coefficients (including coefficient zero) or the name of a kernel (currently "daniell", "dirichlet", "fejer" or "modified.daniell").
\item \texttt{m} the kernel dimension(s) if \texttt{coef} is a name. When \texttt{m} has length larger than one, it means the convolution of kernels of dimension \texttt{m[j]}, for \texttt{j} in 1:length(\texttt{m}). Currently this is supported only for the named "*daniell" kernels.
\item \texttt{name} the name the kernel will be called.
\item \texttt{r} the kernel order for a Fejer kernel.
\item \texttt{k, x} a "tskernel" object.
\item \texttt{type, xlab, ylab, main, \ldots} arguments passed to \texttt{plot.default}.
\end{itemize}
Details

`kernel` is used to construct a general kernel or named specific kernels. The modified Daniell kernel halves the end coefficients.

The `[` method allows natural indexing of kernel objects with indices in `(-m) : m`. The normalization is such that for `k <- kernel(*)`, `sum(k[-k$m : k$m])` is one.

df.kernel returns the ‘equivalent degrees of freedom’ of a smoothing kernel as defined in Brockwell and Davis (1991), page 362, and bandwidth.kernel returns the equivalent bandwidth as defined in Bloomfield (1976), p. 201, with a continuity correction.

Value

`kernel()` returns an object of class "tskernel" which is basically a list with the two components `coef` and the kernel dimension `m`. An additional attribute is "name".

k1 <- kernel("daniell", 50)  # a long moving average
k2 <- kernel("daniell", 10)  # and a short one
plot(k1)
plot(k2)
x1 <- kernapply(x, k1)
x2 <- kernapply(x, k2)
plot(x)
lines(x1, col = "red")  # go long if the short crosses the long upwards
lines(x2, col = "green")  # and go short otherwise

## More interesting kernels
kd <- kernel("daniell", c(3, 3))
kd # note the unusual indexing
kd[-2:2]
plot(kernel("fejer", 100, r = 6))
plot(kernel("modified.daniell", c(7,5,3)))

# Reproduce example 10.4.3 from Brockwell and Davis (1991)
spectrum(sunspot.year, kernel = kernel("daniell", c(11,7,3)), log = "no")
```
kmeans

K-Means Clustering

Description
Perform k-means clustering on a data matrix.

Usage
kmeans(x, centers, iter.max = 10, nstart = 1,
       algorithm = c("Hartigan-Wong", "Lloyd", "Forgy",
                     "MacQueen"), trace = FALSE)

## S3 method for class 'kmeans'
fitted(object, method = c("centers", "classes"), ...)

Arguments
x numeric matrix of data, or an object that can be coerced to such a matrix (such
as a numeric vector or a data frame with all numeric columns).
centers either the number of clusters, say k, or a set of initial (distinct) cluster centres.
If a number, a random set of (distinct) rows in x is chosen as the initial centres.
iter.max the maximum number of iterations allowed.
nstart if centers is a number, how many random sets should be chosen?
algorithm character: may be abbreviated. Note that "Lloyd" and "Forgy" are alternative
names for one algorithm.
object an R object of class "kmeans", typically the result ob of ob <- kmeans(..).
method character: may be abbreviated. "centers" causes fitted to return cluster cen-
ters (one for each input point) and "classes" causes fitted to return a vector
of class assignments.
trace logical or integer number, currently only used in the default method
("Hartigan-Wong"): if positive (or true), tracing information on the progress
of the algorithm is produced. Higher values may produce more tracing informa-
tion.
... not used.

Details
The data given by x are clustered by the k-means method, which aims to partition the points into k
groups such that the sum of squares from points to the assigned cluster centres is minimized. At the
minimum, all cluster centres are at the mean of their Voronoi sets (the set of data points which are
nearest to the cluster centre).

The algorithm of Hartigan and Wong (1979) is used by default. Note that some authors use k-
means to refer to a specific algorithm rather than the general method: most commonly the algorithm
given by MacQueen (1967) but sometimes that given by Lloyd (1957) and Forgy (1965). The
Hartigan–Wong algorithm generally does a better job than either of those, but trying several random
starts (nstart> 1) is often recommended. In rare cases, when some of the points (rows of x) are
extremely close, the algorithm may not converge in the “Quick-Transfer” stage, signalling a warning
(and returning ifault = 4). Slight rounding of the data may be advisable in that case.
For ease of programmatic exploration, \( k = 1 \) is allowed, notably returning the center and withinss. Except for the Lloyd–Forgy method, \( k \) clusters will always be returned if a number is specified. If an initial matrix of centres is supplied, it is possible that no point will be closest to one or more centres, which is currently an error for the Hartigan–Wong method.

**Value**

`kmeans` returns an object of class "`kmeans`" which has a print and a fitted method. It is a list with at least the following components:

- `cluster`: A vector of integers (from 1: \( k \)) indicating the cluster to which each point is allocated.
- `centers`: A matrix of cluster centres.
- `totss`: The total sum of squares.
- `withinss`: Vector of within-cluster sum of squares, one component per cluster.
- `tot.withinss`: Total within-cluster sum of squares, i.e. \( \text{sum(withinss)} \).
- `betweenss`: The between-cluster sum of squares, i.e. \( \text{totss-tot.withinss} \).
- `size`: The number of points in each cluster.
- `iter`: The number of (outer) iterations.

**Note**

The clusters are numbered in the returned object, but they are a set and no ordering is implied. (Their apparent ordering may differ by platform.)

**References**

**Examples**

```r
require(graphics)

# a 2-dimensional example
x <- rbind(matrix(rnorm(100, sd = 0.3), ncol = 2),
           matrix(rnorm(100, mean = 1, sd = 0.3), ncol = 2))
colnames(x) <- c("x", "y")
(cl <- kmeans(x, 2))
plot(x, col = cl$cluster)
points(cl$centers, col = 1:2, pch = 8, cex = 2)

# sum of squares
```
```
ss <- function(x) sum(scale(x, scale = FALSE)^2)

## cluster centers "fitted" to each obs.:
fitted.x <- fitted(cl); head(fitted.x)
resid.x <- x - fitted(cl)

## Equalities : ----------------------------------
cbind(cl[c("betweenss", "tot.withinss", "totss")], # the same two columns
c(ss(fitted.x), ss(resid.x), ss(x)))
stopifnot(all.equal(cl$totss, ss(x)),
  all.equal(cl$tot.withinss, ss(resid.x)),
  all.equal(cl$betweenss, ss(fitted.x)),
  all.equal(cl$betweenss, cl$totss - cl$tot.withinss),
  ## these three are the same:
  all.equal(ss(x), ss(fitted.x) + ss(resid.x))
)

kmeans(x, 1)$withinss # trivial one-cluster, (its W.SS == ss(x))

## random starts do help here with too many clusters
## (and are often recommended anyway!):
## The ordering of the clusters may be platform-dependent.
(cl <- kmeans(x, 5, nstart = 25))
plot(x, col = cl$cluster)
points(cl$centers, col = 1:5, pch = 8)
```

---

### kruskal.test

#### Kruskal-Wallis Rank Sum Test

**Description**

Performs a Kruskal-Wallis rank sum test.

**Usage**

```
kruskal.test(x, ...)
```

**Arguments**

- `x` a numeric vector of data values, or a list of numeric data vectors. Non-numeric elements of a list will be coerced, with a warning.
- `g` a vector or factor object giving the group for the corresponding elements of `x`. Ignored with a warning if `x` is a list.
a formula of the form response ~ group where response gives the data values and group a vector or factor of the corresponding groups.

data an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.

... further arguments to be passed to or from methods.

Details

kruskal.test performs a Kruskal-Wallis rank sum test of the null that the location parameters of the distribution of x are the same in each group (sample). The alternative is that they differ in at least one.

If x is a list, its elements are taken as the samples to be compared, and hence have to be numeric data vectors. In this case, g is ignored, and one can simply use `kruskal.test(x)` to perform the test. If the samples are not yet contained in a list, use `kruskal.test(list(x, ...))`.

Otherwise, x must be a numeric data vector, and g must be a vector or factor object of the same length as x giving the group for the corresponding elements of x.

Value

A list with class "htest" containing the following components:

- **statistic** the Kruskal-Wallis rank sum statistic.
- **parameter** the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- **p.value** the p-value of the test.
- **method** the character string "Kruskal-Wallis rank sum test".
- **data.name** a character string giving the names of the data.

References

The Wilcoxon rank sum test (`wilcox.test`) as the special case for two samples; `lm` together with `anova` for performing one-way location analysis under normality assumptions; with Student’s t test (`t.test`) as the special case for two samples.

`wilcox_test` in package `coin` for exact, asymptotic and Monte Carlo conditional p-values, including in the presence of ties.
Examples

## Hollander & Wolfe (1973), 116.
## Mucociliary efficiency from the rate of removal of dust in normal
## subjects, subjects with obstructive airway disease, and subjects
## with asbestosis.
x <- c(2.9, 3.0, 2.5, 2.6, 3.2) # normal subjects
y <- c(3.8, 2.7, 4.0, 2.4) # with obstructive airway disease
z <- c(2.8, 3.4, 3.7, 2.2, 2.0) # with asbestosis
kruskal.test(list(x, y, z))
## Equivalently,
x <- c(x, y, z)
g <- factor(rep(1:3, c(5, 4, 5)),
    labels = c("Normal subjects",
    "Subjects with obstructive airway disease",
    "Subjects with asbestosis"))
kruskal.test(x, g)

## Formula interface.
require(graphics)
boxplot(Ozone ~ Month, data = airquality)
kruskal.test(Ozone ~ Month, data = airquality)

ks.test

Kolmogorov-Smirnov Tests

Description

Perform a one- or two-sample Kolmogorov-Smirnov test.

Usage

ks.test(x, ...)
## Default S3 method:
ks.test(x, y, ...,
    alternative = c("two.sided", "less", "greater"),
    exact = NULL, simulate.p.value = FALSE, B = 2000)
## S3 method for class 'formula'
ks.test(formula, data, subset, na.action, ...)

Arguments

x

a numeric vector of data values.

y

either a numeric vector of data values, or a character string naming a cumulative
distribution function or an actual cumulative distribution function such as pnorm.
Only continuous CDFs are valid.

... for the default method, parameters of the distribution specified (as a character
string) by y. Otherwise, further arguments to be passed to or from methods.

alternative indicates the alternative hypothesis and must be one of "two.sided" (default),
"less", or "greater". You can specify just the initial letter of the value, but
the argument name must be given in full. See ‘Details’ for the meanings of the
possible values.
ks.test

exact

NULL or a logical indicating whether an exact p-value should be computed. See 'Details' for the meaning of NULL.

simulate.p.value

a logical indicating whether to compute p-values by Monte Carlo simulation. (Ignored for the one-sample test.)

B

an integer specifying the number of replicates used in the Monte Carlo test.

formula

a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs either 1 for a one-sample test or a factor with two levels giving the corresponding groups for a two-sample test.

data

an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset

an optional vector specifying a subset of observations to be used.

na.action

a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").

Details

If y is numeric, a two-sample (Smirnov) test of the null hypothesis that x and y were drawn from the same distribution is performed.

Alternatively, y can be a character string naming a continuous (cumulative) distribution function, or such a function. In this case, a one-sample (Kolmogorov) test is carried out of the null that the distribution function which generated x is distribution y with parameters specified by ... The presence of ties always generates a warning in the one-sample case, as continuous distributions do not generate them. If the ties arose from rounding the tests may be approximately valid, but even modest amounts of rounding can have a significant effect on the calculated statistic.

Missing values are silently omitted from x and (in the two-sample case) y.

The possible values "two.sided", "less" and "greater" of alternative specify the null hypothesis that the true cumulative distribution function (CDF) of x is equal to, not less than or not greater than the hypothesized CDF (one-sample case) or the CDF of y (two-sample case), respectively. The test compares the CDFs taking their maximal difference as test statistic, with the statistic in the "greater" alternative being \( D^+ = \max_u [F_x(u) - F_y(u)] \). Thus in the two-sample case alternative = "greater" includes distributions for which x is stochastically smaller than y (the CDF of x lies above and hence to the left of that for y), in contrast to t.test or wilcox.test.

Exact p-values are not available for the one-sample case in the presence of ties. If exact = NULL (the default), an exact p-value is computed if the sample size is less than 100 in the one-sample case and there are no ties, and if the product of the sample sizes is less than 10000 in the two-sample case, with or without ties (using the algorithm described in Schröer and Trenkler (1995)). Otherwise, the p-value is computed via Monte Carlo simulation in the two-sample case if simulate.p.value is TRUE, or else asymptotic distributions are used whose approximations may be inaccurate in small samples. In the one-sample two-sided case, exact p-values are obtained as described in Marsaglia, Tsang & Wang (2003) (but not using the optional approximation in the right tail, so this can be slow for small p-values). The formula of Birnbaum & Tingey (1951) is used for the one-sample one-sided case.

If a one-sample test is used, the parameters specified in ... must be pre-specified and not estimated from the data. There is some more refined distribution theory for the KS test with estimated parameters (see Durbin, 1973), but that is not implemented in ks.test.
Value

A list inheriting from classes "ks.test" and "htest" containing the following components:

- **statistic**: the value of the test statistic.
- **p.value**: the p-value of the test.
- **alternative**: a character string describing the alternative hypothesis.
- **method**: a character string indicating what type of test was performed.
- **data.name**: a character string giving the name(s) of the data.

Source

Exact distributions for the two-sample (Smirnov) test are computed by the algorithm proposed by Schröer (1991) and Schröer & Trenkler (1995) using numerical improvements along the lines of Viehmann (2021).

References

See Also

- `psmirnov`
- `shapiro.test` which performs the Shapiro-Wilk test for normality.

Examples

```r
require("graphics")
x <- rnorm(50)
y <- runif(30)
# Do x and y come from the same distribution?
ks.test(x, y)
# Does x come from a shifted gamma distribution with shape 3 and rate 2?
```
ksmooth

Kernel Regression Smoother

Description

The Nadaraya–Watson kernel regression estimate.

Usage

```r
ksmooth(x, y, kernel = c("box", "normal"), bandwidth = 0.5,
        range.x = range(x),
        n.points = max(100L, length(x)), x.points)
```

Arguments

- `x`: input x values. Long vectors are supported.
- `y`: input y values. Long vectors are supported.
- `kernel`: the kernel to be used. Can be abbreviated.
- `bandwidth`: the bandwidth. The kernels are scaled so that their quartiles (viewed as probability densities) are at ±0.25*bandwidth.
- `range.x`: the range of points to be covered in the output.
- `n.points`: the number of points at which to evaluate the fit.
- `x.points`: points at which to evaluate the smoothed fit. If missing, `n.points` are chosen uniformly to cover `range.x`. Long vectors are supported.

Value

A list with components

- `x`: values at which the smoothed fit is evaluated. Guaranteed to be in increasing order.
- `y`: fitted values corresponding to `x`.

# test if x is stochastically larger than x2
x2 <- rnorm(50, -1)
plot(ecdf(x), xlim = range(c(x, x2)))
plot(ecdf(x2), add = TRUE, lty = "dashed")
t.test(x, x2, alternative = "g")
wilcox.test(x, x2, alternative = "g")
ks.test(x, x2, alternative = "l")

# with ties, example from Schröer and Trenkler (1995)
# D = 3/7, p = 8/33 = 0.242424..
ks.test(c(1, 2, 2, 3, 3),
c(1, 2, 3, 4, 5, 6)) # -> exact

# formula interface, see ?wilcox.test
ks.test(Ozone ~ Month, data = airquality,
       subset = Month %in% c(5, 8))
Note

This function was implemented for compatibility with S, although it is nowhere near as slow as the S function. Better kernel smoothers are available in other packages such as *KernSmooth*.

Examples

```r
require(graphics)
with(cars, {
  plot(speed, dist)
  lines(ksmooth(speed, dist, "normal", bandwidth = 2), col = 2)
  lines(ksmooth(speed, dist, "normal", bandwidth = 5), col = 3)
})
```

---

**lag**

*Lag a Time Series*

Description

Compute a lagged version of a time series, shifting the time base back by a given number of observations.

`lag` is a generic function; this page documents its default method.

Usage

```r
lag(x, ...)
```

### Default S3 method:

```r
lag(x, k = 1, ...)
```

Arguments

- `x` A vector or matrix or univariate or multivariate time series
- `k` The number of lags (in units of observations).
- `...` further arguments to be passed to or from methods.

Details

Vector or matrix arguments `x` are given a `tsp` attribute via `hasTsp`.

Value

A time series object with the same class as `x`.

Note

Note the sign of `k`: a series lagged by a positive `k` starts *earlier*.

References

See Also
diff, deltat

Examples

lag(ldeaths, 12) # starts one year earlier

Description

Plot time series against lagged versions of themselves. Helps visualizing ‘auto-dependence’ even when auto-correlations vanish.

Usage

lag.plot(x, lags = 1, layout = NULL, set.lags = 1:lags,
main = NULL, asp = 1,
diag = TRUE, diag.col = "gray", type = "p", oma = NULL,
ask = NULL, do.lines = (n <= 150), labels = do.lines,
...)
Details

If just one plot is produced, this is a conventional plot. If more than one plot is to be produced, `par(mfrow)` and several other graphics parameters will be set, so it is not (easily) possible to mix such lag plots with other plots on the same page.

If `ask = NULL`, `par(ask = TRUE)` will be called if more than one page of plots is to be produced and the device is interactive.

Note

It is more flexible and has different default behaviour than the S version. We use `main =` instead of `head =` for internal consistency.

Author(s)

Martin Maechler

See Also

`plot.ts` which is the basic work horse.

Examples

```r
require(graphics)
lag.plot(nhtemp, 8, diag.col = "forest green")
lag.plot(nhtemp, 5, main = "Average Temperatures in New Haven")
## ask defaults to TRUE when we have more than one page:
lag.plot(nhtemp, 6, layout = c(2,1), asp = NA,
        main = "New Haven Temperatures", col.main = "blue")
## Multivariate (but non-stationary! ...)
lag.plot(freeny.x, lags = 3)
## no lines for long series :
lag.plot(sqrt(sunspots), set.lags = c(1:4, 9:12), pch = ".", col = "gold")
```

Description

Fit a line robustly as recommended in *Exploratory Data Analysis*.

Currently by default (`iter = 1`) the initial median-median line is *not* iterated (as opposed to Tukey’s “resistant line” in the references).

Usage

```r
line(x, y, iter = 1)
```
Arguments

- **x, y** the arguments can be any way of specifying x-y pairs. See `xy.coords`.
- **iter** positive integer specifying the number of “polishing” iterations. Note that this was hard coded to 1 in R versions before 3.5.0, and more importantly that such simple iterations may not converge, see Siegel’s 9-point example.

Details

Cases with missing values are omitted.

Contrary to the references where the data is split in three (almost) equally sized groups with symmetric sizes depending on $n$ and $n \ mod \ 3$ and computes medians inside each group, the `line()` code splits into three groups using all observations with $x[.] \ leq q1$ and $x[.] \ geq q2$, where $q1$, $q2$ are (a kind of) quantiles for probabilities $p = 1/3$ and $p = 2/3$ of the form $(x[j1]+x[j2])/2$ where $j1 = \text{floor}(p\cdot(n-1))$ and $j2 = \text{ceiling}(p\cdot(n-1))$, $n = \text{length}(x)$.

Long vectors are not supported yet.

Value

An object of class "tukeyline".

Methods are available for the generic functions `coef`, `residuals`, `fitted`, and `print`.

References

- `lm`

There are alternatives for robust linear regression more robust and more (statistically) efficient, see `rlm()` from `MASS`, or `lmrob()` from `robustbase`.

Examples

```r
require(graphics)

plot(cars)
(z <- line(cars))
abline(coef(z))
## Tukey-Anscombe Plot :
plot(residuals(z) ~ fitted(z), main = deparse(z$call))

## Andrew Siegel's pathological 9-point data, y-values multiplied by 3:
d.AS <- data.frame(x = c(-4:3, 12), y = 3*c(rep(0,6), -5, 5, 1))
c.AS <- with(d.AS, t(sapply(1:10,

```
function(it) line(x, y, iter=it$coefficients)))

dimnames(cAS) <- list(paste("it =", format(1:10)), c("intercept", "slope"))
cAS

## iterations started to oscillate, repeating iteration 7,8 indefinitely

### listof

**A Class for Lists of (Parts of) Model Fits**

**Description**

Class "listof" is used by `aov` and the "lm" method of `alias` for lists of model fits or parts thereof. It is simply a list with an assigned class to control the way methods, especially printing, act on it. It has a `coef` method in this package (which returns an object of this class), and `[` and `print` methods in package `base`.

### lm

**Fitting Linear Models**

**Description**

`lm` is used to fit linear models, including multivariate ones. It can be used to carry out regression, single stratum analysis of variance and analysis of covariance (although `aov` may provide a more convenient interface for these).

**Usage**

`lm(formula, data, subset, weights, na.action, method = "qr", model = TRUE, x = FALSE, y = FALSE, qr = TRUE, singular.ok = TRUE, contrasts = NULL, offset, ...)`

```
## S3 method for class 'lm'
print(x, digits = max(3L, getOption("digits") - 3L), ...)
```

**Arguments**

- `formula` an object of class "formula" (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under 'Details'.
- `data` an optional data frame, list or environment (or object coercible by `as.data.frame` to a data frame) containing the variables in the model. If not found in `data`, the variables are taken from `environment(formula)`, typically the environment from which `lm` is called.
- `subset` an optional vector specifying a subset of observations to be used in the fitting process. (See additional details about how this argument interacts with data-dependent bases in the 'Details' section of the `model.frame` documentation.)
- `weights` an optional vector of weights to be used in the fitting process. Should be `NULL` or a numeric vector. If non-NULL, weighted least squares is used with weights `weights` (that is, minimizing `sum(w*e^2)`); otherwise ordinary least squares is used. See also 'Details',
na.action a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The ‘factory-fresh’ default is na.omit. Another possible value is NULL, no action. Value na.exclude can be useful.

method the method to be used; for fitting, currently only method = "qr" is supported; method = "model.frame" returns the model frame (the same as with model = TRUE, see below).

model, x, y, qr logicals. If TRUE the corresponding components of the fit (the model frame, the model matrix, the response, the QR decomposition) are returned.

singular.ok logical. If FALSE (the default in S but not in R) a singular fit is an error.

contrasts an optional list. See the contrasts.arg of model.matrix.default.

offset this can be used to specify an a priori known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector or matrix of extents matching those of the response. One or more offset terms can be included in the formula instead or as well, and if more than one are specified their sum is used. See model.offset.

... For lm(): additional arguments to be passed to the low level regression fitting functions (see below).

digits the number of significant digits to be passed to format(coef(x), .) when print()ing.

Details

Models for lm are specified symbolically. A typical model has the form response ~ terms where response is the (numeric) response vector and terms is a series of terms which specifies a linear predictor for response. A terms specification of the form first + second indicates all the terms in first together with all the terms in second with duplicates removed. A specification of the form first:second indicates the set of terms obtained by taking the interactions of all terms in first with all terms in second. The specification first*second indicates the cross of first and second. This is the same as first + second + first:second.

If the formula includes an offset, this is evaluated and subtracted from the response.

If response is a matrix a linear model is fitted separately by least-squares to each column of the matrix and the result inherits from "mlm" ("multivariate linear model").

See model.matrix for some further details. The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on: to avoid this pass a terms object as the formula (see aov and demo(glm.vr) for an example).

A formula has an implied intercept term. To remove this use either y ~ x - 1 or y ~ 0 + x. See formula for more details of allowed formulae.

Non-NULL weights can be used to indicate that different observations have different variances (with the values in weights being inversely proportional to the variances); or equivalently, when the elements of weights are positive integers \( w_i \), that each response \( y_i \) is the mean of \( w_i \) unit-weight observations (including the case that there are \( w_i \) observations equal to \( y_i \) and the data have been summarized). However, in the latter case, notice that within-group variation is not used. Therefore, the sigma estimate and residual degrees of freedom may be suboptimal; in the case of replication weights, even wrong. Hence, standard errors and analysis of variance tables should be treated with care.

lm calls the lower level functions lm.fit, etc, see below, for the actual numerical computations. For programming only, you may consider doing likewise.

All of weights, subset and offset are evaluated in the same way as variables in formula, that is first in data and then in the environment of formula.
Value

`lm` returns an object of class "lm" or for multivariate ('multiple') responses of class c("mlm", "lm").

The functions `summary` and `anova` are used to obtain and print a summary and analysis of variance table of the results. The generic accessor functions `coefficients`, `effects`, `fitted.values` and `residuals` extract various useful features of the value returned by `lm`.

An object of class "lm" is a list containing at least the following components:

- `coefficients` a named vector of coefficients
- `residuals` the residuals, that is response minus fitted values.
- `fitted.values` the fitted mean values.
- `rank` the numeric rank of the fitted linear model.
- `weights` (only for weighted fits) the specified weights.
- `df.residual` the residual degrees of freedom.
- `call` the matched call.
- `terms` the `terms` object used.
- `contrasts` (only where relevant) the contrasts used.
- `xlevels` (only where relevant) a record of the levels of the factors used in fitting.
- `offset` the offset used (missing if none were used).
- `y` if requested, the response used.
- `x` if requested, the model matrix used.
- `model` if requested (the default), the model frame used.
- `na.action` (where relevant) information returned by `model.frame` on the special handling of NAs.

In addition, non-null fits will have components `assign`, `effects` and (unless not requested) `qr` relating to the linear fit, for use by extractor functions such as `summary` and `effects`.

Using time series

Considerable care is needed when using `lm` with time series.

Unless `na.action = NULL`, the time series attributes are stripped from the variables before the regression is done. (This is necessary as omitting NAs would invalidate the time series attributes, and if NAs are omitted in the middle of the series the result would no longer be a regular time series.)

Even if the time series attributes are retained, they are not used to line up series, so that the time shift of a lagged or differenced regressor would be ignored. It is good practice to prepare a data argument by `ts.intersect(..., dframe = TRUE)`, then apply a suitable `na.action` to that data frame and call `lm` with `na.action = NULL` so that residuals and fitted values are time series.

Author(s)

The design was inspired by the S function of the same name described in Chambers (1992). The implementation of model formula by Ross Ihaka was based on Wilkinson & Rogers (1973).

lm.fit

Fitter Functions for Linear Models

Description

These are the basic computing engines called by lm used to fit linear models. These should usually not be used directly unless by experienced users. lm.fit() is a bare-bones wrapper to the inner-most QR-based C code, on which glm.fit and lsfit are also based, for even more experienced users.
Usage

```r
lm.fit (x, y, offset = NULL, method = "qr", tol = 1e-7,
        singular.ok = TRUE, ...)
```

```r
lm.wfit(x, y, w, offset = NULL, method = "qr", tol = 1e-7,
        singular.ok = TRUE, ...)
```

`.lm.fit(x, y, tol = 1e-7)

Arguments

- **x**: design matrix of dimension \(n \times p\).
- **y**: vector of observations of length \(n\), or a matrix with \(n\) rows.
- **w**: vector of weights (length \(n\)) to be used in the fitting process for the `wfit` functions. Weighted least squares is used with weights \(w\), i.e., \(\sum(w \times e^2)\) is minimized.
- **offset**: (numeric of length \(n\)). This can be used to specify an *a priori* known component to be included in the linear predictor during fitting.
- **method**: currently, only `method = "qr"` is supported.
- **tol**: tolerance for the `qr` decomposition. Default is `1e-7`.
- **singular.ok**: logical. If `FALSE`, a singular model is an error.
- **...**: currently disregarded.

Details

If \(y\) is a matrix, `offset` can be a numeric matrix of the same dimensions, in which case each column is applied to the corresponding column of \(y\).

Value

A list with components (for `lm.fit` and `lm.wfit`)

- **coefficients**: \(p\) vector
- **residuals**: \(n\) vector or matrix
- **fitted.values**: \(n\) vector or matrix
- **effects**: \(n\) vector of orthogonal single-df effects. The first rank of them correspond to non-aliased coefficients, and are named accordingly.
- **weights**: \(n\) vector — only for the `wfit*` functions.
- **rank**: integer, giving the rank
- **df.residual**: degrees of freedom of residuals
- **qr**: the QR decomposition, see `qr`.

Fits without any columns or non-zero weights do not have the `effects` and `qr` components.

`.lm.fit()` returns a subset of the above, the `qr` part unwrapped, plus a logical component `pivoted` indicating if the underlying QR algorithm did pivot.

See Also

- `lm` which you should use for linear least squares regression, unless you know better.
Examples

```r
require(stats)
set.seed(129)

n <- 7; p <- 2
X <- matrix(rnorm(n * p), n, p) # no intercept!
y <- rnorm(n)
w <- rnorm(n)^2

str(lmw <- lm.wfit(x = X, y = y, w = w))
str(lm. <- lm.fit(x = X, y = y))

## fits w/o intercept:
all.equal(unname(coef(lm(y ~ X-1))),
          unname(coef(lm.fit(X,y))))
all.equal(unname(coef(lm.fit(X,y))),
          coef(.lm.fit(X,y)))
```

```r
if(require("microbenchmark")) {
  mb <- microbenchmark(lm(y~X-1), lm.fit(X,y), .lm.fit(X,y))
  print(mb)
  boxplot(mb, notch=TRUE)
}
```

---

**lm.influence**                  *Regression Diagnostics*

**Description**

This function provides the basic quantities which are used in forming a wide variety of diagnostics for checking the quality of regression fits.

**Usage**

```r
influence(model, ...)
```

## S3 method for class 'lm'

```r
influence(model, do.coef = TRUE, ...)
```

## S3 method for class 'glm'

```r
influence(model, do.coef = TRUE, ...)
```

**Arguments**

- **model**
  - an object as returned by `lm` or `glm`.
- **do.coef**
  - logical indicating if the changed coefficients (see below) are desired. These need \(O(n^2p)\) computing time.
- **...**
  - further arguments passed to or from other methods.
Details

The `influence.measures()` and other functions listed in See Also provide a more user oriented way of computing a variety of regression diagnostics. These all build on `lm.influence`. Note that for GLMs (other than the Gaussian family with identity link) these are based on one-step approximations which may be inadequate if a case has high influence.

An attempt is made to ensure that computed hat values that are probably one are treated as one, and the corresponding rows in `sigma` and `coefficients` are NaN. (Dropping such a case would normally result in a variable being dropped, so it is not possible to give simple drop-one diagnostics.)

`naresid` is applied to the results and so will fill in with NAs if the fit had `na.action = na.exclude`.

Value

A list containing the following components of the same length or number of rows `n`, which is the number of non-zero weights. Cases omitted in the fit are omitted unless a `na.action` method was used (such as `na.exclude`) which restores them.

- **hat**: a vector containing the diagonal of the 'hat' matrix.
- **coefficients**: (unless `do.coef` is false) a matrix whose i-th row contains the change in the estimated coefficients which results when the i-th case is dropped from the regression. Note that aliased coefficients are not included in the matrix.
- **sigma**: a vector whose i-th element contains the estimate of the residual standard deviation obtained when the i-th case is dropped from the regression. (The approximations needed for GLMs can result in this being NaN.)
- **wt.res**: a vector of weighted (or for class `glm` rather deviance) residuals.

Note

The `coefficients` returned by the R version of `lm.influence` differ from those computed by S. Rather than returning the coefficients which result from dropping each case, we return the changes in the coefficients. This is more directly useful in many diagnostic measures. Since these need $O(np^2)$ computing time, they can be omitted by `do.coef = FALSE`.

Note that cases with weights == 0 are dropped (contrary to the situation in S).

If a model has been fitted with `na.action = na.exclude` (see `na.exclude`), cases excluded in the fit are considered here.

References

See the list in the documentation for `influence.measures`.

See Also

- `summary.lm` for `summary` and related methods;
- `influence.measures`;
- `hat` for the hat matrix diagonals;
- `dfbetas, dffits, covratio, cooks.distance, lm`. 
Examples

```r
## Analysis of the life-cycle savings data
given in Belsley, Kuh and Welsch.

summary(lm.SR <- lm(sr ~ pop15 + pop75 + dpi + ddpi,
data = LifeCycleSavings, 
correlation = TRUE)
utils::str(lmI <- lm.influence(lm.SR))

## For more "user level" examples, use example(influence.measures)
```

Description

All these functions are methods for class "lm" objects.

Usage

```r
## S3 method for class 'lm'
family(object, ...)

## S3 method for class 'lm'
formula(x, ...)

## S3 method for class 'lm'
residuals(object, 
type = c("working", "response", "deviance", "pearson", 
"partial"),
...

## S3 method for class 'lm'
labels(object, ...)
```

Arguments

- `object, x`: an object inheriting from class `lm`, usually the result of a call to `lm` or `aov`.
- `type`: the type of residuals which should be returned. Can be abbreviated.
- `...`: further arguments passed to or from other methods.

Details

The generic accessor functions `coef, effects, fitted` and `residuals` can be used to extract various useful features of the value returned by `lm`.

The working and response residuals are ‘observed - fitted’. The deviance and Pearson residuals are weighted residuals, scaled by the square root of the weights used in fitting. The partial residuals are a matrix with each column formed by omitting a term from the model. In all these, zero weight cases are never omitted (as opposed to the standardized `rstudent` residuals, and the `weighted.residuals`).
How residuals treats cases with missing values in the original fit is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the residuals, whereas if na.action = na.exclude they will appear, with residual value NA. See also naresid.

The "lm" method for generic labels returns the term labels for estimable terms, that is the names of the terms with an least one estimable coefficient.

References

See Also

The model fitting function lm, anova.lm.

coeff, deviance, df.residual, effects, fitted, glm for generalized linear models, influence (etc on that page) for regression diagnostics, weighted.residuals, residuals, residuals.glm, summary.lm, weights.

influence.measures for deletion diagnostics, including standardized (rstandard) and studentized (rstudent) residuals.

Examples

###-- Continuing the lm(.) example:

```r
coeff(lm.D90) # the bare coefficients
```

```r
# The 2 basic regression diagnostic plots [plot.lm(.) is preferred]
plot(resid(lm.D90), fitted(lm.D90)) # Tukey-Anscombe's
abline(h = 0, lty = 2, col = "gray")

qqnorm(residuals(lm.D90))
```

## Print Loadings in Factor Analysis

### Description

Extract or print loadings in factor analysis (or principal components analysis).

### Usage

```r
loadings(x, ...)
```

### Examples

```r
# S3 method for class 'loadings'
print(x, digits = 3, cutoff = 0.1, sort = FALSE, ...)
```

```r
# S3 method for class 'factanal'
print(x, digits = 3, ...)
```
Arguments

- **x**: an object of class "factanal" or "princomp" or the loadings component of such an object.
- **digits**: number of decimal places to use in printing uniquenesses and loadings.
- **cutoff**: loadings smaller than this (in absolute value) are suppressed.
- **sort**: logical. If true, the variables are sorted by their importance on each factor. Each variable with any loading larger than 0.5 (in modulus) is assigned to the factor with the largest loading, and the variables are printed in the order of the factor they are assigned to, then those unassigned.
- **...**: further arguments for other methods, ignored for loadings.

Details

'Loadings' is a term from factor analysis, but because factor analysis and principal component analysis (PCA) are often conflated in the social science literature, it was used for PCA by SPSS and hence by princomp in S-PLUS to help SPSS users.

Small loadings are conventionally not printed (replaced by spaces), to draw the eye to the pattern of the larger loadings.

The print method for class "factanal" calls the "loadings" method to print the loadings, and so passes down arguments such as cutoff and sort.

The signs of the loadings vectors are arbitrary for both factor analysis and PCA.

Note

There are other functions called loadings in contributed packages which are S3 or S4 generic: the ... argument is to make it easier for this one to become a default method.

---

**loess**

Local Polynomial Regression Fitting

Description

Fit a locally polynomial surface determined by one or more numerical predictors, using local fitting.

Usage

```r
loess(formula, data, weights, subset, na.action, model = FALSE,
      span = 0.75, enp.target, degree = 2,
      parametric = FALSE, drop.square = FALSE, normalize = TRUE,
      family = c("gaussian", "symmetric"),
      method = c("loess", "model.frame"),
      control = loess.control(...), ...)
```
Arguments

- **formula**: a formula specifying the numeric response and one to four numeric predictors (best specified via an interaction, but can also be specified additively). Will be coerced to a formula if necessary.
- **data**: an optional data frame, list or environment (or object coercible by `as.data.frame`) to a data frame) containing the variables in the model. If not found in data, the variables are taken from `environment(formula)`, typically the environment from which `loess` is called.
- **weights**: optional weights for each case.
- **subset**: an optional specification of a subset of the data to be used.
- **na.action**: the action to be taken with missing values in the response or predictors. The default is given by `getOption("na.action")`.
- **model**: should the model frame be returned?
- **span**: the parameter $\alpha$ which controls the degree of smoothing.
- **enp.target**: an alternative way to specify span, as the approximate equivalent number of parameters to be used.
- **degree**: the degree of the polynomials to be used, normally 1 or 2. (Degree 0 is also allowed, but see the ‘Note’.)
- **parametric**: should any terms be fitted globally rather than locally? Terms can be specified by name, number or as a logical vector of the same length as the number of predictors.
- **drop.square**: for fits with more than one predictor and `degree = 2`, should the quadratic term be dropped for particular predictors? Terms are specified in the same way as for `parametric`.
- **normalize**: should the predictors be normalized to a common scale if there is more than one? The normalization used is to set the 10% trimmed standard deviation to one. Set to false for spatial coordinate predictors and others known to be on a common scale.
- **family**: if "gaussian" fitting is by least-squares, and if "symmetric" a re-descending M estimator is used with Tukey’s biweight function. Can be abbreviated.
- **method**: fit the model or just extract the model frame. Can be abbreviated.
- **control**: control parameters: see `loess.control`.
- **...**: control parameters can also be supplied directly (if `control` is not specified).

Details

Fitting is done locally. That is, for the fit at point $x$, the fit is made using points in a neighbourhood of $x$, weighted by their distance from $x$ (with differences in ‘parametric’ variables being ignored when computing the distance). The size of the neighbourhood is controlled by $\alpha$ (set by `span` or `enp.target`). For $\alpha < 1$, the neighbourhood includes proportion $\alpha$ of the points, and these have tricubic weighting (proportional to $(1 - (\text{dist}/\text{maxdist})^3)^3$). For $\alpha > 1$, all points are used, with the ‘maximum distance’ assumed to be $\alpha^{1/p}$ times the actual maximum distance for $p$ explanatory variables.

For the default family, fitting is by (weighted) least squares. For family=“symmetric” a few iterations of an M-estimation procedure with Tukey’s biweight are used. Be aware that as the initial value is the least-squares fit, this need not be a very resistant fit.

It can be important to tune the control list to achieve acceptable speed. See `loess.control` for details.
Value

An object of class "loess", with print(), summary(), predict and anova methods.

Note

As this is based on cloess, it is similar to but not identical to the loess function of S. In particular, conditioning is not implemented.
The memory usage of this implementation of loess is roughly quadratic in the number of points, with 1000 points taking about 10Mb.
degree = 0, local constant fitting, is allowed in this implementation but not documented in the reference. It seems very little tested, so use with caution.

Author(s)

B. D. Ripley, based on the cloess package of Cleveland, Grosse and Shyu.

Source

The 1998 version of cloess package of Cleveland, Grosse and Shyu. A later version is available as dloess at https://netlib.org/a/.

loess.control, predict.loess.
lowess, the ancestor of loess (with different defaults!).

Examples

cars.lo <- loess(dist ~ speed, cars)
predict(cars.lo, data.frame(speed = seq(5, 30, 1)), se = TRUE)
  # to allow extrapolation

cars.lo2 <- loess(dist ~ speed, cars,
  control = loess.control(surface = "direct"))
predict(cars.lo2, data.frame(speed = seq(5, 30, 1)), se = TRUE)

loess.control

Set Parameters for loess

Description

Set control parameters for loess fits.

Usage

loess.control(surface = c("interpolate", "direct"),
  statistics = c("approximate", "exact", "none"),
  trace.hat = c("exact", "approximate"),
  cell = 0.2, iterations = 4, iterTrace = FALSE, ...)

Arguments

- **surface**: should the fitted surface be computed exactly ("direct") or via interpolation from a k-d tree? Can be abbreviated.
- **statistics**: should the statistics be computed exactly, approximately or not at all? Exact computation can be very slow. Can be abbreviated.
- **trace.hat**: Only for the (default) case (surface = "interpolate", statistics = "approximate"): should the trace of the smoother matrix be computed exactly or approximately? It is recommended to use the approximation for more than about 1000 data points. Can be abbreviated.
- **cell**: if interpolation is used this controls the accuracy of the approximation via the maximum number of points in a cell in the k-d tree. Cells with more than floor(n*span*cell) points are subdivided.
- **iterations**: the number of iterations used in robust fitting, i.e. only if family is "symmetric".
- **iterTrace**: logical (or integer) determining if tracing information during the robust iterations (iterations ≥ 2) is produced.
- **...**: further arguments which are ignored.

Value

A list with components

- **surface**
- **statistics**
- **trace.hat**
- **cell**
- **iterations**
- **iterTrace**

with meanings as explained under ‘Arguments’.

Logistic

**The Logistic Distribution**

Description

Density, distribution function, quantile function and random generation for the logistic distribution with parameters location and scale.

Usage

- dlogis(x, location = 0, scale = 1, log = FALSE)
- plogis(q, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
- qlogis(p, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
- rlogis(n, location = 0, scale = 1)
Arguments

- x, q: vector of quantiles.
- p: vector of probabilities.
- n: number of observations. If length(n) > 1, the length is taken to be the number required.
- location, scale: location and scale parameters.
- log, log.p: logical; if TRUE, probabilities p are given as log(p).
- lower.tail: logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

If location or scale are omitted, they assume the default values of 0 and 1 respectively.

The Logistic distribution with location = \( \mu \) and scale = \( \sigma \) has distribution function

\[
F(x) = \frac{1}{1 + e^{-(x-\mu)/\sigma}}
\]

and density

\[
f(x) = \frac{1}{\sigma} \frac{e^{(x-\mu)/\sigma}}{(1 + e^{(x-\mu)/\sigma})^2}
\]

It is a long-tailed distribution with mean \( \mu \) and variance \( \pi^2/3\sigma^2 \).

Value

dlogis gives the density, plogis gives the distribution function, qlogis gives the quantile function, and rlogis generates random deviates.

The length of the result is determined by n for rlogis, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

qlogis(p) is the same as the well known \('logit'\) function, \( \text{logit}(p) = \log p/(1-p) \), and plogis(x) has consequently been called the \('inverse logit'\).

The distribution function is a rescaled hyperbolic tangent, \( \text{plogis}(x) = (1+ \tanh(x/2))/2 \), and it is called a sigmoid function in contexts such as neural networks.

Source

\[\text{dpq]logis are calculated directly from the definitions.}\]
\[\text{rlogis uses inversion.}\]

References

logLik

Extract Log-Likelihood

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which have methods for this function include: "glm", "lm", "nls" and "Arima". Packages contain methods for other classes, such as "fitdistr", "negbin" and "polr" in package MASS, "multinom" in package nnet and "gls", "gnls" "lme" and others in package nlme.

Usage

logLik(object, ...)

## S3 method for class 'lm'
logLik(object, REML = FALSE, ...)

Arguments

object       any object from which a log-likelihood value, or a contribution to a log-likelihood value, can be extracted.
...
REML

an optional logical value. If TRUE the restricted log-likelihood is returned, else, if FALSE, the log-likelihood is returned. Defaults to FALSE.

Details

logLik is most commonly used for a model fitted by maximum likelihood, and some uses, e.g. by AIC, assume this. So care is needed where other fit criteria have been used, for example REML (the default for "lme").

For a "glm" fit the family does not have to specify how to calculate the log-likelihood, so this is based on using the family's aic() function to compute the AIC. For the gaussian, Gamma and inverse.gaussian families it assumed that the dispersion of the GLM is estimated and has been counted as a parameter in the AIC value, and for all other families it is assumed that the dispersion is known. Note that this procedure does not give the maximized likelihood for "glm" fits from the Gamma and inverse gaussian families, as the estimate of dispersion used is not the MLE.

For "lm" fits it is assumed that the scale has been estimated (by maximum likelihood or REML), and all the constants in the log-likelihood are included. That method is only applicable to single-response fits.

See Also

Distributions for other standard distributions.

Examples

var(rlogis(4000, 0, scale = 5)) # approximately (+/- 3)
pi^2/3 * 5^2

logLik

Extract Log-Likelihood

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which have methods for this function include: "glm", "lm", "nls" and "Arima". Packages contain methods for other classes, such as "fitdistr", "negbin" and "polr" in package MASS, "multinom" in package nnet and "gls", "gnls" "lme" and others in package nlme.

Usage

logLik(object, ...)

## S3 method for class 'lm'
logLik(object, REML = FALSE, ...)

Arguments

object       any object from which a log-likelihood value, or a contribution to a log-likelihood value, can be extracted.
...
REML

an optional logical value. If TRUE the restricted log-likelihood is returned, else, if FALSE, the log-likelihood is returned. Defaults to FALSE.

Details

logLik is most commonly used for a model fitted by maximum likelihood, and some uses, e.g. by AIC, assume this. So care is needed where other fit criteria have been used, for example REML (the default for "lme").

For a "glm" fit the family does not have to specify how to calculate the log-likelihood, so this is based on using the family’s aic() function to compute the AIC. For the gaussian, Gamma and inverse.gaussian families it assumed that the dispersion of the GLM is estimated and has been counted as a parameter in the AIC value, and for all other families it is assumed that the dispersion is known. Note that this procedure does not give the maximized likelihood for "glm" fits from the Gamma and inverse gaussian families, as the estimate of dispersion used is not the MLE.

For "lm" fits it is assumed that the scale has been estimated (by maximum likelihood or REML), and all the constants in the log-likelihood are included. That method is only applicable to single-response fits.
Value

Returns an object of class `logLik`. This is a number with at least one attribute, "df" (degrees of freedom), giving the number of (estimated) parameters in the model.

There is a simple print method for "logLik" objects.

There may be other attributes depending on the method used: see the appropriate documentation. One that is used by several methods is "nobs", the number of observations used in estimation (after the restrictions if `REML = TRUE`).

logLik(fm1)
logLik(fm1, REML = TRUE)
```

---

**loglin**  
*Fitting Log-Linear Models*

Description

`loglin` is used to fit log-linear models to multidimensional contingency tables by Iterative Proportional Fitting.

Usage

```
loglin(table, margin, start = rep(1, length(table)), fit = FALSE,
       eps = 0.1, iter = 20, param = FALSE, print = TRUE)
```
Arguments

- **table**: a contingency table to be fit, typically the output from `table`.
- **margin**: a list of vectors with the marginal totals to be fit.
  (Hierarchical) log-linear models can be specified in terms of these marginal totals which give the 'maximal' factor subsets contained in the model. For example, in a three-factor model, `list(c(1, 2), c(1, 3))` specifies a model which contains parameters for the grand mean, each factor, and the 1-2 and 1-3 interactions, respectively (but no 2-3 or 1-2-3 interaction), i.e., a model where factors 2 and 3 are independent conditional on factor 1 (sometimes represented as \('[12][13]')

  The names of factors (i.e., `names(dimnames(table))`) may be used rather than numeric indices.

- **start**: a starting estimate for the fitted table. This optional argument is important for incomplete tables with structural zeros in `table` which should be preserved in the fit. In this case, the corresponding entries in `start` should be zero and the others can be taken as one.

- **fit**: a logical indicating whether the fitted values should be returned.
- **eps**: maximum deviation allowed between observed and fitted margins.
- **iter**: maximum number of iterations.
- **param**: a logical indicating whether the parameter values should be returned.
- **print**: a logical. If `TRUE`, the number of iterations and the final deviation are printed.

Details

The Iterative Proportional Fitting algorithm as presented in Haberman (1972) is used for fitting the model. At most `iter` iterations are performed, convergence is taken to occur when the maximum deviation between observed and fitted margins is less than `eps`. All internal computations are done in double precision; there is no limit on the number of factors (the dimension of the table) in the model.

Assuming that there are no structural zeros, both the Likelihood Ratio Test and Pearson test statistics have an asymptotic chi-squared distribution with `df` degrees of freedom.

Note that the IPF steps are applied to the factors in the order given in `margin`. Hence if the model is decomposable and the order given in `margin` is a running intersection property ordering then IPF will converge in one iteration.

Package **MASS** contains `loglm`, a front-end to `loglin` which allows the log-linear model to be specified and fitted in a formula-based manner similar to that of other fitting functions such as `lm` or `glm`.

Value

A list with the following components.

- **lrt**: the Likelihood Ratio Test statistic.
- **pearson**: the Pearson test statistic (X-squared).
- **df**: the degrees of freedom for the fitted model. There is no adjustment for structural zeros.
- **margin**: list of the margins that were fit. Basically the same as the input `margin`, but with numbers replaced by names where possible.
The Log Normal Distribution

Description

Density, distribution function, quantile function and random generation for the log normal distribution whose logarithm has mean equal to meanlog and standard deviation equal to sdlog.

Usage

dlnorm(x, meanlog = 0, sdlog = 1, log = FALSE)
plnorm(q, meanlog = 0, sdlog = 1, lower.tail = TRUE, log.p = FALSE)
qlnorm(p, meanlog = 0, sdlog = 1, lower.tail = TRUE, log.p = FALSE)
rlnorm(n, meanlog = 0, sdlog = 1)
Arguments

- **x, q**: vector of quantiles.
- **p**: vector of probabilities.
- **n**: number of observations. If `length(n) > 1`, the length is taken to be the number required.
- **meanlog, sdlog**: mean and standard deviation of the distribution on the log scale with default values of 0 and 1 respectively.
- **log, log.p**: logical; if TRUE, probabilities p are given as log(p).
- **lower.tail**: logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The log normal distribution has density

\[
f(x) = \frac{1}{\sqrt{2\pi}\sigma x} e^{-(\log(x) - \mu)^2 / 2\sigma^2}
\]

where \( \mu \) and \( \sigma \) are the mean and standard deviation of the logarithm. The mean is \( E(X) = e^{\mu + 1/2\sigma^2} \), the median is \( med(X) = e^{\mu} \), and the variance \( Var(X) = e^{2\mu + \sigma^2}(e^{\sigma^2} - 1) \) and hence the coefficient of variation is \( \sqrt{e^{\sigma^2} - 1} \) which is approximately \( \sigma \) when that is small (e.g., \( \sigma < 1/2 \)).

Value

dlnorm gives the density, plnorm gives the distribution function, qlnorm gives the quantile function, and rlnorm generates random deviates.
The length of the result is determined by n for rlnorm, and is the maximum of the lengths of the numerical arguments for the other functions.
The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

The cumulative hazard \( H(t) = -\log(1 - F(t)) \) is \(-plnorm(t, r, lower = FALSE, log = TRUE)\).

Source

dlnorm is calculated from the definition (in ‘Details’). \([pqr]lnorm\) are based on the relationship to the normal.
Consequently, they model a single point mass at \( e^{\text{meanlog}} \) for the boundary case \( \text{sdlog} = 0 \).

References

Distributions for other standard distributions, including dnorm for the normal distribution.
**Examples**

dlnorm(1) == dnorm(0)

---

**lowess**  
*Scatter Plot Smoothing*

**Description**

This function performs the computations for the LOWESS smoother which uses locally-weighted polynomial regression (see the references).

**Usage**

lowess(x, y = NULL, f = 2/3, iter = 3, delta = 0.01 * diff(range(x)))

**Arguments**

- **x**, **y** vectors giving the coordinates of the points in the scatter plot. Alternatively a single plotting structure can be specified – see `xy.coords`.
- **f** the smoother span. This gives the proportion of points in the plot which influence the smooth at each value. Larger values give more smoothness.
- **iter** the number of ‘robustifying’ iterations which should be performed. Using smaller values of `iter` will make `lowess` run faster.
- **delta** See ‘Details’. Defaults to 1/100th of the range of `x`.

**Details**

`lowess` is defined by a complex algorithm, the Ratfor original of which (by W. S. Cleveland) can be found in the R sources as file `src/library/stats/src/lowess.doc`. Normally a local linear polynomial fit is used, but under some circumstances (see the file) a local constant fit can be used. ‘Local’ is defined by the distance to the `floor(f*n)`-th nearest neighbour, and tricubic weighting is used for `x` which fall within the neighbourhood.

The initial fit is done using weighted least squares. If `iter > 0`, further weighted fits are done using the product of the weights from the proximity of the `x` values and case weights derived from the residuals at the previous iteration. Specifically, the case weight is Tukey’s biweight, with cutoff 6 times the MAD of the residuals. (The current R implementation differs from the original in stopping iteration if the MAD is effectively zero since the algorithm is highly unstable in that case.)

delta is used to speed up computation: instead of computing the local polynomial fit at each data point it is not computed for points within `delta` of the last computed point, and linear interpolation is used to fill in the fitted values for the skipped points.

**Value**

`lowess` returns a list containing components `x` and `y` which give the coordinates of the smooth. The smooth can be added to a plot of the original points with the function `lines`: see the examples.
References

See Also

`loess`, a newer formula based version of `lowess` (with different defaults!).

Examples

```r
require(graphics)
plot(cars, main = "lowess(cars)"
lines(lowess(cars), col = 2)
lines(lowess(cars, f = .2), col = 3)
legend(5, 120, c(paste("f = ", c("2/3", ",.2"))), lty = 1, col = 2:3)
```

ls.diag

*Compute Diagnostics for lsfit Regression Results*

Description

Computes basic statistics, including standard errors, t- and p-values for the regression coefficients.

Usage

```r
ls.diag(ls.out)
```

Arguments

- `ls.out` Typically the result of `lsfit()`

Value

A list with the following numeric components.

- `std.dev` The standard deviation of the errors, an estimate of \( \sigma \).
- `hat` diagonal entries \( h_{ii} \) of the hat matrix \( H \)
- `std.res` standardized residuals
- `stud.res` studentized residuals
- `cooks` Cook’s distances
- `dfits` DFITS statistics
- `correlation` correlation matrix
- `std.err` standard errors of the regression coefficients
- `cov.scaled` Scaled covariance matrix of the coefficients
- `cov.unscaled` Unscaled covariance matrix of the coefficients
References

See Also

hat for the hat matrix diagonals, ls.print, lm.influence, summary.lm, anova.

Examples

##-- Using the same data as the lm(.) example:
lsD9 <- lsfit(x = as.numeric(gl(2, 10, 20)), y = weight)
dlsD9 <- ls.diag(lsD9)
utils::str(dlsD9, give.attr = FALSE)
abs(1 - sum(dlsD9$hat) / 2) < 10*.Machine$double.eps # sum(h.ii) = p
plot(dlsD9$hat, dlsD9$stud.res, xlim = c(0, 0.11))
abline(h = 0, lty = 2, col = "lightgray")

ls.print

Print lsfit Regression Results

Description

Computes basic statistics, including standard errors, t- and p-values for the regression coefficients and prints them if print.it is TRUE.

Usage

ls.print(ls.out, digits = 4, print.it = TRUE)

Arguments

ls.out Typically the result of lsfit()
digits The number of significant digits used for printing
print.it a logical indicating whether the result should also be printed

Value

A list with the components

summary The ANOVA table of the regression
coef.table matrix with regression coefficients, standard errors, t- and p-values

Note

Usually you would use summary(lm(...)) and anova(lm(...)) to obtain similar output.

See Also

ls.diag, lsfit, also for examples; lm, lm.influence which usually are preferable.
Find the Least Squares Fit

Description

The least squares estimate of $\beta$ in the model

$$ Y = X\beta + \epsilon $$

is found.

Usage

lsfit(x, y, wt = NULL, intercept = TRUE, tolerance = 1e-07, yname = NULL)

Arguments

- **x**: a matrix whose rows correspond to cases and whose columns correspond to variables.
- **y**: the responses, possibly a matrix if you want to fit multiple left hand sides.
- **wt**: an optional vector of weights for performing weighted least squares.
- **intercept**: whether or not an intercept term should be used.
- **tolerance**: the tolerance to be used in the matrix decomposition.
- **yname**: names to be used for the response variables.

Details

If weights are specified then a weighted least squares is performed with the weight given to the $j$-th case specified by the $j$-th entry in wt.

If any observation has a missing value in any field, that observation is removed before the analysis is carried out. This can be quite inefficient if there is a lot of missing data.

The implementation is via a modification of the LINPACK subroutines which allow for multiple left-hand sides.

Value

A list with the following named components:

- **coef**: the least squares estimates of the coefficients in the model ($\beta$ as stated above).
- **residuals**: residuals from the fit.
- **intercept**: indicates whether an intercept was fitted.
- **qr**: the QR decomposition of the design matrix.

References

mad

See Also

`lm` which usually is preferable; `ls.print, ls.diag`.

Examples

```r
###-- Using the same data as the lm(.) example:
lsD9 <- lsfit(x = unclass(gl(2, 10)), y = weight)
ls.print(lsD9)
```

---

**mad**

*Median Absolute Deviation*

Description

Compute the median absolute deviation, i.e., the (lo-/hi-) median of the absolute deviations from the median, and (by default) adjust by a factor for asymptotically normal consistency.

Usage

```r
mad(x, center = median(x), constant = 1.4826, na.rm = FALSE,
    low = FALSE, high = FALSE)
```

Arguments

- `x` a numeric vector.
- `center` Optionally, the centre: defaults to the median.
- `constant` scale factor.
- `na.rm` if `TRUE` then NA values are stripped from `x` before computation takes place.
- `low` if `TRUE`, compute the ‘lo-median’, i.e., for even sample size, do not average the two middle values, but take the smaller one.
- `high` if `TRUE`, compute the ‘hi-median’, i.e., take the larger of the two middle values for even sample size.

Details

The actual value calculated is `constant * cMedian(abs(x - center))` with the default value of `center` being `median(x)`, and `cMedian` being the usual, the ‘low’ or ‘high’ median, see the arguments description for `low` and `high` above.

In the case of `n = 1` non-missing values and default center, the result is 0, consistent with “no deviation from the center”.

The default constant = 1.4826 (approximately $1/\Phi^{-1}(\frac{3}{4}) = 1/qnorm(3/4)$) ensures consistency, i.e.,

$$E[\text{mad}(X_1, \ldots, X_n)] = \sigma$$

for $X_i$ distributed as $N(\mu, \sigma^2)$ and large $n$.

If `na.rm` is `TRUE` then NA values are stripped from `x` before computation takes place. If this is not done then an NA value in `x` will cause `mad` to return NA.
See Also

`IQR` which is simpler but less robust, `median`, `var`.

Examples

```r
mad(c(1:9))
print(mad(c(1:9), constant = 1)) ==
  mad(c(1:8, 100), constant = 1)  # = 2 ; TRUE
x <- c(1,2,3,5,7,8)
sort(abs(x - median(x)))
c(mad(x, constant = 1),
  mad(x, constant = 1, low = TRUE),
  mad(x, constant = 1, high = TRUE))
```

---

### mahalanobis

**Mahalanobis Distance**

Returns the squared Mahalanobis distance of all rows in `x` and the vector \( \mu = \text{center} \) with respect to \( \Sigma = \text{cov} \). This is (for vector `x`) defined as

\[
D^2 = (x - \mu)' \Sigma^{-1} (x - \mu)
\]

**Usage**

`mahalanobis(x, center, cov, inverted = FALSE, ...)`

**Arguments**

- `x` vector or matrix of data with, say, `p` columns.
- `center` mean vector of the distribution or second data vector of length `p` or recyclable to that length. If set to `FALSE`, the centering step is skipped.
- `cov` covariance matrix \((p \times p)\) of the distribution.
- `inverted` logical. If `TRUE`, `cov` is supposed to contain the inverse of the covariance matrix.
- `...` passed to `solve` for computing the inverse of the covariance matrix (if `inverted` is false).

**See Also**

`cov`, `var`

**Examples**

```r
require(graphics)
ma <- cbind(1:6, 1:3)
(S <- var(ma))
mahalanobis(c(0, 0), S)
x <- matrix(rnorm(100*3), ncol = 3)
stopifnot(mahalanobis(x, 0, diag(ncol(x))) == rowSums(x*x))
```
Here, $D^2$ = usual squared Euclidean distances

```r
Sx <- cov(x)
D2 <- mahalanobis(x, colMeans(x), Sx)
plot(density(D2, bw = 0.5),
     main="Squared Mahalanobis distances, n=100, p=3") ; rug(D2)
qqplot(qchisq(ppoints(100), df = 3), D2,
     main = expression("Q-Q plot of Mahalanobis" * ~D^2 * 
                     " vs. quantiles of" * ~ chi[3]^2))
abline(0, 1, col = 'gray')
```

---

### make.link

Create a Link for GLM Families

**Description**

This function is used with the `family` functions in `glm()`. Given the name of a link, it returns a link function, an inverse link function, the derivative $d\mu/d\eta$ and a function for domain checking.

**Usage**

```r
make.link(link)
```

**Arguments**

- `link` character; one of "logit", "probit", "cauchit", "cloglog", "identity", "log", "sqrt", "1/mu^2", "inverse".

**Value**

A object of class "link-glm", a list with components

- `linkfun` Link function function(mu)
- `linkinv` Inverse link function function(eta)
- `mu.eta` Derivative function(eta) $d\mu/d\eta$
- `valideta` function(eta)\{ TRUE if eta is in the domain of linkinv \}
- `name` a name to be used for the link

**See Also**

`power`, `glm`, `family`.

**Examples**

```r
utils::str(make.link("logit"))
```
makepredictcall  Utility Function for Safe Prediction

Description
A utility to help `model.frame.default` create the right matrices when predicting from models with terms like (univariate) `poly` or `ns`.

Usage

```r
makepredictcall(var, call)
```

Arguments

- `var`  
  A variable.
- `call`  
  The term in the formula, as a call.

Details

This is a generic function with methods for `poly`, `bs` and `ns`: the default method handles `scale`. If `model.frame.default` encounters such a term when creating a model frame, it modifies the `predvars` attribute of the terms supplied by replacing the term with one which will work for predicting new data. For example `makepredictcall.ns` adds arguments for the knots and intercept.

To make use of this, have your model-fitting function return the `terms` attribute of the model frame, or copy the `predvars` attribute of the `terms` attribute of the model frame to your `terms` object.

To extend this, make sure the term creates variables with a class, and write a suitable method for that class.

Value

A replacement for `call` for the `predvars` attribute of the terms.

See Also

- `model.frame`, `poly`, `scale`; `bs` and `ns` in package `splines`.
- `cars` for an example of prediction from a polynomial fit.

Examples

```r
require(graphics)
## using poly: this did not work in R < 1.5.0
fm <- lm(weight ~ poly(height, 2), data = women)
plot(women, xlab = "Height (in)", ylab = "Weight (lb)"
ht <- seq(57, 73, length.out = 200)
nD <- data.frame(height = ht)
pfm <- predict(fm, nD)
lines(ht, pfm)
pf2 <- predict(update(fm, ~ stats::poly(height, 2)), nD)
stopifnot(all.equal(pfm, pf2))  ## was off (rel.diff. 0.0766) in R <= 3.5.0

## see also example(cars)
```
## manova

### Multivariate Analysis of Variance

**Description**

A class for the multivariate analysis of variance.

**Usage**

```r
manova(...)```

**Arguments**

... Arguments to be passed to `aov`.

**Details**

Class "manova" differs from class "aov" in selecting a different summary method. Function `manova` calls `aov` and then add class "manova" to the result object for each stratum.

**Value**

See `aov` and the comments in ‘Details’ here.

**References**

**See Also**

`aov`, `summary.manova`, the latter containing more examples.

**Examples**

```r
## Set orthogonal contrasts.
op <- options(contrasts = c("contr.helmert", "contr.poly"))

## Fake a 2nd response variable
npk2 <- within(npk, foo <- rnorm(24))
(npk2.aov <- manova(cbind(yield, foo) ~ block + N*P*K, npk2))
summary(npk2.aov)

(npk2.aovE <- manova(cbind(yield, foo) ~ N*P*K + Error(block), npk2))
summary(npk2.aovE)
```
Cochran-Mantel-Haenszel Chi-Squared Test for Count Data

Description

Performs a Cochran-Mantel-Haenszel chi-squared test of the null that two nominal variables are conditionally independent in each stratum, assuming that there is no three-way interaction.

Usage

mantelhaen.test(x, y = NULL, z = NULL, 
alternative = c("two.sided", "less", "greater"), 
correct = TRUE, exact = FALSE, conf.level = 0.95)

Arguments

x either a 3-dimensional contingency table in array form where each dimension is at least 2 and the last dimension corresponds to the strata, or a factor object with at least 2 levels.

y a factor object with at least 2 levels; ignored if x is an array.

z a factor object with at least 2 levels identifying to which stratum the corresponding elements in x and y belong; ignored if x is an array.

alternative indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. Only used in the 2 by 2 by K case.

correct a logical indicating whether to apply continuity correction when computing the test statistic. Only used in the 2 by 2 by K case.

exact a logical indicating whether the Mantel-Haenszel test or the exact conditional test (given the strata margins) should be computed. Only used in the 2 by 2 by K case.

conf.level confidence level for the returned confidence interval. Only used in the 2 by 2 by K case.

Details

If x is an array, each dimension must be at least 2, and the entries should be nonnegative integers. NA's are not allowed. Otherwise, x, y and z must have the same length. Triples containing NA's are removed. All variables must take at least two different values.

Value

A list with class "htest" containing the following components:

statistic Only present if no exact test is performed. In the classical case of a 2 by 2 by K table (i.e., of dichotomous underlying variables), the Mantel-Haenszel chi-squared statistic; otherwise, the generalized Cochran-Mantel-Haenszel statistic.

parameter the degrees of freedom of the approximate chi-squared distribution of the test statistic (1 in the classical case). Only present if no exact test is performed.

p.value the p-value of the test.
conf.int a confidence interval for the common odds ratio. Only present in the 2 by 2 by K case.
estimate an estimate of the common odds ratio. If an exact test is performed, the conditional Maximum Likelihood Estimate is given; otherwise, the Mantel-Haenszel estimate. Only present in the 2 by 2 by K case.
null.value the common odds ratio under the null of independence, 1. Only present in the 2 by 2 by K case.
alternative a character string describing the alternative hypothesis. Only present in the 2 by 2 by K case.
method a character string indicating the method employed, and whether or not continuity correction was used.
data.name a character string giving the names of the data.

Note
The asymptotic distribution is only valid if there is no three-way interaction. In the classical 2 by 2 by K case, this is equivalent to the conditional odds ratios in each stratum being identical. Currently, no inference on homogeneity of the odds ratios is performed.

See also the example below.

## Classical Mantel-Haenszel test
mantelhaen.test(Rabbits)
## => p = 0.047, some evidence for higher cure rate of immediate
## injection
## Exact conditional test
mantelhaen.test(Rabbits, exact = TRUE)
## => p = 0.040
## Exact conditional test for one-sided alternative of a higher
## cure rate for immediate injection
mantelhaen.test(Rabbits, exact = TRUE, alternative = "greater")
```
## => p = 0.020

## UC Berkeley Student Admissions
mantelhaen.test(UCBAdmissions)
## No evidence for association between admission and gender
## when adjusted for department. However,
apply(UCBAdmissions, 3, function(x) (x[1,1]*x[2,2])/(x[1,2]*x[2,1]))
## This suggests that the assumption of homogeneous (conditional)
## odds ratios may be violated. The traditional approach would be
## using the Woolf test for interaction:
woolf <- function(x) {
  x <- x + 1 / 2
  k <- dim(x)[3]
  or <- apply(x, 3, function(x) (x[1,1]*x[2,2])/(x[1,2]*x[2,1]))
  w <- apply(x, 3, function(x) 1 / sum(1 / x))
  1 - pchisq(sum(w * (log(or) - weighted.mean(log(or), w))^2), k - 1)
}
woolf(UCBAdmissions)
## => p = 0.003, indicating that there is significant heterogeneity.
## (And hence the Mantel-Haenszel test cannot be used.)

## Job Satisfaction example.
Satisfaction <-
as.table(array(c(1, 2, 0, 0, 3, 3, 1, 2,
                 11, 17, 8, 4, 2, 3, 5, 2,
                 1, 0, 0, 1, 3, 0, 1,
                 2, 5, 7, 9, 1, 1, 3, 6),
                dim = c(4, 4, 2),

### mauchly.test

**Mauchly’s Test of Sphericity**

#### Description

Tests whether a Wishart-distributed covariance matrix (or transformation thereof) is proportional to a given matrix.

#### Usage

mauchly.test(object, ...)
## S3 method for class 'mlm'
mauchly.test

## S3 method for class 'SSD'

mauchly.test(object, Sigma = diag(nrow = p),
T = Thin.row(Proj(M) - Proj(X)), M = diag(nrow = p), X = ~0,
idata = data.frame(index = seq_len(p)), ...)

Arguments

- **object**: object of class SSD or mlm.
- **Sigma**: matrix to be proportional to.
- **T**: transformation matrix. By default computed from M and X.
- **M**: formula or matrix describing the outer projection (see below).
- **X**: formula or matrix describing the inner projection (see below).
- **idata**: data frame describing intra-block design.
- **...**: arguments to be passed to or from other methods.

Details

This is a generic function with methods for classes "mlm" and "SSD".

The basic method is for objects of class SSD the method for mlm objects just extracts the SSD matrix and invokes the corresponding method with the same options and arguments.

The T argument is used to transform the observations prior to testing. This typically involves transformation to intra-block differences, but more complicated within-block designs can be encountered, making more elaborate transformations necessary. A matrix T can be given directly or specified as the difference between two projections onto the spaces spanned by M and X, which in turn can be given as matrices or as model formulas with respect to idata (the tests will be invariant to parametrization of the quotient space M/X).

The common use of this test is in repeated measurements designs, with X = ~1. This is almost, but not quite the same as testing for compound symmetry in the untransformed covariance matrix.

Notice that the defaults involve p, which is calculated internally as the dimension of the SSD matrix, and a couple of hidden functions in the stats namespace, namely proj which calculates projection matrices from design matrices or model formulas and Thin.row which removes linearly dependent rows from a matrix until it has full row rank.

Value

An object of class "htest"

Note

The p-value differs slightly from that of SAS because a second order term is included in the asymptotic approximation in R.

Examples

```r
utils::example(SSD) # Brings in the mlmfit and reacttime objects

### traditional test of intrasubj. contrasts
mauchly.test(mlmfit, X = ~1)

### tests using intra-subject 3x2 design
idata <- data.frame(deg = gl(3, 1, 6, labels = c(0,4,8)),
                      noise = gl(2, 3, 6, labels = c("A","P")))
mauchly.test(mlmfit, X = ~ deg + noise, idata = idata)
mauchly.test(mlmfit, M = ~ deg + noise, X = ~ noise, idata = idata)
```

### mcnemar.test

McNemar’s Chi-squared Test for Count Data

Description

Performs McNemar’s chi-squared test for symmetry of rows and columns in a two-dimensional contingency table.

Usage

```r
mcnemar.test(x, y = NULL, correct = TRUE)
```

Arguments

- `x` either a two-dimensional contingency table in matrix form, or a factor object.
- `y` a factor object; ignored if `x` is a matrix.
- `correct` a logical indicating whether to apply continuity correction when computing the test statistic.

Details

The null is that the probabilities of being classified into cells 
\([i,j]\) and \([j,i]\) are the same.

If `x` is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both `x` and `y` must be vectors or factors of the same length. Incomplete cases are removed, vectors are coerced into factors, and the contingency table is computed from these.

Continuity correction is only used in the 2-by-2 case if `correct` is `TRUE`.

Value

A list with class "htest" containing the following components:

- `statistic` the value of McNemar’s statistic.
- `parameter` the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- `p.value` the p-value of the test.
- `method` a character string indicating the type of test performed, and whether continuity correction was used.
- `data.name` a character string giving the name(s) of the data.
**median**

**Examples**

```
## Presidential Approval Ratings.
## Approval of the President's performance in office in two surveys,
## one month apart, for a random sample of 1600 voting-age Americans.
Performance <-
  matrix(c(794, 86, 150, 570),
         nrow = 2,
         dimnames = list("1st Survey" = c("Approve", "Disapprove"),
                        "2nd Survey" = c("Approve", "Disapprove")))
Performance
mcnemar.test(Performance)
## => significant change (in fact, drop) in approval ratings
```

<table>
<thead>
<tr>
<th>median</th>
<th>Median Value</th>
</tr>
</thead>
</table>

**Description**

Compute the sample median.

**Usage**

```
mведian(x, na.rm = FALSE, ...)
## Default S3 method:
mmedian(x, na.rm = FALSE, ...)
```

**Arguments**

- `x` an object for which a method has been defined, or a numeric vector containing the values whose median is to be computed.
- `na.rm` a logical value indicating whether NA values should be stripped before the computation proceeds.
- `...` potentially further arguments for methods; not used in the default method.

**Details**

This is a generic function for which methods can be written. However, the default method makes use of is.na, sort and mean from package base all of which are generic, and so the default method will work for most classes (e.g., "Date") for which a median is a reasonable concept.

**Value**

The default method returns a length-one object of the same type as `x`, except when `x` is logical or integer of even length, when the result will be double.

If there are no values or if `na.rm = FALSE` and there are NA values the result is NA of the same type as `x` (or more generally the result of `x[NA_integer_]`).
References

quantile for general quantiles.

Examples

median(1:4)  # = 2.5 [even number]
median(c(1:3, 100, 1000))  # = 3 [odd, robust]

medpolish

Median Polish (Robust Two-way Decomposition) of a Matrix

Description

Fits an additive model (two-way decomposition) using Tukey’s median polish procedure.

Usage

medpolish(x, eps = 0.01, maxiter = 10, trace.iter = TRUE, na.rm = FALSE)

Arguments

x
a numeric matrix.
eps
real number greater than 0. A tolerance for convergence: see ‘Details’.
maxiter
the maximum number of iterations
trace.iter
logical. Should progress in convergence be reported?
na.rm
logical. Should missing values be removed?

Details

The model fitted is additive (constant + rows + columns). The algorithm works by alternately removing the row and column medians, and continues until the proportional reduction in the sum of absolute residuals is less than eps or until there have been maxiter iterations. The sum of absolute residuals is printed at each iteration of the fitting process, if trace.iter is TRUE. If na.rm is FALSE the presence of any NA value in x will cause an error, otherwise NA values are ignored.

medpolish returns an object of class medpolish (see below). There are printing and plotting methods for this class, which are invoked via the generics print and plot.

Value

An object of class medpolish with the following named components:

overall
the fitted constant term.
row
the fitted row effects.
col
the fitted column effects.
residuals
the residuals.
name
the name of the dataset.

require(graphics)

## Deaths from sport parachuting; from ABC of EDA, p.224:
deads <-
  rbind(c(14,15,14),
    c( 7, 4, 7),
    c( 8, 2,10),
    c(15, 9,10),
    c(15, 9,10))
dimnames(deaths) <- list(c("1-24", "25-74", "75-199", "200++", "NA"),
                        paste(1973:1975))
deads
# (med.d <- medpolish(deaths))
plot(med.d)
## Check decomposition:
all(deaths ==
    med.d$overall + outer(med.d$row,med.d$col,`+`) + med.d$residuals)
```

---

**model.extract**

*Extract Components from a Model Frame*

**Description**

Returns the response, offset, subset, weights or other special components of a model frame passed as optional arguments to `model.frame`.

**Usage**

```r
model.extract(frame, component)
model.offset(x)
model.response(data, type = "any")
model.weights(x)
```

**Arguments**

- **frame, x, data** a model frame, see `model.frame`.
- **component** literal character string or name. The name of a component to extract, such as "weights" or "subset".
- **type** One of "any", "numeric" or "double". Using either of latter two coerces the result to have storage mode "double".
Details
model.extract is provided for compatibility with S, which does not have the more specific functions. It is also useful to extract e.g. the etastart and mustart components of a glm fit.
model.extract(m, "offset") and model.extract(m, "response") are equivalent to model.offset(m) and model.response(m) respectively. model.offset sums any terms specified by offset terms in the formula or by offset arguments in the call producing the model frame: it does check that the offset is numeric.
model.weights is slightly different from model.extract(, "weights") in not naming the vector it returns.

Value
The specified component of the model frame, usually a vector. model.response() now drops a possible "Asis" class (stemming from I(.)).
model.offset returns NULL if no offset was specified.

model.extract(a, "response")
stopifnot(model.extract(a, "response") == model.response(a))

a <- model.frame(ncases/(ncases + ncontrols) ~ agegp + tobgp + alcgp,
data = esoph, weights = ncases + ncontrols)
model.response(a)
(mw <- model.extract(a, "weights"))
stopifnot(identical(unname(mw), model.weights(a)))

a <- model.frame(cbind(ncases, ncontrols) ~ agegp,
something = tobgp, data = esoph)
names(a)
stopifnot(model.extract(a, "something") == esoph$tobgp)
model.frame

subset = NULL, na.action,
drop.unused.levels = FALSE, xlev = NULL, ...)

## S3 method for class 'aovlist'
model.frame(formula, data = NULL, ...)

## S3 method for class 'glm'
model.frame(formula, ...)

## S3 method for class 'lm'
model.frame(formula, ...)

get_all_vars(formula, data, ...)

Arguments

formula a model formula or terms object or an R object.
data a data frame, list or environment (or object coercible by as.data.frame to a data frame), containing the variables in formula. Neither a matrix nor an array will be accepted.
subset a specification of the rows/observations to be used: defaults to all. This can be any valid indexing vector (see [.data.frame) for the rows of data, or a (logical) expression using variables in data or if that is not supplied, in formula. (See additional details about how this argument interacts with data-dependent bases under ‘Details’ below.)
na.action an optional (name of a) function for treating missing values (NAs). The default is first, any na.action attribute of data, second a na.action setting of options, and third na.fail if that is unset. The ‘factory-fresh’ default is na.omit. Another possible value is NULL.
drop.unused.levels should factors have unused levels dropped? Defaults to FALSE.
xlev a named list of character vectors giving the full set of levels to be assumed for each factor.
... for model.frame methods, a mix of further arguments such as data, na.action, subset to pass to the default method. Any additional arguments (such as offset and weights or other named arguments) which reach the default method are used to create further columns in the model frame, with parenthesised names such as "(offset)". For get_all_vars, further named columns to include in the model frame.

Details

Exactly what happens depends on the class and attributes of the object formula. If this is an object of fitted-model class such as "lm", the method will either return the saved model frame used when fitting the model (if any, often selected by argument model = TRUE) or pass the call used when fitting on to the default method. The default method itself can cope with rather standard model objects such as those of class "lqs" from package MASS if no other arguments are supplied.

The rest of this section applies only to the default method.

If either formula or data is already a model frame (a data frame with a "terms" attribute) and the other is missing, the model frame is returned. Unless formula is a terms object, as.formula and
then terms is called on it. (If you wish to use the keep.order argument of terms.formula, pass a terms object rather than a formula.)

Row names for the model frame are taken from the data argument if present, then from the names of the response in the formula (or rownames if it is a matrix), if there is one.

All the variables in formula, subset and in ... are looked for first in data and then in the environment of formula (see the help for formula() for further details) and collected into a data frame. Then the subset expression is evaluated, and it is used as a row index to the data frame. Then the na.action function is applied to the data frame (and may well add attributes). The levels of any factors in the data frame are adjusted according to the drop.unused.levels and xlev arguments: if xlev specifies a factor and a character variable is found, it is converted to a factor (as from R 2.10.0).

Because variables in the formula are evaluated before rows are dropped based on subset, the characteristics of data-dependent bases such as orthogonal polynomials (i.e. from terms using poly) or splines will be computed based on the full data set rather than the subsetted one.

Unless na.action = NULL, time-series attributes will be removed from the variables found (since they will be wrong if NAs are removed).

Note that all the variables in the formula are included in the data frame, even those preceded by -. Only variables whose type is raw, logical, integer, real, complex or character can be included in a model frame: this includes classed variables such as factors (whose underlying type is integer), but excludes lists.

get_all_vars returns a data.frame containing the variables used in formula plus those specified in ... which are recycled to the number of data frame rows. Unlike model.frame.default, it returns the input variables and not those resulting from function calls in formula.

Value

A data.frame containing the variables used in formula plus those specified in .... It will have additional attributes, including "terms" for an object of class "terms" derived from formula, and possibly "na.action" giving information on the handling of NAs (which will not be present if no special handling was done, e.g. by na.pass).

model.matrix

ncol(ncars) == ncol(cars) + 1)

---

Construct Design Matrices

Description

model.matrix creates a design (or model) matrix, e.g., by expanding factors to a set of dummy variables (depending on the contrasts) and expanding interactions similarly.

Usage

model.matrix(object, ...)

## Default S3 method:
model.matrix(object, data = environment(object),
contrasts.arg = NULL, xlev = NULL, ...)

## S3 method for class 'lm'
model.matrix(object, ...)

Arguments

object an object of an appropriate class. For the default method, a model formula or a terms object.
data a data frame created with model.frame. If another sort of object, model.frame is called first.
contrasts.arg a list, whose entries are values (numeric matrices, functions or character strings naming functions) to be used as replacement values for the contrasts replacement function and whose names are the names of columns of data containing factors.
xlev to be used as argument of model.frame if data is such that model.frame is called.
... further arguments passed to or from other methods.

Details

model.matrix creates a design matrix from the description given in terms(object), using the data in data which must supply variables with the same names as would be created by a call to model.frame(object) or, more precisely, by evaluating attr(terms(object), "variables"). If data is a data frame, there may be other columns and the order of columns is not important. Any character variables are coerced to factors. After coercion, all the variables used on the right-hand side of the formula must be logical, integer, numeric or factor.

If contrasts.arg is specified for a factor it overrides the default factor coding for that variable and any "contrasts" attribute set by C or contrasts. Whereas invalid contrasts.args have been ignored always, they are warned about since R version 3.6.0.

In an interaction term, the variable whose levels vary fastest is the first one to appear in the formula (and not in the term), so in ~ a + b + b:a the interaction will have a varying fastest.

By convention, if the response variable also appears on the right-hand side of the formula it is dropped (with a warning), although interactions involving the term are retained.
Value

The design matrix for a regression-like model with the specified formula and data.

There is an attribute "assign", an integer vector with an entry for each column in the matrix giving the term in the formula which gave rise to the column. Value 0 corresponds to the intercept (if any), and positive values to terms in the order given by the term.labels attribute of the terms structure corresponding to object.

If there are any factors in terms in the model, there is an attribute "contrasts", a named list with an entry for each factor. This specifies the contrasts that would be used in terms in which the factor is coded by contrasts (in some terms dummy coding may be used), either as a character vector naming a function or as a numeric matrix.

model.frame, model.extract, terms

sparse.model.matrix from package Matrix for creating sparse model matrices, which may be more efficient in large dimensions.

Examples

ff <- log(Volume) ~ log(Height) + log(Girth)
utils::str(m <- model.frame(ff, trees))
mat <- model.matrix(ff, m)

dd <- data.frame(a = gl(3,4), b = gl(4,1,12)) # balanced 2-way
options("contrasts") # typically 'treatment' (for unordered factors)
model.matrix(~ a + b, dd)
model.matrix(~ a + b, dd, contrasts.arg = list(a = "contr.sum"))
model.matrix(~ a + b, dd, contrasts.arg = list(a = "contr.sum", b = contr.poly))
m.orth <- model.matrix(~a+b, dd, contrasts.arg = list(a = "contr.helmert"))
crossprod(m.orth) # m.orth is ALMOST orthogonal
# invalid contrasts... ignored with a warning:
stopifnot(identical(
  model.matrix(~ a + b, dd),
  model.matrix(~ a + b, dd, contrasts.arg = "contr.FOO"))
)
model.tables

Usage

model.tables(x, ...)

## S3 method for class 'aov'
model.tables(x, type = "effects", se = FALSE, cterms, ...)

## S3 method for class 'aovlist'
model.tables(x, type = "effects", se = FALSE, ...)

Arguments

x a model object, usually produced by aov
type type of table: currently only "effects" and "means" are implemented. Can be abbreviated.
se should standard errors be computed?
cterm A character vector giving the names of the terms for which tables should be computed. The default is all tables.
... further arguments passed to or from other methods.

Details

For type = "effects" give tables of the coefficients for each term, optionally with standard errors.
For type = "means" give tables of the mean response for each combinations of levels of the factors in a term.
The "aov" method cannot be applied to components of a "aovlist" fit.

Value

An object of class "tables.aov", as list which may contain components
tables A list of tables for each requested term.
n The replication information for each term.
se Standard error information.

Warning

The implementation is incomplete, and only the simpler cases have been tested thoroughly.
Weighted aov fits are not supported.

npk.aov <- aov(yield ~ block + N*P*K, npk)
model.tables(npk.aov, "means", se = TRUE)

## as a test, not particularly sensible statistically
npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
model.tables(npk.aovE, se = TRUE)
model.tables(npk.aovE, "means")
monthplot

Plot a Seasonal or other Subseries from a Time Series

Description

These functions plot seasonal (or other) subseries of a time series. For each season (or other category), a time series is plotted.

Usage

```r
monthplot(x, ...)  
## S3 method for class 'stl'  
monthplot(x, labels = NULL, ylab = choice, choice = "seasonal", ...)  
## S3 method for class 'StructTS'  
monthplot(x, labels = NULL, ylab = choice, choice = "sea", ...)  
## S3 method for class 'ts'  
monthplot(x, labels = NULL, times = time(x), phase = cycle(x), ylab = deparse1(substitute(x)), ...)  
## Default S3 method:  
monthplot(x, labels = 1L:12L, ylab = deparse1(substitute(x)), times = seq_along(x), phase = (times - 1L)%%length(labels) + 1L, base = mean, axes = TRUE, type = c("l", "h"), box = TRUE, add = FALSE, col = par("col"), lty = par("lty"), lwd = par("lwd"), col.base = col, lty.base = lty, lwd.base = lwd, ...)```

Arguments

- **x**: Time series or related object.
- **labels**: Labels to use for each ‘season’.
- **ylab**: y label.
- **times**: Time of each observation.
- **phase**: Indicator for each ‘season’.
- **base**: Function to use for reference line for subseries.
- **choice**: Which series of an stl or StructTS object?
- **...**: Arguments to be passed to the default method or graphical parameters.
- **axes**: Should axes be drawn (ignored if add = TRUE)?
- **type**: Type of plot. The default is to join the points with lines, and “h” is for histogram-like vertical lines.
- **box**: Should a box be drawn (ignored if add = TRUE)?
- **add**: Should thus just add on an existing plot.
Details

These functions extract subseries from a time series and plot them all in one frame. The `ts`, `stl`, and `StructTS` methods use the internally recorded frequency and start and finish times to set the scale and the seasons. The default method assumes observations come in groups of 12 (though this can be changed).

If the `labels` are not given but the `phase` is given, then the `labels` default to the unique values of the `phase`. If both are given, then the `phase` values are assumed to be indices into the `labels` array, i.e., they should be in the range from 1 to `length(labels)`.

Value

These functions are executed for their side effect of drawing a seasonal subseries plot on the current graphical window.

Author(s)

Duncan Murdoch

mood.test

Mood Two-Sample Test of Scale

Description

Performs Mood's two-sample test for a difference in scale parameters.

Usage

mood.test(x, ...)

## Default S3 method:
mood.test(x, y,
  alternative = c("two.sided", "less", "greater"), ...)

## S3 method for class 'formula'
mood.test(formula, data, subset, na.action, ...)

Arguments

x, y numeric vectors of data values.
alternative indicates the alternative hypothesis and must be one of "two.sided" (default), "greater" or "less" all of which can be abbreviated.
formula a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.
data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").
... further arguments to be passed to or from methods.

Details

The underlying model is that the two samples are drawn from \( f(x - l) \) and \( f((x - l)/s)/s \), respectively, where \( l \) is a common location parameter and \( s \) is a scale parameter.

The null hypothesis is \( s = 1 \).

There are more useful tests for this problem.

In the case of ties, the formulation of Mielke (1967) is employed.

Value

A list with class "htest" containing the following components:

statistic the value of the test statistic.
p.value the p-value of the test.
alternative a character string describing the alternative hypothesis. You can specify just the initial letter.
method the character string "Mood two-sample test of scale".
data.name a character string giving the names of the data.

**Multinom**

The Multinomial Distribution

**Description**

Generate multinomially distributed random number vectors and compute multinomial probabilities.

**Usage**

```r
rmultinom(n, size, prob)
dmultinom(x, size = NULL, prob, log = FALSE)
```

**Arguments**

- `x` vector of length `K` of integers in `0:size`.
- `n` number of random vectors to draw.
- `size` integer, say `N`, specifying the total number of objects that are put into `K` boxes in the typical multinomial experiment. For `dmultinom`, it defaults to `sum(x)`.
- `prob` numeric non-negative vector of length `K`, specifying the probability for the `K` classes; is internally normalized to sum 1. Infinite and missing values are not allowed.
- `log` logical; if `TRUE`, log probabilities are computed.
Details

If \( x \) is a \( K \)-component vector, \( \text{dmultinom}(x, \text{prob}) \) is the probability

\[
P(X_1 = x_1, \ldots, X_K = x_k) = C \times \prod_{j=1}^{K} \pi_j^{x_j}
\]

where \( C \) is the ‘multinomial coefficient’ \( C = N!/(x_1! \cdots x_K!) \) and \( N = \sum_{j=1}^{K} x_j \).

By definition, each component \( X_j \) is binomially distributed as \( \text{Bin}(\text{size}, \text{prob}[j]) \) for \( j = 1, \ldots, K \).

The \( \text{rmultinom}() \) algorithm draws binomials \( X_j \) from \( \text{Bin}(n_j, P_j) \) sequentially, where \( n_1 = N \) (\( N := \text{size} \)), \( P_1 = \pi_1 \) (\( \pi \) is prob scaled to sum 1), and for \( j \geq 2 \), recursively, \( n_j = N - \sum_{k=1}^{j-1} X_k \) and \( P_j = \pi_j/(1 - \sum_{k=1}^{j-1} \pi_k) \).

Value

For \( \text{rmultinom}() \), an integer \( K \times n \) matrix where each column is a random vector generated according to the desired multinomial law, and hence summing to \( \text{size} \). Whereas the transposed result would seem more natural at first, the returned matrix is more efficient because of columnwise storage.

Note

dmultinom is currently not vectorized at all and has no C interface (API); this may be amended in the future.

See Also

Distributions for standard distributions, including \( \text{dbinom} \) which is a special case conceptually.

Examples

\[
\text{rmultinom}(10, \text{size} = 12, \text{prob} = c(0.1,0.2,0.8))
\]

\[
\text{pr} <- c(1,3,6,10) \ # \text{normalization not necessary for generation}
\text{rmultinom}(10, 20, \text{prob} = \text{pr})
\]

\[
\text{## all possible outcomes of Multinom}(N = 3, K = 3)
\text{X} <- \text{t(as.matrix(expand.grid(0:3, 0:3)))}; \text{X} <- \text{X[, colSums(X) <= 3]}
\text{X} <- \text{rbind(X, 3:3 - colSums(X))}; \text{dimnames(X) <- list(letters[1:3], NULL)}
\text{X}
\text{round(apply(X, 2, function(x) \text{dmultinom}(x, \text{prob} = c(1,2,5))), 3)}
\]
Arguments

object any object whose NA action is given.
...

Details

na.action is a generic function, and na.action.default its default method. The latter extracts the "na.action" component of a list if present, otherwise the "na.action" attribute.

When model.frame is called, it records any information on NA handling in a "na.action" attribute. Most model-fitting functions return this as a component of their result.

Value

Information from the action which was applied to object if NAs were handled specially, or NULL.

References

See Also

options("na.action"), na.omit, na.fail, also for na.exclude, na.pass.

Examples

na.action(na.omit(c(1, NA)))

na.contiguous Find Longest Contiguous Stretch of non-NAs

Description

Find the longest consecutive stretch of non-missing values in a time series object. (In the event of a tie, the first such stretch.)

Usage

na.contiguous(object, ...)

Arguments

object a univariate or multivariate time series.
...

Value

A time series without missing values. The class of object will be preserved.

See Also

na.omit and na.omit.ts; na.fail
na.fail

Handle Missing Values in Objects

Examples

na.contiguous(presidents)

Description

These generic functions are useful for dealing with NAs in e.g., data frames. na.fail returns the object if it does not contain any missing values, and signals an error otherwise. na.omit returns the object with incomplete cases removed. na.pass returns the object unchanged.

Usage

na.fail(object, ...)
na.omit(object, ...)
na.exclude(object, ...)
na.pass(object, ...)

Arguments

object an R object, typically a data frame
...

further arguments special methods could require.

Details

At present these will handle vectors, matrices and data frames comprising vectors and matrices (only).

If na.omit removes cases, the row numbers of the cases form the "na.action" attribute of the result, of class "omit".

na.exclude differs from na.omit only in the class of the "na.action" attribute of the result, which is "exclude". This gives different behaviour in functions making use of naresid and napredict: when na.exclude is used the residuals and predictions are padded to the correct length by inserting NAs for cases omitted by na.exclude.

References

See Also

na.action; options with argument na.action for setting NA actions; and lm and glm for functions using these. na.contiguous as alternative for time series.
Examples

DF <- data.frame(x = c(1, 2, 3), y = c(0, 10, NA))
na.omit(DF)
m <- as.matrix(DF)
na.omit(m)
stopifnot(all(na.omit(1:3) == 1:3)) # does not affect objects with no NA's
try(na.fail(DF)) #> Error: missing values in ...

options("na.action")

naprint

Adjust for Missing Values

Description

Use missing value information to report the effects of an na.action.

Usage

naprint(x, ...)

Arguments

x An object produced by an na.action function.

... further arguments passed to or from other methods.

Details

This is a generic function, and the exact information differs by method. naprint.omit reports the number of rows omitted: naprint.default reports an empty string.

Value

A character string providing information on missing values, for example the number.

naresid

Adjust for Missing Values

Description

Use missing value information to adjust residuals and predictions.

Usage

naresid(omit, x, ...)
napredict(omit, x, ...)
Arguments

- `omit`: an object produced by an `na.action` function, typically the "na.action" attribute of the result of `na.omit` or `na.exclude`.
- `x`: a vector, data frame, or matrix to be adjusted based upon the missing value information.
- `...`: further arguments passed to or from other methods.

Details

These are utility functions used to allow `predict`, `fitted` and `residuals` methods for modelling functions to compensate for the removal of NAs in the fitting process. They are used by the default, "lm", "glm" and "nls" methods, and by further methods in packages `MASS`, `rpart` and `survival`. Also used for the scores returned by `factanal`, `prcomp` and `princomp`.

The default methods do nothing. The default method for the `na.exclude` action is to pad the object with NAs in the correct positions to have the same number of rows as the original data frame.

Currently `naresid` and `napredict` are identical, but future methods need not be. `naresid` is used for residuals, and `napredict` for fitted values, predictions and `weights`.

Value

These return a similar object to `x`.

Note

In the early 2000s, packages `rpart` and `survival` contained versions of these functions that had an `na.omit` action equivalent to that now used for `na.exclude`.

NegBinomial

The Negative Binomial Distribution

Description

Density, distribution function, quantile function and random generation for the negative binomial distribution with parameters `size` and `prob`.

Usage

```r
dnbinom(x, size, prob, mu, log = FALSE)
pnbinom(q, size, prob, mu, lower.tail = TRUE, log.p = FALSE)
qnbinom(p, size, prob, mu, lower.tail = TRUE, log.p = FALSE)
rnbinom(n, size, prob, mu)
```

Arguments

- `x`: vector of (non-negative integer) quantiles.
- `q`: vector of quantiles.
- `p`: vector of probabilities.
- `n`: number of observations. If `length(n) > 1`, the length is taken to be the number required.
NegBinomial

size target for number of successful trials, or dispersion parameter (the shape parameter of the gamma mixing distribution). Must be strictly positive, need not be integer.
prob probability of success in each trial. 0 < prob <= 1.
mu alternative parametrization via mean: see ‘Details’.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The negative binomial distribution with \( \text{size} = n \) and \( \text{prob} = p \) has density

\[
p(x) = \frac{\Gamma(x + n)}{\Gamma(n)x!} p^n (1 - p)^x
\]

for \( x = 0, 1, 2, \ldots, n > 0 \) and \( 0 < p \leq 1 \).

This represents the number of failures which occur in a sequence of Bernoulli trials before a target number of successes is reached. The mean is \( \mu = n(1 - p)/p \) and variance \( n(1 - p)/p^2 \).

A negative binomial distribution can also arise as a mixture of Poisson distributions with mean distributed as a gamma distribution (see \texttt{pgamma}) with scale parameter \((1 - \text{prob})/\text{prob}\) and shape parameter \text{size}. (This definition allows non-integer values of \text{size}.)

An alternative parametrization (often used in ecology) is by the mean \( \mu \) (see above), and \text{size}, the dispersion parameter, where \( \text{prob} = \text{size}/(\text{size}+\mu) \). The variance is \( \mu + \mu^2/\text{size} \) in this parametrization.

If an element of \( x \) is not integer, the result of \texttt{dnbinom} is zero, with a warning.

The case \text{size} == 0 is the distribution concentrated at zero. This is the limiting distribution for \text{size} approaching zero, even if \( \mu \) rather than \text{prob} is held constant. Notice though, that the mean of the limit distribution is 0, whatever the value of \( \mu \).

The quantile is defined as the smallest value \( x \) such that \( F(x) \geq p \), where \( F \) is the distribution function.

Value

dnbinom gives the density, \texttt{pnbinom} gives the distribution function, \texttt{qbinom} gives the quantile function, and \texttt{rbinom} generates random deviates.

Invalid \text{size} or \text{prob} will result in return value \text{NaN}, with a warning.

The length of the result is determined by \( n \) for \texttt{rbinom}, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

\texttt{rbinom} returns a vector of type \texttt{integer} unless generated values exceed the maximum representable integer when \texttt{double} values are returned.

Source

dnbinom computes via binomial probabilities, using code contributed by Catherine Loader (see \texttt{dbinom}).

\texttt{pnbinom} uses \texttt{pbeta}.
nbinom uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.

rbinom uses the derivation as a gamma mixture of Poisson distributions, see

**See Also**

Distributions for standard distributions, including dbinom for the binomial, dpois for the Poisson and dgeom for the geometric distribution, which is a special case of the negative binomial.

**Examples**

```r
require(graphics)
x <- 0:11
dbinom(x, size = 1, prob = 1/2) * 2^(1 + x) # == 1
126 / dbinom(0:8, size = 2, prob = 1/2) # theoretically integer

## Cumulative ('p') = Sum of discrete prob.s ('d'); Relative error :
## summary(1 - cumsum(dbinom(x, size = 2, prob = 1/2)) / pnbinom(x, size = 2, prob = 1/2))

x <- 0:0.15
size <- (1:20)/4
persp(x, size, dnb <- outer(x, size, function(x,s) dbinom(x, s, prob = 0.4)),
xlab = "x", ylab = "s", zlab = "density", theta = 150)
title(tit <- "negative binomial density(x,s, pr = 0.4) vs. x & s")
image (x, size, log10(dnb), main = paste("log ", tit, "]"))
contour(x, size, log10(dnb), add = TRUE)

## Alternative parametrization
x1 <- rbinom(500, mu = 4, size = 1)
x2 <- rbinom(500, mu = 4, size = 10)
x3 <- rbinom(500, mu = 4, size = 100)
h1 <- hist(x1, breaks = 20, plot = FALSE)
h2 <- hist(x2, breaks = h1$breaks, plot = FALSE)
h3 <- hist(x3, breaks = h1$breaks, plot = FALSE)
barplot(rbind(h1$counts, h2$counts, h3$counts),
    beside = TRUE, col = c("red","blue","cyan"),
    names.arg = round(h1$breaks[-length(h1$breaks)]))
```

---

**nextn**

Find Highly Composite Numbers

**Description**

nextn returns the smallest integer, greater than or equal to n, which can be obtained as a product of powers of the values contained in factors.

nextn() is intended to be used to find a suitable length to zero-pad the argument of fft so that the transform is computed quickly. The default value for factors ensures this.
Usage

\texttt{nextn(n, factors = c(2,3,5))}

Arguments

- \texttt{n}: a vector of integer numbers (of type "integer" or "double").
- \texttt{factors}: a vector of positive integer factors (at least 2 and preferably relative prime, see the note).

Value

a vector of the same \texttt{length} as \texttt{n}, of type "integer" when the values are small enough (determined before computing them) and "double" otherwise.

Note

If the factors in \texttt{factors} are \texttt{not} relative prime, i.e., have themselves a common factor larger than one, the result may be wrong in the sense that it may not be the \textit{smallest} integer. E.g., \texttt{nextn(91, c(2,6))} returns 128 instead of 96 as \texttt{nextn(91, c(2,3))} returns.

When the resulting \texttt{N <- nextn(\ldots)} is larger than $2^{53}$, a warning with the true 64-bit integer value is signalled, as integers above that range may not be representable in double precision.

If you really need to deal with such large integers, it may be advisable to use package \texttt{gmp}.

See Also

\texttt{convolve, fft}.

Examples

\begin{verbatim}
nextn(1001) # 1024
table(nextn(599:630))
n <- 1:100 ; plot(n, nextn(n) - n, type = "o", lwd=2, cex=1/2)
\end{verbatim}

\texttt{.nlm}

Non-Linear Minimization

Description

This function carries out a minimization of the function \texttt{f} using a Newton-type algorithm. See the references for details.

Usage

\begin{verbatim}
nlm(f, p, ..., hessian = FALSE, typsize = rep(1, length(p)),
    fscale = 1, print.level = 0, ndigit = 12, gradtol = 1e-6,
    stepmax = max(1000 * sqrt(sum((p/typsize)^2)), 1000),
    steptol = 1e-6, iterlim = 100, check.analyicals = TRUE)
\end{verbatim}
Arguments

- **f**: the function to be minimized, returning a single numeric value. This should be a function with first argument a vector of the length of `p` followed by any other arguments specified by the `...` argument.
  
  If the function value has an attribute called `gradient` or both `gradient` and `hessian` attributes, these will be used in the calculation of updated parameter values. Otherwise, numerical derivatives are used. `deriv` returns a function with suitable `gradient` attribute and optionally a `hessian` attribute.

- **p**: starting parameter values for the minimization.

- **...**: additional arguments to be passed to `f`.

- **hessian**: if `TRUE`, the hessian of `f` at the minimum is returned.

- **typsize**: an estimate of the size of each parameter at the minimum.

- **fscale**: an estimate of the size of `f` at the minimum.

- **print.level**: this argument determines the level of printing which is done during the minimization process. The default value of 0 means that no printing occurs, a value of 1 means that initial and final details are printed and a value of 2 means that full tracing information is printed.

- **ndigit**: the number of significant digits in the function `f`.

- **gradtol**: a positive scalar giving the tolerance at which the scaled gradient is considered close enough to zero to terminate the algorithm. The scaled gradient is a measure of the relative change in `f` in each direction `p[i]` divided by the relative change in `p[i]`.

- **stepmax**: a positive scalar which gives the maximum allowable scaled step length. `stepmax` is used to prevent steps which would cause the optimization function to overflow, to prevent the algorithm from leaving the area of interest in parameter space, or to detect divergence in the algorithm. `stepmax` would be chosen small enough to prevent the first two of these occurrences, but should be larger than any anticipated reasonable step.

- **steptol**: A positive scalar providing the minimum allowable relative step length.

- **iterlim**: a positive integer specifying the maximum number of iterations to be performed before the program is terminated.

- **check.analyticals**: a logical scalar specifying whether the analytic gradients and Hessians, if they are supplied, should be checked against numerical derivatives at the initial parameter values. This can help detect incorrectly formulated gradients or Hessians.

Details

Note that arguments after `...` must be matched exactly.

If a gradient or hessian is supplied but evaluates to the wrong mode or length, it will be ignored if `check.analyticals = TRUE` (the default) with a warning. The hessian is not even checked unless the gradient is present and passes the sanity checks.

The C code for the “perturbed” Cholesky, `choldc()` has had a bug in all R versions before 3.4.1.

From the three methods available in the original source, we always use method “1” which is line search.

The functions supplied should always return finite (including not `NA` and not `NaN`) values: for the function value itself non-finite values are replaced by the maximum positive value with a warning.
**Value**

A list containing the following components:

- **minimum**: the value of the estimated minimum of \( f \).
- **estimate**: the point at which the minimum value of \( f \) is obtained.
- **gradient**: the gradient at the estimated minimum of \( f \).
- **hessian**: the hessian at the estimated minimum of \( f \) (if requested).
- **code**: an integer indicating why the optimization process terminated.
  - 1: relative gradient is close to zero, current iterate is probably solution.
  - 2: successive iterates within tolerance, current iterate is probably solution.
  - 3: last global step failed to locate a point lower than estimate. Either estimate is an approximate local minimum of the function or steptol is too small.
  - 4: iteration limit exceeded.
  - 5: maximum step size stepmax exceeded five consecutive times. Either the function is unbounded below, becomes asymptotic to a finite value from above in some direction or stepmax is too small.
- **iterations**: the number of iterations performed.

**Source**

The current code is by Saikat DebRoy and the R Core team, using a C translation of Fortran code by Richard H. Jones.

**References**

**See Also**

- `optim` and `nlminb`.
- `constrOptim` for constrained optimization, `optimize` for one-dimensional minimization and `uniroot` for root finding. `deriv` to calculate analytical derivatives.

For nonlinear regression, `nls` may be better.

**Examples**

```r
f <- function(x) sum((x-1:length(x))^2)
nlm(f, c(10,10))
nlm(f, c(10,10), print.level = 2)
utils::str(nlm(f, c(5), hessian = TRUE))

f <- function(x, a) sum((x-a)^2)
nlm(f, c(10,10), a = c(3,5))
f <- function(x, a)
{
  res <- sum((x-a)^2)
```

---

**nlm** 1585
## nlminb

### Optimization using PORT routines

**Description**

Unconstrained and box-constrained optimization using PORT routines.

For historical compatibility.

**Usage**

```r
nlminb(start, objective, gradient = NULL, hessian = NULL, ..., scale = 1, control = list(), lower = -Inf, upper = Inf)
```

**Arguments**

- `start` numeric vector, initial values for the parameters to be optimized.
- `objective` Function to be minimized. Must return a scalar value. The first argument to `objective` is the vector of parameters to be optimized, whose initial values are supplied through `start`. Further arguments (fixed during the course of the optimization) to `objective` may be specified as well (see ...).
- `gradient` Optional function that takes the same arguments as `objective` and evaluates the gradient of `objective` at its first argument. Must return a vector as long as `start`.
- `hessian` Optional function that takes the same arguments as `objective` and evaluates the hessian of `objective` at its first argument. Must return a square matrix of order `length(start)`. Only the lower triangle is used.
- `...` Further arguments to be supplied to `objective`.
- `scale` See PORT documentation (or leave alone).
- `control` A list of control parameters. See below for details.
- `lower, upper` vectors of lower and upper bounds, replicated to be as long as `start`. If unspecified, all parameters are assumed to be unconstrained.

**Details**

Any names of `start` are passed on to `objective` and where applicable, `gradient` and `hessian`. The parameter vector will be coerced to double.

If any of the functions returns `NA` or `NaN` this is an error for the gradient and Hessian, and such values for function evaluation are replaced by `+Inf` with a warning.
Value

A list with components:

par  The best set of parameters found.
objective  The value of objective corresponding to par.
convergence  An integer code. 0 indicates successful convergence.
message  A character string giving any additional information returned by the optimizer, or NULL. For details, see PORT documentation.
iterations  Number of iterations performed.
evaluations  Number of objective function and gradient function evaluations

Control parameters

Possible names in the control list and their default values are:

eval.max  Maximum number of evaluations of the objective function allowed. Defaults to 200.
iter.max  Maximum number of iterations allowed. Defaults to 150.
trace  The value of the objective function and the parameters is printed every trace‘th iteration. Defaults to 0 which indicates no trace information is to be printed.
abs.tol  Absolute tolerance. Defaults to 0 so the absolute convergence test is not used. If the objective function is known to be non-negative, the previous default of 1e-20 would be more appropriate.
rel.tol  Relative tolerance. Defaults to 1e-10.
x.tol  X tolerance. Defaults to 1.5e-8.
xf.tol  false convergence tolerance. Defaults to 2.2e-14.
step.min, step.max  Minimum and maximum step size. Both default to 1.
sing.tol  singular convergence tolerance; defaults to rel.tol.
scale.init  ...
diff.g  an estimated bound on the relative error in the objective function value.

**nls**

Nonlinear Least Squares
Description

Determine the nonlinear (weighted) least-squares estimates of the parameters of a nonlinear model.

Usage

nls(formula, data, start, control, algorithm,
    trace, subset, weights, na.action, model,
    lower, upper, ...)  

Arguments

formula    a nonlinear model formula including variables and parameters. Will be coerced to a formula if necessary.
data      an optional data frame in which to evaluate the variables in formula and weights. Can also be a list or an environment, but not a matrix.
start      a named list or named numeric vector of starting estimates. When start is missing (and formula is not a self-starting model, see selfStart), a very cheap guess for start is tried (if algorithm != "plinear").
control    an optional list of control settings. See nls.control for the names of the settable control values and their effect.
algorithmm character string specifying the algorithm to use. The default algorithm is a Gauss-Newton algorithm. Other possible values are "plinear" for the Golub-Pereyra algorithm for partially linear least-squares models and "port" for the 'nl2sol' algorithm from the Fort library – see the references. Can be abbreviated.
trace     logical value indicating if a trace of the iteration progress should be printed. Default is FALSE. If TRUE the residual (weighted) sum-of-squares, the convergence criterion and the parameter values are printed at the conclusion of each iteration. Note that format() is used, so these mostly depend on getOption("digits"). When the "plinear" algorithm is used, the conditional estimates of the linear parameters are printed after the nonlinear parameters. When the "port" algorithm is used the objective function value printed is half the residual (weighted) sum-of-squares.
subset    an optional vector specifying a subset of observations to be used in the fitting process.
weights    an optional numeric vector of (fixed) weights. When present, the objective function is weighted least squares.
n.a.actiona function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The ‘factory-fresh’ default is na.omit. Value na.exclude can be useful.
model    logical. If true, the model frame is returned as part of the object. Default is FALSE.
lower,upper vectors of lower and upper bounds, replicated to be as long as start. If unspecified, all parameters are assumed to be unconstrained. Bounds can only be used with the "port" algorithm. They are ignored, with a warning, if given for other algorithms.

...     Additional optional arguments. None are used at present.
Details

An nls object is a type of fitted model object. It has methods for the generic functions anova, coef, confint, deviance, df.residual, fitted, formula, logLik, predict, print, profile, residuals, summary, vcov and weights.

Variables in formula (and weights if not missing) are looked for first in data, then the environment of formula and finally along the search path. Functions in formula are searched for first in the environment of formula and then along the search path.

Arguments subset and na.action are supported only when all the variables in the formula taken from data are of the same length; other cases give a warning.

Note that the anova method does not check that the models are nested: this cannot easily be done automatically, so use with care.

Value

A list of

- an nlsModel object incorporating the model.
- the expression that was passed to nls as the data argument. The actual data values are present in the environment of the m components, e.g., environment(m$conv).
- the matched call with several components, notably algorithm.
- the "na.action" attribute (if any) of the model frame.
- the "dataClasses" attribute (if any) of the "terms" attribute of the model frame.
- if model = TRUE, the model frame.
- if weights is supplied, the weights.
- a list with convergence information.
- the control list used, see the control argument.
- for an algorithm = "port" fit only, a convergence code (0 for convergence) and message.

To use these is deprecated, as they are available from convInfo now.

Warning

The default settings of nls generally fail on artificial “zero-residual” data problems.

The nls function uses a relative-offset convergence criterion that compares the numerical imprecision at the current parameter estimates to the residual sum-of-squares. This performs well on data of the form

\[ y = f(x, \theta) + \varepsilon \]

(with \( var(\varepsilon) > 0 \)). It fails to indicate convergence on data of the form

\[ y = f(x, \theta) \]

because the criterion amounts to comparing two components of the round-off error. To avoid a zero-divide in computing the convergence testing value, a positive constant scaleOffset should be added to the denominator sum-of-squares; it is set in control, as in the example below; this does not yet apply to algorithm = "port".

The algorithm = "port" code appears unfinished, and does not even check that the starting value is within the bounds. Use with caution, especially where bounds are supplied.
Note

Setting `warnOnly = TRUE` in the `control` argument (see `nls.control`) returns a non-converged object (since R version 2.5.0) which might be useful for further convergence analysis, but not for inference.

Examples

```r
require(graphics)

DNase1 <- subset(DNase, Run == 1)

## using a selfStart model
fm1DNase1 <- nls(density ~ SSlogis(log(conc), Asym, xmid, scal), DNase1)
summary(fm1DNase1)

## the coefficients only:
coef(fm1DNase1)

## including their SE, etc:
coef(summary(fm1DNase1))

## using conditional linearity
fm2DNase1 <- nls(density ~ 1/(1 + exp((xmid - log(conc))/scal)),
    data = DNase1,
    start = list(xmid = 0, scal = 1),
    algorithm = "plinear")
summary(fm2DNase1)

## without conditional linearity
fm3DNase1 <- nls(density ~ Asym/(1 + exp((xmid - log(conc))/scal)),
    data = DNase1,
    start = list(Asym = 3, xmid = 0, scal = 1))
summary(fm3DNase1)

## using Port's nl2sol algorithm
fm4DNase1 <- nls(density ~ Asym/(1 + exp((xmid - log(conc))/scal)),
    data = DNase1,
    start = list(Asym = 3, xmid = 0, scal = 1),
    algorithm = "port")
```
summary(fm4DNase1)

### weighted nonlinear regression

```r
treated <- Puromycin[Puromycin$state == "treated",]
weighted.MM <- function(resp, conc, vm, k)
{
  ## Purpose: exactly as white book p. 451 -- RHS for nls()
  ## Weighted version of Michaelis-Menten model
  ## ----------------------------------------------------------
  ## Arguments: 'y', 'x' and the two parameters (see book)
  ## ----------------------------------------------------------
  ## Author: Martin Maechler, Date: 23 Mar 2001

  pred <- (vm * conc)/(k + conc)
  (resp - pred) / sqrt(pred)
}

pur.wt <- nls(~ weighted.MM(rate, conc, vm, k), data = treated,
  start = list(vm = 200, k = 0.1))
summary(pur.wt)

### Passing arguments using a list that cannot be coerced to a data.frame

```R
```
nls

```
rbind(coef(Pur.wt), coef(Pur.wt1), coef(Pur.wt.grad))

## In this example, there seems no advantage to providing the gradient.  
## In other cases, there might be.

## The two examples below show that you can fit a model to  
## artificial data with noise but not to artificial data  
## without noise.

x <- 1:10
y <- 2*x + 3  # perfect fit

## terminates in an error, because convergence cannot be confirmed:
try(nls(y ~ a + b*x, start = list(a = 0.12345, b = 0.54321)))

## adjusting the convergence test by adding 'scaleOffset' to its denominator RSS:

nls(y ~ a + b*x, start = list(a = 0.12345, b = 0.54321),
   control = list(scaleOffset = 1, printEval=TRUE))

## Alternatively jittering the "too exact" values, slightly:
set.seed(27)
yeps <- y + rnorm(length(y), sd = 0.01)  # added noise
nls(yeps ~ a + b*x, start = list(a = 0.12345, b = 0.54321))

## the nls() internal cheap guess for starting values can be sufficient:
x <- -(1:100)/10
y <- 100 + 10 * exp(x / 2) + rnorm(x)/10

nlmod <- nls(y ~ Const + A * exp(B * x))

plot(x,y, main = "nls(*), data, true function and fit, n=100")
curve(100 + 10 * exp(x / 2), col = 4, add = TRUE)
lines(x, predict(nlmod), col = 2)

## Here, requiring close convergence, must use more accurate numerical differentiation,  
## as this typically gives Error: "step factor .. reduced below 'minFactor' .."

try(nlm1 <- update(nlmod, control = list(tol = 1e-7)))
o2 <- options(digits = 10)  # more accuracy for 'trace'

## central differencing works here typically (PR#18165: not converging on *some*):

ctr2 <- nls.control(nDcentral=TRUE, tol = 8e-8, # <- even smaller than above  
                     warnOnly =  
                     TRUE || # << work around; e.g. needed on some ATLAS-Lapack setups  
                       (grepl("^aarch64.*linux", R.version$platform)  
                        && grepl("^NixOS", osVersion)  
                       ))

(nlm2 <- update(nlmod, control = ctr2, trace = TRUE)); options(o2)

## --> convergence tolerance 4.997e-8 (in 11 iter.)

## The muscle dataset in MASS is from an experiment on muscle  
## contraction on 21 animals. The observed variables are Strip  
## (identifier of muscle), Conc (Cacl concentration) and Length  
## (resulting length of muscle section).

if(requireNamespace("MASS", quietly = TRUE)) withAutoprint({
  ## The non linear model considered is  
  ## Length = alpha + beta*exp(-Conc/theta) + error  
  ## where theta is constant but alpha and beta may vary with Strip.
```
with(MASS::muscle, table(Strip)) # 2, 3 or 4 obs per strip

## We first use the plinear algorithm to fit an overall model, 
## ignoring that alpha and beta might vary with Strip.
musc.1 <- nls(Length ~ cbind(1, exp(-Conc/th)), MASS::muscle, 
               start = list(th = 1), algorithm = "plinear")
summary(musc.1)

## Then we use nls' indexing feature for parameters in non-linear 
## models to use the conventional algorithm to fit a model in which 
## alpha and beta vary with Strip. The starting values are provided 
## by the previously fitted model.
## Note that with indexed parameters, the starting values must be 
## given in a list (with names):
b <- coef(musc.1)
musc.2 <- nls(Length ~ a[Strip] + b[Strip]*exp(-Conc/th), MASS::muscle,

summary(musc.2)
}

---

**nls.control**

*Control the Iterations in nls*

**Description**

Allow the user to set some characteristics of the *nls* nonlinear least squares algorithm.

**Usage**

```r
nls.control(maxiter = 50, tol = 1e-05, minFactor = 1/1024, 
printEval = FALSE, warnOnly = FALSE, scaleOffset = 0, 
nDcentral = FALSE)
```

**Arguments**

- `maxiter` A positive integer specifying the maximum number of iterations allowed.
- `tol` A positive numeric value specifying the tolerance level for the relative offset convergence criterion.
- `minFactor` A positive numeric value specifying the minimum step-size factor allowed on any step in the iteration. The increment is calculated with a Gauss-Newton algorithm and successively halved until the residual sum of squares has been decreased or until the step-size factor has been reduced below this limit.
- `printEval` a logical specifying whether the number of evaluations (steps in the gradient direction taken each iteration) is printed.
- `warnOnly` a logical specifying whether the number of evaluations (steps in the gradient direction taken each iteration) is printed.

**nls.control**

`Control the Iterations in nls`

**Description**

Allow the user to set some characteristics of the *nls* nonlinear least squares algorithm.

**Usage**

```r
nls.control(maxiter = 50, tol = 1e-05, minFactor = 1/1024, 
            printEval = FALSE, warnOnly = FALSE, scaleOffset = 0, 
            nDcentral = FALSE)
```

**Arguments**

- `maxiter` A positive integer specifying the maximum number of iterations allowed.
- `tol` A positive numeric value specifying the tolerance level for the relative offset convergence criterion.
- `minFactor` A positive numeric value specifying the minimum step-size factor allowed on any step in the iteration. The increment is calculated with a Gauss-Newton algorithm and successively halved until the residual sum of squares has been decreased or until the step-size factor has been reduced below this limit.
- `printEval` a logical specifying whether the number of evaluations (steps in the gradient direction taken each iteration) is printed.
- `warnOnly` a logical specifying whether the number of evaluations (steps in the gradient direction taken each iteration) is printed.
NLSstAsymptotic

scaleOffset

a constant to be added to the denominator of the relative offset convergence
criterion calculation to avoid a zero divide in the case where the fit of a model to
data is very close. The default value of 0 keeps the legacy behaviour of nls().
A value such as 1 seems to work for problems of reasonable scale with very
small residuals.

nDcentral

only when numerical derivatives are used: logical indicating if central differ-
ences should be employed, i.e., numericDeriv(*, central=TRUE) be used.

Value

A list with components

maxiter
tol
minFactor
printEval
warnOnly
scaleOffset
nDcentral

with meanings as explained under ‘Arguments’.

Author(s)

Douglas Bates and Saikat DebRoy; John C. Nash for part of the scaleOffset option.

NLSstAsymptotic  Fit the Asymptotic Regression Model

Description

Fits the asymptotic regression model, in the form b0 + b1*(1-exp(-exp(lrc) * x)) to the xy data.
This can be used as a building block in determining starting estimates for more complicated models.

Usage

NLSstAsymptotic(xy)
Arguments

xy                  a sortedXyData object

Value

A numeric value of length 3 with components labelled b0, b1, and lrc. b0 is the estimated intercept on the y-axis, b1 is the estimated difference between the asymptote and the y-intercept, and lrc is the estimated logarithm of the rate constant.

Lob.329)), digits = 3)

NLSstClosestX

Inverse Interpolation

Description

Use inverse linear interpolation to approximate the x value at which the function represented by xy is equal to yval.

Usage

NLSstClosestX(xy, yval)

Arguments

xy                  a sortedXyData object
yval                a numeric value on the y scale

Value

A single numeric value on the x scale.

```

---

**NLSstLfAsymptote**  
*Horizontal Asymptote on the Left Side*

**Description**

Provide an initial guess at the horizontal asymptote on the left side (i.e., small values of \( x \)) of the graph of \( y \) versus \( x \) from the `xy` object. Primarily used within initial functions for self-starting nonlinear regression models.

**Usage**

```r
NLSstLfAsymptote(xy)
```

**Arguments**

- `xy`: a `sortedXyData` object

**Value**

A single numeric value estimating the horizontal asymptote for small \( x \).

**Author(s)**

José Pinheiro and Douglas Bates

NLSstLfAsymptote( DN.srt )
```
NLSstRtAsymptote  

**Horizontal Asymptote on the Right Side**

**Description**

Provide an initial guess at the horizontal asymptote on the right side (i.e., large values of x) of the graph of y versus x from the xy object. Primarily used within initial functions for self-starting nonlinear regression models.

**Usage**

\[
\text{NLSstRtAsymptote}(xy)
\]

**Arguments**

- \(xy\): a sortedXyData object

**Value**

A single numeric value estimating the horizontal asymptote for large x.

**Author(s)**

José Pinheiro and Douglas Bates

**See Also**

NLSstRtAsymptote(DN.srt)
```

---

**nobs**

*Extract the Number of Observations from a Fit*

**Description**

Extract the number of ‘observations’ from a model fit. This is principally intended to be used in computing BIC (see \texttt{AIC}).

**Usage**

\[
\text{nobs(object, ...)}
\]

## Default S3 method:

\[
\text{nobs(object, use.fallback = FALSE, ...)}
\]
Normal

The Normal Distribution

Description

Density, distribution function, quantile function and random generation for the normal distribution with mean equal to mean and standard deviation equal to sd.

Usage

dnorm(x, mean = 0, sd = 1, log = FALSE)
pnorm(q, mean = 0, sd = 1, lower.tail = TRUE, log.p = FALSE)
qnorm(p, mean = 0, sd = 1, lower.tail = TRUE, log.p = FALSE)
rnorm(n, mean = 0, sd = 1)

Arguments

x, q  vector of quantiles.
p  vector of probabilities.
n  number of observations. If length(n) > 1, the length is taken to be the number required.
mean  vector of means.
sd  vector of standard deviations.
log, log.p  logical; if TRUE, probabilities p are given as log(p).
lower.tail  logical; if TRUE (default), probabilities are \( P[X \leq x] \) otherwise, \( P[X > x] \).
Details

If `mean` or `sd` are not specified they assume the default values of 0 and 1, respectively.

The normal distribution has density

\[ f(x) = \frac{1}{\sqrt{2\pi}\sigma} e^{-(x-\mu)^2/2\sigma^2} \]

where \( \mu \) is the mean of the distribution and \( \sigma \) the standard deviation.

Value

dnorm gives the density, pnorm gives the distribution function, qnorm gives the quantile function, and rnorm generates random deviates.

The length of the result is determined by \( n \) for rnorm, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

For \( sd = 0 \) this gives the limit as \( sd \) decreases to 0, a point mass at \( mu \). \( sd < 0 \) is an error and returns NaN.

Source

For pnorm, based on

For qnorm, the code is based on a C translation of

which provides precise results up to about 16 digits for \( \log.p=FALSE \). For log scale probabilities in the extreme tails, since R version 4.1.0, extensively since 4.3.0, asymptotic expansions are used which have been derived and explored in

For rnorm, see RNG for how to select the algorithm and for references to the supplied methods.

References

See Also

Distributions for other standard distributions, including dlnorm for the Lognormal distribution.
**Examples**

```r
eval <- expression(dnorm(0) == 1/sqrt(2*pi))
edval <- eval()
edval
```

```
numericDeriv(expr, theta, rho = parent.frame(), dir = 1, 
            eps = .Machine$double.eps ^ (1/if(central) 3 else 2), central = FALSE)
```

**numericDeriv**  
**Evaluate Derivatives Numerically**

**Description**

`numericDeriv` numerically evaluates the gradient of an expression.

**Usage**

`numericDeriv(expr, theta, rho = parent.frame(), dir = 1, 
            eps = .Machine$double.eps ^ (1/if(central) 3 else 2), central = FALSE)`

**Arguments**

- `expr`: expression or call to be differentiated. Should evaluate to a numeric vector.
- `theta`: character vector of names of numeric variables used in `expr`.
- `rho`: environment containing all the variables needed to evaluate `expr`.
- `dir`: numeric vector of directions, typically with values in -1, 1 to use for the finite differences; will be recycled to the length of `theta`.
- `eps`: a positive number, to be used as unit step size `h` for the approximate numerical derivative `(f(x + h) - f(x))/h` or the central version, see `central`. 

central logical indicating if central divided differences should be computed, i.e., \((f(x + h) - f(x - h))/2h\). These are typically more accurate but need more evaluations of \(f()\).

Details

This is a front end to the C function numeric_deriv, which is described in Writing R Extensions. The numeric variables must be of type double and not integer.

Value

The value of \(\text{eval(expr, envir = rho)}\) plus a matrix attribute "gradient". The columns of this matrix are the derivatives of the value with respect to the variables listed in theta.

Author(s)

Saikat DebRoy <saikat@stat.wisc.edu>; tweaks and eps, central options by R Core Team.

Examples

myenv <- new.env()
myenv$mean <- 0.
myenv$sd <- 1.
myenv$x <- seq(-3., 3., length.out = 31)
nD <- numericDeriv(quote(pnorm(x, mean, sd)), c("mean", "sd"), myenv)
str(nD)
## Visualize :
require(graphics)
matplot(myenv$x, cbind(c(nD), attr(nD, "gradient")), type="l")
abline(h=0, lty=3)
## "gradient" is close to the true derivatives, you don't see any diff.:
curve( - dnorm(x), col=2, lty=3, lwd=2, add=TRUE)
curve(-x*dnorm(x), col=3, lty=3, lwd=2, add=TRUE)
##
# shows 1.609e-8 on most platforms
all.equal(attr(nD,"gradient"),
    with(myenv, cbind(-dnorm(x), -x*dnorm(x))))

offset        Include an Offset in a Model Formula

Description

An offset is a term to be added to a linear predictor, such as in a generalised linear model, with known coefficient 1 rather than an estimated coefficient.

Usage

offset(object)
oneway.test

Arguments

object An offset to be included in a model frame

Details

There can be more than one offset in a model formula, but - is not supported for offset terms (and is equivalent to +).

Value

The input value.

See Also

model.offset, model.frame.

For examples see glm and Insurance in package MASS.

oneway.test

Test for Equal Means in a One-Way Layout

Description

Test whether two or more samples from normal distributions have the same means. The variances are not necessarily assumed to be equal.

Usage

oneway.test(formula, data, subset, na.action, var.equal = FALSE)

Arguments

formula a formula of the form lhs ~ rhs where lhs gives the sample values and rhs the corresponding groups.

data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").

var.equal a logical variable indicating whether to treat the variances in the samples as equal. If TRUE, then a simple F test for the equality of means in a one-way analysis of variance is performed. If FALSE, an approximate method of Welch (1951) is used, which generalizes the commonly known 2-sample Welch test to the case of arbitrarily many samples.

Details

If the right-hand side of the formula contains more than one term, their interaction is taken to form the grouping.
Value

A list with class "htest" containing the following components:

- **statistic**: the value of the test statistic.
- **parameter**: the degrees of freedom of the exact or approximate F distribution of the test statistic.
- **p.value**: the p-value of the test.
- **method**: a character string indicating the test performed.
- **data.name**: a character string giving the names of the data.

References

See Also

The standard t test (*t.test*) as the special case for two samples; the Kruskal-Wallis test (*kruskal.test*) for a nonparametric test for equal location parameters in a one-way layout.

Examples

```r
## Not assuming equal variances
oneway.test(extra ~ group, data = sleep)
## Assuming equal variances
oneway.test(extra ~ group, data = sleep, var.equal = TRUE)
## which gives the same result as
anova(lm(extra ~ group, data = sleep))
```

---

**optim**

*General-purpose Optimization*

Description

General-purpose optimization based on Nelder–Mead, quasi-Newton and conjugate-gradient algorithms. It includes an option for box-constrained optimization and simulated annealing.

Usage

```
optim(par, fn, gr = NULL, ..., 
method = c("Nelder-Mead", "BFGS", "CG", "L-BFGS-B", "SANN", "Brent"),
lower = -Inf, upper = Inf,
control = list(), hessian = FALSE)

optimHess(par, fn, gr = NULL, ..., control = list())
```
Arguments

- **par**: Initial values for the parameters to be optimized over.
- **fn**: A function to be minimized (or maximized), with first argument the vector of parameters over which minimization is to take place. It should return a scalar result.
- **gr**: A function to return the gradient for the "BFGS", "CG" and "L-BFGS-B" methods. If it is NULL, a finite-difference approximation will be used. For the "SANN" method it specifies a function to generate a new candidate point. If it is NULL a default Gaussian Markov kernel is used.
- **...**: Further arguments to be passed to `fn` and `gr`.
- **method**: The method to be used. See 'Details'. Can be abbreviated.
- **lower, upper**: Bounds on the variables for the "L-BFGS-B" method, or bounds in which to search for method "Brent".
- **control**: A list of control parameters. See 'Details'.
- **hessian**: Logical. Should a numerically differentiated Hessian matrix be returned?

Details

Note that arguments after ... must be matched exactly.

By default `optim` performs minimization, but it will maximize if `control$fnscale` is negative. `optimHess` is an auxiliary function to compute the Hessian at a later stage if `hessian = TRUE` was forgotten.

The default method is an implementation of that of Nelder and Mead (1965), that uses only function values and is robust but relatively slow. It will work reasonably well for non-differentiable functions.

Method "BFGS" is a quasi-Newton method (also known as a variable metric algorithm), specifically that published simultaneously in 1970 by Broyden, Fletcher, Goldfarb and Shanno. This uses function values and gradients to build up a picture of the surface to be optimized.

Method "CG" is a conjugate gradients method based on that by Fletcher and Reeves (1964) (but with the option of Polak–Ribiére or Beale–Sorenson updates). Conjugate gradient methods will generally be more fragile than the BFGS method, but as they do not store a matrix they may be successful in much larger optimization problems.

Method "L-BFGS-B" is that of Byrd et al. (1995) which allows box constraints, that is each variable can be given a lower and/or upper bound. The initial value must satisfy the constraints. This uses a limited-memory modification of the BFGS quasi-Newton method. If non-trivial bounds are supplied, this method will be selected, with a warning.

Nocedal and Wright (1999) is a comprehensive reference for the previous three methods.

Method "SANN" is by default a variant of simulated annealing given in Belisle (1992). Simulated annealing belongs to the class of stochastic global optimization methods. It uses only function values but is relatively slow. It will also work for non-differentiable functions. This implementation uses the Metropolis function for the acceptance probability. By default the next candidate point is generated from a Gaussian Markov kernel with scale proportional to the actual temperature. If a function to generate a new candidate point is given, method "SANN" can also be used to solve combinatorial optimization problems. Temperatures are decreased according to the logarithmic cooling schedule as given in Belisle (1992, p. 890); specifically, the temperature is set to $\text{temp} / \log((((t-1) \% / \text{tmax}) * \text{tmax} + \exp(1)))$, where $t$ is the current iteration step and $\text{temp}$ and $\text{tmax}$ are specifiable via `control`, see below. Note that the "SANN" method depends critically on the
settings of the control parameters. It is not a general-purpose method but can be very useful in getting to a good value on a very rough surface.

Method "Brent" is for one-dimensional problems only, using optimize(). It can be useful in cases where optim() is used inside other functions where only method can be specified, such as in mle from package stats4.

Function fn can return NA or Inf if the function cannot be evaluated at the supplied value, but the initial value must have a computable finite value of fn. (Except for method "L-BFGS-B" where the values should always be finite.)

optim can be used recursively, and for a single parameter as well as many. It also accepts a zero-length par, and just evaluates the function with that argument.

The control argument is a list that can supply any of the following components:

- trace Non-negative integer. If positive, tracing information on the progress of the optimization is produced. Higher values may produce more tracing information: for method "L-BFGS-B" there are six levels of tracing. (To understand exactly what these do see the source code: higher levels give more detail.)

- fnscale An overall scaling to be applied to the value of fn and gr during optimization. If negative, turns the problem into a maximization problem. Optimization is performed on fn(par)/fnscale.

- parscale A vector of scaling values for the parameters. Optimization is performed on par/parscale and these should be comparable in the sense that a unit change in any element produces about a unit change in the scaled value. Not used (nor needed) for method = "Brent".

- ndeps A vector of step sizes for the finite-difference approximation to the gradient, on par/parscale scale. Defaults to 1e-3.

- maxit The maximum number of iterations. Defaults to 100 for the derivative-based methods, and 500 for "Nelder-Mead".
  For "SANN" maxit gives the total number of function evaluations: there is no other stopping criterion. Defaults to 10000.

- abstol The absolute convergence tolerance. Only useful for non-negative functions, as a tolerance for reaching zero.

- reltol Relative convergence tolerance. The algorithm stops if it is unable to reduce the value by a factor of reltol * (abs(val) + reltol) at a step. Defaults to sqrt(.Machine$double.eps), typically about 1e-8.

- alpha, beta, gamma Scaling parameters for the "Nelder-Mead" method. alpha is the reflection factor (default 1.0), beta the contraction factor (0.5) and gamma the expansion factor (2.0).

- REPORT The frequency of reports for the "BFGS", "L-BFGS-B" and "SANN" methods if control$trace is positive. Defaults to every 10 iterations for "BFGS" and "L-BFGS-B", or every 100 temperatures for "SANN".

- warn.1d.NelderMead a logical indicating if the (default) "Nelder-Mead" method should signal a warning when used for one-dimensional minimization. As the warning is sometimes inappropriate, you can suppress it by setting this option to false.

- lmm is an integer giving the number of BFGS updates retained in the "L-BFGS-B" method. It defaults to 5.

- factr controls the convergence of the "L-BFGS-B" method. Convergence occurs when the reduction in the objective is within this factor of the machine tolerance. Default is 1e7, that is a tolerance of about 1e-8.
pgtol helps control the convergence of the "L-BFGS-B" method. It is a tolerance on the projected gradient in the current search direction. This defaults to zero, when the check is suppressed.

temp controls the "SANN" method. It is the starting temperature for the cooling schedule. Defaults to 10.

tmax is the number of function evaluations at each temperature for the "SANN" method. Defaults to 10.

Any names given to par will be copied to the vectors passed to fn and gr. Note that no other attributes of par are copied over.

The parameter vector passed to fn has special semantics and may be shared between calls: the function should not change or copy it.

Value

For optim, a list with components:

par The best set of parameters found.
value The value of fn corresponding to par.
counts A two-element integer vector giving the number of calls to fn and gr respectively. This excludes those calls needed to compute the Hessian, if requested, and any calls to fn to compute a finite-difference approximation to the gradient.
convergence An integer code. 0 indicates successful completion (which is always the case for "SANN" and "Brent"). Possible error codes are
1 indicates that the iteration limit maxit had been reached.
10 indicates degeneracy of the Nelder–Mead simplex.
51 indicates a warning from the "L-BFGS-B" method; see component message for further details.
52 indicates an error from the "L-BFGS-B" method; see component message for further details.
message A character string giving any additional information returned by the optimizer, or NULL.

hessian Only if argument hessian is true. A symmetric matrix giving an estimate of the Hessian at the solution found. Note that this is the Hessian of the unconstrained problem even if the box constraints are active.

For optimHess, the description of the hessian component applies.

Note

optim will work with one-dimensional pars, but the default method does not work well (and will warn). Method "Brent" uses optimize and needs bounds to be available; "BFGS" often works well enough if not.

Source

The code for methods "Nelder–Mead", "BFGS" and "CG" was based originally on Pascal code in Nash (1990) that was translated by p2c and then hand-optimized. Dr Nash has agreed that the code can be made freely available.

The code for method "L-BFGS-B" is based on Fortran code by Zhu, Byrd, Lu-Chen and Nocedal obtained from Netlib (file ‘opt/lbfgs_bcm.shar’: another version is in ‘toms/778’).

The code for method "SANN" was contributed by A. Trapletti.

## 1-D minimization: "Brent" or optimize() being preferred.. but NM may be ok and "unavoidable",
## ---------------- so we can suppress the check+warning :

optimize

One Dimensional Optimization

Description
The function optimize searches the interval from lower to upper for a minimum or maximum of the function f with respect to its first argument.

optimise is an alias for optimize.

Usage
optimize(f, interval, ..., lower = min(interval), upper = max(interval),
  maximum = FALSE,
  tol = .Machine$double.eps^0.25)

optimise(f, interval, ..., lower = min(interval), upper = max(interval),
  maximum = FALSE,
  tol = .Machine$double.eps^0.25)

Arguments

f the function to be optimized. The function is either minimized or maximized over its first argument depending on the value of maximum.

interval a vector containing the end-points of the interval to be searched for the minimum.

... additional named or unnamed arguments to be passed to f.

lower the lower end point of the interval to be searched.

upper the upper end point of the interval to be searched.

maximum logical. Should we maximize or minimize (the default)?

tol the desired accuracy.

Details
Note that arguments after ... must be matched exactly.

The method used is a combination of golden section search and successive parabolic interpolation, and was designed for use with continuous functions. Convergence is never much slower than that for a Fibonacci search. If f has a continuous second derivative which is positive at the minimum (which is not at lower or upper), then convergence is superlinear, and usually of the order of about 1.324.

The function f is never evaluated at two points closer together than $\epsilon|x_0| + (tol/3)$, where $\epsilon$ is approximately $\sqrt{\text{.Machine\$double\$eps}}$ and $x_0$ is the final abscissa optimize()$minimum. If f is a unimodal function and the computed values of f are always unimodal when separated by at least $\epsilon |x| + (tol/3)$, then $x_0$ approximates the abscissa of the global minimum of f on the interval lower, upper with an error less than $\epsilon |x_0| + tol$.  

```r
system.time(r0 <- optimize(function(x) (x-pi)^2, c(0, 10)))
system.time(ro <- optim(1, function(x) (x-pi)^2, control=list(warn.1d.NelderMead = FALSE)))
r0$minimum - pi # 0 (perfect), on one platform
ro$par - pi # ~= 1.9e-4 on one platform
utils::str(ro)
```
If \( f \) is not unimodal, then \( \text{optimize()} \) may approximate a local, but perhaps non-global, minimum to the same accuracy.

The first evaluation of \( f \) is always at \( x_1 = a + (1 - \phi)(b - a) \) where \((a, b) = (\text{lower}, \text{upper})\) and \( \phi = (\sqrt{5} - 1)/2 = 0.61803.. \) is the golden section ratio. Almost always, the second evaluation is at \( x_2 = a + \phi(b - a) \). Note that a local minimum inside \([x_1, x_2]\) will be found as solution, even when \( f \) is constant in there, see the last example.

\( f \) will be called as \( f(x, \ldots) \) for a numeric value of \( x \).

The argument passed to \( f \) has special semantics and used to be shared between calls. The function should not copy it.

**Value**

A list with components \text{minimum} (or \text{maximum}) and \text{objective} which give the location of the minimum (or maximum) and the value of the function at that point.

**Source**

A C translation of Fortran code [https://netlib.org/fmm/fmin.f](https://netlib.org/fmm/fmin.f) (author(s) unstated) based on the Algol 60 procedure \text{localmin} given in the reference.

**References**

**See Also**

\text{nlm}, \text{uniroot}.

**Examples**

```r
require(graphics)

f <- function (x, a) (x - a)^2
xmin <- optimize(f, c(0, 1), tol = 0.0001, a = 1/3)

## See where the function is evaluated:
optimize(function(x) x^2*(print(x)-1), lower = 0, upper = 10)

## "wrong" solution with unlucky interval and piecewise constant f():
f <- function(x) ifelse(x > -1, ifelse(x < 4, exp(-1/abs(x - 1)), 10), 10)
fp <- function(x) { print(x); f(x) }

plot(f, -2,5, ylim = 0:1, col = 2)
optimize(fp, c(-4, 20)) # doesn't see the minimum
optimize(fp, c(-7, 20)) # ok
```
**order.dendrogram**

**Ordering or Labels of the Leaves in a Dendrogram**

**Description**

These functions return the order (index) or the "label" attribute for the leaves in a dendrogram. These indices can then be used to access the appropriate components of any additional data.

**Usage**

order.dendrogram(x)

```r
## S3 method for class 'dendrogram'
labels(object, ...)
```

**Arguments**

- `x`, `object` a dendrogram (see as.dendrogram).
- `...` additional arguments

**Details**

The indices or labels for the leaves in left to right order are retrieved.

**Value**

A vector with length equal to the number of leaves in the dendrogram is returned. From `r <- order.dendrogram()`, each element is the index into the original data (from which the dendrogram was computed).

**Author(s)**

R. Gentleman (order.dendrogram) and Martin Maechler (labels.dendrogram).

**See Also**

reorder, dendrogram.

**Examples**

```r
set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
hc$order
dd <- as.dendrogram(hc)
order.dendrogram(dd) ## the same :
stopifnot(hc$order == order.dendrogram(dd))

d2 <- as.dendrogram(hclust(dist(USArrests)))
labels(d2) ## in this case the same as
stopifnot(identical(labels(d2), rownames(USArrests)[order.dendrogram(d2)]))
```
Adjust P-values for Multiple Comparisons

Description

Given a set of p-values, returns p-values adjusted using one of several methods.

Usage

p.adjust(p, method = p.adjust.methods, n = length(p))

p.adjust.methods
# c("holm", "hochberg", "hommel", "bonferroni", "BH", "BY",
# "fdr", "none")

Arguments

p numeric vector of p-values (possibly with NAs). Any other R object is coerced by as.numeric.
method correction method, a character string. Can be abbreviated.
n number of comparisons, must be at least length(p); only set this (to non-default) when you know what you are doing!

Details

The adjustment methods include the Bonferroni correction ("bonferroni") in which the p-values are multiplied by the number of comparisons. Less conservative corrections are also included by Holm (1979) ("holm"), Hochberg (1988) ("hochberg"), Hommel (1988) ("hommel"), Benjamini & Hochberg (1995) ("BH" or its alias "fdr"), and Benjamini & Yekutieli (2001) ("BY"), respectively. A pass-through option ("none") is also included. The set of methods are contained in the p.adjust.methods vector for the benefit of methods that need to have the method as an option and pass it on to p.adjust.

The first four methods are designed to give strong control of the family-wise error rate. There seems no reason to use the unmodified Bonferroni correction because it is dominated by Holm’s method, which is also valid under arbitrary assumptions.

Hochberg’s and Hommel’s methods are valid when the hypothesis tests are independent or when they are non-negatively associated (Sarkar, 1998; Sarkar and Chang, 1997). Hommel’s method is more powerful than Hochberg’s, but the difference is usually small and the Hochberg p-values are faster to compute.

The "BH" (aka "fdr") and "BY" methods of Benjamini, Hochberg, and Yekutieli control the false discovery rate, the expected proportion of false discoveries amongst the rejected hypotheses. The false discovery rate is a less stringent condition than the family-wise error rate, so these methods are more powerful than the others.

Note that you can set n larger than length(p) which means the unobserved p-values are assumed to be greater than all the observed p for "bonferroni" and "holm" methods and equal to 1 for the other methods.

Value

A numeric vector of corrected p-values (of the same length as p, with names copied from p).
References

See Also

`pairwise.*` functions such as `pairwise.t.test`.

Examples

```r
require(graphics)

set.seed(123)
x <- rnorm(50, mean = c(rep(0, 25), rep(3, 25)))
p <- 2*pnorm(sort(-abs(x)))

round(p, 3)
round(p.adjust(p), 3)
round(p.adjust(p, "BH"), 3)

## or all of them at once (dropping the "fdr" alias):
p.adj <- sapply(p.adjust.M, function(meth) p.adjust(p, meth))
p.adj.60 <- sapply(p.adjust.M, function(meth) p.adjust(p, meth, n = 60))
stopifnot(identical(p.adj[,"none"], p), p.adj <= p.adj.60)
round(p.adj, 3)
## or a bit nicer:
noquote(apply(p.adj, 2, format.pval, digits = 3))

## and a graphic:
matplot(p, p.adj, ylab="p.adjust(p, meth)", type = "l", asp = 1, lty = 1:6,
main = "P-value adjustments")
legend(0.7, 0.6, p.adjust.M, col = 1:6, lty = 1:6)
```
## Can work with NA's:
pN <- p; iN <- c(46, 47); pN[iN] <- NA
pN.a <- sapply(p.adjust.M, function(meth) p.adjust(pN, meth))
## The smallest 20 P-values all affected by the NA's:
round((pN.a / p.adj)[1:20, , 4])

---

**Pair**

**Construct a Paired-Data Object**

### Description

Combines two vectors into an object of class "Pair".

### Usage

```r
Pair(x, y)
```

### Arguments

- `x`: a vector, the 1st element of the pair.
- `y`: a vector, the 2nd element of the pair. Should have the same length as `x`.

### Value

A 2-column matrix of class "Pair".

### Note

Mostly designed as part of the formula interface to paired tests.

### See Also

- `t.test`
- `wilcox.test`
- `pairwise.prop.test`
pairwise.t.test

Arguments

- **x**: Vector of counts of successes or a matrix with 2 columns giving the counts of successes and failures, respectively.
- **n**: Vector of counts of trials; ignored if x is a matrix.
- **...**: Additional arguments to pass to `prop.test`

Value

Object of class "pairwise.htest"

See Also

`prop.test`, `p.adjust`

Examples

```r
smokers <- c( 83, 90, 129, 70 )
patients <- c( 86, 93, 136, 82 )
pairwise.prop.test(smokers, patients)
```

Description

Calculate pairwise comparisons between group levels with corrections for multiple testing

Usage

```r
pairwise.t.test(x, g, p.adjust.method = p.adjust.methods,
                 pool.sd = !paired, paired = FALSE,
                 alternative = c("two.sided", "less", "greater"),
                 ...)```

Arguments

- **x**: response vector.
- **g**: grouping vector or factor.
- **p.adjust.method**: Method for adjusting p values (see `p.adjust`).
- **pool.sd**: switch to allow/disallow the use of a pooled SD
- **paired**: a logical indicating whether you want paired t-tests.
- **alternative**: a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". Can be abbreviated.
- **...**: additional arguments to pass to `t.test`.
Details

The pool.sd switch calculates a common SD for all groups and uses that for all comparisons (this can be useful if some groups are small). This method does not actually call \texttt{t.test}, so extra arguments are ignored. Pooling does not generalize to paired tests so pool.sd and paired cannot both be TRUE.

Only the lower triangle of the matrix of possible comparisons is being calculated, so setting alternative to anything other than "two.sided" requires that the levels of \texttt{g} are ordered sensibly.

Value

Object of class "pairwise.htest"

See Also

\texttt{t.test}, \texttt{p.adjust}

Examples

attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
pairwise.t.test(Ozone, Month)
pairwise.t.test(Ozone, Month, p.adjust.method = "bonf")
pairwise.t.test(Ozone, Month, pool.sd = FALSE)
detach()

pairwise.table 

\begin{tabular}{l}
\textit{Tabulate p values for pairwise comparisons}\n\end{tabular}

Description

Creates table of p values for pairwise comparisons with corrections for multiple testing.

Usage

\texttt{pairwise.table(compare.levels, level.names, p.adjust.method)}

Arguments

\begin{itemize}
  \item \texttt{compare.levels} \texttt{a function} to compute (raw) p value given indices \texttt{i} and \texttt{j}.
  \item \texttt{level.names} \texttt{names of the group levels}
  \item \texttt{p.adjust.method} \texttt{a character string specifying the method for multiple testing adjustment; almost always one of \texttt{p.adjust.methods}. Can be abbreviated.}
\end{itemize}

Details

Functions that do multiple group comparisons create separate compare.levels functions (assumed to be symmetrical in \texttt{i} and \texttt{j}) and passes them to this function.
pairwise.wilcox.test

Pairwise Wilcoxon Rank Sum Tests

Description

Calculate pairwise comparisons between group levels with corrections for multiple testing.

Usage

pairwise.wilcox.test(x, g, p.adjust.method = p.adjust.methods,
                  paired = FALSE, ...)

Arguments

x response vector.
g grouping vector or factor.
paired a logical indicating whether you want a paired test.
... additional arguments to pass to wilcox.test.

Details

Extra arguments that are passed on to wilcox.test may or may not be sensible in this context. In particular, only the lower triangle of the matrix of possible comparisons is being calculated, so setting alternative to anything other than "two.sided" requires that the levels of g are ordered sensibly.

Value

Object of class "pairwise.htest"

See Also

wilcox.test, p.adjust

Examples

attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
## These give warnings because of ties :
pairwise.wilcox.test(Ozone, Month)
pairwise.wilcox.test(Ozone, Month, p.adjust.method = "bonf")
detach()
plot.acf

Plot Autocovariance and Autocorrelation Functions

Description

Plot method for objects of class "acf".

Usage

## S3 method for class 'acf'
plot(x, ci = 0.95, type = "h", xlab = "Lag", ylab = NULL,
     ylim = NULL, main = NULL,
     ci.col = "blue", ci.type = c("white", "ma"),
     max.mfrow = 6, ask = Npgs > 1 && dev.interactive(),
     mar = if (nser > 2) c(3,2,2,0.8) else par("mar"),
     oma = if (nser > 2) c(1,1.2,1,1) else par("oma"),
     mgp = if (nser > 2) c(1.5,0.6,0) else par("mgp"),
     xpd = par("xpd"),
     cex.main = if (nser > 2) 1 else par("cex.main"),
     verbose = getOption("verbose"),
     ...)

Arguments

x an object of class "acf".

.ci coverage probability for confidence interval. Plotting of the confidence interval is suppressed if ci is zero or negative.

type the type of plot to be drawn, default to histogram like vertical lines.

xlab the x label of the plot.

ylab the y label of the plot.

ylim numeric of length 2 giving the y limits for the plot.

main overall title for the plot.

ci.col colour to plot the confidence interval lines.

ci.type should the confidence limits assume a white noise input or for lag k an MA(k−1) input? Can be abbreviated.

max.mfrow positive integer; for multivariate x indicating how many rows and columns of plots should be put on one page, using par(mfrow = c(m,m)).

ask logical; if TRUE, the user is asked before a new page is started.

mar, oma, mgp, xpd, cex.main graphics parameters as in par(*), by default adjusted to use smaller than default margins for multivariate x only.

verbose logical. Should R report extra information on progress?

... graphics parameters to be passed to the plotting routines.

Note

The confidence interval plotted in plot.acf is based on an uncorrelated series and should be treated with appropriate caution. Using ci.type = "ma" may be less potentially misleading.
See Also

acf which calls plot.acf by default.

Examples

require(graphics)

z4 <- ts(matrix(rnorm(400), 100, 4), start = c(1961, 1), frequency = 12)
z7 <- ts(matrix(rnorm(700), 100, 7), start = c(1961, 1), frequency = 12)
acf(z4)
acf(z7, max.mfrow = 7)  # squeeze onto 1 page
acf(z7)  # multi-page
plot.HoltWinters

Plot function for "HoltWinters" objects

Description

Produces a chart of the original time series along with the fitted values. Optionally, predicted values (and their confidence bounds) can also be plotted.

Usage

```r
## S3 method for class 'HoltWinters'
plot(x, predicted.values = NA, intervals = TRUE,
    separator = TRUE, col = 1, col.predicted = 2,
    col.intervals = 4, col.separator = 1, lty = 1,
    lty.predicted = 1, lty.intervals = 1, lty.separator = 3,
    ylab = "Observed / Fitted",
    main = "Holt-Winters filtering",
    ylim = NULL, ...)
```

Arguments

- `x` Object of class "HoltWinters"
- `predicted.values` Predicted values as returned by `predict.HoltWinters`
- `intervals` If TRUE, the prediction intervals are plotted (default).
- `separator` If TRUE, a separating line between fitted and predicted values is plotted (default).
- `col, lty` Color/line type of original data (default: black solid).
- `col.predicted, lty.predicted` Color/line type of fitted and predicted values (default: red solid).
- `col.intervals, lty.intervals` Color/line type of prediction intervals (default: blue solid).
- `col.separator, lty.separator` Color/line type of observed/predicted values separator (default: black dashed).
- `ylab` Label of the y-axis.
- `main` Main title.
- `ylim` Limits of the y-axis. If NULL, the range is chosen such that the plot contains the original series, the fitted values, and the predicted values if any.
- `...` Other graphics parameters.

plot.isoreg

Plot Method for isoreg Objects

Description

The plot and lines method for R objects of class isoreg.

Usage

## S3 method for class 'isoreg'
plot(x, plot.type = c("single", "row.wise", "col.wise"),
     main = paste("Isotonic regression", deparse(x$call)),
     main2 = "Cumulative Data and Convex Minorant",
     xlab = "x0", ylab = "x$y",
     par.fit = list(col = "red", cex = 1.5, pch = 13, lwd = 1.5),
     mar = if (both) 0.1 + c(3.5, 2.5, 1, 1) else par("mar"),
     mgp = if (both) c(1.6, 0.7, 0) else par("mgp"),
     grid = length(x$x) < 12, ...)

## S3 method for class 'isoreg'
lines(x, col = "red", lwd = 1.5,
       do.points = FALSE, cex = 1.5, pch = 13, ...)

Arguments

x

an isoreg object.

plot.type

character indicating which type of plot is desired. The first (default) only draws
the data and the fit, where the others add a plot of the cumulative data and fit.
Can be abbreviated.

main

main title of plot, see title.

main2

title for second (cumulative) plot.

xlab, ylab

x- and y- axis annotation.

par.fit

a list of arguments (for points and lines) for drawing the fit.

mar, mgp

graphical parameters, see par, mainly for the case of two plots.

grid

logical indicating if grid lines should be drawn. If true, grid() is used for the
first plot, where as vertical lines are drawn at ‘touching’ points for the cumulative
plot.

do.points

for lines(): logical indicating if the step points should be drawn as well (and
as they are drawn in plot()).

col, lwd, cex, pch

graphical arguments for lines(), where cex and pch are only used when
do.points is TRUE.

...

further arguments passed to and from methods.
See Also

`isoreg` for computation of isoreg objects.

Examples

```r
require(graphics)

utils::example(isoreg) # for the examples there

plot(y3, main = "simple plot(.) + lines(isoreg())")
lines(ir3)

##' same' plot as above, "proving" that only ranks of 'x' are important
plot(isoreg(2*(1:9), c(1,0,4,3,3,5,4,2,0)), plot.type = "row", log = "x")

plot(ir3, plot.type = "row", ylab = "y3")
plot(isoreg(y3 - 4), plot.type = "r", ylab = "y3 - 4")
plot(ir4, plot.type = "ro", ylab = "y4", xlab = "x = 1:n")

## experiment a bit with these (C-c C-j):
plot(isoreg(sample(9), y3), plot.type = "row")
plot(isoreg(sample(9), y3), plot.type = "col.wise")

plot(ir <- isoreg(sample(10), sample(10, replace = TRUE)),
     plot.type = "r")
```

Description

Six plots (selectable by which) are currently available: a plot of residuals against fitted values, a Scale-Location plot of \( \sqrt{|\text{residuals}|} \) against fitted values, a Q-Q plot of residuals, a plot of Cook’s distances versus row labels, a plot of residuals against leverages, and a plot of Cook’s distances against leverage/(1-leverage). By default, the first three and 5 are provided.

Usage

```r
## S3 method for class 'lm'
plot(x, which = c(1,2,3,5),
     caption = list("Residuals vs Fitted", "Q-Q Residuals", 
                    "Scale-Location", "Cook's distance", 
                    "Residuals vs Leverage", 
                    expression("Cook's dist vs Leverage* " * h[ii] / (1 - h[ii])))
     expression("Cook's dist vs Leverage* " * h[ii] / (1 - h[ii])))
     panel = if(add.smooth) function(x, y, ...) 
               panel.smooth(x, y, iter=iter.smooth, ...) else points,
     sub.caption = NULL, main = "",
     ask = prod(par("mfcol")) < length(which) && dev.interactive(), 
     ...,
     id.n = 3, labels.id = names(residuals(x)), cex.id = 0.75,
     qqline = TRUE, cook.levels = c(0.5, 1.0),
     cook.col = 8, cook.lty = 2, cook.legendChanges = list(),
```

plot.lm

Plot Diagnostics for an lm Object
add.smooth = getOption("add.smooth"),
iter.smooth = if(isGlm) 0 else 3,
label.pos = c(4,2),
cex.caption = 1, cex.oma.main = 1.25,
, extend.ylim.f = 0.08
)

Arguments

x

lm object, typically result of lm or glm.

which

a subset of the numbers 1:6, by default 1:3, 5, referring to
1. "Residuals vs Fitted", aka 'Tukey-Anscombe' plot
2. "Residual Q-Q" plot
3. "Scale-Location"
4. "Cook's distance"
5. "Residuals vs Leverage"
6. "Cook's dist vs Lev./(1-Lev.)"

See also 'Details' below.

caption

captions to appear above the plots; character vector or list of valid graphics annotations, see as.graphicsAnnot, of length 6, the j-th entry corresponding to which[j], see also the default vector in 'Usage'. Can be set to "" or NA to suppress all captions.

panel

panel function. The useful alternative to points, panel.smooth can be chosen by add.smooth = TRUE.

sub.caption

common title—above the figures if there are more than one; used as sub (s.title) otherwise. If NULL, as by default, a possible abbreviated version of deparse(x$call) is used.

main

title to each plot—in addition to caption.

ask

logical; if TRUE, the user is asked before each plot, see par(ask=.).

... other parameters to be passed through to plotting functions.

id.n

number of points to be labelled in each plot, starting with the most extreme.

labels.id

vector of labels, from which the labels for extreme points will be chosen. NULL uses observation numbers.

cex.id

magnification of point labels.

qqline

logical indicating if a qqline() should be added to the normal Q-Q plot.

cook.levels

levels of Cook’s distance at which to draw contours.

cook.col, cook.lty

color and line type to use for these contour lines.

cook.legendChanges

a list (or NULL to suppress the call) of arguments to legend which should be modified from (or added to) the plot.lm() default list(x = "bottomleft", legend = "Cook's distance", lty = cook.lty, col = cook.col, text.col = cook.col, bty = "n", x.intersp = 1/4, y.intersp = 1/8).

add.smooth

logical indicating if a smoother should be added to most plots; see also panel above.
iter.smooth  the number of robustness iterations, the argument iter in panel.smooth(); the default uses no such iterations for glm fits which is particularly desirable for the (predominant) case of binary observations, but also for other models where the response distribution can be highly skewed.

label.pos  positioning of labels, for the left half and right half of the graph respectively, for plots 1-3, 5, 6.

cex.caption  controls the size of caption.

cex.oma.main  controls the size of the sub.caption only if that is above the figures when there is more than one.

extend.ylim.f  a numeric vector of length 1 or 2, to be used in ylim <- extendrange(r=ylim, f = *) for plots 1 and 5 when id.n is non-empty.

Details

sub.caption—by default the function call—is shown as a subtitle (under the x-axis title) on each plot when plots are on separate pages, or as a subtitle in the outer margin (if any) when there are multiple plots per page.

The ‘Scale-Location’ plot (which=3), also called ‘Spread-Location’ or ‘S-L’ plot, takes the square root of the absolute residuals in order to diminish skewness ($\sqrt{|E|}$ is much less skewed than $|E|$ for Gaussian zero-mean $E$).

The ‘S-L’, the Q-Q, and the Residual-Leverage (which=5) plot use standardized residuals which have identical variance (under the hypothesis). They are given as $R_i/(s \times \sqrt{1-h_{ii}})$ where the ‘leverages’ $h_{ii}$ are the diagonal entries of the hat matrix, influence()$hat (see also hat), and where the Residual-Leverage plot uses the standardized Pearson residuals (residuals.glm(type = “pearson”)) for $R[i]$. The Residual-Leverage plot (which=5) shows contours of equal Cook’s distance, for values of cook.levels (by default 0.5 and 1) and omits cases with leverage one with a warning. If the leverages are constant (as is typically the case in a balanced aov situation) the plot uses factor level combinations instead of the leverages for the x-axis. (The factor levels are ordered by mean fitted value.) In the Cook’s distance vs leverage/(1-leverage) (= “leverage*”) plot (which=6), contours of standardized residuals (rstandard(.)) that are equal in magnitude are lines through the origin. These lines are labelled with the magnitudes. The x-axis is labeled with the (non equidistant) leverages $h_{ii}$.

For the glm case, the Q-Q plot is based on the absolute value of the standardized deviance residuals. When the saddlepoint approximation applies, these have an approximate half-normal distribution. The saddlepoint approximation is exact for the normal and inverse Gaussian family, and holds approximately for the Gamma family with small dispersion (large shape) and for the Poisson and binomial families with large counts (Dunn and Smyth 2018).

## Analysis of the life-cycle savings data
## given in Belsley, Kuh and Welsch.
lm.SR <- lm(sr ~ pop15 + pop75 + dpi + ddpi, data = LifeCycleSavings)
plot(lm.SR)

## 4 plots on 1 page;
## allow room for printing model formula in outer margin:
par(mfrow = c(2, 2), oma = c(0, 0, 2, 0)) -> opar
plot(lm.SR)
plot(lm.SR, id.n = NULL) # no id's
plot(lm.SR, id.n = 5, labels.id = NULL) # 5 id numbers

## Was default in R <= 2.1.x:
## Cook's distances instead of Residual-Leverage plot
plot(lm.SR, which = 1:4)

## All the above fit a smooth curve where applicable
## by default unless "add.smooth" is changed.
## Give a smoother curve by increasing the lowess span:
plot(lm.SR, panel = function(x, y) panel.smooth(x, y, span = 1))

par(mfrow = c(2, 1)) # same oma as above
plot(lm.SR, which = 1:2, sub.caption = "Saving Rates, n=50, p=5")

## Cook's distance tweaking
par(mfrow = c(2, 3)) # same oma ...
plot(lm.SR, which = 1:6, cook.col = "royalblue")

## A case where over plotting of the "legend" is to be avoided:
if(dev.interactive(TRUE)) getOption("device")$height = 6, width = 4)
par(mfrow = c(3,1), mar = c(5,5,4,2)/2 +.1, mgp = c(1.4, .5, 0))
plot(lm.SR, which = 5, extend.ylim.f = c(0.2, 0.08))
plot(lm.SR, which = 5, cook.lty = "dotdash",
     cook.legendChanges = list(x = "bottomright", legend = "Cook"))
plot(lm.SR, which = 5, cook.legendChanges = NULL) # no "legend"

par(opar) # reset par()s
Plot Ridge Functions for Projection Pursuit Regression Fit

Description

Plot the ridge functions for a projection pursuit regression (ppr) fit.

Usage

```r
## S3 method for class 'ppr'
plot(x, ask, type = "o", cex = 1/2,
    main = quote(bquote("term"[.(i)]*": \hat{beta}[.(i)] == .(bet.i)])),
    xlab = quote(bquote(bold(alpha)[.(i)]^T * bold(x))),
    ylab = ", "

Arguments

x an R object of class "ppr" as produced by a call to ppr.
ask the graphics parameter ask: see par for details. If set to TRUE will ask between
the plot of each cross-section.
type the type of line (see plot.default) to draw.
cex plot symbol expansion factor (relative to par("cex")).
main, xlab, ylab axis annotations, see also title. Can be an expression (depending on i and
bet.i), as by default which will be evaluated.
... further graphical parameters, passed to plot().
```

Value

None

Side Effects

A series of plots are drawn on the current graphical device, one for each term in the fit.

See Also

ppr, par

Examples

```r
require(graphics)
rock1 <- within(rock, { area1 <- area/10000; peri1 <- peri/10000 })
par(mfrow = c(3,2)) # maybe: , pty = "s"
rock.ppr <- ppr(log(perm) ~ area1 + peri1 + shape,
    data = rock1, nterms = 2, max.terms = 5)
plot(rock.ppr, main = "ppr(log(perm)~ ., nterms=2, max.terms=5)"
plot(update(rock.ppr, bass = 5), main = "update(..., bass = 5)"
plot(update(rock.ppr, sm.method = "gcv", gcvpen = 2),
    main = "update(..., sm.method="gcv", gcvpen=2)"
```
Description

Plot and pairs methods for objects of class "profile".

Usage

```r
## S3 method for class 'profile'
plot(x, ...)                   
## S3 method for class 'profile'
pairs(x, colours = 2:3, which = names(x), ...)
```

Arguments

- `x`: an object inheriting from class "profile".
- `colours`: colours to be used for the mean curves conditional on `x` and `y` respectively.
- `which`: names or number of parameters in pairs plot
- `...`: arguments passed to or from other methods.

Details

This is the main plot method for objects created by `profile.glm`. It can also be called on objects created by `profile.nls`, but they have a specific method, `plot.profile.nls`.

The pairs method shows, for each pair of parameters `x` and `y`, two curves intersecting at the maximum likelihood estimate, which give the loci of the points at which the tangents to the contours of the bivariate profile likelihood become vertical and horizontal, respectively. In the case of an exactly bivariate normal profile likelihood, these two curves would be straight lines giving the conditional means of `y|x` and `x|y`, and the contours would be exactly elliptical. The which argument allows you to select a subset of parameters; the default corresponds to the set of parameters that have been profiled.

Author(s)

Originally, D. M. Bates and W. N. Venables for S (in 1996). Taken from MASS where these functions were re-written by B. D. Ripley for R (by 1998).

See Also

`profile.glm`, `profile.nls`.

Examples

```r
## see ?profile.glm for another example using glm fits.

## a version of example(profile.nls) from R >= 2.8.0
fm1 <- nls(demand ~ SSasympOrig(Time, A, lrc), data = BOD)
pr1 <- profile(fm1, alphamax = 0.1)
stats:::plot.profile(pr1) ## override dispatch to plot.profile.nls
pairs(pr1) # a little odd since the parameters are highly correlated
```
## an example from ?nls

```r
x <- -(1:100)/10
y <- 100 + 10 * exp(x / 2) + rnorm(x)/10
nlmod <- nls(y ~ Const + A * exp(B * x), start=list(Const=100, A=10, B=1))
pairs(profile(nlmod))
```

## example from Dobson (1990) (see ?glm)

```r
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3,1,9)
treatment <- gl(3,3)
## this example is only formally a Poisson model. It is really a
## comparison of 3 multinomials. Only the interaction parameters are of
## interest.
glm.D93i <- glm(counts ~ outcome * treatment, family = poisson())
pr1 <- profile(glm.D93i)
pr2 <- profile(glm.D93i, which=6:9)
plot(pr1)
plot(pr2)
pairs(pr1)
pairs(pr2)
```

---

**plot.profile.nls**  
*Plot a profile.nls Object*

### Description

Displays a series of plots of the profile t function and interpolated confidence intervals for the parameters in a nonlinear regression model that has been fit with `nls` and profiled with `profile.nls`.

### Usage

```r
## S3 method for class 'profile.nls'
plot(x, levels, conf = c(0.99, 0.95, 0.90, 0.80, 0.50)/100,
     absVal = TRUE, ylab = NULL, lty = 2, ...)
```

### Arguments

- `x`  
an object of class "profile.nls"

- `levels`  
levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually `conf` is used instead of giving `levels` explicitly.

- `conf`  
a numeric vector of confidence levels for profile-based confidence intervals on the parameters. Defaults to `c(0.99, 0.95, 0.90, 0.80, 0.50)`.  

- `absVal`  
a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t. Defaults to `TRUE`.

- `lty`  
the line type to be used for axis and dropped lines.

- `ylab, ...`  
other arguments to the `plot.default` function can be passed here (but not `xlab, xlim, ylim` nor `type`).
plot.spec

Plotting Spectral Densities

Description

Plotting method for objects of class "spec". For multivariate time series it plots the marginal spectra of the series or pairs plots of the coherency and phase of the cross-spectra.

Usage

```r
## S3 method for class 'spec'
plot(x, add = FALSE, ci = 0.95, log = c("yes", "dB", "no"),
     xlab = "frequency", ylab = NULL, type = "l",
     ci.col = "blue", ci.lty = 3,
     main = NULL, sub = NULL,
     plot.type = c("marginal", "coherency", "phase"),
```

Details

The plots are produced in a set of hard-coded colours, but as these are coded by number their effect can be changed by setting the `palette`. Colour 1 is used for the axes and 4 for the profile itself. Colours 3 and 6 are used for the axis line at zero and the horizontal/vertical lines dropping to the axes.

Author(s)

Douglas M. Bates and Saikat DebRoy

References

See Also

`nls`, `profile.nls`
plot.spec

...

plot.spec.phase(x, ci = 0.95,
  xlab = "frequency", ylab = "phase",
  ylim = c(-pi, pi), type = "l",
  main = NULL, ci.col = "blue", ci.lty = 3, ...)

plot.spec.coherency(x, ci = 0.95,
  xlab = "frequency",
  ylab = "squared coherency",
  ylim = c(0, 1), type = "l",
  main = NULL, ci.col = "blue", ci.lty = 3, ...)

Arguments

x an object of class "spec".

add logical. If TRUE, add to already existing plot. Only valid for plot.type = "marginal".

ci coverage probability for confidence interval. Plotting of the confidence bar/limits is omitted unless ci is strictly positive.

log If "dB", plot on log10 (decibel) scale, otherwise use conventional log scale or linear scale. Logical values are also accepted. The default is "yes" unless options(ts.S.compat = TRUE) has been set, when it is "dB". Only valid for plot.type = "marginal".

xlab the x label of the plot.

ylab the y label of the plot. If missing a suitable label will be constructed.

type the type of plot to be drawn, defaults to lines.

CI.col colour for plotting confidence bar or confidence intervals for coherency and phase.

ci.lty line type for confidence intervals for coherency and phase.

main overall title for the plot. If missing, a suitable title is constructed.

sub a subtitle for the plot. Only used for plot.type = "marginal". If missing, a description of the smoothing is used.

plot.type For multivariate time series, the type of plot required. Only the first character is needed.

ylim... Graphical parameters.

spectrum
Plot Step Functions

Description
Method of the generic `plot` for `stepfun` objects and utility for plotting piecewise constant functions.

Usage
```r
## S3 method for class 'stepfun'
plot(x, xval, xlim, ylim = range(c(y, Fn.kn)),
    xlab = "x", ylab = "f(x)", main = NULL,
    add = FALSE, verticals = TRUE, do.points = (n < 1000),
    pch = par("pch"), col = par("col"),
    col.points = col, cex.points = par("cex"),
    col.hor = col, col.vert = col,
    lty = par("lty"), lwd = par("lwd"), ...)

## S3 method for class 'stepfun'
lines(x, ...)
```

Arguments
- `x`: an R object inheriting from "stepfun".
- `xval`: numeric vector of abscissa values at which to evaluate `x`. Defaults to `knots(x)` restricted to `xlim`.
- `xlim, ylim`: limits for the plot region: see `plot.window`. Both have sensible defaults if omitted.
- `xlab, ylab`: labels for x and y axis.
- `main`: main title.
- `add`: logical; if TRUE only `add` to an existing plot.
- `verticals`: logical; if TRUE, draw vertical lines at steps.
- `do.points`: logical; if TRUE, also draw points at the (xlim restricted) knot locations. Default is true, for sample size < 1000.
- `pch`: character; point character if `do.points`.
- `col`: default color of all points and lines.
- `col.points`: character or integer code; color of points if `do.points`.
- `cex.points`: numeric; character expansion factor if `do.points`.
- `col.hor`: color of horizontal lines.
- `col.vert`: color of vertical lines.
- `lty, lwd`: line type and thickness for all lines.
- `...`: further arguments of `plot(.)`, or if(`add`) `segments(.)`. 
**Value**

A list with two components

- **t**  
  abscissa (x) values, including the two outermost ones.

- **y**  
  y values ‘in between’ the t[].

**Author(s)**

**See Also**

`ecdf` for empirical distribution functions as special step functions, `approxfun` and `splinefun`.

**Examples**

```r
require(graphics)
y0 <- c(1,2,4,3)
sfun0 <- stepfun(1:3, y0, f = 0)
sfun.2 <- stepfun(1:3, y0, f = .2)
sfun1 <- stepfun(1:3, y0, right = TRUE)

tt <- seq(0, 3, by = 0.1)
op <- par(mfrow = c(2,2))
plot(sfun0); plot(sfun0, xval = tt, add = TRUE, col.hor = "bisque")
plot(sfun.2);plot(sfun.2, xval = tt, add = TRUE, col = "orange") # all colors
plot(sfun1);lines(sfun1, xval = tt, col.hor = "coral")
##-- This is revealing :
plot(sfun0, verticals = FALSE,
     main = "stepfun(x, y0, f=f) for f = 0, .2, 1")
for(i in 1:3)
  lines(list(sfun0, sfun.2, stepfun(1:3, y0, f = 1))[i], col = i)
legend(2.5, 1.9, paste("f =", c(0, 0.2, 1)), col = 1:3, lty = 1, y.intersp = 1)
par(op)

##-- this works too (automatic call to ecdf(.)):
plot.stepfun(rt(50, df = 3), col.vert = "gray20")
```

---

**plot.ts**

Plotting Time-Series Objects

**Description**

Plotting method for objects inheriting from class "ts".
Usage

## S3 method for class 'ts'
plot(x, y = NULL, plot.type = c("multiple", "single"),
    xy.labels, xy.lines, panel = lines, nc, yax.flip = FALSE,
    mar.multi = c(0, 5.1, 0, if(yax.flip) 5.1 else 2.1),
    oma.multi = c(6, 0, 5, 0), axes = TRUE, ...)

## S3 method for class 'ts'
lines(x, ...)

Arguments

x, y  
time series objects, usually inheriting from class "ts".
plot.type  
for multivariate time series, should the series by plotted separately (with a common time axis) or on a single plot? Can be abbreviated.
xy.labels  
logical, indicating if text() labels should be used for an x-y plot, or character, supplying a vector of labels to be used. The default is to label for up to 150 points, and not for more.
xy.lines  
logical, indicating if lines should be drawn for an x-y plot. Defaults to the value of xy.labels if that is logical, otherwise to TRUE.
panel  
a function(x, col, bg, pch, type, ...) which gives the action to be carried out in each panel of the display for plot.type = "multiple". The default is lines.
nc  
the number of columns to use when type = "multiple". Defaults to 1 for up to 4 series, otherwise to 2.
yax.flip  
logical indicating if the y-axis (ticks and numbering) should flip from side 2 (left) to 4 (right) from series to series when type = "multiple".
mar.multi, oma.multi  
the (default) par settings for plot.type = "multiple". Modify with care!
axes  
logical indicating if x- and y- axes should be drawn.
...  
additional graphical arguments, see plot, plot.default and par.

Details

If y is missing, this function creates a time series plot, for multivariate series of one of two kinds depending on plot.type.

If y is present, both x and y must be univariate, and a scatter plot y ~ x will be drawn, enhanced by using text if xy.labels is TRUE or character, and lines if xy.lines is TRUE.

See Also

ts for basic time series construction and access functionality.

Examples

require(graphics)

## Multivariate
z <- ts(matrix(rt(200 * 8, df = 3), 200, 8),
    start = c(1961, 1), frequency = 12)
The Poisson Distribution

Description

Density, distribution function, quantile function and random generation for the Poisson distribution with parameter \( \lambda \).

Usage

dpois(x, lambda, log = FALSE)
ppois(q, lambda, lower.tail = TRUE, log.p = FALSE)
qpois(p, lambda, lower.tail = TRUE, log.p = FALSE)
rpois(n, lambda)

Arguments

- `x` vector of (non-negative integer) quantiles.
- `q` vector of quantiles.
- `p` vector of probabilities.
- `n` number of random values to return.
- `lambda` vector of (non-negative) means.
- `log, log.p` logical; if TRUE, probabilities p are given as log(p).
- `lower.tail` logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).
Details

The Poisson distribution has density

\[ p(x) = \frac{\lambda^x e^{-\lambda}}{x!} \]

for \( x = 0, 1, 2, \ldots \). The mean and variance are \( E(X) = Var(X) = \lambda \).

Note that \( \lambda = 0 \) is really a limit case (setting \( 0^0 = 1 \)) resulting in a point mass at 0, see also the example.

If an element of \( x \) is not integer, the result of \( \text{dpois} \) is zero, with a warning. \( p(x) \) is computed using Loader’s algorithm, see the reference in \( \text{dbinom} \).

The quantile is right continuous: \( \text{qpois}(p, \lambda) \) is the smallest integer \( x \) such that \( P(X \leq x) \geq p \).

Setting \( \text{lower.tail} = \text{FALSE} \) allows to get much more precise results when the default, \( \text{lower.tail} = \text{TRUE} \) would return 1, see the example below.

Value

dpois gives the (log) density, ppois gives the (log) distribution function, qpois gives the quantile function, and rpois generates random deviates.

Invalid \( \lambda \) will result in return value NaN, with a warning.

The length of the result is determined by \( n \) for rpois, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

rpois returns a vector of type integer unless generated values exceed the maximum representable integer when double values are returned.

Source

dpois uses C code contributed by Catherine Loader (see \( \text{dbinom} \)).
ppois uses pgamma.
qpois uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.
rpois uses

See Also

Distributions for other standard distributions, including \( \text{dbinom} \) for the binomial and \( \text{dnbinom} \) for the negative binomial distribution.

poisson.test.

Examples

require(graphics)

-\log(dpois(0:7, lambda = 1) * gamma(1+ 0:7)) # == 1
Ni <- rpois(50, lambda = 4); table(factor(Ni, 0:max(Ni)))
1 - ppois(10*(15:25), lambda = 100)  # becomes 0 (cancellation)
ppois(10*(15:25), lambda = 100, lower.tail = FALSE)  # no cancellation

par(mfrow = c(2, 1))
x <- seq(-0.01, 5, 0.01)
plot(x, ppois(x, 1), type = "s", ylab = "F(x)", main = "Poisson(1) CDF")
plot(x, pbinom(x, 100, 0.01), type = "s", ylab = "F(x)",
     main = "Binomial(100, 0.01) CDF")

## The (limit) case lambda = 0 :
stopifnot(identical(dpois(0,0), 1),
identical(ppois(0,0), 1),
identical(qpois(1,0), 0))

---

**poisson.test**

*Exact Poisson tests*

**Description**

Performs an exact test of a simple null hypothesis about the rate parameter in Poisson distribution, or for the ratio between two rate parameters.

**Usage**

```r
poisson.test(x, T = 1, r = 1,
    alternative = c("two.sided", "less", "greater"),
    conf.level = 0.95)
```

**Arguments**

- `x` number of events. A vector of length one or two.
- `T` time base for event count. A vector of length one or two.
- `r` hypothesized rate or rate ratio
- `alternative` indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.
- `conf.level` confidence level for the returned confidence interval.

**Details**

Confidence intervals are computed similarly to those of `binom.test` in the one-sample case, and using `binom.test` in the two sample case.

**Value**

A list with class "htest" containing the following components:

- `statistic` the number of events (in the first sample if there are two.)
- `parameter` the corresponding expected count
- `p.value` the p-value of the test.
- `conf.int` a confidence interval for the rate or rate ratio.
- `estimate` the estimated rate or rate ratio.
null.value the rate or rate ratio under the null, r.
alternative a character string describing the alternative hypothesis.
method the character string "Exact Poisson test" or "Comparison of Poisson rates" as appropriate.
data.name a character string giving the names of the data.

Note
The rate parameter in Poisson data is often given based on a “time on test” or similar quantity (person-years, population size, or expected number of cases from mortality tables). This is the role of the T argument.
The one-sample case is effectively the binomial test with a very large n. The two sample case is converted to a binomial test by conditioning on the total event count, and the rate ratio is directly related to the odds in that binomial distribution.

See Also
binom.test

Examples
### These are paraphrased from data sets in the ISwR package
## SMR, Welsh Nickel workers
poisson.test(137, 24.19893)
## eba1977, compare Fredericia to other three cities for ages 55-59
poisson.test(c(11, 6+8+7), c(800, 1083+1050+878))
Arguments

- **x, newdata**: A numeric vector or an object with mode "numeric" (such as a Date) at which to evaluate the polynomial. x can also be a matrix. Missing values are not allowed in x.

- **degree**: The degree of the polynomial. Must be less than the number of unique points when raw is false, as by default.

- **coefs**: Coefficients for prediction, coefficients from a previous fit.

- **raw**: Logical indicating if raw and not orthogonal polynomials.

- **simple**: Logical indicating if a simple matrix (with no further attributes but dimnames) should be returned. For speedup only.

- **object**: An object inheriting from class "poly", normally the result of a call to poly with a single vector argument.

- **...**: poly, polym: further vectors.

- **predict.poly**: Arguments to be passed to or from other methods.

Details

Although formally degree should be named (as it follows ...), an unnamed second argument of length 1 will be interpreted as the degree, such that poly(x, 3) can be used in formulas.

The orthogonal polynomial is summarized by the coefficients, which can be used to evaluate it via the three-term recursion given in Kennedy & Gentle (1980, pp. 343-4), and used in the predict part of the code.

poly using ... is just a convenience wrapper for polym: coef is ignored. Conversely, if polym is called with a single argument in ... it is a wrapper for poly.

Value

For poly and polym() (when simple=FALSE and coefs=NULL as per default):

A matrix with rows corresponding to points in x and columns corresponding to the degree, with attributes "degree" specifying the degrees of the columns and (unless raw = TRUE) "coefs" which contains the centering and normalization constants used in constructing the orthogonal polynomials and class c("poly", "matrix").

For poly(*, simple=TRUE), polym(*, coefs=<non-NULL>), and predict.poly(): a matrix.

Note

This routine is intended for statistical purposes such as contr.poly: it does not attempt to orthogonalize to machine accuracy.

Author(s)

R Core Team. Keith Jewell (Campden BRI Group, UK) contributed improvements for correct prediction on subsets.

Examples

od <- options(digits = 3)  # avoid too much visual clutter
(z <- poly(1:10, 3))
predict(z, seq(2, 4, 0.5))
zapsmall(poly(seq(4, 6, 0.5), 3, coefs = attr(z, "coefs")))

zm <- zapsmall(polym(1:4, c(1, 4:6), degree = 3))  # or just poly():
(z1 <- zapsmall(poly(cbind(1:4, c(1, 4:6)), degree = 3)))
## they are the same:
stopifnot(all.equal(zm, z1, tolerance = 1e-15))

## poly(<matrix>, df) --- used to fail till July 14 (vive la France!), 2017:

m2 <- cbind(1:4, c(1, 4:6))

pm2 <- zapsmall(poly(m2, 3))  # "unnamed degree = 3"

stopifnot(all.equal(pm2, zm, tolerance = 1e-15))

options(od)

Description

Creates a link object based on the link function $\eta = \mu^\lambda$.

Usage

power(lambda = 1)

Arguments

lambda  a real number.

Details

If lambda is non-positive, it is taken as zero, and the log link is obtained. The default lambda = 1 gives the identity link.

Value

A list with components linkfun, linkinv, mu.eta, and valideta. See make.link for information on their meaning.

References

See Also

make.link, family

To raise a number to a power, see Arithmetic.

To calculate the power of a test, see various functions in the stats package, e.g., power.t.test.

Examples

```r
power()
quasi(link = power(1/3))[c("linkfun", "linkinv")]
```

```
power.anova.test

Power Calculations for Balanced One-Way Analysis of Variance Tests

Description

Compute power of test or determine parameters to obtain target power.

Usage

power.anova.test(groups = NULL, n = NULL,
                 between.var = NULL, within.var = NULL,
                 sig.level = 0.05, power = NULL)

Arguments

groups       Number of groups
n            Number of observations (per group)
between.var  Between group variance
within.var   Within group variance
sig.level    Significance level (Type I error probability)
power        Power of test (1 minus Type II error probability)

Details

Exactly one of the parameters groups, n, between.var, power, within.var, and sig.level must
be passed as NULL, and that parameter is determined from the others. Notice that sig.level has
non-NULL default so NULL must be explicitly passed if you want it computed.

Value

Object of class "power.htest", a list of the arguments (including the computed one) augmented
with method and note elements.

Note

uniroot is used to solve power equation for unknowns, so you may see errors from it, notably
about inability to bracket the root when invalid arguments are given.
power.prop.test

**Description**

Compute the power of the two-sample test for proportions, or determine parameters to obtain a target power.

**Usage**

```r
power.prop.test(n = NULL, p1 = NULL, p2 = NULL, sig.level = 0.05, 
power = NULL, 
alternative = c("two.sided", "one.sided"), 
strict = FALSE, tol = .Machine$double.eps^0.25)
```

**Arguments**

- `n` number of observations (per group)
- `p1` probability in one group
- `p2` probability in other group
- `sig.level` significance level (Type I error probability)
- `power` power of test (1 minus Type II error probability)
- `alternative` one- or two-sided test. Can be abbreviated.
- `strict` use strict interpretation in two-sided case
- `tol` numerical tolerance used in root finding, the default providing (at least) four significant digits.
power.prop.test

Details

Exactly one of the parameters n, p1, p2, power, and sig.level must be passed as NULL, and that parameter is determined from the others. Notice that sig.level has a non-NULL default so NULL must be explicitly passed if you want it computed.

If strict = TRUE is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.

Note that not all conditions can be satisfied, e.g., for

\[ \text{power.prop.test(n=30, p1=0.90, p2=NULL, power=0.8, strict=TRUE)} \]

there is no proportion p2 between p1 = 0.9 and 1, as you’d need a sample size of at least \( n = 74 \) to yield the desired power for \((p1, p2) = (0.9, 1)\).

For these impossible conditions, currently a warning (warning) is signalled which may become an error (stop) in the future.

Value

Object of class "power.htest", a list of the arguments (including the computed one) augmented with method and note elements.

Note

uniroot is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given. If one of \( p1 \) and \( p2 \) is computed, then \( p1 < p2 \) is assumed and will hold, but if you specify both, \( p2 \leq p1 \) is allowed.

Author(s)

Peter Dalgaard. Based on previous work by Claus Ekstrøm

Examples

\[
\begin{align*}
&\text{power.prop.test(n=50, p1 = .50, p2 = .75)} \quad \#\# \Rightarrow \text{power} = 0.740 \\
&\text{power.prop.test(p1 = .50, p2 = .75, power = .90)} \quad \#\# \Rightarrow \text{n} = 76.7 \\
&\text{power.prop.test(n = 50, p1 = .5, power = .90)} \quad \#\# \Rightarrow \ p2 = 0.6026 \\
&\text{power.prop.test(n = 50, p1 = .5, p2 = 0.9, power = .90, sig.level=NULL)} \\
&\quad \#\# \Rightarrow \text{sig.l} = 0.00131 \\
&\text{power.prop.test(p1 = .5, p2 = 0.501, sig.level=.001, power=0.90)} \\
&\quad \#\# \Rightarrow \text{n} = 10451937 \\
\end{align*}
\]

try(
  power.prop.test(n=30, p1=0.90, p2=NULL, power=0.8)
) # a warning (which may become an error)

# Reason:

\[
\begin{align*}
&\text{power.prop.test( \quad p1=0.90, p2= 1.0, power=0.8) \#\#-> \text{n} = 73.37}
\end{align*}
\]
power.t.test  

Power calculations for one and two sample t tests

Description
Compute the power of the one- or two-sample t test, or determine parameters to obtain a target power.

Usage
```
power.t.test(n = NULL, delta = NULL, sd = 1, sig.level = 0.05, 
power = NULL, 
type = c("two.sample", "one.sample", "paired"), 
alternative = c("two.sided", "one.sided"), 
strict = FALSE, tol = .Machine$double.eps^0.25)
```

Arguments
- `n` number of observations (per group)
- `delta` true difference in means
- `sd` standard deviation
- `sig.level` significance level (Type I error probability)
- `power` power of test (1 minus Type II error probability)
- `type` string specifying the type of t test. Can be abbreviated.
- `alternative` one- or two-sided test. Can be abbreviated.
- `strict` use strict interpretation in two-sided case
- `tol` numerical tolerance used in root finding, the default providing (at least) four significant digits.

Details
Exactly one of the parameters `n`, `delta`, `power`, `sd`, and `sig.level` must be passed as `NULL`, and that parameter is determined from the others. Notice that the last two have non-NULL defaults, so `NULL` must be explicitly passed if you want to compute them.

If `strict = TRUE` is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.

Value
Object of class "power.htest", a list of the arguments (including the computed one) augmented with `method` and `note` elements.

Note
`uniroot` is used to solve the power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.
PP.test

t.test, uniroot

Examples

power.t.test(n = 20, delta = 1)
power.t.test(power = .90, delta = 1)
power.t.test(power = .90, delta = 1, alternative = "one.sided")

Description

Computes the Phillips-Perron test for the null hypothesis that \( x \) has a unit root against a stationary alternative.

Usage

PP.test(x, lshort = TRUE)

Arguments

x a numeric vector or univariate time series.

lshort a logical indicating whether the short or long version of the truncation lag parameter is used.

Details

The general regression equation which incorporates a constant and a linear trend is used and the corrected t-statistic for a first order autoregressive coefficient equals one is computed. To estimate \( \sigma^2 \) the Newey-West estimator is used. If lshort is TRUE, then the truncation lag parameter is set to \( \text{trunc}(4*(n/100)^{0.25}) \), otherwise \( \text{trunc}(12*(n/100)^{0.25}) \) is used. The p-values are interpolated from Table 4.2, page 103 of Banerjee et al. (1993).

Missing values are not handled.

Value

A list with class "htest" containing the following components:

statistic the value of the test statistic.

parameter the truncation lag parameter.

p.value the p-value of the test.

method a character string indicating what type of test was performed.

data.name a character string giving the name of the data.
Author(s)
A. Trapletti

Examples
```r
x <- rnorm(1000)
PP.test(x)
y <- cumsum(x) # has unit root
PP.test(y)
```

ppoints

Ordinates for Probability Plotting

Description
Generates the sequence of probability points \((1:m - a)/(m + (1-a)\cdot a)\) where \(m\) is either \(n\), if length(n)==1, or length(n).

Usage
```r
ppoints(n, a = if(n <= 10) 3/8 else 1/2)
```

Arguments
- \(n\) either the number of points generated or a vector of observations.
- \(a\) the offset fraction to be used; typically in \((0, 1)\).

Details
If \(0 < a < 1\), the resulting values are within \((0, 1)\) (excluding boundaries). In any case, the resulting sequence is symmetric in \([0, 1]\), i.e., \(p + rev(p) == 1\).

ppoints() is used in qqplot and qqnorm to generate the set of probabilities at which to evaluate the inverse distribution.

The choice of \(a\) follows the documentation of the function of the same name in Becker et al. (1988), and appears to have been motivated by results from Blom (1958) on approximations to expect normal order statistics (see also quantile).

The probability points for the continuous sample quantile types 5 to 9 (see quantile) can be obtained by taking \(a\) as, respectively, 1/2, 0, 1, 1/3, and 3/8.

**ppr**

### Projection Pursuit Regression

**Description**

Fit a projection pursuit regression model.

**Usage**

```r
ppr(x, ...)```

## S3 method for class 'formula'
ppr(formula, data, weights, subset, na.action, contrasts = NULL, ..., model = FALSE)

## Default S3 method:
ppr(x, y, weights = rep(1, n),
    ww = rep(1, q), nterms, max.terms = nterms, optlevel = 2,
    sm.method = c("supsmu", "spline", "gcvspline"),
    bass = 0, span = 0, df = 5, gcvpen = 1, trace = FALSE, ...)
```

See Also

qqplot, qqnorm.

**Examples**

```r
ppoints(4) # the same as ppoints(1:4)
ppoints(10)
ppoints(10, a = 1/2)

## Visualize including the fractions:
require(graphics)
p.ppoints <- function(n, ..., add = FALSE, col = par("col")) {
  pn <- ppoints(n, ...)
  if(add)
    points(pn, pn, col = col)
  else {
    tit <- match.call(); tit[[1]] <- quote(ppoints)
    plot(pn, pn, main = deparse(tit), col=col,
         xlim = 0:1, ylim = 0:1, xaxs = "i", yaxs = "i")
    abline(0, 1, col = adjustcolor(1, 1/4), lty = 3)
  }
  if(!add & requireNamespace("MASS", quietly = TRUE))
    text(pn, pn, as.character(MASS::fractions(pn)),
         adj = c(0,0)-1/4, cex = 3/4, xpd = NA, col=col)
  abline(h = pn, v = pn, col = adjustcolor(col, 1/2), lty = 2, lwd = 1/2)
}

p.ppoints(4)
p.ppoints(10)
p.ppoints(10, a = 1/2)
p.ppoints(21)
p.ppoints(8) ; p.ppoints(8, a = 1/2, add=TRUE, col="tomato")
```
Arguments

formula a formula specifying one or more numeric response variables and the explanatory variables.

x numeric matrix of explanatory variables. Rows represent observations, and columns represent variables. Missing values are not accepted.

y numeric matrix of response variables. Rows represent observations, and columns represent variables. Missing values are not accepted.

nterms number of terms to include in the final model.

data a data frame (or similar: see model.frame) from which variables specified in formula are preferentially to be taken.

weights a vector of weights \( w_i \) for each case.

ww a vector of weights for each response, so the fit criterion is the sum over case \( i \) and responses \( j \) of \( w_i \) \( w_j \) \((y_{ij} - \text{fit}_{ij})^2\) divided by the sum of \( w_i \).

subset an index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)

na.action a function to specify the action to be taken if NAs are found. The default action is given by getOption("na.action"). (NOTE: If given, this argument must be named.)

contrasts the contrasts to be used when any factor explanatory variables are coded.

max.terms maximum number of terms to choose from when building the model.

optlevel integer from 0 to 3 which determines the thoroughness of an optimization routine in the SMART program. See the ‘Details’ section.

sm.method the method used for smoothing the ridge functions. The default is to use Friedman’s super smoother \texttt{supsmu}. The alternatives are to use the smoothing spline code underlying \texttt{smooth.spline}, either with a specified (equivalent) degrees of freedom for each ridge functions, or to allow the smoothness to be chosen by GCV.

Can be abbreviated.

bass super smoother bass tone control used with automatic span selection (see \texttt{supsmu}); the range of values is 0 to 10, with larger values resulting in increased smoothing.

span super smoother span control (see \texttt{supsmu}). The default, 0, results in automatic span selection by local cross validation. span can also take a value in (0, 1].

df if \texttt{sm.method} is "spline" specifies the smoothness of each ridge term via the requested equivalent degrees of freedom.

gcvpen if \texttt{sm.method} is "gcv spline" this is the penalty used in the GCV selection for each degree of freedom used.

trace logical indicating if each spline fit should produce diagnostic output (about lambda and df), and the \texttt{supsmu} fit about its steps.

... arguments to be passed to or from other methods.

model logical. If true, the model frame is returned.
**Details**

The basic method is given by Friedman (1984) and based on his code. This code has been shown to be extremely sensitive to the Fortran compiler used.

The algorithm first adds up to \texttt{max.terms} ridge terms one at a time; it will use less if it is unable to find a term to add that makes sufficient difference. It then removes the least important term at each step until \texttt{nterms} terms are left.

The levels of optimization (argument \texttt{optlevel}) differ in how thoroughly the models are refitted during this process. At level 0 the existing ridge terms are not refitted. At level 1 the projection directions are not refitted, but the ridge functions and the regression coefficients are. Levels 2 and 3 refit all the terms and are equivalent for one response; level 3 is more careful to re-balance the contributions from each regressor at each step and so is a little less likely to converge to a saddle point of the sum of squares criterion.

**Value**

A list with the following components, many of which are for use by the method functions.

- \texttt{call} the matched call
- \texttt{p} the number of explanatory variables (after any coding)
- \texttt{q} the number of response variables
- \texttt{mu} the argument \texttt{nterms}
- \texttt{ml} the argument \texttt{max.terms}
- \texttt{gof} the overall residual (weighted) sum of squares for the selected model
- \texttt{gofn} the overall residual (weighted) sum of squares against the number of terms, up to \texttt{max.terms}. Will be invalid (and zero) for less than \texttt{nterms}.
- \texttt{df} the argument \texttt{df}
- \texttt{edf} if \texttt{sm.method} is \texttt{"spline"} or \texttt{"gcv spline"} the equivalent number of degrees of freedom for each ridge term used.
- \texttt{xnames} the names of the explanatory variables
- \texttt{ynames} the names of the response variables
- \texttt{alpha} a matrix of the projection directions, with a column for each ridge term
- \texttt{beta} a matrix of the coefficients applied for each response to the ridge terms: the rows are the responses and the columns the ridge terms
- \texttt{yb} the weighted means of each response
- \texttt{ys} the overall scale factor used: internally the responses are divided by \texttt{ys} to have unit total weighted sum of squares.
- \texttt{fitted.values} the fitted values, as a matrix if \texttt{q} > 1.
- \texttt{residuals} the residuals, as a matrix if \texttt{q} > 1.
- \texttt{smod} internal work array, which includes the ridge functions evaluated at the training set points.
- \texttt{model} (only if \texttt{model = TRUE}) the model frame.

**Source**

Friedman (1984): converted to double precision and added interface to smoothing splines by B. D. Ripley, originally for the \texttt{MASS} package.

detach()
```
**prcomp**

**Principal Components Analysis**

**Description**

Performs a principal components analysis on the given data matrix and returns the results as an object of class `prcomp`.

**Usage**

```r
prcomp(x, ...)  
## S3 method for class 'formula'
prcomp(formula, data = NULL, subset, na.action, ...)  
## Default S3 method:
prcomp(x, retx = TRUE, center = TRUE, scale. = FALSE,  
      tol = NULL, rank. = NULL, ...)  
## S3 method for class 'prcomp'
predict(object, newdata, ...)  
```

**Arguments**

- `formula`: a formula with no response variable, referring only to numeric variables.
- `data`: an optional data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- `subset`: an optional vector used to select rows (observations) of the data matrix `x`.
- `na.action`: a function which indicates what should happen when the data contain NAs. The default is set by the `na.action` setting of `options`, and is `na.fail` if that is unset. The ‘factory-fresh’ default is `na.omit`.
- `...`: arguments passed to or from other methods. If `x` is a formula one might specify `scale.` or `tol`.
- `x`: a numeric or complex matrix (or data frame) which provides the data for the principal components analysis.
- `retx`: a logical value indicating whether the rotated variables should be returned.
- `center`: a logical value indicating whether the variables should be shifted to be zero centered. Alternately, a vector of length equal the number of columns of `x` can be supplied. The value is passed to `scale`.
- `scale.`: a logical value indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is `FALSE` for consistency with S, but in general scaling is advisable. Alternatively, a vector of length equal the number of columns of `x` can be supplied. The value is passed to `scale`.
- `tol`: a value indicating the magnitude below which components should be omitted. (Components are omitted if their standard deviations are less than or equal to `tol` times the standard deviation of the first component.) With the default null setting, no components are omitted (unless `rank.` is specified
less than \(\min(\text{dim}(x))\). Other settings for \(\text{tol}\) could be \(\text{tol} = 0\) or \(\text{tol} = \sqrt{\text{Machine$double$eps}}\), which would omit essentially constant components.

- **rank.** optionally, a number specifying the maximal rank, i.e., maximal number of principal components to be used. Can be set as alternative or in addition to \(\text{tol}\), useful notably when the desired rank is considerably smaller than the dimensions of the matrix.

- **object** object of class inheriting from "prcomp"

- **newdata** An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, newdata must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.

### Details

The calculation is done by a singular value decomposition of the (centered and possibly scaled) data matrix, not by using \texttt{eigen} on the covariance matrix. This is generally the preferred method for numerical accuracy. The print method for these objects prints the results in a nice format and the plot method produces a scree plot.

Unlike \texttt{princomp}, variances are computed with the usual divisor \(N - 1\).

Note that \(\text{scale} = \text{TRUE}\) cannot be used if there are zero or constant (for \(\text{center} = \text{TRUE}\)) variables.

### Value

\texttt{prcomp} returns a list with class "prcomp" containing the following components:

- **sdev** the standard deviations of the principal components (i.e., the square roots of the eigenvalues of the covariance/correlation matrix, though the calculation is actually done with the singular values of the data matrix).

- **rotation** the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). The function \texttt{princomp} returns this in the element \texttt{loadings}.

- **x** if \(\text{retx}\) is true the value of the rotated data (the centred (and scaled if requested) data multiplied by the \texttt{rotation} matrix) is returned. Hence, \(\text{cov}(x)\) is the diagonal matrix \(\text{diag}(\text{sdev}^2)\). For the formula method, \texttt{napredict()} is applied to handle the treatment of values omitted by the \texttt{na.action}.

- **center, scale** the centering and scaling used, or \texttt{FALSE}.

### Note

The signs of the columns of the rotation matrix are arbitrary, and so may differ between different programs for PCA, and even between different builds of \texttt{R}.

predict

Model Predictions

Description

predict is a generic function for predictions from the results of various model fitting functions. The function invokes particular methods which depend on the class of the first argument.

Usage

predict(object, ...)

Arguments

object a model object for which prediction is desired.
...
additional arguments affecting the predictions produced.
predict.Arima

**Details**

Most prediction methods which are similar to those for linear models have an argument `newdata` specifying the first place to look for explanatory variables to be used for prediction. Some considerable attempts are made to match up the columns in `newdata` to those used for fitting, for example that they are of comparable types and that any factors have the same level set in the same order (or can be transformed to be so).

Time series prediction methods in package `stats` have an argument `n.ahead` specifying how many time steps ahead to predict.

Many methods have a logical argument `se.fit` saying if standard errors are to returned.

**Value**

The form of the value returned by `predict` depends on the class of its argument. See the documentation of the particular methods for details of what is produced by that method.

**References**

**See Also**

`SafePrediction` for prediction from (univariable) polynomial and spline fits.

**Examples**

```r
require(stats)

## All the "predict" methods found
## NB most of the methods in the standard packages are hidden.
## Output will depend on what namespaces are (or have been) loaded.

for(fn in methods("predict"))
  try({
    f <- eval(substitute(getAnywhere(fn)$objs[[1]], list(fn = fn)))
    cat(fn, ":
    t", deparse(args(f)), "\n")
  }, silent = TRUE)
```

---

**predict.Arima**

**Forecast from ARIMA fits**

**Description**

Forecast from models fitted by `arima`.
predict.Arima

Usage

```r
## S3 method for class 'Arima'
predict(object, n.ahead = 1, newxreg = NULL,
        se.fit = TRUE, ...)
```

Arguments

- `object`: The result of an arima fit.
- `n.ahead`: The number of steps ahead for which prediction is required.
- `newxreg`: New values of `xreg` to be used for prediction. Must have at least `n.ahead` rows.
- `se.fit`: Logical: should standard errors of prediction be returned?
- `...`: arguments passed to or from other methods.

Details

Finite-history prediction is used, via `KalmanForecast`. This is only statistically efficient if the MA part of the fit is invertible, so `predict.Arima` will give a warning for non-invertible MA models.

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and the regression coefficients. According to Harvey (1993, pp. 58–9) the effect is small.

Value

A time series of predictions, or if `se.fit = TRUE`, a list with components `pred`, the predictions, and `se`, the estimated standard errors. Both components are time series.

References

See Also

`arima`

Examples

```r
od <- options(digits = 5) # avoid too much spurious accuracy
predict(arima(lh, order = c(3,0,0)), n.ahead = 12)

(fit <- arima(USAccDeaths, order = c(0,1,1),
              seasonal = list(order = c(0,1,1))))
predict(fit, n.ahead = 6)
options(od)
```
predict.glm

Predict Method for GLM Fits

Description

Obtains predictions and optionally estimates standard errors of those predictions from a fitted generalized linear model object.

Usage

```r
## S3 method for class 'glm'
predict(object, newdata = NULL,
type = c("link", "response", "terms"),
se.fit = FALSE, dispersion = NULL, terms = NULL,
na.action = na.pass, ...)
```

Arguments

- `object`: a fitted object of class inheriting from "glm".
- `newdata`: optionally, a data frame in which to look for variables with which to predict. If omitted, the fitted linear predictors are used.
- `type`: the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and `type = "response"` gives the predicted probabilities. The "terms" option returns a matrix giving the fitted values of each term in the model formula on the linear predictor scale. The value of this argument can be abbreviated.
- `se.fit`: logical switch indicating if standard errors are required.
- `dispersion`: the dispersion of the GLM fit to be assumed in computing the standard errors. If omitted, that returned by `summary` applied to the object is used.
- `terms`: with `type = "terms"` by default all terms are returned. A character vector specifies which terms are to be returned.
- `na.action`: function determining what should be done with missing values in `newdata`. The default is to predict NA.
- `...`: further arguments passed to or from other methods.

Details

If `newdata` is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the residuals, whereas if `na.action = na.exclude` they will appear (in predictions and standard errors), with residual value NA. See also `napredict`.
**predict.HoltWinters**  
Prediction Function for Fitted Holt-Winters Models

**Description**

Computes predictions and prediction intervals for models fitted by the Holt-Winters method.

**Value**

If `se.fit = FALSE`, a vector or matrix of predictions. For `type = "terms"` this is a matrix with a column per term, and may have an attribute "constant".

If `se.fit = TRUE`, a list with components

- **fit**: Predictions, as for `se.fit = FALSE`
- **se.fit**: Estimated standard errors.
- **residual.scale**: A scalar giving the square root of the dispersion used in computing the standard errors.

**Note**

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

**See Also**

- `glm`, `SafePrediction`

**Examples**

```r
require(graphics)

    type = "response"))
```

```text
predict.HoltWinters
Prediction Function for Fitted Holt-Winters Models

Value

If se.fit = FALSE, a vector or matrix of predictions. For type = "terms" this is a matrix with a column per term, and may have an attribute "constant".

If se.fit = TRUE, a list with components

- **fit**: Predictions, as for se.fit = FALSE.
- **se.fit**: Estimated standard errors.
- **residual.scale**: A scalar giving the square root of the dispersion used in computing the standard errors.

Note

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

Usage

## S3 method for class 'HoltWinters'
predict(object, n.ahead = 1, prediction.interval = FALSE,
       level = 0.95, ...)

Arguments

object An object of class HoltWinters.
n.ahead Number of future periods to predict.
prediction.interval logical. If TRUE, the lower and upper bounds of the corresponding prediction
   intervals are computed.
level Confidence level for the prediction interval.
... arguments passed to or from other methods.

Value

A time series of the predicted values. If prediction intervals are requested, a multiple time series is
returned with columns fit, lwr and upr for the predicted values and the lower and upper bounds
respectively.

Examples

require(graphics)

m <- HoltWinters(co2)
p <- predict(m, 50, prediction.interval = TRUE)
plot(m, p)
Predicted values based on linear model object.

## S3 method for class 'lm'
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
interval = c("none", "confidence", "prediction"),
level = 0.95, type = c("response", "terms"),
terms = NULL, na.action = na.pass,
pred.var = res.var/weights, weights = 1,
rankdeficient = c("warnif", "simple", "non-estim", "NA", "NAwarn"),
tol = 1e-6, verbose = FALSE,
...)

**Arguments**

- **object**: Object of class inheriting from "lm"
- **newdata**: An optional data frame in which to look for variables with which to predict. If omitted, the fitted values are used.
- **se.fit**: A switch indicating if standard errors are required.
- **scale**: Scale parameter for std.err. calculation.
- **df**: Degrees of freedom for scale.
- **interval**: Type of interval calculation. Can be abbreviated.
- **level**: Tolerance/confidence level.
- **type**: Type of prediction (response or model term). Can be abbreviated.
- **terms**: If type = "terms", which terms (default is all terms), a character vector.
- **na.action**: function determining what should be done with missing values in newdata. The default is to predict NA.
- **pred.var**: the variance(s) for future observations to be assumed for prediction intervals. See ’Details’.
- **weights**: variance weights for prediction. This can be a numeric vector or a one-sided model formula. In the latter case, it is interpreted as an expression evaluated in newdata.
- **rankdeficient**: a character string specifying what should happen in the case of a rank deficient model, i.e., when object$rank < ncol(model.matrix(object)).

- "warnif": gives a warning only in case of predicting 'non-estimable' cases, i.e., vectors not in the same predictor subspace as the original data (with tolerance tol). In that case, the non-estimable indices are also returned as attribute "non-estim" (see rankdeficient="non-estim").
- "simple": is back compatible to R < 4.3.0, possibly giving dubious predictions in non-estimable cases, and always signalling a warning.
"non-estim": gives the same predictions without warning, and with an attribute attr(*, "non-estim") with indices in 1:nrow(newdata) of new data observations which are deemed non-estimable.

"NA": predicts NA for non-estimable new data, silently. Often recommended in new code.

"NAwarn": predicts NA for non-estimable new data with a warning.

tol

non-negative number determining how non-estimability is determined in rank deficient cases.

verbose

logical indicating if messages should be produced about rank deficiency handling.

... further arguments passed to or from other methods.

Details

predict.lm produces predicted values, obtained by evaluating the regression function in the frame newdata (which defaults to model.frame(object)). If the logical se.fit is TRUE, standard errors of the predictions are calculated. If the numeric argument scale is set (with optional df), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting intervals specifies computation of confidence or prediction (tolerance) intervals at the specified level, sometimes referred to as narrow vs. wide intervals.

If the fit is rank-deficient, some of the columns of the design matrix will have been dropped during the lm computations, and corresponding coef() components set to NA. Prediction from such a fit only makes sense if newdata is contained in the same subspace as the original data. Other newdata entries (rows) are non-estimable. This is now checked (up to numerical tolerance tol) unless rankdeficient == "simple", which corresponds to previous behaviour, warns always and predicts using the non-NA coefficients with the corresponding columns of the design matrix. The new default option, rankdeficient == "warnif" checks if there are "non-estimable" cases (up to tolerance tol) and only warns in that case. All further rankdeficient options also check and either predict NA or mark the non-estimable cases differently.

If newdata is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit are handled is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the predictions, whereas if na.action = na.exclude they will appear (in predictions, standard errors or interval limits), with value NA. See also napredict.

The prediction intervals are for a single observation at each case in newdata (or by default, the data used for the fit) with error variance(s) pred.var. This can be a multiple of res.var, the estimated value of σ²: the default is to assume that future observations have the same error variance as those used for fitting. If weights is supplied, the inverse of this is used as a scale factor. For a weighted fit, if the prediction is for the original data frame, weights defaults to the weights used for the model fit, with a warning since it might not be the intended result. If the fit was weighted and newdata is given, the default is to assume constant prediction variance, with a warning.

Value

predict.lm produces a vector of predictions or a matrix of predictions and bounds with column names fit, lwr, and upr if interval is set. For type = "terms" this is a matrix with a column per term and may have an attribute "constant".

If se.fit is TRUE, a list with the following components is returned:

fit vector or matrix as above

se.fit standard error of predicted means
predict.lm

residual.scale  residual standard deviations
df  degrees of freedom for residual

Note

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

Notice that prediction variances and prediction intervals always refer to future observations, possibly corresponding to the same predictors as used for the fit. The variance of the residuals will be smaller.

Strictly speaking, the formula used for prediction limits assumes that the degrees of freedom for the fit are the same as those for the residual variance. This may not be the case if res.var is not obtained from the fit.

                   tolerance = 1e-12, check.attributes = FALSE))
\end{verbatim}
**predict.loess**  
**Predict LOESS Curve or Surface**

**Description**  
Predictions from a loess fit, optionally with standard errors.

**Usage**
```
## S3 method for class 'loess'
predict(object, newdata = NULL, se = FALSE,
         na.action = na.pass, ...)
```

**Arguments**
- `object`: an object fitted by loess.
- `newdata`: an optional data frame in which to look for variables with which to predict, or a matrix or vector containing exactly the variables needs for prediction. If missing, the original data points are used.
- `se`: should standard errors be computed?
- `na.action`: function determining what should be done with missing values in data frame `newdata`. The default is to predict `NA`.
- `...`: arguments passed to or from other methods.

**Details**
The standard errors calculation `se = TRUE` is slower than prediction, notably as it needs a relatively large workspace (memory), notably matrices of dimension $N \times Nf$ where $f = \text{span}$, i.e., `se = TRUE` is $O(N^2)$ and hence stops when the sample size $N$ is larger than about 40'600 (for default `span = 0.75`).

When the fit was made using `surface = "interpolate"` (the default), `predict.loess` will not extrapolate – so points outside an axis-aligned hypercube enclosing the original data will have missing (NA) predictions and standard errors.

**Value**
If `se = FALSE`, a vector giving the prediction for each row of `newdata` (or the original data). If `se = TRUE`, a list containing components
```
fit        the predicted values.
se         an estimated standard error for each predicted value.
residual.scale the estimated scale of the residuals used in computing the standard errors.
df         an estimate of the effective degrees of freedom used in estimating the residual scale, intended for use with t-based confidence intervals.
```

If `newdata` was the result of a call to `expand.grid`, the predictions (and s.e.'s if requested) will be an array of the appropriate dimensions.

Predictions from infinite inputs will be NA since `loess` does not support extrapolation.
predict.nls

Predicting from Nonlinear Least Squares Fits

Description

predict.nls produces predicted values, obtained by evaluating the regression function in the frame newdata. If the logical se.fit is TRUE, standard errors of the predictions are calculated. If the numeric argument scale is set (with optional df), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting intervals specifies computation of confidence or prediction (tolerance) intervals at the specified level. At present se.fit and interval are ignored.

Usage

# S3 method for class 'nls'
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
        interval = c("none", "confidence", "prediction"),
        level = 0.95, ...)

Arguments

object An object that inherits from class nls.
newdata A named list or data frame in which to look for variables with which to predict. If newdata is missing the fitted values at the original data points are returned.
se.fit A logical value indicating if the standard errors of the predictions should be calculated. Defaults to FALSE. At present this argument is ignored.
scale  A numeric scalar. If it is set (with optional df), it is used as the residual standard deviation in the computation of the standard errors, otherwise this information is extracted from the model fit. At present this argument is ignored.

df  A positive numeric scalar giving the number of degrees of freedom for the scale estimate. At present this argument is ignored.

interval  A character string indicating if prediction intervals or a confidence interval on the mean responses are to be calculated. At present this argument is ignored.

level  A numeric scalar between 0 and 1 giving the confidence level for the intervals (if any) to be calculated. At present this argument is ignored.

...  Additional optional arguments. At present no optional arguments are used.

Value

predict.nls produces a vector of predictions. When implemented, interval will produce a matrix of predictions and bounds with column names fit, lwr, and upr. When implemented, if se.fit is TRUE, a list with the following components will be returned:

- **fit**: vector or matrix as above
- **se.fit**: standard error of predictions
- **residual.scale**: residual standard deviations
- **df**: degrees of freedom for residual

Note

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

     main = "BOD data and fitted first-order curve",
     xlim = c(0,7), ylim = c(0,20) )
tt <- seq(0, 8, length.out = 101)
lines(tt, predict(fm, list(Time = tt)))
par(opar)
```
predict.smooth.spline  Predict from Smoothing Spline Fit

Description

Predict a smoothing spline fit at new points, return the derivative if desired. The predicted fit is linear beyond the original data.

Usage

## S3 method for class 'smooth.spline'
predict(object, x, deriv = 0, ...)

Arguments

- **object**: a fit from smooth.spline.
- **x**: the new values of x.
- **deriv**: integer; the order of the derivative required.
- **...**: further arguments passed to or from other methods.

Value

A list with components

- **x**: The input x.
- **y**: The fitted values or derivatives at x.

  lines(pp <- predict(cars.spl, xx, deriv = d), col = "red")
}
points(kn, pp$y[i.kn], pch = 3, col = "dark red")
abline(h = 0, lty = 3, col = "gray")
}
detach(); par(op)

---

**preplot**

*Pre-computations for a Plotting Object*

**Description**

Compute an object to be used for plots relating to the given model object.

**Usage**

```r
preplot(object, ...)
```

**Arguments**

- `object` a fitted model object.
- `...` additional arguments for specific methods.

**Details**

Only the generic function is currently provided in base R, but some add-on packages have methods. Principally here for S compatibility.

**Value**

An object set up to make a plot that describes object.

---

**princomp**

*Principal Components Analysis*

**Description**

`princomp` performs a principal components analysis on the given numeric data matrix and returns the results as an object of class `princomp`.
Usage

princomp(x, ...)

## S3 method for class 'formula'
princomp(formula, data = NULL, subset, na.action, ...)

## Default S3 method:
princomp(x, cor = FALSE, scores = TRUE, covmat = NULL,
        subset = rep_len(TRUE, nrow(as.matrix(x))), fix_sign = TRUE, ...)

## S3 method for class 'princomp'
predict(object, newdata, ...)

Arguments

- **formula**: a formula with no response variable, referring only to numeric variables.
- **data**: an optional data frame (or similar: see `model.frame`) containing the variables in the formula formula. By default the variables are taken from environment(formula).
- **subset**: an optional vector used to select rows (observations) of the data matrix x.
- **na.action**: a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The 'factory-fresh' default is na.omit.
- **x**: a numeric matrix or data frame which provides the data for the principal components analysis.
- **cor**: a logical value indicating whether the calculation should use the correlation matrix or the covariance matrix. (The correlation matrix can only be used if there are no constant variables.)
- **scores**: a logical value indicating whether the score on each principal component should be calculated.
- **covmat**: a covariance matrix, or a covariance list as returned by `cov.wt` (and `cov.mve` or `cov.mcd` from package MASS). If supplied, this is used rather than the covariance matrix of x.
- **fix_sign**: Should the signs of the loadings and scores be chosen so that the first element of each loading is non-negative?
- **...**: arguments passed to or from other methods. If x is a formula one might specify cor or scores.
- **object**: Object of class inheriting from "princomp".
- **newdata**: An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, newdata must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.

Details

princomp is a generic function with "formula" and "default" methods.

The calculation is done using `eigen` on the correlation or covariance matrix, as determined by cor. (This was done for compatibility with the S-PLUS result.) A preferred method of calculation is to use `svd` on x, as is done in `prcomp`. 
Note that the default calculation uses divisor \( N \) for the covariance matrix.

The `print` method for these objects prints the results in a nice format and the `plot` method produces a scree plot (`screeplot`). There is also a `biplot` method.

If \( x \) is a formula then the standard NA-handling is applied to the scores (if requested): see `napredict`.

`princomp` only handles so-called R-mode PCA, that is feature extraction of variables. If a data matrix is supplied (possibly via a formula) it is required that there are at least as many units as variables. For Q-mode PCA use `prcomp`.

**Value**

`princomp` returns a list with class "princomp" containing the following components:

- `sdev` the standard deviations of the principal components.
- `loadings` the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). This is of class "loadings": see `loadings` for its `print` method.
- `center` the means that were subtracted.
- `scale` the scalings applied to each variable.
- `n.obs` the number of observations.
- `scores` if `scores = TRUE`, the scores of the supplied data on the principal components. These are non-null only if \( x \) was supplied, and if `covmat` was also supplied if it was a covariance list. For the formula method, `napredict()` is applied to handle the treatment of values omitted by the `na.action`.
- `call` the matched call.
- `na.action` If relevant.

**Note**

The signs of the columns of the loadings and scores are arbitrary, and so may differ between different programs for PCA, and even between different builds of \( R \): `fix_sign = TRUE` alleviates that.

**References**

**See Also**

**Examples**

```r
require(graphics)

## The variances of the variables in the
## USArrests data vary by orders of magnitude, so scaling is appropriate
(pc.cr <- princomp(USArrests)) # inappropriate
princomp(USArrests, cor = TRUE) # ^=^ prcomp(USArrests, scale=TRUE)
## Similar, but different:
## The standard deviations differ by a factor of sqrt(49/50)
```
print.power.htest

summary(pc.cr <- princomp(USArrests, cor = TRUE))
loadings(pc.cr)  # note that blank entries are small but not zero
oct# The signs of the columns of the loadings are arbitrary
plot(pc.cr)  # shows a screeplot.
biplot(pc.cr)

## Formula interface
princomp(~ ., data = USArrests, cor = TRUE)

## NA-handling
USArrests[1, 2] <- NA
pc.cr <- princomp(~ Murder + Assault + UrbanPop,
data = USArrests, na.action = na.exclude, cor = TRUE)
pc.cr$scores[1:5,]

## (Simple) Robust PCA:
## Classical:
(pc.cl <- princomp(stackloss))
## Robust:
(pc.rob <- princomp(stackloss, covmat = MASS::cov.rob(stackloss)))

print.power.htest  

Description

Printing objects of class "htest" or "power.htest", respectively, by simple print methods.

Usage

## S3 method for class 'htest'
print(x, digits = getOption("digits"), prefix = "\t", ...)

## S3 method for class 'power.htest'
print(x, digits = getOption("digits"), ...)

Arguments

x  
object of class "htest" or "power.htest".
digits  
number of significant digits to be used.
prefix  
string, passed to strwrap for displaying the method component of the htest object.
...  
further arguments to be passed to or from methods.

Details

Both print methods traditionally have not obeyed the digits argument properly. They now do, the htest method mostly in expressions like max(1, digits - 2).

A power.htest object is just a named list of numbers and character strings, supplemented with method and note elements. The method is displayed as a title, the note as a footnote, and the remaining elements are given in an aligned 'name = value' format.
Value

the argument x, invisibly, as for all print methods.

(ptt <- power.t.test(n = 20, delta = 1))
print(ptt, digits = 4) # using less digits than default
print(ptt, digits = 12) # using more
```

print.ts Printing and Formatting of Time-Series Objects

Description

Notably for calendar related time series objects, format and print methods showing years, months and or quarters respectively.

Usage

```r
## S3 method for class 'ts'
print(x, calendar, ...)
.preformat.ts(x, calendar, ...)
```

Arguments

- `x` a time series object.
- `calendar` enable/disable the display of information about month names, quarter names or year when printing. The default is TRUE for a frequency of 4 or 12, FALSE otherwise.
- `...` additional arguments to print (or format methods).

Details

The print method for "ts" objects prints a header (basically of tsp(x)), if calendar is false, and then prints the result of .preformat.ts(x, *), which is typically a matrix with rownames built from the calendar times where applicable.

See Also

print, ts.
printCoefmat

Examples

print(ts(1:10, frequency = 7, start = c(12, 2)), calendar = TRUE)

print(sunsp.1 <- window(sunspot.month, end=c(1756, 12)))
m <- .preformat.ts(sunsp.1) # a character matrix

printCoefmat

Print Coefficient Matrices

Description

Utility function to be used in higher-level print methods, such as those for summary.lm, summary.glm and anova. The goal is to provide a flexible interface with smart defaults such that often, only x needs to be specified.

Usage

printCoefmat(x, digits = max(3,getOption("digits") - 2),
            signif.stars = getOption("show.signif.stars"),
            signif.legend = signif.stars,
            dig.tst = max(1, min(5, digits - 1)),
            cs.ind = 1L:k, tst.ind = k + 1L,
            zap.ind = integer(), P.values = NULL,
            has.Pvalue = nc >= 4L && length(cn <- colnames(x)) &&
            substr(cn[nc], 1L, 3L) %in% c("Pr(" , "p-v"),
            eps.Pvalue = .Machine$double.eps,
            na.print = "NA", quote = FALSE, right = TRUE, ...)

Arguments

x a numeric matrix like object, to be printed.
digits minimum number of significant digits to be used for most numbers.
signif.stars logical; if TRUE, P-values are additionally encoded visually as 'significance stars' in order to help scanning of long coefficient tables. It defaults to the show.signif.stars slot of options.
signif.legend logical; if TRUE, a legend for the 'significance stars' is printed provided signif.stars = TRUE.
dig.tst minimum number of significant digits for the test statistics, see tst.ind.
cs.ind indices (integer) of column numbers which are (like) coefficients and standard errors to be formatted together.
tst.ind indices (integer) of column numbers for test statistics.
zap.ind indices (integer) of column numbers which should be formatted by zapsmall, i.e., by 'zapping' values close to 0.
P.values logical or NULL; if TRUE, the last column of x is formatted by format.pval as P values. If P.values = NULL, the default, it is set to TRUE only if options("show.coef.Pvalue") is TRUE and x has at least 4 columns and the last column name of x starts with "Pr".
has.Pvalue logical; if TRUE, the last column of x contains P values; in that case, it is printed if and only if P.values (above) is true.
eps.Pvalue number, passed to `format.pval()` as eps.
na.print a character string to code NA values in printed output.
quote, right,... further arguments passed to `print.default`.

Value
Invisibly returns its argument, x.

Author(s)
Martin Maechler

op <- options(show.coef.Pvalues = FALSE)
printCoefmat(cmat, digits = 2)
printCoefmat(cmat, digits = 2, P.values = TRUE)
options(op) # restore
```

profile

Generic Function for Profiling Models

Description
Investigates the behavior of the objective function near the solution represented by fitted. See documentation on method functions for further details.

Usage
`profile(fitted, ...)`

Arguments
- `fitted` the original fitted model object.
- `...` additional parameters. See documentation on individual methods.

Value
A list with an element for each parameter being profiled. See the individual methods for further details.
profile.glm

See Also

profile.nls, profile.glm...
plot.profile.
For profiling R code, see Rprof.

Profile glm Objects

Description

Investigates the profile log-likelihood function for a fitted model of class "glm".

Usage

## S3 method for class 'glm'
profile(fitted, which = 1:p, alpha = 0.01, maxsteps = 10,
del = zmax/5, trace = FALSE, test = c("LRT", "Rao"), ...)

Arguments

- fitted: the original fitted model object.
- which: the original model parameters which should be profiled. This can be a numeric or character vector. By default, all parameters are profiled.
- alpha: highest significance level allowed for the profile z-statistics.
- maxsteps: maximum number of points to be used for profiling each parameter.
- del: suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.
- trace: logical: should the progress of profiling be reported?
- test: profile Likelihood Ratio test or Rao Score test.
- ...: further arguments passed to or from other methods.

Details

The profile z-statistic is defined either as (case test = "LRT") the square root of change in deviance with an appropriate sign, or (case test = "Rao") as the similarly signed square root of the Rao Score test statistic. The latter is defined as the squared gradient of the profile log likelihood divided by the profile Fisher information, but more conveniently calculated via the deviance of a Gaussian GLM fitted to the residuals of the profiled model.

Value

A list of classes "profile.glm" and "profile" with an element for each parameter being profiled. The elements are data-frames with two variables

- par.vals: a matrix of parameter values for each fitted model.
- tau or z: the profile t or z-statistics (the name depends on whether there is an estimated dispersion parameter.)
**profile.nls**

Method for Profiling nls Objects

Description

Investigates the profile log-likelihood function for a fitted model of class "nls".

Usage

```r
## S3 method for class 'nls'
profile(fitted, which = 1:npar, maxpts = 100, alphamax = 0.01, delta.t = cutoff/5, ...)
```

Arguments

- **fitted**: the original fitted model object.
- **which**: the original model parameters which should be profiled. This can be a numeric or character vector. By default, all non-linear parameters are profiled.
- **maxpts**: maximum number of points to be used for profiling each parameter.
- **alphamax**: highest significance level allowed for the profile t-statistics.
- **delta.t**: suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.
- **...**: further arguments passed to or from other methods.

Details

The profile t-statistics is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.
Value

A list with an element for each parameter being profiled. The elements are data-frames with two variables:

- par.vals: a matrix of parameter values for each fitted model.
- tau: the profile t-statistics.

Examples

```r
# obtain the fitted object
fm1 <- nls(demand ~ SSasympOrig(Time, A, lrc), data = BOD)
# get the profile for the fitted model: default level is too extreme
pr1 <- profile(fm1, alphamax = 0.05)
# profiled values for the two parameters
pr1$A
pr1$lrc

# see also example(plot.profile.nls)
```

Description

`proj` returns a matrix or list of matrices giving the projections of the data onto the terms of a linear model. It is most frequently used for `aov` models.

Usage

```r
proj(object, ...)  
## S3 method for class 'aov'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)  
## S3 method for class 'aovlist'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)
```
## Default S3 method:
proj(object, onedf = TRUE, ...)

## S3 method for class 'lm'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

Arguments

object          An object of class "lm" or a class inheriting from it, or an object with a similar
                structure including in particular components qr and effects.

onedf          A logical flag. If TRUE, a projection is returned for all the columns of the model
                matrix. If FALSE, the single-column projections are collapsed by terms of the
                model (as represented in the analysis of variance table).

unweighted.scale
If the fit producing object used weights, this determines if the projections cor-
respond to weighted or unweighted observations.

...          Swallow and ignore any other arguments.

Details

A projection is given for each stratum of the object, so for aov models with an Error term the result
is a list of projections.

Value

A projection matrix or (for multi-stratum objects) a list of projection matrices.

Each projection is a matrix with a row for each observations and either a column for each
term (onedf = FALSE) or for each coefficient (onedf = TRUE). Projection matrices from the default
method have orthogonal columns representing the projection of the response onto the column space
of the Q matrix from the QR decomposition. The fitted values are the sum of the projections, and
the sum of squares for each column is the reduction in sum of squares from fitting that column (after
those to the left of it).

The methods for lm and aov models add a column to the projection matrix giving the residuals (the
projection of the data onto the orthogonal complement of the model space).

Strictly, when onedf = FALSE the result is not a projection, but the columns represent sums of
projections onto the columns of the model matrix corresponding to that term. In this case the matrix
does not depend on the coding used.

Author(s)

The design was inspired by the S function of the same name described in Chambers et al. (1992).

---

**prop.test**

**Test of Equal or Given Proportions**

**Description**

prop.test can be used for testing the null that the proportions (probabilities of success) in several groups are the same, or that they equal certain given values.

**Usage**

```
prop.test(x, n, p = NULL,
          alternative = c("two.sided", "less", "greater"),
          conf.level = 0.95, correct = TRUE)
```

**Arguments**

- `x` a vector of counts of successes, a one-dimensional table with two entries, or a two-dimensional table (or matrix) with 2 columns, giving the counts of successes and failures, respectively.
- `n` a vector of counts of trials; ignored if `x` is a matrix or a table.
- `p` a vector of probabilities of success. The length of `p` must be the same as the number of groups specified by `x`, and its elements must be greater than 0 and less than 1.
- `alternative` a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter. Only used for testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.
- `conf.level` confidence level of the returned confidence interval. Must be a single number between 0 and 1. Only used when testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.
- `correct` a logical indicating whether Yates’ continuity correction should be applied where possible.
Details

Only groups with finite numbers of successes and failures are used. Counts of successes and failures must be nonnegative and hence not greater than the corresponding numbers of trials which must be positive. All finite counts should be integers.

If p is NULL and there is more than one group, the null tested is that the proportions in each group are the same. If there are two groups, the alternatives are that the probability of success in the first group is less than, not equal to, or greater than the probability of success in the second group, as specified by alternative. A confidence interval for the difference of proportions with confidence level as specified by conf.level and clipped to \([-1, 1]\) is returned. Continuity correction is used only if it does not exceed the difference of the sample proportions in absolute value. Otherwise, if there are more than 2 groups, the alternative is always "two.sided", the returned confidence interval is NULL, and continuity correction is never used.

If there is only one group, then the null tested is that the underlying probability of success is \(p\), or .5 if \(p\) is not given. The alternative is that the probability of success is less than, not equal to, or greater than \(p\) or 0.5, respectively, as specified by alternative. A confidence interval for the underlying proportion with confidence level as specified by conf.level and clipped to \([0, 1]\) is returned. Continuity correction is used only if it does not exceed the difference between sample and null proportions in absolute value. The confidence interval is computed by inverting the score test.

Finally, if \(p\) is given and there are more than 2 groups, the null tested is that the underlying probabilities of success are those given by \(p\). The alternative is always "two.sided", the returned confidence interval is NULL, and continuity correction is never used.

Value

A list with class "htest" containing the following components:

- **statistic**: the value of Pearson’s chi-squared test statistic.
- **parameter**: the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- **p.value**: the p-value of the test.
- **estimate**: a vector with the sample proportions \(x/n\).
- **conf.int**: a confidence interval for the true proportion if there is one group, or for the difference in proportions if there are 2 groups and \(p\) is not given, or NULL otherwise. In the cases where it is not NULL, the returned confidence interval has an asymptotic confidence level as specified by conf.level, and is appropriate to the specified alternative hypothesis.
- **null.value**: the value of \(p\) if specified by the null, or NULL otherwise.
- **alternative**: a character string describing the alternative.
- **method**: a character string indicating the method used, and whether Yates’ continuity correction was applied.
- **data.name**: a character string giving the names of the data.

Examples

```r
elements <- rbinom(1, size = 100, prob = .5)
prop.test(elements, 100) # continuity correction TRUE by default
prop.test(elements, 100, correct = FALSE)
```

```r
## Data from Fleiss (1981), p. 139.
## H0: The null hypothesis is that the four populations from which
## the patients were drawn have the same true proportion of smokers.
## A: The alternative is that this proportion is different in at
## least one of the populations.

elements <- c( 83, 90, 129, 70 )
patients <- c( 86, 93, 136, 82 )
prop.test(elements, patients)
```

---

**prop.trend.test**

*Test for trend in proportions*

**Description**

Performs chi-squared test for trend in proportions, i.e., a test asymptotically optimal for local alternatives where the log odds vary in proportion with score. By default, score is chosen as the group numbers.

**Usage**

```r
prop.trend.test(x, n, score = seq_along(x))
```

**Arguments**

- `x` Number of events
- `n` Number of trials
- `score` Group score

**Value**

An object of class "htest" with title, test statistic, p-value, etc.

**Note**

This really should get integrated with *prop.test*

prop.trend.test(smokers, patients)
prop.trend.test(smokers, patients, c(0,0,0,1))
```

Description

qqnorm is a generic function the default method of which produces a normal QQ plot of the values in y. qqline adds a line to a "theoretical", by default normal, quantile-quantile plot which passes through the probs quantiles, by default the first and third quartiles.

qqplot produces a QQ plot of two datasets. If conf.level is given, a confidence band for a function transforming the distribution of x into the distribution of y is plotted based on Switzer (1976). The QQ plot can be understood as an estimate of such a treatment function. If exact = NULL (the default), an exact confidence band is computed if the product of the sample sizes is less than 10000, with or without ties. Otherwise, asymptotic distributions are used whose approximations may be inaccurate in small samples. Monte-Carlo approximations based on B random permutations are computed when simulate = TRUE. Confidence bands are in agreement with Smirnov's test, that is, the bisecting line is covered by the band if the null of both samples coming from the same distribution cannot be rejected at the same level.

Graphical parameters may be given as arguments to qqnorm, qqplot and qqline.

Usage
```
qqnorm(y, ...)
## Default S3 method:
qqnorm(y, ylim, main = "Normal Q-Q Plot",
      xlab = "Theoretical Quantiles", ylab = "Sample Quantiles",
      plot.it = TRUE, datax = FALSE, ...)

qqline(y, datax = FALSE, distribution = qnorm,
       probs = c(0.25, 0.75), qtype = 7, ...)

qqplot(x, y, plot.it = TRUE,
       xlab = deparse1(substitute(x)),
       ylab = deparse1(substitute(y)), ...,
       conf.level = NULL,
       conf.args = list(exact = NULL, simulate.p.value = FALSE,
                         B = 2000, col = NA, border = NULL))
```
Arguments

- **x**: The first sample for `qqplot`.
- **y**: The second or only data sample.
- **xlab, ylab, main**: plot labels. The `xlab` and `ylab` refer to the y and x axes respectively if `datax = TRUE`.
- **plot.it**: logical. Should the result be plotted?
- **datax**: logical. Should data values be on the x-axis?
- **distribution**: quantile function for reference theoretical distribution.
- **probs**: numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.
- **qtype**: the type of quantile computation used in `quantile`.
- **ylim, ...**: graphical parameters.
- **conf.level**: confidence level of the band. The default, NULL, does not lead to the computation of a confidence band.
- **conf.args**: list of arguments defining confidence band computation and visualisation: `exact` is NULL (see details) or a logical indicating whether an exact p-value should be computed, `simulate.p.value` is a logical indicating whether to compute p-values by Monte Carlo simulation, `B` defines the number of replicates used in the Monte Carlo test, `col` and `border` define the color for filling and border of the confidence band (the default, NA and NULL, is to leave the band unfilled with black borders).

Value

For `qqnorm` and `qqplot`, a list with components

- **x**: The x coordinates of the points that were/would be plotted
- **y**: The original y vector, i.e., the corresponding y coordinates including NAs. If `conf.level` was specified to `qqplot`, the list contains additional components `lwr` and `upr` defining the confidence band.

x <- rnorm(50)
y <- rnorm(50, mean = .5, sd = .95)
ex <- TRUE
### p = 0.112
(pval <- ks.test(x, y, exact = ex)$p.value)
```

## 88.8% confidence band with bisecting line
## touching the lower bound
```r
qqplot(x, y, pch = 19, conf.level = 1 - pval, 
    conf.args = list(exact = ex, col = "lightgrey"))
abline(a = 0, b = 1)
```

---

**quade.test**

**Quade Test**

**Description**

Performs a Quade test with unreplicated blocked data.
quade.test

Usage

quade.test(y, ...)

## Default S3 method:
quade.test(y, groups, blocks, ...)

## S3 method for class 'formula'
quade.test(formula, data, subset, na.action, ...)

Arguments

y either a numeric vector of data values, or a data matrix.
groups a vector giving the group for the corresponding elements of y if this is a vector; ignored if y is a matrix. If not a factor object, it is coerced to one.
blocks a vector giving the block for the corresponding elements of y if this is a vector; ignored if y is a matrix. If not a factor object, it is coerced to one.
formula a formula of the form a ~ b | c, where a, b and c give the data values and corresponding groups and blocks, respectively.
data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").
... further arguments to be passed to or from methods.

Details

quade.test can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in y for each combination of levels of groups and blocks) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of blocks, the location parameter of y is the same in each of the groups.

If y is a matrix, groups and blocks are obtained from the column and row indices, respectively. NA's are not allowed in groups or blocks; if y contains NA's, corresponding blocks are removed.

Value

A list with class "htest" containing the following components:

statistic the value of Quade's F statistic.
parameter a vector with the numerator and denominator degrees of freedom of the approximate F distribution of the test statistic.
p.value the p-value of the test.
method the character string "Quade test".
data.name a character string giving the names of the data.

stopifnot(all.equal(qTst, qTs, tolerance = 1e-15))
```

### quantile

#### Sample Quantiles

**Description**

The generic function `quantile` produces sample quantiles corresponding to the given probabilities. The smallest observation corresponds to a probability of 0 and the largest to a probability of 1.

**Usage**

```r
quantile(x, ...)
```

## Default S3 method:
```r
quantile(x, probs = seq(0, 1, 0.25), na.rm = FALSE,
         names = TRUE, type = 7, digits = 7, ...)
```
**quantile**

**Arguments**

- **x**: numeric vector whose sample quantiles are wanted, or an object of a class for which a method has been defined (see also 'details'). `NA` and `NaN` values are not allowed in numeric vectors unless `na.rm` is `TRUE`.

- **probs**: numeric vector of probabilities with values in `[0, 1]`. (Values up to ‘2e-14’ outside that range are accepted and moved to the nearby endpoint.)

- **na.rm**: logical; if true, any `NA` and `NaN`’s are removed from `x` before the quantiles are computed.

- **names**: logical; if true, the result has a `names` attribute. Set to `FALSE` for speedup with many `probs`.

- **type**: an integer between 1 and 9 selecting one of the nine quantile algorithms detailed below to be used.

- **digits**: used only when `names` is true: the precision to use when formatting the percentages. In R versions up to 4.0.x, this had been set to `max(2,getOption("digits"))`, internally.

- **...**: further arguments passed to or from other methods.

**Details**

A vector of length `length(probs)` is returned; if `names = TRUE`, it has a `names` attribute. `NA` and `NaN` values in `probs` are propagated to the result.

The default method works with classed objects sufficiently like numeric vectors that `sort` and (not needed by types 1 and 3) addition of elements and multiplication by a number work correctly. Note that this is in a namespace, the copy of `sort` in base will be used, not some S4 generic of that name. Also note that that is no check on the ‘correctly’, and so e.g. `quantile` can be applied to complex vectors which (apart from ties) will be ordered on their real parts.

There is a method for the date-time classes (see “POSIXt”). Types 1 and 3 can be used for class “Date” and for ordered factors.

**Types**

`quantile` returns estimates of underlying distribution quantiles based on one or two order statistics from the supplied elements in `x` at probabilities in `probs`. One of the nine quantile algorithms discussed in Hyndman and Fan (1996), selected by `type`, is employed.

All sample quantiles are defined as weighted averages of consecutive order statistics. Sample quantiles of type `i` are defined by:

\[ Q_i(p) = (1 - \gamma)x_j + \gamma x_{j+1} \]

where \(1 \leq i \leq 9\), \(\frac{i-m}{n} \leq p < \frac{i-m+1}{n}\), \(x_j\) is the \(j\)-th order statistic, \(n\) is the sample size, the value of \(\gamma\) is a function of \(j = \lfloor np + m \rfloor\) and \(g = np + m - j\), and \(m\) is a constant determined by the sample quantile type.

**Discontinuous sample quantile types 1, 2, and 3**

For types 1, 2 and 3, \(Q_i(p)\) is a discontinuous function of \(p\), with \(m = 0\) when \(i = 1\) and \(i = 2\), and \(m = -1/2\) when \(i = 3\).

- **Type 1** Inverse of empirical distribution function. \(\gamma = 0\) if \(g = 0\), and 1 otherwise.

- **Type 2** Similar to type 1 but with averaging at discontinuities. \(\gamma = 0.5\) if \(g = 0\), and 1 otherwise (SAS default, see Wicklin (2017)).
Type 3 Nearest even order statistic (SAS default till ca. 2010). $\gamma = 0$ if $g = 0$ and $j$ is even, and 1 otherwise.

Continuous sample quantile types 4 through 9

For types 4 through 9, $Q_i(p)$ is a continuous function of $p$, with $\gamma = g$ and $m$ given below. The sample quantiles can be obtained equivalently by linear interpolation between the points $(p_k, x_k)$ where $x_k$ is the $k$-th order statistic. Specific expressions for $p_k$ are given below.

Type 4 $m = 0$. $p_k = \frac{k}{n}$. That is, linear interpolation of the empirical cdf.

Type 5 $m = \frac{1}{2}$. $p_k = \frac{k - 0.5}{n}$. That is a piecewise linear function where the knots are the values midway through the steps of the empirical cdf. This is popular amongst hydrologists.

Type 6 $m = p$. $p_k = \frac{k}{n+1}$. Thus $p_k = \text{E}[F(x_k)]$. This is used by Minitab and by SPSS.

Type 7 $m = 1 - p$. $p_k = \frac{k - 1}{n+1}$. In this case, $p_k = \text{mode}[F(x_k)]$. This is used by S.

Type 8 $m = \frac{(p + 1)/3}{n+1/2}$. Then $p_k \approx \text{median}[F(x_k)]$. The resulting quantile estimates are approximately median-unbiased regardless of the distribution of $x$.

Type 9 $m = \frac{p/4 + 3/8}{n+1/2}$. The resulting quantile estimates are approximately unbiased for the expected order statistics if $x$ is normally distributed.

Further details are provided in Hyndman and Fan (1996) who recommended type 8. The default method is type 7, as used by S and by R < 2.0.0. Makkonen argues for type 6, also as already proposed by Weibull in 1939. The Wikipedia page contains further information about availability of these 9 types in software.

dcdf for empirical distributions of which quantile is an inverse; boxplot.stats and fivenum for computing other versions of quartiles, etc.

Examples

```r
quantile(x <- rnorm(1001)) # Extremes & Quartiles by default
quantile(x, probs = c(0.1, 0.5, 1, 2, 5, 10, 50, NA)/100)
```

```r
### Compare different types
quantAll <- function(x, prob, 
  t(vapply(1:9, function(typ) quantile(x, probs = prob, type = typ, ...),
```
quantile(x, prob=0:1)

p <- c(0.1, 0.5, 1, 2, 5, 10, 50)/100
signif(quantAll(x, p), 4)

## 0% and 100% are equal to min(), max() for all types:
stopifnot(t(quantAll(x, prob=0:1)) == range(x))

## for complex numbers:
z <- complex(real = x, imaginary = -10*x)
signif(quantAll(z, p), 4)

r2dtable **Random 2-way Tables with Given Marginals**

Description

Generate random 2-way tables with given marginals using Patefield’s algorithm.

Usage

r2dtable(n, r, c)

Arguments

- **n** a non-negative numeric giving the number of tables to be drawn.
- **r** a non-negative vector of length at least 2 giving the row totals, to be coerced to integer. Must sum to the same as **c**.
- **c** a non-negative vector of length at least 2 giving the column totals, to be coerced to integer.

Value

A list of length **n** containing the generated tables as its components.

Examples

## Fisher's Tea Drinker data.
TeaTasting <-
matrix(c(3, 1, 1, 3),
      nrow = 2,
dimnames = list(Guess = c("Milk", "Tea"),
                  Truth = c("Milk", "Tea")))

## Simulate permutation test for independence based on the maximum
## Pearson residuals (rather than their sum).
rowTotals <- rowSums(TeaTasting)
colTotals <- colSums(TeaTasting)
nOfCases <- sum(rowTotals)
expected <- outer(rowTotals, colTotals) / nOfCases
maxSqResid <- function(x) max((x - expected) ^ 2 / expected)
simMaxSqResid <-
  sapply(r2dtable(1000, rowTotals, colTotals), maxSqResid)
simMaxSqResid >= maxSqResid(TeaTasting)) / 1000
## Fisher's exact test gives p = 0.4857 ...

read.ftable

Manipulate Flat Contingency Tables

Description

Read, write and coerce 'flat' (contingency) tables, aka ftables.

Usage

read.ftable(file, sep = "", quote = "\\",
  row.var.names, col.vars, skip = 0)
write.ftable(x, file = "", quote = TRUE, append = FALSE,
  digits = getOption("digits"), sep = " ", ...)
## S3 method for class 'ftable'
format(x, quote = TRUE, digits = getOption("digits"),
  method = c("non.compact", "row.compact", "col.compact", "compact"),
  lsep = " ",
  justify = c("left", "right"),
  ...
## S3 method for class 'ftable'
print(x, digits = getOption("digits"), ...)

Arguments

defile either a character string naming a file or a connection which the data are to be read from or written to. "" indicates input from the console for reading and output to the console for writing.

sep the field separator string. Values on each line of the file are separated by this string.

quote a character string giving the set of quoting characters for read.ftable: to disable quoting altogether, use quote="". For write.table, a logical indicating whether strings in the data will be surrounded by double quotes.

row.var.names a character vector with the names of the row variables, in case these cannot be determined automatically.

col.vars a list giving the names and levels of the column variables, in case these cannot be determined automatically.

skip the number of lines of the data file to skip before beginning to read data.

x an object of class "ftable".

append logical. If TRUE and file is the name of a file (and not a connection or "|cmd"), the output from write.ftable is appended to the file. If FALSE, the contents of file will be overwritten.
digits: an integer giving the number of significant digits to use for (the cell entries of) x.

method: string specifying how the "ftable" object is formatted (and printed if used as in write.ftable() or the print method). Can be abbreviated. Available methods are (see the examples):

"non.compact" the default representation of an "ftable" object.
"row.compact" a row-compact version without empty cells below the column labels.
"col.compact" a column-compact version without empty cells to the right of the row labels.
"compact" a row- and column-compact version. This may imply a row and a column label sharing the same cell. They are then separated by the string lsep.

lsep: only for method = "compact", the separation string for row and column labels.

justify: character vector of length (one or) two, specifying how string justification should happen in format(...), first for the labels, then the table entries.

... further arguments to be passed to or from methods; for write() and print(), notably arguments such as method, passed to format().

Details

read.ftable reads in a flat-like contingency table from a file. If the file contains the written representation of a flat table (more precisely, a header with all information on names and levels of column variables, followed by a line with the names of the row variables), no further arguments are needed. Similarly, flat tables with only one column variable the name of which is the only entry in the first line are handled automatically. Other variants can be dealt with by skipping all header information using skip, and providing the names of the row variables and the names and levels of the column variable using row.var.names and col.vars, respectively. See the examples below.

Note that flat tables are characterized by their 'ragged' display of row (and maybe also column) labels. If the full grid of levels of the row variables is given, one should instead use read.table to read in the data, and create the contingency table from this using xtabs.

write.ftable writes a flat table to a file, which is useful for generating 'pretty' ASCII representations of contingency tables. Different versions are available via the method argument, which may be useful, for example, for constructing LaTeX tables.

ftable for more information on flat contingency tables.

Examples

## Agresti (1990), page 157, Table 5.8.
## Not in ftable standard format, but o.k.
file <- tempfile()
cat(" Intercourse
"Race Gender Yes No\n"White Male 43 134\n", sep = "\n", file = file)
read.ftable(file, method = "row.compact")
rect.hclust

**Description**

Draws rectangles around the branches of a dendrogram highlighting the corresponding clusters. First the dendrogram is cut at a certain level, then a rectangle is drawn around selected branches.

**Usage**

```r
rect.hclust(tree, k = NULL, which = NULL, x = NULL, h = NULL,
border = 2, cluster = NULL)
```

**Arguments**

- `tree`: an object of the type produced by `hclust`.
**relevel**

Reorder Levels of Factor

**Description**

The levels of a factor are re-ordered so that the level specified by `ref` is first and the others are moved down. This is useful for `contr.treatment` contrasts which take the first level as the reference.

**Usage**

```r
relevel(x, ref, ...)```

**Arguments**

- `x` an unordered factor.
- `ref` the reference level, typically a string.
- `...` additional arguments for future methods.

**Details**

This, as `reorder()`, is a special case of simply calling `factor(x, levels = levels(x)[...])`. 

**Examples**

```r
require(graphics)

hca <- hclust(dist(USArrests))
plot(hca)
rect.hclust(hca, k = 3, border = "red")
x <- rect.hclust(hca, h = 50, which = c(2,7), border = 3:4)
x

relevel

Reorder Levels of Factor

k, h Scalar. Cut the dendrogram such that either exactly k clusters are produced or by cutting at height h.

which, x A vector selecting the clusters around which a rectangle should be drawn. which selects clusters by number (from left to right in the tree), x selects clusters containing the respective horizontal coordinates. Default is which = 1:k.

border Vector with border colors for the rectangles.

cluster Optional vector with cluster memberships as returned by `cutree(hclust.obj, k = k)`, can be specified for efficiency if already computed.

**Value**

(Invisibly) returns a list where each element contains a vector of data points contained in the respective cluster.

**See Also**

`hclust`, `identify.hclust`.

**Examples**

```r
require(graphics)

hca <- hclust(dist(USArrests))
plot(hca)
rect.hclust(hca, k = 3, border = "red")
x <- rect.hclust(hca, h = 50, which = c(2,7), border = 3:4)
x
```
Value

A factor of the same length as x.

See Also

factor, contr.treatment, levels, reorder.

Examples

warpbreaks$tension <- relevel(warpbreaks$tension, ref = "M")
summary(lm(breaks ~ wool + tension, data = warpbreaks))

Description

reorder is a generic function. The "default" method treats its first argument as a categorical variable, and reorders its levels based on the values of a second variable, usually numeric.

Usage

reorder(x, ...)

## Default S3 method:
reorder(x, X, FUN = mean, ..., order = is.ordered(x), decreasing = FALSE)

Arguments

x an atomic vector, usually a factor (possibly ordered). The vector is treated as a categorical variable whose levels will be reordered. If x is not a factor, its unique values will be used as the implicit levels.

X a vector of the same length as x, whose subset of values for each unique level of x determines the eventual order of that level.

FUN a function whose first argument is a vector and returns a scalar, to be applied to each subset of X determined by the levels of x.

... optional: extra arguments supplied to FUN

order logical, whether return value will be an ordered factor rather than a factor.

decreasing logical, whether the levels will be ordered in increasing or decreasing order.

Details

This, as relevel(), is a special case of simply calling factor(x, levels = levels(x)[....]).
Value

A factor or an ordered factor (depending on the value of `order`), with the order of the levels determined by `FUN` applied to `x` grouped by `x`. By default, the levels are ordered such that the values returned by `FUN` are in increasing order. Empty levels will be dropped.

Additionally, the values of `FUN` applied to the subsets of `X` (in the original order of the levels of `x`) is returned as the "scores" attribute.

`reorder.dendrogram`, `levels`, `relevel`.

Examples

```r
require(graphics)

bymedian <- with(InsectSprays, reorder(spray, count, median))
boxplot(count ~ bymedian, data = InsectSprays,
       xlab = "Type of spray", ylab = "Insect count",
       main = "InsectSprays data", varwidth = TRUE,
       col = "lightgray")

bymedianR <- with(InsectSprays, reorder(spray, count, median, decreasing=TRUE))
stopifnot(exprs = {
    identical(attr(bymedian, "scores") -> sc,
     attr(bymedianR,"scores"))
    identical(nms <- names(sc), LETTERS[1:6])
    identical(levels(bymedian ), nms[isc <- order(sc)])
    identical(levels(bymedianR), nms[rev(isc)])
})
```

reorder.dendrogram    Reorder a Dendrogram

Description

A method for the generic function `reorder`.

There are many different orderings of a dendrogram that are consistent with the structure imposed. This function takes a dendrogram and a vector of values and reorders the dendrogram in the order of the supplied vector, maintaining the constraints on the dendrogram.

Usage

```r
## S3 method for class 'dendrogram'
reorder(x, wts, agglo.FUN = sum, ...)
```
Arguments

- `x`: the (dendrogram) object to be reordered.
- `wts`: numeric weights (arbitrary values) for reordering.
- `agglo.FUN`: a function for weights agglomeration, see below.
- `...`: additional arguments

Details

Using the weights `wts`, the leaves of the dendrogram are reordered so as to be in an order as consistent as possible with the weights. At each node, the branches are ordered in increasing weights where the weight of a branch is defined as \( f(w_j) \) where \( f \) is `agglo.FUN` and \( w_j \) is the weight of the \( j \)-th sub branch.

Value

A dendrogram where each node has a further attribute `value` with its corresponding weight.

Author(s)

R. Gentleman and M. Maechler

See Also

- `reorder`
- `rev.dendrogram` which simply reverses the nodes’ order; `heatmap`, `cophenetic`.

Examples

```r
require(graphics)
set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
dd <- as.dendrogram(hc)
dd.reorder <- reorder(dd, 10:1)
plot(dd, main = "random dendrogram 'dd'")

op <- par(mfcol = 1:2)
plot(dd.reorder, main = "reorder(dd, 10:1)")
plot(reorder(dd, 10:1, agglo.FUN = mean), main = "reorder(dd, 10:1, mean)")
par(op)
```

replications | Number of Replications of Terms
-------------|-----------------------------

Description

Returns a vector or a list of the number of replicates for each term in the formula.

Usage

```r
replications(formula, data = NULL, na.action)
```
Arguments

formula a formula or a terms object or a data frame.
data a data frame used to find the objects in formula.
na.action function for handling missing values. Defaults to a na.action attribute of data, then a setting of the option na.action, or na.fail if that is not set.

Details

If formula is a data frame and data is missing, formula is used for data with the formula ~ .. Any character vectors in the formula are coerced to factors.

Value

A vector or list with one entry for each term in the formula giving the number(s) of replications for each level. If all levels are balanced (have the same number of replications) the result is a vector, otherwise it is a list with a component for each terms, as a vector, matrix or array as required.

A test for balance is !is.list(replications(formula,data)).

Author(s)

The design was inspired by the S function of the same name described in Chambers et al. (1992).

K = factor(K), yield = yield)
replications(~ . - yield, npk)
### Reshape Grouped Data

**Description**

This function reshapes a data frame between ‘wide’ format (with repeated measurements in separate columns of the same row) and ‘long’ format (with the repeated measurements in separate rows).

**Usage**

```r
reshape(data, varying = NULL, v.names = NULL, timevar = "time",
idvar = "id", ids = 1:NROW(data),
times = seq_along(varying[[1]]),
drop = NULL, direction, new.row.names = NULL,
sep = ".",
split = if (sep == "") {
  list(regexp = \[A-Za-z]\[0-9\], include = TRUE)
} else {
  list(regexp = sep, include = FALSE, fixed = TRUE)
}
```

#### Typical usage for converting from long to wide format:

```r
# reshape(data, direction = "wide",
# idvar = "___", timevar = "___", # mandatory
# v.names = c(___), # time-varying variables
# varying = list(____)) # auto-generated if missing
```

#### Typical usage for converting from wide to long format:

#### If names of wide-format variables are in a 'nice' format

```r
# reshape(data, direction = "long",
# varying = c(___), # vector
# sep) # to help guess 'v.names' and 'times'
```

#### To specify long-format variable names explicitly

```r
# reshape(data, direction = "long",
# varying = ___, # list / matrix / vector (use with care)
# v.names = ___, # vector of variable names in long format
# timevar, times, # name / values of constructed time variable
# idvar, ids) # name / values of constructed id variable
```

**Arguments**

- `data`: a data frame
- `varying`: names of sets of variables in the wide format that correspond to single variables in long format (‘time-varying’). This is canonically a list of vectors of variable names, but it can optionally be a matrix of names, or a single vector of names.
In each case, when `direction = "long"`, the names can be replaced by indices which are interpreted as referring to `names(data)`. See ‘Details’ for more details and options.

**v.names**

names of variables in the long format that correspond to multiple variables in the wide format. See ‘Details’.

**timevar**

the variable in long format that differentiates multiple records from the same group or individual. If more than one record matches, the first will be taken (with a warning).

**idvar**

Names of one or more variables in long format that identify multiple records from the same group/individual. These variables may also be present in wide format.

**ids**

the values to use for a newly created idvar variable in long format.

**times**

the values to use for a newly created timevar variable in long format. See ‘Details’.

**drop**

a vector of names of variables to drop before reshaping.

**direction**

character string, partially matched to either "wide" to reshape to wide format, or "long" to reshape to long format.

**new.row.names**

character or NULL: a non-null value will be used for the row names of the result.

**sep**

A character vector of length 1, indicating a separating character in the variable names in the wide format. This is used for guessing `v.names` and `times` arguments based on the names in `varying`. If `sep == ""`, the split is just before the first numeral that follows an alphabetic character. This is also used to create variable names when reshaping to wide format.

**split**

A list with three components, `regexp`, `include`, and (optionally) `fixed`. This allows an extended interface to variable name splitting. See ‘Details’.

**Details**

Although `reshape()` can be used in a variety of contexts, the motivating application is data from longitudinal studies, and the arguments of this function are named and described in those terms. A longitudinal study is characterized by repeated measurements of the same variable(s), e.g., height and weight, on each unit being studied (e.g., individual persons) at different time points (which are assumed to be the same for all units). These variables are called time-varying variables. The study may include other variables that are measured only once for each unit and do not vary with time (e.g., gender and race); these are called time-constant variables.

A ‘wide’ format representation of a longitudinal dataset will have one record (row) for each unit, typically with some time-constant variables that occupy single columns, and some time-varying variables that occupy multiple columns (one column for each time point). A ‘long’ format representation of the same dataset will have multiple records (rows) for each individual, with the time-constant variables being constant across these records and the time-varying variables varying across the records. The ‘long’ format dataset will have two additional variables: a ‘time’ variable identifying which time point each record comes from, and an ‘id’ variable showing which records refer to the same unit.

The type of conversion (long to wide or wide to long) is determined by the `direction` argument, which is mandatory unless the data argument is the result of a previous call to `reshape`. In that case, the operation can be reversed simply using `reshape(data)` (the other arguments are stored as attributes on the data frame).

Conversion from long to wide format with `direction = "wide"` is the simpler operation, and is mainly useful in the context of multivariate analysis where data is often expected as a wide-format
matrix. In this case, the time variable `timevar` and id variable `idvar` must be specified. All other variables are assumed to be time-varying, unless the time-varying variables are explicitly specified via the `v.names` argument. A warning is issued if time-constant variables are not actually constant.

Each time-varying variable is expanded into multiple variables in the wide format. The names of these expanded variables are generated automatically, unless they are specified as the varying argument in the form of a list (or matrix) with one component (or row) for each time-varying variable. If `varying` is a vector of names, it is implicitly converted into a matrix, with one row for each time-varying variable. Use this option with care if there are multiple time-varying variables, as the ordering (by column, the default in the `matrix` constructor) may be unintuitive, whereas the explicit list or matrix form is unambiguous.

Conversion from wide to long with `direction = "long"` is the more common operation as most (univariate) statistical modeling functions expect data in the long format. In the simpler case where there is only one time-varying variable, the corresponding columns in the wide format input can be specified as the varying argument, which can be either a vector of column names or the corresponding column indices. The name of the corresponding variable in the long format output combining these columns can be optionally specified as the `v.names` argument, and the name of the time variables as the `timevar` argument. The values to use as the time values corresponding to the different columns in the wide format can be specified as the `times` argument. If `v.names` is unspecified, the function will attempt to guess `v.names` and `times` from `varying` (an explicitly specified `times` argument is unused in that case). The default expects variable names like `x.1`, `x.2`, where `sep = "."` specifies to split at the dot and drop it from the name. To have alphabetic followed by numeric times use `sep = ""`.

Multiple time-varying variables can be specified in two ways, either with `varying` as an atomic vector as above, or as a list (or a matrix). The first form is useful (and mandatory) if the automatic variable name splitting as described above is used; this requires the names of all time-varying variables to be suitably formatted in the same manner, and `v.names` to be unspecified. If `varying` is a list (with one component for each time-varying variable) or a matrix (one row for each time-varying variable), variable name splitting is not attempted, and `v.names` and `times` will generally need to be specified, although they will default to, respectively, the first variable name in each set, and sequential times.

Also, guessing is not attempted if `v.names` is given explicitly, even if `varying` is an atomic vector. In that case, the number of time-varying variables is taken to be the length of `v.names`, and `varying` is implicitly converted into a matrix, with one row for each time-varying variable. As in the case of long to wide conversion, the matrix is filled up by column, so careful attention needs to be paid to the order of variable names (or indices) in `varying`, which is taken to be like `x.1, y.1, x.2, y.2` (i.e., variables corresponding to the same time point need to be grouped together).

The `split` argument should not usually be necessary. The `split$regexp` component is passed to either `strsplit` or `regexp`, where the latter is used if `split$include` is `TRUE`, in which case the splitting occurs after the first character of the matched string. In the `strsplit` case, the separator is not included in the result, and it is possible to specify fixed-string matching using `split$fixed`.

**Value**

The reshaped data frame with added attributes to simplify reshaping back to the original form.

**See Also**

`stack`, `aperm`, `relist` for reshaping the result of `unlist`. `xtabs` and `as.data.frame.table` for creating contingency tables and converting them back to data frames.
Examples

```r
summary(Indometh) # data in long format

## long to wide (direction = "wide") requires idvar and timevar at a minimum
reshape(Indometh, direction = "wide", idvar = "Subject", timevar = "time")

## can also explicitly specify name of combined variable
wide <- reshape(Indometh, direction = "wide", idvar = "Subject",
    timevar = "time", v.names = "conc", sep = ".")
wide

## reverse transformation
reshape(wide, direction = "long")
reshape(wide, idvar = "Subject", varying = list(2:12),
    v.names = "conc", direction = "long")

## times need not be numeric
df <- data.frame(id = rep(1:4, rep(2,4)),
    visit = I(rep(c("Before","After"), 4)),
    x = rnorm(4), y = runif(4))

reshape(df, timevar = "visit", idvar = "id", direction = "wide")

## warns that y is really varying
reshape(df, timevar = "visit", idvar = "id", direction = "wide", v.names = "x")

## unbalanced 'long' data leads to NA fill in 'wide' form
df2 <- df[1:7, ]

reshape(df2, timevar = "visit", idvar = "id", direction = "wide")

## Alternative regular expressions for guessing names
df3 <- data.frame(id = 1:4, age = c(40,50,60,50), dose1 = c(1,2,1,2),
    dose2 = c(2,1,2,1), dose4 = c(3,3,3,3))

    time = rep(c(1,1,2,2), 3), score = rnorm(12))

wide <- reshape(df3, idvar = c("school", "class"), direction = "wide")
wide

## transform back
reshape(wide)
```
residuals

*Extract Model Residuals*

**Description**

`residuals` is a generic function which extracts model residuals from objects returned by modeling functions.

`resid` is an alias for `residuals`, abbreviated to encourage users to access object components through an accessor function rather than by directly referencing an object slot.

All object classes which are returned by model fitting functions should provide a `residuals` method. (Note that the method is for `residuals` and not `resid`.)

Methods can make use of `naresid` methods to compensate for the omission of missing values. The default, `nls` and `smooth.spline` methods do.

**Usage**

```r
residuals(object, ...)  
resid(object, ...)
```

**Arguments**

- `object` an object for which the extraction of model residuals is meaningful.
- `...` other arguments.

**Value**

Residuals extracted from the object `object`.

**References**

**See Also**

- `coefficients`, `fitted.values`, `glm`, `lm`
- `influence.measures` for standardized (`rstandard`) and studentized (`rstudent`) residuals.

---

runmed

*Running Medians – Robust Scatter Plot Smoothing*

**Description**

Compute running medians of odd span. This is the ‘most robust’ scatter plot smoothing possible. For efficiency (and historical reason), you can use one of two different algorithms giving identical results.
Usage

runmed(x, k, endrule = c("median", "keep", "constant"),
algorithm = NULL,
na.action = c("+Big_alternate", "-Big_alternate", "na.omit", "fail"),
print.level = 0)

Arguments

x numeric vector, the ‘dependent’ variable to be smoothed.
k integer width of median window; must be odd. Turlach had a default of \( k = 1 + 2 \times \min((n-1)/2, \text{ceiling}(0.1\times n)) \). Use \( k = 3 \) for ‘minimal’ robust smoothing eliminating isolated outliers.
endrule character string indicating how the values at the beginning and the end (of the data) should be treated. Can be abbreviated. Possible values are:
- "keep" keeps the first and last \( \frac{k}{2} \) values at both ends, where \( k = \frac{k}{2} \) is the half-bandwidth \( k = k/2 \), i.e., \( y[j] = x[j] \) for \( j \in \{1, \ldots, k/2; n - k/2 + 1, \ldots, n\} \);
- "constant" copies median(\( y[1:k/2] \)) to the first values and analogously for the last ones making the smoothed ends constant;
- "median" the default, smooths the ends by using symmetrical medians of subsequently smaller bandwidth, but for the very first and last value where Tukey’s robust end-point rule is applied, see smoothEnds.
algorithm character string (partially matching "Turlach" or "Stuetzle") or the default NULL, specifying which algorithm should be applied. The default choice depends on \( n = \text{length}(x) \) and \( k \) where "Turlach" will be used for larger problems.
na.action character string determining the behavior in the case of NA or NaN in x, (partially matching) one of
- "+Big_alternate" Here, all the NAs in x are first replaced by alternating \( \pm B \) where \( B \) is a “Big” number (with \( 2B < M* \), where \( M* = .\text{Machine}$\ double.xmax \). The replacement values are “from left” \( (+B, -B, +B, \ldots) \), i.e. start with "+".
- "-Big_alternate" almost the same as "+Big_alternate", just starting with \( -B \) ("-Big...").
- "na.omit" the result is the same as runmed(x[!is.na(x)], k, ..).
- "fail" the presence of NAs in x will raise an error.
print.level integer, indicating verboseness of algorithm; should rarely be changed by average users.

Details

Apart from the end values, the result \( y = \text{runmed}(x, k) \) simply has \( y[j] = \text{median}(x[(j-k)/2:(j+k)/2]) \), \( k = 2k/2 + 1 \), computed very efficiently.

The two algorithms are internally entirely different:
- "Turlach" is the Härdle–Steiger algorithm (see Ref.) as implemented by Berwin Turlach. A tree algorithm is used, ensuring performance \( O(n \log k) \) where \( n = \text{length}(x) \) which is asymptotically optimal.
- "Stuetzle" is the (older) Stuetzle–Friedman implementation which makes use of median updating when one observation enters and one leaves the smoothing window. While this performs as \( O(n \times k) \) which is slower asymptotically, it is considerably faster for small \( k \) or \( n \).
Note that, both algorithms (and the `smoothEnds()` utility) now “work” also when \(x\) contains non-finite entries (\(\pm \text{Inf}, \text{NaN}, \text{and NA}\)):

"Turlach" .......
"Stuetzle" currently simply works by applying the underlying math library (‘libm’) arithmetic for the non-finite numbers; this may optionally change in the future.

Currently long vectors are only supported for `algorithm = "Stuetzle"`.

Value

vector of smoothed values of the same length as \(x\) with an attribute \(k\) containing (the ‘oddified’) \(k\).

Author(s)

Martin Maechler <maechler@stat.math.ethz.ch>, based on Fortran code from Werner Stuetzle and S-PLUS and C code from Berwin Turlach.

References

See Also

`smoothEnds` which implements Tukey’s end point rule and is called by default from `runmed(*, endrule = "median")`. `smooth` uses running medians of 3 for its compound smoothers.

Examples

```r
require(graphics)
utils::example(nhtemp)
myNHT <- as.vector(nhtemp)
plot(myNHT, type = "b", ylim = c(48, 60), main = "Running Medians Example")
lines(runmed(myNHT, 7), col = "red")

# special: multiple y values for one x
plot(cars, main = "'cars' data and runmed(dist, 3)"
lines(cars, col = "light gray", type = "c")
with(cars, lines(speed, runmed(dist, k = 3), col = 2))

# nice quadratic with a few outliers
y <- ys <- (-20:20)^2
y[c(1,10,21,41)] <- c(150, 30, 400, 450)
all(y == runmed(y, 1)) # 1-neighbourhood <=> interpolation
plot(y) # lines(y, lwd = .1, col = "light gray")

rWishart

Random Wishart Distributed Matrices

Description

Generate n random matrices, distributed according to the Wishart distribution with parameters Sigma and df, $W_p(\Sigma, m)$, $m = df$, $\Sigma = Sigma$.

Usage

rWishart(n, df, Sigma)

Arguments

n  integer sample size.

df  numeric parameter, “degrees of freedom”.

Sigma  positive definite ($p \times p$) “scale” matrix, the matrix parameter of the distribution.

Details

If $X_1, \ldots, X_m$, $X_i \in \mathbf{R}^p$ is a sample of $m$ independent multivariate Gaussians with mean (vector) 0, and covariance matrix $\Sigma$, the distribution of $M = X'X$ is $W_p(\Sigma, m)$.

Consequently, the expectation of $M$ is

$$E[M] = m \times \Sigma.$$
Further, if $\Sigma$ is scalar ($p = 1$), the Wishart distribution is a scaled chi-squared ($\chi^2$) distribution with $df$ degrees of freedom, $W_1(\sigma^2, m) = \sigma^2 \chi^2_m$.

The component wise variance is

$$\text{Var}(M_{ij}) = m(\Sigma_{ij}^2 + \Sigma_{ii}\Sigma_{jj}).$$

**Value**

a numeric array, say $R$, of dimension $p \times p \times n$, where each $R[,,i]$ is a positive definite matrix, a realization of the Wishart distribution $W_p(\Sigma, m), \ m = df, \ \Sigma = \Sigma.$

**Author(s)**

Douglas Bates

**References**

**See Also**

`cov`, `rnorm`, `rchisq`.

**Examples**

```r
## Artificial
S <- toeplitz((10:1)/10)
set.seed(11)
R <- rWishart(1000, 20, S)
dim(R)  # 10 10 1000
mR <- apply(R, 1:2, mean)  # ~= E[ Wish(S, 20) ] = 20 * S
stopifnot(all.equal(mR, 20*S, tolerance = .009))

## See Details, the variance is
Va <- 20 * (S^2 + tcrossprod(diag(S)))
vR <- apply(R, 1:2, var)
stopifnot(all.equal(vR, Va, tolerance = 1/16))
```

**scatter.smooth**

*Scatter Plot with Smooth Curve Fitted by loess*

**Description**

Plot and add a smooth curve computed by `loess` to a scatter plot.

**Usage**

```r
scatter.smooth(x, y = NULL, span = 2/3, degree = 1,
               family = c("symmetric", "gaussian"),
               xlab = NULL, ylab = NULL,
               ylim = range(y, pred$y, na.rm = TRUE),
               evaluation = 50, ..., lpars = list())
```

```r
loess.smooth(x, y, span = 2/3, degree = 1,
             family = c("symmetric", "gaussian"), evaluation = 50, ...)
```
scatter.smooth

Arguments

x, y  the x and y arguments provide the x and y coordinates for the plot. Any reasonable way of defining the coordinates is acceptable. See the function `xy.coords` for details.

span  smoothness parameter for `loess`.

degree  degree of local polynomial used.

family  if "gaussian" fitting is by least-squares, and if `family = "symmetric"` a re-descending M estimator is used. Can be abbreviated.

xlab  label for x axis.

ylab  label for y axis.

ylim  the y limits of the plot.

evaluation  number of points at which to evaluate the smooth curve.

...  For `scatter.smooth()`, graphical parameters, passed to `plot()` only. For `loess.smooth`, control parameters passed to `loess.control`.

lpars  a list of arguments to be passed to `lines()`.

Details

`loess.smooth` is an auxiliary function which evaluates the `loess` smooth at `evaluation` equally spaced points covering the range of `x`.

Value

For `scatter.smooth`, none.

For `loess.smooth`, a list with two components, `x` (the grid of evaluation points) and `y` (the smoothed values at the grid points).

See Also

`loess`; `smoothScatter` for scatter plots with smoothed density color representation.

Examples

```r
require(graphics)

with(cars, scatter.smooth(speed, dist))
## or with dotted thick smoothed line results :
with(cars, scatter.smooth(speed, dist, lpars =
  list(col = "red", lwd = 3, lty = 3)))
```
screeplot  Scree Plots

Description

screeplot.default plots the variances against the number of the principal component. This is also the plot method for classes "princomp" and "prcomp".

Usage

screeplot(x, ...)  
## Default S3 method:  
screeplot(x, npcs = min(10, length(x$sdev)), type = c("barplot", "lines"), main = deparse1(substitute(x)), ...)

Arguments

x  an object containing a sdev component, such as that returned by princomp() and prcomp().

npcs  the number of components to be plotted.

type  the type of plot. Can be abbreviated.

main,...  graphics parameters.

References

See Also

princomp and prcomp.

Examples

require(graphics)

## The variances of the variables in the
## USArrests data vary by orders of magnitude, so scaling is appropriate
(pc.cr <- princomp(USArrests, cor = TRUE))  # inappropriate
screeplot(pc.cr)

fit <- princomp(covmat = Harman74.cor)
screeplot(fit)
screeplot(fit, npcs = 24, type = "lines")
sd

Standard Deviation

Description

This function computes the standard deviation of the values in x. If na.rm is TRUE then missing values are removed before computation proceeds.

Usage

sd(x, na.rm = FALSE)

Arguments

x a numeric vector or an R object but not a factor coercible to numeric by as.double(x).

na.rm logical. Should missing values be removed?

Details

Like var this uses denominator $n - 1$.

The standard deviation of a length-one or zero-length vector is NA.

See Also

var for its square, and mad, the most robust alternative.

Examples

sd(1:2) ^ 2

se.contrast

Standard Errors for Contrasts in Model Terms

Description

Returns the standard errors for one or more contrasts in an aov object.

Usage

se.contrast(object, ..., 
## S3 method for class 'aov'
se.contrast(object, contrast.obj,
    coef = contr.helmert(ncol(contrast))[[, 1],
    data = NULL, ...)
Arguments

- **object**: A suitable fit, usually from aov.
- **contrast.obj**: The contrasts for which standard errors are requested. This can be specified via a list or via a matrix. A single contrast can be specified by a list of logical vectors giving the cells to be contrasted. Multiple contrasts should be specified by a matrix, each column of which is a numerical contrast vector (summing to zero).
- **coef**: used when contrast.obj is a list; it should be a vector of the same length as the list with zero sum. The default value is the first Helmert contrast, which contrasts the first and second cell means specified by the list.
- **data**: The data frame used to evaluate contrast.obj.
- **...**: further arguments passed to or from other methods.

Details

Contrasts are usually used to test if certain means are significantly different; it can be easier to use `se.contrast` than compute them directly from the coefficients.

In multistratum models, the contrasts can appear in more than one stratum, in which case the standard errors are computed in the lowest stratum and adjusted for efficiencies and comparisons between strata. (See the comments in the note in the help for `aov` about using orthogonal contrasts.) Such standard errors are often conservative.

Suitable matrices for use with coef can be found by calling `contrasts` and indexing the columns by a factor.

Value

A vector giving the standard errors for each contrast.

See Also

- `contrasts`, `model.tables`

Examples

```r
N <- c(0,1,0,1,1,1,0,0,0,1,1,0,1,1,0,1,0,1,1,0,1,1,0,0)

library(nlme)
fit2 <- lme(Yield ~ A + B*C, random = ~1 | Block, data = aovdat)
summary(fit2)$tTable # same estimates, similar (but smaller) se's.
Description

Construct self-starting nonlinear models to be used in \texttt{nls}, etc. Via function \texttt{initial} to compute approximate parameter values from data, such models are “self-starting”, i.e., do not need a \texttt{start} argument in, e.g., \texttt{nls()}.

Usage

\texttt{selfStart(model, initial, parameters, template)}

Arguments

- \texttt{model} a function object defining a nonlinear model or a nonlinear \texttt{formula} object of the form \texttt{~ expression}.
- \texttt{initial} a function object, taking arguments \texttt{mCall}, \texttt{data}, and \texttt{LHS}, \texttt{and} \ldots, representing, respectively, a matched call to the function model, a data frame in which to interpret the variables in \texttt{mCall}, and the expression from the left-hand side of the model formula in the call to \texttt{nls}. This function should return initial values for the parameters in model. The \ldots is used by \texttt{nls()} to pass its control and trace arguments for the cases where \texttt{initial()} itself calls \texttt{nls()} as it does for the ten self-starting nonlinear models in \texttt{R}'s \texttt{stats} package.
- \texttt{parameters} a character vector specifying the terms on the right hand side of model for which initial estimates should be calculated. Passed as the \texttt{namevec} argument to the \texttt{deriv} function.
- \texttt{template} an optional prototype for the calling sequence of the returned object, passed as the \texttt{function.arg} argument to the \texttt{deriv} function. By default, a template is generated with the covariates in model coming first and the parameters in model coming last in the calling sequence.

Details

\texttt{nls()} calls \texttt{getInitial} and the \texttt{initial} function for these self-starting models.

This function is generic; methods functions can be written to handle specific classes of objects.

Value

a \texttt{function} object of class "selfStart", for the \texttt{formula} method obtained by applying \texttt{deriv} to the right hand side of the model formula. An initial attribute (defined by the \texttt{initial} argument) is added to the function to calculate starting estimates for the parameters in the model automatically.

Author(s)

José Pinheiro and Douglas Bates

\texttt{nls}, \texttt{getInitial}.

Each of the following are “selfStart” models (with examples) \texttt{SSasymp}, \texttt{SSasympOff}, \texttt{SSasympOrig}, \texttt{SSbiexp}, \texttt{SSfol}, \texttt{SSfpl}, \texttt{SSgompertz}, \texttt{SSlogis}, \texttt{SSmicmen}, \texttt{SSweibull}.

Further, package \texttt{nlme}'s \texttt{nlsList}.
Examples

```r
## self-starting logistic model

## The "initializer" (finds initial values for parameters from data):
initLogis <- function(mCall, data, LHS, ...) {
    xy <- sortedXyData(mCall[["x"]], LHS, data)
    if(nrow(xy) < 4)
        stop("too few distinct input values to fit a logistic model")
    z <- xy["y"]
    ## transform to proportion, i.e. in (0,1):
    rng <- range(z); dz <- diff(rng)
    z <- (z - rng[1L] + 0.05 * dz)/(1.1 * dz)
    xy["z"] <- log(z/(1 - z)) # logit transformation
    aux <- coef(lm(x ~ z, xy))
    pars <- coef(nls(y ~ 1/(1 + exp((xmid - x)/scal)),
                   data = xy,
                   start = list(xmid = aux[[1L]], scal = aux[[2L]]),
                   algorithm = "plinear", ...))
    setNames(pars [c(".lin", "xmid", "scal")],
             mCall[c("Asym", "xmid", "scal")])
}

mySSlogis <- selfStart(~ Asym/(1 + exp((xmid - x)/scal)),
                       initial = initLogis,
                       parameters = c("Asym", "xmid", "scal"))

getInitial(weight ~ mySSlogis(Time, Asym, xmid, scal),
            data = subset(ChickWeight, Chick == 1))
```

```
# first.order.log.model is a function object defining a first order
# compartment model
# first.order.log.initial is a function object which calculates initial
# values for the parameters in first.order.log.model
# self-starting first order compartment model

## Not run:
SSfol <- selfStart(first.order.log.model, first.order.log.initial)
```

## Explore the self-starting models already available in R's "stats":
pos.st <- which("package:stats" == search())
mSS <- apropos("^SS..", where = TRUE, ignore.case = FALSE)
(mSS <- unname(mSS[names(mSS) == pos.st]))
fSS <- sapply(mSS, get, pos = pos.st, mode = "function")
all(sapply(fSS, inherits, "selfStart")) # -> TRUE

## Show the argument list of each self-starting function:
str(fSS, give.attr = FALSE)
```

## self-starting first order compartment model
```
**setNames**

This is a convenience function that sets the names on an object and returns the object. It is most useful at the end of a function definition where one is creating the object to be returned and would prefer not to store it under a name just so the names can be assigned.

**Usage**

```
setNames(object = nm, nm)
```

**Arguments**

- `object`: an object for which a `names` attribute will be meaningful
- `nm`: a character vector of names to assign to the object

**Value**

An object of the same sort as `object` with the new names assigned.

**Author(s)**

Douglas M. Bates and Saikat DebRoy

**See Also**

- `unname` for removing names.

**Examples**

```
setNames( 1:3, c("foo", "bar", "baz") )
# this is just a short form of
tmp <- 1:3
names(tmp) <- c("foo", "bar", "baz")
tmp
## special case of character vector, using default
setNames(nm = c("First", "2nd"))
```

---

**shapiro.test**

**Shapiro-Wilk Normality Test**

**Description**

Performs the Shapiro-Wilk test of normality.

**Usage**

```
shapiro.test(x)
```

**Arguments**

- `x`: a numeric vector of data values. Missing values are allowed, but the number of non-missing values must be between 3 and 5000.
Value

A list with class "htest" containing the following components:

- **statistic**: the value of the Shapiro-Wilk statistic.
- **p.value**: an approximate p-value for the test. This is said in Royston (1995) to be adequate for p.value < 0.1.
- **method**: the character string "Shapiro-Wilk normality test".
- **data.name**: a character string giving the name(s) of the data.

Source

The algorithm used is a C translation of the Fortran code described in Royston (1995). The calculation of the p value is exact for \( n = 3 \), otherwise approximations are used, separately for \( 4 \leq n \leq 11 \) and \( n \geq 12 \).

References

See Also

- `qqnorm` for producing a normal quantile-quantile plot.

Examples

```r
shapiro.test(rnorm(100, mean = 5, sd = 3))
shapiro.test(runif(100, min = 2, max = 4))
```

sigma

Extract Residual Standard Deviation 'Sigma'

Description

Extract the estimated standard deviation of the errors, the “residual standard deviation” (misnamed also “residual standard error”, e.g., in `summary.lm()`’s output, from a fitted model).

Many classical statistical models have a scale parameter, typically the standard deviation of a zero-mean normal (or Gaussian) random variable which is denoted as \( \sigma \). `sigma(.)` extracts the estimated parameter from a fitted model, i.e., \( \hat{\sigma} \).

Usage

```r
sigma(object, ...)
```

## Default S3 method:
`sigma(object, use.fallback = TRUE, ...)`
Arguments

- **object**: an R object, typically resulting from a model fitting function such as `lm`.
- **use.fallback**: logical, passed to `nobs`.
- **...**: potentially further arguments passed to and from methods. Passed to `deviance(*, ...)` for the default method.

Details

The `stats` package provides the S3 generic, a default method, and a method for objects of class "glm". The default method is correct typically for (asymptotically / approximately) generalized gaussian ("least squares") problems, since it is defined as

\[
\text{sigma.default} \leftarrow \text{function (object, use.fallback = TRUE, ...)} \\
\quad \text{sqrt( deviance(object, ...) / (NN - PP) )}
\]

where \( NN \leftarrow \text{nobs(object, use.fallback = use.fallback) } \) and \( PP \leftarrow \text{sum(!is.na(coef(object)))} \) – where in older R versions this was \( \text{length(coef(object))} \) which is too large in case of undetermined coefficients, e.g., for rank deficient model fits.

Value

Typically a number, the estimated standard deviation of the errors ("residual standard deviation") for Gaussian models, and—less interpretably—the square root of the residual deviance per degree of freedom in more general models.

Very strictly speaking, \( \hat{\sigma} \) ("\( \sigma \) hat") is actually \( \sqrt{\sigma^2} \).

For generalized linear models (class "glm"), the `sigma.glm` method returns the square root of the dispersion parameter (See `summary.glm`). For families with free dispersion parameter, `sigma` is estimated from the root mean square of the Pearson residuals. For families with fixed dispersion, `sigma` is not estimated from the residuals but extracted directly from the family of the fitted model. Consequently, for binomial or Poisson GLMs, `sigma` is exactly 1.

For multivariate linear models (class "mlm"), a vector of sigmas is returned, each corresponding to one column of \( Y \).

Note

The misnomer "Residual standard error" has been part of too many R (and S) outputs to be easily changed there.

See Also

- `deviance`, `nobs`, `vcov`, `summary.glm`

Examples

```r
## -- lm() ------------------------------
lm1 <- lm(Fertility ~ . , data = swiss)
sigma(lm1) # ~= 7.165 = "Residual standard error" printed from summary(lm1)
stopifnot(all.equal(sigma(lm1), summary(lm1)$sigma, tolerance=1e-15))

## -- nls() -----------------------------
DNase1 <- subset(DNase, Run == 1)
```
fm.DN1 <- nls(density ~ SSlogis(log(conc), Asym, xmid, scal), DNase1)
sigma(fm.DN1) # =~ 0.01919 as from summary(.
stopifnot(all.equal(sigma(fm.DN1), summary(fm.DN1)$sigma, tolerance=1e-15))

## -- glm() -----------------------------
## -- a) Binomial -- Example from MASS
ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20-numdead)
sigma(budworm.lg <- glm(SF ~ sex*ldose, family = binomial))

## -- b) Poisson -- from ?glm :
## Dobson (1990) Page 93: Randomized Controlled Trial :
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3,1,9)
treatment <- gl(3,3)
sigma(glm.D93 <- glm(counts ~ outcome + treatment, family = poisson()))
## equal to
sqrt(summary(glm.D93)$dispersion) # == 1
## and the *Quasi*poisson’s dispersion
sigma(glm.qD93 <- update(glm.D93, family = quasipoisson()))
sigma (glm.qD93)^2 # 1.2933 equal to
summary(glm.qD93)$dispersion # == 1.2933

## -- Multivariate lm() "mlm" ---------
utils::example("SSD", echo=FALSE)
sigma(mlmfit) # is the same as (but more efficient than)
sqrt(diag(estVar(mlmfit)))

---

**SignRank**

**Distribution of the Wilcoxon Signed Rank Statistic**

**Description**

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon Signed Rank statistic obtained from a sample with size n.

**Usage**

dsignrank(x, n, log = FALSE)
psignrank(q, n, lower.tail = TRUE, log.p = FALSE)
qsignrank(p, n, lower.tail = TRUE, log.p = FALSE)
rsignrank(nn, n)

**Arguments**

- **x, q** vector of quantiles.
- **p** vector of probabilities.
- **nn** number of observations. If length(nn) > 1, the length is taken to be the number required.
SignRank

n  number(s) of observations in the sample(s). A positive integer, or a vector of such integers.

log, log.p  logical; if TRUE, probabilities p are given as log(p).

lower.tail  logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

This distribution is obtained as follows. Let \( x \) be a sample of size \( n \) from a continuous distribution symmetric about the origin. Then the Wilcoxon signed rank statistic is the sum of the ranks of the absolute values \( x[i] \) for which \( x[i] \) is positive. This statistic takes values between 0 and \( n(n+1)/2 \), and its mean and variance are \( n(n+1)/4 \) and \( n(n+1)(2n+1)/24 \), respectively.

If either of the first two arguments is a vector, the recycling rule is used to do the calculations for all combinations of the two up to the length of the longer vector.

Value

dsignrank gives the density, psignrank gives the distribution function, qsignrank gives the quantile function, and rsignrank generates random deviates.

The length of the result is determined by \( nn \) for \( rsignrank \), and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( nn \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

Author(s)

Kurt Hornik; efficiency improvement by Ivo Ugrina.

wilcox.test to calculate the statistic from data, find p values and so on.

Distributions for standard distributions, including dWilcoxon for the distribution of two-sample Wilcoxon rank sum statistic.

Examples

```r
require(graphics)

par(mfrow = c(2,2))
for(n in c(4:5,10,40)) {
  x <- seq(0, n*(n+1)/2, length.out = 501)
  plot(x, dsignrank(x, n = n), type = "l",
       main = paste0("dsignrank(x, n = ", n, ")")
}
```
Simulate Responses

Description

Simulate one or more responses from the distribution corresponding to a fitted model object.

Usage

`simulate(object, nsim = 1, seed = NULL, ...)`

Arguments

- `object`: an object representing a fitted model.
- `nsim`: number of response vectors to simulate. Defaults to 1.
- `seed`: an object specifying if and how the random number generator should be initialized ('seeded').
  For the "lm" method, either NULL or an integer that will be used in a call to `set.seed` before simulating the response vectors. If set, the value is saved as the "seed" attribute of the returned value. The default, NULL will not change the random generator state, and return `.Random.seed` as the "seed" attribute, see 'Value'.
- `...`: additional optional arguments.

Details

This is a generic function. Consult the individual modeling functions for details on how to use this function.

Package stats has a method for "lm" objects which is used for `lm` and `glm` fits. There is a method for fits from `glm.nb` in package MASS, and hence the case of negative binomial families is not covered by the "lm" method.

The methods for linear models fitted by `lm` or `glm(family = "gaussian")` assume that any weights which have been supplied are inversely proportional to the error variance. For other GLMs the (optional) `simulate` component of the `family` object is used—there is no appropriate simulation method for ‘quasi’ models as they are specified only up to two moments.

For binomial and Poisson GLMs the dispersion is fixed at one. Integer prior weights \( w_i \) can be interpreted as meaning that observation \( i \) is an average of \( w_i \) observations, which is natural for binomials specified as proportions but less so for a Poisson, for which prior weights are ignored with a warning.

For a gamma GLM the shape parameter is estimated by maximum likelihood (using function `gamma.shape` in package MASS). The interpretation of weights is as multipliers to a basic shape parameter, since dispersion is inversely proportional to shape.

For an inverse gaussian GLM the model assumed is \( IG(\mu_i, \lambda w_i) \) (see https://en.wikipedia.org/wiki/Inverse_Gaussian_distribution) where \( \lambda \) is estimated by the inverse of the dispersion estimate for the fit. The variance is \( \mu_i^3 / (\lambda w_i) \) and hence inversely proportional to the prior weights. The simulation is done by function `rinvGauss` from the SuppDists package, which must be installed.
Value

Typically, a list of length \( \text{nsim} \) of simulated responses. Where appropriate the result can be a data frame (which is a special type of list).

For the "lm" method, the result is a data frame with an attribute "seed". If argument seed is NULL, the attribute is the value of \(.\text{Random.seed}\) before the simulation was started; otherwise it is the value of the argument with a "kind" attribute with value as.list(RNGkind()).

See Also

\( \text{RNG} \) about random number generation in \( \text{R} \), \text{fitted.values} and \text{residuals} for related methods; \text{glm}, \text{lm} for model fitting.

There are further examples in the ‘simulate.R’ tests file in the sources for package \text{stats}.

Examples

```r
x <- 1:5
mod1 <- lm(c(1:3, 7, 6) ~ x)
S1 <- simulate(mod1, nsim = 4)
## repeat the simulation:
.Random.seed <- attr(S1, "seed")
identical(S1, simulate(mod1, nsim = 4))

S2 <- simulate(mod1, nsim = 200, seed = 101)
rowMeans(S2) # should be about the same as fitted(mod1)

## repeat identically:
(sseed <- attr(S2, "seed")) # seed; RNGkind as attribute
stopifnot(identical(S2, simulate(mod1, nsim = 200, seed = sseed)))

## To be sure about the proper RNGkind, e.g., after
RNGversion("2.7.0")
## first set the RNG kind, then simulate
do.call(RNGkind, attr(sseed, "kind"))
identical(S2, simulate(mod1, nsim = 200, seed = sseed))

## Binomial GLM examples
yb1 <- matrix(c(4, 4, 5, 7, 8, 6, 6, 5, 3, 2), ncol = 2)
modb1 <- glm(yb1 ~ x, family = binomial)
S3 <- simulate(modb1, nsim = 4)
# each column of S3 is a two-column matrix.

x2 <- sort(runif(100))
yb2 <- rbinom(100, prob = plogis(2*(x2-1)), size = 1)
yb2 <- factor(1 + yb2, labels = c("failure", "success"))
modb2 <- glm(yb2 ~ x2, family = binomial)
S4 <- simulate(modb2, nsim = 4)
# each column of S4 is a factor
```
Distribution function, quantile function and random generation for the distribution of the Smirnov statistic.

Usage

```r
psmirnov(q, sizes, z = NULL,
          alternative = c("two.sided", "less", "greater"),
          exact = TRUE, simulate = FALSE, B = 2000,
          lower.tail = TRUE, log.p = FALSE)
qsmirnov(p, sizes, z = NULL,
          alternative = c("two.sided", "less", "greater"),
          exact = TRUE, simulate = FALSE, B = 2000)
rsmirnov(n, sizes, z = NULL,
          alternative = c("two.sided", "less", "greater"))
```

Arguments

- `q`: a numeric vector of quantiles.
- `p`: a numeric vector of probabilities.
- `sizes`: an integer vector of length two giving the sample sizes.
- `z`: a numeric vector of the pooled data values in both samples when the exact conditional distribution of the Smirnov statistic given the data shall be computed.
- `alternative`: one of "two.sided" (default), "less", or "greater" indicating whether absolute (two-sided, default) or raw (one-sided) differences of frequencies define the test statistic. See 'Details'.
- `exact`: NULL or a logical indicating whether the exact (conditional on the pooled data values in `z`) distribution or the asymptotic distribution should be used.
- `simulate`: a logical indicating whether to compute the distribution function by Monte Carlo simulation.
- `B`: an integer specifying the number of replicates used in the Monte Carlo test.
- `lower.tail`: a logical, if TRUE (default), probabilities are $P[D < q]$, otherwise, $P[D \geq q]$.
- `log.p`: a logical, if TRUE (default), probabilities are given as log-probabilities.
- `n`: an integer giving number of observations.

Details

For samples $x$ and $y$ with respective sizes $n_x$ and $n_y$ and empirical cumulative distribution functions $F_{x,n_x}$ and $F_{y,n_y}$, the Smirnov statistic is

$$D = \sup_c |F_{x,n_x}(c) - F_{y,n_y}(c)|$$

in the two-sided case,

$$D^+ = \sup_c (F_{x,n_x}(c) - F_{y,n_y}(c))$$

in the one-sided "greater" case, and

$$D^- = \sup_c (F_{y,n_y}(c) - F_{x,n_x}(c))$$

in the one-sided "less" case.
These statistics are used in the Smirnov test of the null that $x$ and $y$ were drawn from the same distribution, see \texttt{ks.test}.

If the underlying common distribution function $F$ is continuous, the distribution of the test statistics does not depend on $F$, and has a simple asymptotic approximation. For arbitrary $F$, one can compute the conditional distribution given the pooled data values $z$ of $x$ and $y$, either exactly (feasible provided that the product $n_x n_y$ of the sample sizes is “small enough”) or approximately Monte Carlo simulation. If the pooled data values $z$ are not specified, a pooled sample without ties is assumed.

**Value**

\texttt{psmirnov} gives the distribution function, \texttt{qsmirnov} gives the quantile function, and \texttt{rsmirnov} generates random deviates.

**See Also**

\texttt{ks.test} for references on the algorithms used for computing exact distributions.

---

**smooth**

\textit{Tukey’s (Running Median) Smoothing}

**Description**

Tukey’s smoothers, 3RS3R, 3RSS, 3R, etc.

**Usage**

\begin{verbatim}
smooth(x, kind = c("3RS3R", "3RSS", "3R", "S"),
       twiceit = FALSE, endrule = c("Tukey", "copy"), do.ends = FALSE)
\end{verbatim}

**Arguments**

- \texttt{x} a vector or time series
- \texttt{kind} a character string indicating the kind of smoother required; defaults to "3RS3R".
- \texttt{twiceit} logical, indicating if the result should be ‘twiced’. Twicing a smoother $S(y)$ means $S(y) + S(y - S(y))$, i.e., adding smoothed residuals to the smoothed values. This decreases bias (increasing variance).
- \texttt{endrule} a character string indicating the rule for smoothing at the boundary. Either "Tukey" (default) or "copy".
- \texttt{do.ends} logical, indicating if the 3-splitting of ties should also happen at the boundaries (ends). This is only used for \texttt{kind} = "S".

**Details**

3 is Tukey’s short notation for running \texttt{medians} of length 3,
3R stands for Repeated 3 until convergence, and
S for Splitting of horizontal stretches of length 2 or 3.

Hence, 3RS3R is a concatenation of 3R, S and 3R, 3RSS similarly, whereas 3R3R means first 3R and then (S and 3) Repeated until convergence – which can be bad.
smooth

Value

An object of class "tukeysmooth" (which has print and summary methods) and is a vector or time series containing the smoothed values with additional attributes.

Note

Note that there are other smoothing methods which provide rather better results. These were designed for hand calculations and may be used mainly for didactical purposes.

Since R version 1.2, smooth does really implement Tukey's end-point rule correctly (see argument endrule).

kind = "3RSR" had been the default till R-1.1, but it can have very bad properties, see the examples.

Note that repeated application of smooth(*) does smooth more, for the "3RS*" kinds.

lines(sm, col = 2, lwd = 1.25)
**smooth.spline**  
*Fit a Smoothing Spline*

**Description**
Fits a cubic smoothing spline to the supplied data.

**Usage**
```
smooth.spline(x, y = NULL, w = NULL, df, spar = NULL, lambda = NULL, cv = FALSE,
  all.knots = FALSE, nknots = .nknots.smspl,
  keep.data = TRUE, df.offset = 0, penalty = 1,
  control.spar = list(), tol = 1e-6 * IQR(x), keep.stuff = FALSE)
```

`.nknots.smspl(n)`

**Arguments**
- **x**  
a vector giving the values of the predictor variable, or a list or a two-column matrix specifying x and y.
- **y**  
responses. If y is missing or NULL, the responses are assumed to be specified by x, with x the index vector.
- **w**  
onoptional vector of weights of the same length as x; defaults to all 1.
- **df**  
the desired equivalent number of degrees of freedom (trace of the smoother matrix). Must be in \((1, n_x]\), \(n_x\) the number of unique x values, see below.
- **spar**  
smoothing parameter, typically (but not necessarily) in \((0, 1]\). When spar is specified, the coefficient \(\lambda\) of the integral of the squared second derivative in the fit (penalized log likelihood) criterion is a monotone function of spar, see the details below. Alternatively lambda may be specified instead of the scale free \(\text{spar} = s\).
- **lambda**  
if desired, the internal (design-dependent) smoothing parameter \(\lambda\) can be specified instead of spar. This may be desirable for resampling algorithms such as cross validation or the bootstrap.
- **cv**  
ordinary leave-one-out (TRUE) or ‘generalized’ cross-validation (GCV) when FALSE; is used for smoothing parameter computation only when both spar and df are not specified; it is used however to determine cv.crit in the result. Setting it to NA for speedup skips the evaluation of leverages and any score.
- **all.knots**  
if TRUE, all distinct points in x are used as knots. If FALSE (default), a subset of x[] is used, specifically x[j] where the nknots indices are evenly spaced in 1:n, see also the next argument nknots.
  
  Alternatively, a strictly increasing numeric vector specifying “all the knots” to be used; must be rescaled to [0, 1] already such that it corresponds to the ans $fit$knots sequence returned, not repeating the boundary knots.
- **nknots**  
integer or function giving the number of knots to use when all.knots = FALSE. If a function (as by default), the number of knots is nknots(nx). By default using .nknots.smspl(), for \(n_x > 49\) this is less than \(n_x\), the number of unique x values, see the Note.
smooth.spline

keep.data logical specifying if the input data should be kept in the result. If TRUE (as per default), fitted values and residuals are available from the result.

df.offset allows the degrees of freedom to be increased by df.offset in the GCV criterion.

penalty the coefficient of the penalty for degrees of freedom in the GCV criterion.

control.spar optional list with named components controlling the root finding when the smoothing parameter spar is computed, i.e., missing or NULL, see below.

Note that this is partly experimental and may change with general spar computation improvements!

low: lower bound for spar; defaults to -1.5 (used to implicitly default to 0 in R versions earlier than 1.4).

high: upper bound for spar; defaults to +1.5.

tol: the absolute precision (tolerance) used; defaults to 1e-4 (formerly 1e-3).

tol: a tolerance for sameness or uniqueness of the x values. The values are binned into bins of size tol and values which fall into the same bin are regarded as the same. Must be strictly positive (and finite).

keep.stuff an experimental logical indicating if the result should keep extras from the internal computations. Should allow to reconstruct the X matrix and more.

n for .nknots.smpl; typically the number of unique x values (aka nx).

Details

Neither x nor y are allowed to containing missing or infinite values.

The x vector should contain at least four distinct values. ‘Distinct’ here is controlled by tol: values which are regarded as the same are replaced by the first of their values and the corresponding y and w are pooled accordingly.

Unless lambda has been specified instead of spar, the computational λ used (as a function of s = spar) is λ = r · 256^{3s-1} where r = tr(X’WX)/tr(Σ), Σ is the matrix given by Σ_{ij} = \int B_i''(t)B_j''(t)dt, X is given by X_{ij} = B_j(x_i), W is the diagonal matrix of weights (scaled such that its trace is n, the original number of observations) and B_k(.) is the k-th B-spline.

Note that with these definitions, f_i = f(x_i), and the B-spline basis representation f = Xc (i.e., c is the vector of spline coefficients), the penalized log likelihood is L = (y - f)'W(y - f) + \lambda c'Σc, and hence c is the solution of the (ridge regression) (X'WX + \lambda Σ)c = X'Wy.

If spar and lambda are missing or NULL, the value of df is used to determine the degree of smoothing. If df is missing as well, leave-one-out cross-validation (ordinary or ‘generalized’ as determined by cv) is used to determine \lambda.

Note that from the above relation, spar is s = s0 + 0.0601 · log λ.

Note however that currently the results may become very unreliable for spar values smaller than about -1 or -2. The same may happen for values larger than 2 or so. Don’t think of setting spar or the controls low and high outside such a safe range, unless you know what you are doing! Similarly, specifying lambda instead of spar is delicate, notably as the range of “safe” values for lambda is not scale-invariant and hence entirely data dependent.
The ‘generalized’ cross-validation method GCV will work correctly when there are duplicated points in $x$. However, it is ambiguous what leave-one-out cross-validation means with duplicated points, and the internal code uses an approximation that involves leaving out groups of duplicated points. $\text{cv} = \text{TRUE}$ is best avoided in that case.

**Value**

An object of class "smooth.spline" with components

- $x$ the distinct $x$ values in increasing order, see the ‘Details’ above.
- $y$ the fitted values corresponding to $x$.
- $w$ the weights used at the unique values of $x$.
- $\text{yin}$ the $y$ values used at the unique $y$ values.
- $\text{tol}$ the $\text{tol}$ argument (whose default depends on $x$).
- $\text{data}$ only if $\text{keep.data} = \text{TRUE}$: itself a list with components $x$, $y$ and $w$ of the same length. These are the original $(x_i, y_i, w_i), i = 1, \ldots, n$, values where $\text{data}$ may have repeated values and hence be longer than the above $x$ component; see details.
- $n$ an integer; the (original) sample size.
- $\text{lev}$ (when $\text{cv}$ was not $\text{NA}$) leverages, the diagonal values of the smoother matrix.
- $\text{cv}$ the $\text{cv}$ argument used; i.e., FALSE, TRUE, or NA.
- $\text{cv.crit}$ cross-validation score, ‘generalized’ or true, depending on $\text{cv}$. The CV score is often called “PRESS” (and labeled on $\text{print()}$), for ‘PREdiction Sum of Squares’. Note that this is not the same as the (CV or GCV) score which is minimized during fitting (and returned in $\text{crit}$), e.g., in the case of $\text{nx} < n$ (where $\text{nx}$ is the number of unique $x$ values).
- $\text{pen.crit}$ the penalized criterion, a non-negative number; simply the (weighted) residual sum of squares (RSS), $\sum(w \times \text{residuals}()^2)$.
- $\text{crit}$ the criterion value minimized in the underlying Fortran routine ‘sslvrg’. When $\text{df}$ has been specified, the criterion is $3 + (\text{tr}(S\lambda) - \text{df})^2$, where the 3+ is there for numerical (and historical) reasons.
- $\text{df}$ equivalent degrees of freedom used. Note that (currently) this value may become quite imprecise when the true $\text{df}$ is between 1 and 2.
- $\text{spar}$ the value of $\text{spar}$ computed or given, unless it has been given as $c(\lambda = \ast)$, when it set to NA here.
- $\text{ratio}$ (when $\text{spar}$ above is not NA), the value $r$, the ratio of two matrix traces.
- $\lambda$ the value of $\lambda$ corresponding to $\text{spar}$, see the details above.
- $\text{iparms}$ named integer(3) vector where $\text{..}$.ipars["iter"] gives number of spar computing iterations used.
- $\text{auxMat}$ experimental; when $\text{keep.stuff}$ was true, a “flat” numeric vector containing parts of the internal computations.
- $\text{fit}$ list for use by $\text{predict.smooth.spline}$, with components
  - $\text{knot}$ the knot sequence (including the repeated boundary knots), scaled into $[0, 1]$ (via $\text{min}$ and $\text{range}$).
  - $\text{nk}$: number of coefficients or number of ‘proper’ knots plus 2.
  - $\text{coef}$: coefficients for the spline basis used.
  - $\text{min}$, $\text{range}$: numbers giving the corresponding quantities of $x$.
- $\text{call}$ the matched call.

$\text{method}(\text{class} = \text{"smooth.spline"})$ shows a $\text{hatvalues}()$ method based on the $\text{lev}$ vector above.
smooth.spline

Note

The number of unique x values, \( nx = n_x \), are determined by the tol argument, equivalently to

\[
 nx <- \text{length}(x) - \sum(\text{duplicated( round((x - \text{mean}(x)) / tol) }))
\]

The default all.knots = FALSE and nknots = .nknots.smspl, entails using only \( O(n_x^{0.2}) \) knots instead of \( n_x \) for \( n_x > 49 \). This cuts speed and memory requirements, but not drastically anymore since R version 1.5.1 where it is only \( O(n_k) + O(n) \) where \( n_k \) is the number of knots.

In this case where not all unique x values are used as knots, the result is a regression spline rather than a smoothing spline in the strict sense, but very close unless a small smoothing parameter (or large df) is used.

Author(s)

R implementation by B. D. Ripley and Martin Maechler (spar/lambda, etc).

Source

This function is based on code in the GAMFIT Fortran program by T. Hastie and R. Tibshirani (originally taken from http://lib.stat.cmu.edu/general/gamfit) which makes use of spline code by Finbarr O’Sullivan. Its design parallels the smooth.spline function of Chambers & Hastie (1992).

References

predict.smooth.spline for evaluating the spline and its derivatives.

Examples

```r
require(graphics)
plot(dist ~ speed, data = cars, main = "data(cars) & smoothing splines")
cars.spl <- with(cars, smooth.spline(speed, dist))
cars.spl
## This example has duplicate points, so avoid cv = TRUE
lines(cars.spl, col = "blue")
ss10 <- smooth.spline(cars[,"speed"], cars[,"dist"], df = 10)
lines(ss10, lty = 2, col = "red")
legend(5,120, c(paste("default [C.V.] => df =",round(cars.spl$df,1)),
"s( * , df = 10)"), col = c("blue","red"), lty = 1:2,
bg = "bisque")

## Residual (Tukey Anscombe) plot:
plot(residuals(cars.spl) ~ fitted(cars.spl))
abline(h = 0, col = "gray")
```
## consistency check:

```r
cars.spl <- smooth.spline(cars)  # GCV
fitted(cars.spl) + residuals(cars.spl)
```

## The chosen inner knots in original x-scale:

```r
with(cars.spl$fit, min + range * knot[-c(1:3, nk+1 +1:3)]) # == unique(cars$speed)
```

## Visualize the behavior of .nknots.smspl()

```r
nKnots <- Vectorize(.nknots.smspl) ; c.. <- adjustcolor("gray20",.5)
curve(nKnots, 1, 250, n=250)
abline(0,1, lty=2, col=c..); text(90,90,"y = x", col=c.., adj=-.25)
abline(h=100,lty=2); abline(v=200, lty=2)
```

```r
n <- c(1:799, seq(800, 3490, by=10), seq(3500, 10000, by = 50))
plot(n, nKnots(n), type="l", main = "Vectorize(.nknots.smspl) (n)"
abline(0,1, lty=2, col=c..); text(180,180,"y = x", col=c..)
n0 <- c(50, 200, 800, 3200); c0 <- adjustcolor("blue3", .5)
lines(n0, nKnots(n0), type="h", col=c0)
axis(1, at=n0, line=-2, col.ticks=c0, col=NA, col.axis=c0)
axis(4, at=.nknots.smspl(10000), line=-.5, col=c..,col.axis=c.., las=1)
```

###-- artificial example

```r
y18 <- c(1:3, 5, 4, 7:3, 2*(2:5), rep(10, 4))
xx <- seq(1, length(y18), length.out = 201)
s2 <- smooth.spline(y18) # GCV
(s02 <- smooth.spline(y18, spar = 0.2))
s02. <- smooth.spline(y18, spar = 0.2, cv = NA)
plot(y18, main = deparse(s2$call), col.main = 2)
lines(s2, col = "gray"); lines(predict(s2, xx), col = 2)
lines(predict(s02, xx), col = 3); mtext(deparse(s02$call), col = 3)
```

### Specifying 'lambda' instead of usual spar :

```r
(s2. <- smooth.spline(y18, lambda = s2$lambda, tol = s2$tol))
```

### The following shows the problematic behavior of 'spar' searching:

```r
(s2 <- smooth.spline(y18, control =
  list(trace = TRUE, tol = 1e-6, low = -1.5)))
(s2m <- smooth.spline(y18, cv = TRUE, control =
  list(trace = TRUE, tol = 1e-6, low = -1.5)))
```

## smoothEnds

Smooth end points of a vector y using subsequently smaller medians and Tukey's end point rule at the very end. (of odd span),

**smoothEnds(y, k = 3)**
smoothEnds

Arguments

y  dependent variable to be smoothed (vector).
k  width of largest median window; must be odd.

Details

smoothEnds is used to only do the 'end point smoothing', i.e., change at most the observations closer to the beginning/end than half the window k. The first and last value are computed using Tukey's end point rule, i.e., \( \text{sm}[1] = \text{median}(y[1], \text{sm}[2], 3*\text{sm}[2] - 2*\text{sm}[3], \text{na.rm}=\text{TRUE}) \).

In R versions 3.6.0 and earlier, missing values (NA) in y typically lead to an error, whereas now the equivalent of median(\*, na.rm=TRUE) is used.

Value

vector of smoothed values, the same length as y.

## With missing values (for R >= 3.6.1): yN <- y; yN[c(2,40)] <- NA rN <- sapply(eRules, function(R) runmed(yN, 7, endrule=R)) matlines(rN, type = "b", pch = 4, lwd = 3, lty=2,
  col = adjustcolor(c("red", "orange4", "orange1"), 0.5))
sortedXyData

Create a sortedXyData Object

Description

This is a constructor function for the class of sortedXyData objects. These objects are mostly used in the initial function for a self-starting nonlinear regression model, which will be of the selfStart class.

Usage

sortedXyData(x, y, data)

Arguments

x
a numeric vector or an expression that will evaluate in data to a numeric vector

y
a numeric vector or an expression that will evaluate in data to a numeric vector

data
an optional data frame in which to evaluate expressions for x and y, if they are given as expressions

Value

A sortedXyData object. This is a data frame with exactly two numeric columns, named x and y. The rows are sorted so the x column is in increasing order. Duplicate x values are eliminated by averaging the corresponding y values.

Author(s)

José Pinheiro and Douglas Bates

Examples

DNase.2 <- DNase[ DNase$Run == "2", ]
sortedXyData( expression(log(conc)), expression(density), DNase.2 )
spec.ar

Estimate Spectral Density of a Time Series from AR Fit

Description
Fits an AR model to \( x \) (or uses the existing fit) and computes (and by default plots) the spectral density of the fitted model.

Usage

\[
\text{spec.ar}(x, \text{n.freq}, \text{order} = \text{NULL}, \text{plot} = \text{TRUE}, \text{na.action} = \text{na.fail}, \\
\text{method} = \text{"yule-walker"}, \ldots)
\]

Arguments

\( x \) A univariate (not yet:or multivariate) time series or the result of a fit by \text{ar}.
\( \text{n.freq} \) The number of points at which to plot.
\( \text{order} \) The order of the AR model to be fitted. If omitted, the order is chosen by AIC.
\( \text{plot} \) Plot the periodogram?
\( \text{na.action} \) NA action function.
\( \text{method} \) method for \text{ar} fit.
\( \ldots \) Graphical arguments passed to \text{plot.spec}.

Value
An object of class "spec". The result is returned invisibly if \text{plot} is true.

Warning
Some authors, for example Thomson (1990), warn strongly that AR spectra can be misleading.

Note
The multivariate case is not yet implemented.

References

See Also
\text{ar}, \text{spectrum}. 
Examples

```r
require(graphics)

spec.ar(lh)

spec.ar(ldeaths)
spec.ar(ldeaths, method = "burg")

spec.ar(log(lynx))
spec.ar(log(lynx), method = " burg", add = TRUE, col = "purple")
spec.ar(log(lynx), method = "mle", add = TRUE, col = "forest green")
spec.ar(log(lynx), method = "ols", add = TRUE, col = "blue")
```

DESCRIPTION

`spec.pgram` calculates the periodogram using a fast Fourier transform, and optionally smooths the result with a series of modified Daniell smoothers (moving averages giving half weight to the end values).

Usage

```r
spec.pgram(x, spans = NULL, kernel, taper = 0.1, pad = 0, fast = TRUE, demean = FALSE, detrend = TRUE, plot = TRUE, na.action = na.fail, ...)
```

Arguments

- **x**: univariate or multivariate time series.
- **spans**: vector of odd integers giving the widths of modified Daniell smoothers to be used to smooth the periodogram.
- **kernel**: alternatively, a kernel smoother of class "tskernel".
- **taper**: specifies the proportion of data to taper. A split cosine bell taper is applied to this proportion of the data at the beginning and end of the series.
- **pad**: proportion of data to pad. Zeros are added to the end of the series to increase its length by the proportion pad.
- **fast**: logical; if TRUE, pad the series to a highly composite length.
- **demean**: logical. If TRUE, subtract the mean of the series.
- **detrend**: logical. If TRUE, remove a linear trend from the series. This will also remove the mean.
- **plot**: plot the periodogram?
- **na.action**: NA action function.
- **...**: graphical arguments passed to `plot.spec`.
Details

The raw periodogram is not a consistent estimator of the spectral density, but adjacent values are asymptotically independent. Hence a consistent estimator can be derived by smoothing the raw periodogram, assuming that the spectral density is smooth.

The series will be automatically padded with zeros until the series length is a highly composite number in order to help the Fast Fourier Transform. This is controlled by the `fast` and not the `pad` argument.

The periodogram at zero is in theory zero as the mean of the series is removed (but this may be affected by tapering): it is replaced by an interpolation of adjacent values during smoothing, and no value is returned for that frequency.

Value

A list object of class "spec" (see `spectrum`) with the following additional components:

- `kernel` The kernel argument, or the kernel constructed from spans.
- `df` The distribution of the spectral density estimate can be approximated by a (scaled) chi square distribution with `df` degrees of freedom.
- `bandwidth` The equivalent bandwidth of the kernel smoother as defined by Bloomfield (1976, page 201).
- `taper` The value of the taper argument.
- `pad` The value of the pad argument.
- `detrend` The value of the detrend argument.
- `demean` The value of the demean argument.

The result is returned invisibly if `plot` is true.

spectrum(mdeaths, spans = c(3,3))
```
spec.taper

Taper a Time Series by a Cosine Bell

Description

Apply a cosine-bell taper to a time series.

Usage

spec.taper(x, p = 0.1)

Arguments

x

A univariate or multivariate time series

p

The proportion to be tapered at each end of the series, either a scalar (giving the proportion for all series) or a vector of the length of the number of series (giving the proportion for each series).

Details

The cosine-bell taper is applied to the first and last p[1] observations of time series x[, 1].

Value

A new time series object.

See Also

spec.pgram, cpgram
**spectrum**

*Spectral Density Estimation*

**Description**

The *spectrum* function estimates the spectral density of a time series.

**Usage**

```r
spectrum(x, ..., method = c("pgram", "ar"))
```

**Arguments**

- `x`: A univariate or multivariate time series.
- `method`: String specifying the method used to estimate the spectral density. Allowed methods are "pgram" (the default) and "ar". Can be abbreviated.
- `...`: Further arguments to specific spec methods or `plot.spec`.

**Details**

`spectrum` is a wrapper function which calls the methods `spec.pgram` and `spec.ar`.

The spectrum here is defined (for historical compatibility) with scaling $1/\text{frequency}(x)$. This makes the spectral density a density over the range $(-\text{frequency}(x)/2, +\text{frequency}(x)/2]$, whereas a more common scaling is $2\pi$ and range $(-0.5, 0.5]$ (e.g., Bloomfield) or 1 and range $(-\pi, \pi]$.

If available, a confidence interval will be plotted by `plot.spec`: this is asymmetric, and the width of the centre mark indicates the equivalent bandwidth.

**Value**

An object of class "spec", which is a list containing at least the following components:

- `freq`: vector of frequencies at which the spectral density is estimated. (Possibly approximate Fourier frequencies.) The units are the reciprocal of cycles per unit time (and not per observation spacing): see 'Details' below.
- `spec`: Vector (for univariate series) or matrix (for multivariate series) of estimates of the spectral density at frequencies corresponding to `freq`.
- `coh`: NULL for univariate series. For multivariate time series, a matrix containing the squared coherency between different series. Column $i + (j - 1) \times (j - 2)/2$ of `coh` contains the squared coherency between columns $i$ and $j$ of `x`, where $i < j$.
- `phase`: NULL for univariate series. For multivariate time series a matrix containing the cross-spectrum phase between different series. The format is the same as `coh`.
- `series`: The name of the time series.
- `snames`: For multivariate input, the names of the component series.
- `method`: The method used to calculate the spectrum.

The result is returned invisibly if `plot` is true.
The default plot for objects of class "spec" is quite complex, including an error bar and default title, subtitle and axis labels. The defaults can all be overridden by supplying the appropriate graphical parameters.

---

**splinefun**

**Interpolating Splines**

**Description**
Perform cubic (or Hermite) spline interpolation of given data points, returning either a list of points obtained by the interpolation or a *function* performing the interpolation.
**splinefun**

**Usage**

`splinefun(x, y = NULL,`  
method = c("fmm", "periodic", "natural", "monoH.FC", "hyman"),  
ties = mean)

`spline(x, y = NULL, n = 3*length(x), method = "fmm",`  
`xmin = min(x), xmax = max(x), xout, ties = mean)

`splinefunH(x, y, m)

**Arguments**

- **x, y**: vectors giving the coordinates of the points to be interpolated. Alternatively a single plotting structure can be specified: see `xy.coords`.  
  - y must be increasing or decreasing for method = "hyman".

- **m** (for `splinefunH()`): vector of slopes \( m_i \) at the points \((x_i, y_i)\); these together determine the Hermite “spline” which is piecewise cubic, (only) once differentiable continuously.

- **method**: specifies the type of spline to be used. Possible values are "fmm", "natural", "periodic", "monoH.FC" and "hyman". Can be abbreviated.

- **n**: if `xout` is left unspecified, interpolation takes place at \( n \) equally spaced points spanning the interval \([\text{xmin}, \text{xmax}]\).

- **xmin, xmax**: left-hand and right-hand endpoint of the interpolation interval (when `xout` is unspecified).

- **xout**: an optional set of values specifying where interpolation is to take place.

- **ties**: handling of tied \( x \) values. The string "ordered" or a function (or the name of a function) taking a single vector argument and returning a single number or a length-2 list of both, see `approx` and its ‘Details’ section, and the example below.

**Details**

The inputs can contain missing values which are deleted, so at least one complete \((x, y)\) pair is required. If `method = "fmm"`, the spline used is that of Forsythe, Malcolm and Moler (an exact cubic is fitted through the four points at each end of the data, and this is used to determine the end conditions). Natural splines are used when `method = "natural"`, and periodic splines when `method = "periodic".

The method "monoH.FC" computes a monotone Hermite spline according to the method of Fritsch and Carlson. It does so by determining slopes such that the Hermite spline, determined by \((x_i, y_i, m_i)\), is monotone (increasing or decreasing) iff the data are.

Method "hyman" computes a monotone cubic spline using Hyman filtering of an `method = "fmm"` fit for strictly monotonic inputs.

These interpolation splines can also be used for extrapolation, that is prediction at points outside the range of \( x \). Extrapolation makes little sense for `method = "fmm"`; for natural splines it is linear using the slope of the interpolating curve at the nearest data point.

**Value**

`spline` returns a list containing components `x` and `y` which give the ordinates where interpolation took place and the interpolated values.
splinefun returns a function with formal arguments \texttt{x} and \texttt{deriv}, the latter defaulting to zero. This function can be used to evaluate the interpolating cubic spline (\texttt{deriv = 0}), or its derivatives (\texttt{deriv} = 1, 2, 3) at the points \texttt{x}, where the spline function interpolates the data points originally specified. It uses data stored in its environment when it was created, the details of which are subject to change.

**Warning**

The value returned by \texttt{splinefun} contains references to the code in the current version of R: it is not intended to be saved and loaded into a different R session. This is safer in R \geq 3.0.0.

**Author(s)**

R Core Team.

Simon Wood for the original code for Hyman filtering.

## here, and both are 'much worse' than the regular fmm spline.

SSasym

Self-Starting nls Asymptotic Model

Description

This selfStart model evaluates the asymptotic regression function and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters Asym, R0, and lrc for a given set of data.

Note that SSweibull() generalizes this asymptotic model with an extra parameter.

Usage

SSasymp(input, Asym, R0, lrc)

Arguments

input a numeric vector of values at which to evaluate the model.
Asym a numeric parameter representing the horizontal asymptote on the right side (very large values of input).
R0 a numeric parameter representing the response when input is zero.
lrc a numeric parameter representing the natural logarithm of the rate constant.
```
SSasymp

Value

a numeric vector of the same length as input. It is the value of the expression
\( \text{Asym} + (\text{R0} - \text{Asym}) \times \exp(-\exp(\text{lrc}) \times \text{input}) \). If all of the arguments \( \text{Asym}, \text{R0}, \) and \( \text{lrc} \) are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

Self-Starting nls Asymptotic Model with an Offset

Description

This selfStart model evaluates an alternative parametrization of the asymptotic regression function and the gradient with respect to those parameters. It has an initial attribute that creates initial estimates of the parameters Asym, lrc, and c0.

Usage

SSasympOff(input, Asym, lrc, c0)

Arguments

input  a numeric vector of values at which to evaluate the model.
Asym  a numeric parameter representing the horizontal asymptote on the right side (very large values of input).
lrc  a numeric parameter representing the natural logarithm of the rate constant.
c0  a numeric parameter representing the input for which the response is zero.

Value

a numeric vector of the same length as input. It is the value of the expression Asym*(1 - exp(-exp(lrc)*(input - c0))). If all of the arguments Asym, lrc, and c0 are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

**SSasympOrig**

**Self-Starting nls Asymptotic Model through the Origin**

### Description

This *selfStart* model evaluates the asymptotic regression function through the origin and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters **Asym** and **lrc** for a given set of data.

### Usage

```r
SSasympOrig(input, Asym, lrc)
```

### Arguments

- **input**: a numeric vector of values at which to evaluate the model.
- **Asym**: a numeric parameter representing the horizontal asymptote.
- **lrc**: a numeric parameter representing the natural logarithm of the rate constant.

### Value

A numeric vector of the same length as input. It is the value of the expression \( \text{Asym} \times (1 - \exp(-\exp(\text{lrc}) \times \text{input})) \). If all of the arguments **Asym** and **lrc** are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSbiexp   Self-Starting nls Biesponential Model

Description

This selfStart model evaluates the biexponential model function and its gradient. It has an initial attribute that creates initial estimates of the parameters A1, lrc1, A2, and lrc2.
Usage

SSbiexp(input, A1, lrc1, A2, lrc2)

Arguments

- **input**: a numeric vector of values at which to evaluate the model.
- **A1**: a numeric parameter representing the multiplier of the first exponential.
- **lrc1**: a numeric parameter representing the natural logarithm of the rate constant of the first exponential.
- **A2**: a numeric parameter representing the multiplier of the second exponential.
- **lrc2**: a numeric parameter representing the natural logarithm of the rate constant of the second exponential.

Value

A numeric vector of the same length as *input*. It is the value of the expression \( A1 \cdot \exp(-\exp(lrc1) \cdot \text{input}) + A2 \cdot \exp(-\exp(lrc2) \cdot \text{input}) \). If all of the arguments \( A1, lrc1, A2, \) and \( lrc2 \) are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

## SSD

### Description

Functions to compute matrix of residual sums of squares and products, or the estimated variance matrix for multivariate linear models.

### Usage

```r
# S3 method for class 'mlm'
SSD(object, ...)

# S3 methods for class 'SSD' and 'mlm'
estVar(object, ...)
```

### Arguments

- **object**: object of class "mlm", or "SSD" in the case of `estVar`.
- **...**: Unused

### Value

- **SSD()** returns a list of class "SSD" containing the following components
  - **SSD**: The residual sums of squares and products matrix
  - **df**: Degrees of freedom
  - **call**: Copied from object

- **estVar** returns a matrix with the estimated variances and covariances.
SSfol

Self-Starting nls First-order Compartment Model

Description

This selfStart model evaluates the first-order compartment function and its gradient. It has an initial attribute that creates initial estimates of the parameters lKe, lKa, and lCl.

Usage

SSfol(Dose, input, lKe, lKa, lCl)

Arguments

Dose  
a numeric value representing the initial dose.

input  
a numeric vector at which to evaluate the model.

lKe  
a numeric parameter representing the natural logarithm of the elimination rate constant.

lKa  
a numeric parameter representing the natural logarithm of the absorption rate constant.

lCl  
a numeric parameter representing the natural logarithm of the clearance.
Value

a numeric vector of the same length as `input`, which is the value of the expression

\[
    \text{Dose} \times \exp(lKe+lKa-lCl) \times (\exp(-\exp(lKe)\times\text{input}) - \exp(-\exp(lKa)\times\text{input})) \\
    \div (\exp(lKa) - \exp(lKe))
\]

If all of the arguments `lKe`, `lKa`, and `lCl` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

**SSfpl**

*Self-Starting nls Four-Parameter Logistic Model*

Description

This `selfStart` model evaluates the four-parameter logistic function and its gradient. It has an initial attribute computing initial estimates of the parameters `A`, `B`, `xmid`, and `scal` for a given set of data.

Usage

`SSfpl(input, A, B, xmid, scal)`

Arguments

- `input` a numeric vector of values at which to evaluate the model.
- `A` a numeric parameter representing the horizontal asymptote on the left side (very small values of `input`).
- `B` a numeric parameter representing the horizontal asymptote on the right side (very large values of `input`).
- `xmid` a numeric parameter representing the `input` value at the inflection point of the curve. The value of SSfpl will be midway between `A` and `B` at `xmid`.
- `scal` a numeric scale parameter on the input axis.
Value

a numeric vector of the same length as input. It is the value of the expression
\( A + (B - A) / (1 + \exp((xmid - input) / scal)) \). If all of the arguments \( A, B, xmid, \) and \( scal \) are names of
objects, the gradient matrix with respect to these names is attached as an attribute named \( \text{gradient} \).

SSgompertz

Self-Starting nls Gompertz Growth Model

Description

This selfStart model evaluates the Gompertz growth model and its gradient. It has an initial attribute that creates initial estimates of the parameters Asym, b2, and b3.

Usage

SSgompertz(x, Asym, b2, b3)

Arguments

- x: a numeric vector of values at which to evaluate the model.
- Asym: a numeric parameter representing the asymptote.
- b2: a numeric parameter related to the value of the function at x = 0
- b3: a numeric parameter related to the scale the x axis.

Value

a numeric vector of the same length as input. It is the value of the expression Asym*exp(-b2*b3^x). If all of the arguments Asym, b2, and b3 are names of objects the gradient matrix with respect to these names is attached as an attribute named gradient.

SSlogis

Self-Starting nls Logistic Model

Description

This selfStart model evaluates the logistic function and its gradient. It has an initial attribute that creates initial estimates of the parameters Asym, xmid, and scal. In R 3.4.2 and earlier, that init function failed when min(input) was exactly zero.

Usage

SSlogis(input, Asym, xmid, scal)

Arguments

input a numeric vector of values at which to evaluate the model.
Asym a numeric parameter representing the asymptote.
xmid a numeric parameter representing the x value at the inflection point of the curve. The value of SSlogis will be Asym/2 at xmid.
scal a numeric scale parameter on the input axis.

Value

a numeric vector of the same length as input. It is the value of the expression Asym/(1+exp((xmid-input)/scal)). If all of the arguments Asym, xmid, and scal are names of objects the gradient matrix with respect to these names is attached as an attribute named gradient.

SSmicmen

Self-Starting nls Michaelis-Menten Model

Description

This selfStart model evaluates the Michaelis-Menten model and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters Vm and K

Usage

SSmicmen(input, Vm, K)

Arguments

input a numeric vector of values at which to evaluate the model.
Vm a numeric parameter representing the maximum value of the response.
K a numeric parameter representing the input value at which half the maximum response is attained. In the field of enzyme kinetics this is called the Michaelis parameter.
SSmicmen

Value

A numeric vector of the same length as input. It is the value of the expression \( \frac{V_m \times \text{input}}{(K + \text{input})} \). If both the arguments \( V_m \) and \( K \) are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

SSweibull

Self-Starting nls Weibull Growth Curve Model

Description

This selfStart model evaluates the Weibull model for growth curve data and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters \(\text{Asym}, \text{Drop}, \text{lrc},\) and \(\text{pwr}\) for a given set of data.

Usage

\[
\text{SSweibull}(x, \text{Asym}, \text{Drop}, \text{lrc}, \text{pwr})
\]

Arguments

- \(x\): a numeric vector of values at which to evaluate the model.
- \(\text{Asym}\): a numeric parameter representing the horizontal asymptote on the right side (very small values of \(x\)).
- \(\text{Drop}\): a numeric parameter representing the change from \(\text{Asym}\) to the \(y\) intercept.
- \(\text{lrc}\): a numeric parameter representing the natural logarithm of the rate constant.
- \(\text{pwr}\): a numeric parameter representing the power to which \(x\) is raised.

Details

This model is a generalization of the SSasymp model in that it reduces to SSasymp when \(\text{pwr}\) is unity.

Value

A numeric vector of the same length as \(x\). It is the value of the expression \(\text{Asym}-\text{Drop} \times \exp(-\exp(\text{lrc}) \times x^{\text{pwr}})\). If all of the arguments \(\text{Asym}, \text{Drop}, \text{lrc},\) and \(\text{pwr}\) are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

\begin{verbatim}
start                          Encode the Terminal Times of Time Series
\end{verbatim}

Description

Extract and encode the times the first and last observations were taken. Provided only for compatibility with \texttt{S} version 2.

Usage

\begin{verbatim}
start(x, ...)  
end(x, ...)
\end{verbatim}

Arguments

\begin{verbatim}
x                  a univariate or multivariate time-series, or a vector or matrix.
...
extra arguments for future methods.
\end{verbatim}

Details

These are generic functions, which will use the \texttt{tsp} attribute of \texttt{x} if it exists. Their default methods decode the start time from the original time units, so that for a monthly series 1995.5 is represented as \texttt{c(1995, 7)}. For a series of frequency \texttt{f}, time \texttt{n+i/f} is presented as \texttt{c(n, i+1)} (even for \texttt{i = 0} and \texttt{f = 1}).

Warning

The representation used by \texttt{start} and \texttt{end} has no meaning unless the frequency is supplied.

See Also

\texttt{ts, time, tsp}.  

Description

This is a utility function, used in \texttt{lm} and \texttt{glm} methods for \texttt{anova(..., test \neq NULL)} and should not be used by the average user.

Usage

\begin{verbatim}
stat.anova(table, test = c("Rao", "LRT", "Chisq", "F", "Cp"),
           scale, df.scale, n)
\end{verbatim}

Arguments

- \texttt{table}: numeric matrix as results from \texttt{anova.glm(..., test = NULL)}.
- \texttt{test}: a character string, partially matching one of "Rao", "LRT", "Chisq", "F" or "Cp".
- \texttt{scale}: a residual mean square or other scale estimate to be used as the denominator in an F test.
- \texttt{df.scale}: degrees of freedom corresponding to \texttt{scale}.
- \texttt{n}: number of observations.

Value

A matrix which is the original \texttt{table}, augmented by a column of test statistics, depending on the \texttt{test} argument.

References

See Also

\texttt{anova.lm}, \texttt{anova.glm}.

Examples

\begin{verbatim}
##-- Continued from '?glm':
print(ag <- anova(glm.D93))
stat.anova(ag$table, test = "Cp",
           scale = sum(resid(glm.D93, "pearson")^2)/4,
           df.scale = 4, n = 9)
\end{verbatim}
Description

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as the next release.

Details

There are currently no deprecated functions in this package.

step

Choose a model by AIC in a Stepwise Algorithm

Description

Select a formula-based model by AIC.

Usage

step(object, scope, scale = 0, direction = c("both", "backward", "forward"), trace = 1, keep = NULL, steps = 1000, k = 2, ...)

Arguments

object an object representing a model of an appropriate class (mainly "lm" and "glm"). This is used as the initial model in the stepwise search.

scope defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components upper and lower, both formulae. See the details for how to specify the formulae and how they are used.

scale used in the definition of the AIC statistic for selecting the models, currently only for lm, aov and glm models. The default value, 0, indicates the scale should be estimated; see extractAIC.

direction the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the scope argument is missing the default for direction is "backward". Values can be abbreviated.

trace if positive, information is printed during the running of step. Larger values may give more detailed information.

keep a filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically keep will select a subset of the components of the object and return them. The default is not to keep anything.
steps the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.

k the multiple of the number of degrees of freedom used for the penalty. Only $k = 2$ gives the genuine AIC: $k = \log(n)$ is sometimes referred to as BIC or SBC.

... any additional arguments to `extractAIC`.

Details

step uses `add1` and `drop1` repeatedly; it will work for any method for which they work, and that is determined by having a valid method for extractAIC. When the additive constant can be chosen so that AIC is equal to Mallows’ $C_p$, this is done and the tables are labelled appropriately.

The set of models searched is determined by the `scope` argument. The right-hand-side of its lower component is always included in the model, and right-hand-side of the model is included in the upper component. If `scope` is a single formula, it specifies the upper component, and the lower model is empty. If `scope` is missing, the initial model is used as the upper model.

Models specified by `scope` can be templates to update object as used by `update.formula`. So using `.` in a `scope` formula means ‘what is already there’, with `.^2` indicating all interactions of existing terms.

There is a potential problem in using `glm` fits with a variable scale, as in that case the deviance is not simply related to the maximized log-likelihood. The "glm" method for function `extractAIC` makes the appropriate adjustment for a gaussian family, but may need to be amended for other cases. (The binomial and poisson families have fixed scale by default and do not correspond to a particular maximum-likelihood problem for variable scale.)

Value

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the `keep=` argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding `lm`, `aov` and `survreg` fits, for example).

Warning

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and R’s default of `na.action = na.omit` is used. We suggest you remove the missing values first.

Calls to the function `nobs` are used to check that the number of observations involved in the fitting process remains unchanged.

Note

This function differs considerably from the function in S, which uses a number of approximations and does not in general compute the correct AIC.

This is a minimal implementation. Use `stepAIC` in package MASS for a wider range of object classes.
stepfun

Author(s)

B. D. Ripley: step is a slightly simplified version of stepAIC in package MASS (Venables & Ripley, 2002 and earlier editions).

The idea of a step function follows that described in Hastie & Pregibon (1992); but the implementation in R is more general.

stepfun

Step Functions - Creation and Class

Description

Given the vectors \((x_1, \ldots, x_n)\) and \((y_0, y_1, \ldots, y_n)\) (one value more!), \texttt{stepfun}(x, y, \ldots) returns an interpolating ‘step’ function, say \(fn\). I.e., \(fn(t) = c_i\) (constant) for \(t \in (x_i, x_{i+1})\) and at the abscissa values, if (by default) \texttt{right} = FALSE, \(fn(x_i) = y_i\) and for \texttt{right} = TRUE, \(fn(x_i) = y_{i-1}\), for \(i = 1, \ldots, n\).

The value of the constant \(c_i\) above depends on the ‘continuity’ parameter \(f\). For the default, \texttt{right} = FALSE, \(f = 0\), \(fn\) is a \texttt{cadlag} function, i.e., continuous from the right, limits from the left, so that the function is piecewise constant on intervals that include their left endpoint. In general, \(c_i\) is interpolated in between the neighbouring \(y\) values, \(c_i = (1-f)y_i + f \cdot y_{i+1}\). Therefore, for non-0 values of \(f\), \(fn\) may no longer be a proper step function, since it can be discontinuous from both sides, unless \texttt{right} = TRUE, \(f = 1\) which is left-continuous (i.e., constant pieces contain their right endpoint).
Usage

```r
stepfun(x, y, f = as.numeric(right), ties = "ordered", 
       right = FALSE)
```

```r
is.stepfun(x)
knots(Fn, ...)
```

```r
## S3 method for class 'stepfun'
print(x, digits = getOption("digits") - 2, ...)
```

```r
## S3 method for class 'stepfun'
summary(object, ...)
```

Arguments

- **x** numeric vector giving the knots or jump locations of the step function for `stepfun()`. For the other functions, `x` is as `object` below.
- **y** numeric vector one longer than `x`, giving the heights of the function values between the `x` values.
- **f** a number between 0 and 1, indicating how interpolation outside the given `x` values should happen. See `approxfun`.
- **ties** Handling of tied `x` values. Either a function or the string "ordered". See `approxfun`.
- **right** logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa.
- **Fn, object** an R object inheriting from "stepfun".
- **digits** number of significant digits to use, see `print`.
- **...** potentially further arguments (required by the generic).

Value

A function of class "stepfun", say `fn`.

There are methods available for summarizing ("summary(.)"), representing ("print(.)") and plotting ("plot(.)", see `plot.stepfun") "stepfun" objects.

The **environment** of `fn` contains all the information needed:

- "x", "y" the original arguments
- "n" number of knots (x values)
- "f" continuity parameter
- "yleft", "yright" the function values outside the knots
- "method" (always == "constant", from `approxfun(.)`).

The knots are also available via `knots(fn)`.
Note

The objects of class "stepfun" are not intended to be used for permanent storage and may change structure between versions of R (and did at R 3.0.0). They can usually be re-created by

```r
eval(attr(old_obj, "call"), environment(old_obj))
```

since the data used is stored as part of the object’s environment.

stopifnot(identical(y0[-1], sfun0(1:3)), # right = FALSE
          identical(y0[-4], sfun1c(1:3))) # right = TRUE
```

stl

Seasonal Decomposition of Time Series by Loess

Description

Decompose a time series into seasonal, trend and irregular components using loess, acronym STL.
Usage

stl(x, s.window, s.degree = 0,
    t.window = NULL, t.degree = 1,
    l.window = nextodd(period), l.degree = t.degree,
    s.jump = ceiling(s.window/10),
    t.jump = ceiling(t.window/10),
    l.jump = ceiling(l.window/10),
    robust = FALSE,
    inner = if(robust) 1 else 2,
    outer = if(robust) 15 else 0,
    na.action = na.fail)

Arguments

x          univariate time series to be decomposed. This should be an object of class "ts"
           with a frequency greater than one.
s.window   either the character string "periodic" or the span (in lags) of the loess win-
           dow for seasonal extraction, which should be odd and at least 7, according to
           Cleveland et al. This has no default.
s.degree   degree of locally-fitted polynomial in seasonal extraction. Should be zero or
           one.
t.window   the span (in lags) of the loess window for trend extraction, which
           should be odd. If NULL, the default, nextodd(ceiling((1.5*period) /
           (1-(1.5/s.window)))) is taken.
t.degree   degree of locally-fitted polynomial in trend extraction. Should be zero or one.
l.window   the span (in lags) of the loess window of the low-pass filter used for each
           subseries. Defaults to the smallest odd integer greater than or equal to
           frequency(x) which is recommended since it prevents competition between
           the trend and seasonal components. If not an odd integer its given value is in-
           creased to the next odd one.
l.degree   degree of locally-fitted polynomial for the subseries low-pass filter. Must be 0
           or 1.
s.jump, t.jump, l.jump
           integers at least one to increase speed of the respective smoother. Linear inter-
           polation happens between every *, jump-th value.
robust     logical indicating if robust fitting be used in the loess procedure.
inner      integer; the number of ‘inner’ (backfitting) iterations; usually very few (2) iter-
           ations suffice.
outer      integer; the number of ‘outer’ robustness iterations.
na.action  action on missing values.

Details

The seasonal component is found by loess smoothing the seasonal sub-series (the series of all January
values, ...); if s.window = "periodic" smoothing is effectively replaced by taking the mean.
The seasonal values are removed, and the remainder smoothed to find the trend. The overall level is
removed from the seasonal component and added to the trend component. This process is iterated
a few times. The remainder component is the residuals from the seasonal plus trend fit.
Several methods for the resulting class "stl" objects, see, plot.stl.
stl

Value

stl returns an object of class "stl" with components

- `time.series`: a multiple time series with columns seasonal, trend and remainder.
- `weights`: the final robust weights (all one if fitting is not done robustly).
- `call`: the matched call.
- `win`: integer (length 3 vector) with the spans used for the "s", "t", and "l" smoothers.
- `deg`: integer (length 3) vector with the polynomial degrees for these smoothers.
- `jump`: integer (length 3) vector with the 'jumps' (skips) used for these smoothers.
- `ni`: number of inner iterations
- `no`: number of outer robustness iterations

Author(s)

B.D. Ripley; Fortran code by Cleveland et al. (1990) from 'netlib'.

References

See Also

- `plot.stl` for stl methods; `loess` in package stats (which is not actually used in stl).
- `StructTS` for different kind of decomposition.

Examples

```r
require(graphics)

plot(stl(nottem, "per"))
plot(stl(nottem, s.window = 7, t.window = 50, t.jump = 1))

plot(stl(log(co2), s.window = 21))
summary(stllc)
### linear trend, strict period.
plot(stl(log(co2), s.window = "per", t.window = 1000))

### Two STL plotted side by side :
  stmd <- stl(mdeaths, s.window = "per") # non-robust
summary(stmR <- stl(mdeaths, s.window = "per", robust = TRUE))
op <- par(mar = c(0, 4, 0, 3), oma = c(5, 0, 4, 0), mfcol = c(4, 2))
plot(stmd, set.pars = NULL, labels = NULL,
     main = "stl(mdeaths, s.w = \"per\", robust = FALSE / TRUE )")
plot(stmR, set.pars = NULL)
  # mark the 'outliers' :
  (iO <- which(stmR $ weights < 1e-8)) # 10 were considered outliers
sts <- stmR$time.series
points(time(sts)[iO], 0.8* sts[,"remainder"][iO], pch = 4, col = "red")
par(op) # reset
```
**Methods for STL Objects**

**Description**
Methods for objects of class `stl`, typically the result of `stl`. The `plot` method does a multiple figure plot with some flexibility.

There are also (non-visible) `print` and `summary` methods.

**Usage**
```
## S3 method for class 'stl'
plot(x, labels = colnames(X),
     set.pars = list(mar = c(0, 6, 0, 6), oma = c(6, 0, 4, 0),
                    tck = -0.01, mfrow = c(nplot, 1)),
     main = NULL, range.bars = TRUE, ...,
     col.range = "light gray")
```

**Arguments**
- `x` stl object.
- `labels` character of length 4 giving the names of the component time-series.
- `set.pars` settings for `par(.)` when setting up the plot.
- `main` plot main title.
- `range.bars` logical indicating if each plot should have a bar at its right side which are of equal heights in user coordinates.
- `...` further arguments passed to or from other methods.
- `col.range` colour to be used for the range bars, if plotted. Note this appears after `...` and so cannot be abbreviated.

**See Also**
- `plot.ts` and `stl`, particularly for examples.

---

**Fit Structural Time Series**

**Description**
Fit a structural model for a time series by maximum likelihood.

**Usage**
```
StructTS(x, type = c("level", "trend", "BSM"), init = NULL,
         fixed = NULL, optim.control = NULL)
```
Arguments

`x`  
a univariate numeric time series. Missing values are allowed.
`type`  
the class of structural model. If omitted, a BSM is used for a time series with `frequency(x) > 1`, and a local trend model otherwise. Can be abbreviated.
`init`  
initial values of the variance parameters.
`fixed`  
optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in `fixed` will be varied. Probably most useful for setting variances to zero.
`optim.control`  
List of control parameters for `optim`. Method "L-BFGS-B" is used.

Details

Structural time series models are (linear Gaussian) state-space models for (univariate) time series based on a decomposition of the series into a number of components. They are specified by a set of error variances, some of which may be zero.

The simplest model is the local level model specified by `type = "level"`. This has an underlying level \( \mu_t \) which evolves by

\[
\mu_{t+1} = \mu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)
\]

The observations are

\[
x_t = \mu_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)
\]

There are two parameters, \( \sigma_\xi^2 \) and \( \sigma_\epsilon^2 \). It is an ARIMA(0,1,1) model, but with restrictions on the parameter set.

The local linear trend model, `type = "trend"`, has the same measurement equation, but with a time-varying slope in the dynamics for \( \mu_t \), given by

\[
\mu_{t+1} = \mu_t + \nu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)
\]
\[
\nu_{t+1} = \nu_t + \zeta_t, \quad \zeta_t \sim N(0, \sigma_\zeta^2)
\]

with three variance parameters. It is not uncommon to find \( \sigma_\zeta^2 = 0 \) (which reduces to the local level model) or \( \sigma_\xi^2 = 0 \), which ensures a smooth trend. This is a restricted ARIMA(0,2,2) model.

The basic structural model, `type = "BSM"`, is a local trend model with an additional seasonal component. Thus the measurement equation is

\[
x_t = \mu_t + \gamma_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)
\]

where \( \gamma_t \) is a seasonal component with dynamics

\[
\gamma_{t+1} = -\gamma_t + \cdots + \gamma_{t-s+2} + \omega_t, \quad \omega_t \sim N(0, \sigma_\omega^2)
\]

The boundary case \( \sigma_\omega^2 = 0 \) corresponds to a deterministic (but arbitrary) seasonal pattern. (This is sometimes known as the ‘dummy variable’ version of the BSM.)

Value

A list of class "StructTS" with components:

`coef` the estimated variances of the components.
`loglik` the maximized log-likelihood. Note that as all these models are non-stationary this includes a diffuse prior for some observations and hence is not comparable to `arima` nor different types of structural models.
StructTS

loglik0  the maximized log-likelihood with the constant used prior to R 3.0.0, for backwards compatibility.

data    the time series x.
residuals the standardized residuals.

fitted  a multiple time series with one component for the level, slope and seasonal components, estimated contemporaneously (that is at time t and not at the end of the series).

call    the matched call.
series  the name of the series x.

code    the convergence code returned by optim.

model, model0 Lists representing the Kalman filter used in the fitting. See KalmanLike. model0 is the initial state of the filter, model its final state.

xtsp    the tsp attributes of x.

Note
Optimization of structural models is a lot harder than many of the references admit. For example, the AirPassengers data are considered in Brockwell & Davis (1996): their solution appears to be a local maximum, but nowhere near as good a fit as that produced by StructTS. It is quite common to find fits with one or more variances zero, and this can include $\sigma^2$.

References

See Also
KalmanLike, tsSmooth; stl for different kind of (seasonal) decomposition.

Examples
```r
## see also JohnsonJohnson, Nile and AirPassengers
require(graphics)
trees <- window(treering, start = 0)
(fit <- StructTS(trees, type = "level"))
plot(trees)
lines(fitted(fit), col = "green")
tsdia(fit)

(fit <- StructTS(log10(UKgas), type = "BSM"))
par(mfrow = c(4, 1))  # to give appropriate aspect ratio for next plot.
plot(log10(UKgas))
plot(cbind(fitted(fit), resids=resid(fit)), main = "UK gas consumption")
```
## keep some parameters fixed; trace optimizer:
StructTS(log10(UKgas), type = "BSM", fixed = c(0.1, 0.001, NA, NA),
optim.control = list(trace = TRUE))

---

**Summary**

**Summary of an Analysis of Variance Model**

### Description

Summarize an analysis of variance model.

### Usage

```r
## S3 method for class 'aov'
summary(object, intercept = FALSE, split,
         expand.split = TRUE, keep.zero.df = TRUE, ...)

## S3 method for class 'aovlist'
summary(object, ...)
```

### Arguments

- **object**
  An object of class "aov" or "aovlist".

- **intercept**
  logical: should intercept terms be included?

- **split**
  an optional named list, with names corresponding to terms in the model. Each component is itself a list with integer components giving contrasts whose contributions are to be summed.

- **expand.split**
  logical: should the split apply also to interactions involving the factor?

- **keep.zero.df**
  logical: should terms with no degrees of freedom be included?

- **...**
  Arguments to be passed to or from other methods, for `summary.aovlist` including those for `summary.aov`.

### Value

An object of class c("summary.aov", "listof") or "summary.aovlist" respectively.

For fits with a single stratum the result will be a list of ANOVA tables, one for each response (even if there is only one response): the tables are of class "anova" inheriting from class "data.frame". They have columns "Df", "Sum Sq", "Mean Sq", as well as "F value" and "Pr(>F)" if there are non-zero residual degrees of freedom. There is a row for each term in the model, plus one for "Residuals" if there are any.

For multistratum fits the return value is a list of such summaries, one for each stratum.

### Note

The use of `expand.split = TRUE` is little tested: it is always possible to set it to `FALSE` and specify exactly all the splits required.

### See Also

- `aov`, `summary`, `model.tables`, `TukeyHSD`
## Examples

### For a simple example see example(aov)

```r
# Cochran and Cox (1957, p.164)
# 3x3 factorial with ordered factors, each is average of 12.
CC <- data.frame(
  y = c(449, 413, 326, 409, 358, 291, 341, 278, 312)/12,
  P = ordered(gl(3, 3)),
  N = ordered(gl(3, 1, 9))
)
CC.aov <- aov(y ~ N * P, data = CC , weights = rep(12, 9))
summary(CC.aov)
```

```r
# Split both main effects into linear and quadratic parts.
summary(CC.aov, split = list(N = list(L = 1, Q = 2),
                              P = list(L = 1, Q = 2)))
```

```r
# Split only the interaction
summary(CC.aov, split = list("N:P" = list(L.L = 1, Q = 2:4)))
```

```r
# Split on just one var
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)))
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)),
       expand.split = FALSE)
```

---

### summary.glm

**Summarizing Generalized Linear Model Fits**

**Description**

These functions are all methods for class `glm` or `summary.glm` objects.

**Usage**

```r
## S3 method for class 'glm'
summary(object, dispersion = NULL, correlation = FALSE, 
         symbolic.cor = FALSE, ...)

## S3 method for class 'summary.glm'
print(x, digits = max(3, getOption("digits") - 3), 
      symbolic.cor = x$symbolic.cor, 
      signif.stars = getOption("show.signif.stars"),
      show.residuals = FALSE, ...)
```

**Arguments**

- `object` an object of class "glm", usually, a result of a call to `glm`.
- `x` an object of class "summary.glm", usually, a result of a call to `summary.glm`.
- `dispersion` the dispersion parameter for the family used. Either a single numerical value or NULL (the default), when it is inferred from `object` (see ‘Details’).
- `correlation` logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
digits
symbolic.cor
signif.stars
show.residuals
...
cov.unscaled the unscaled (dispersion = 1) estimated covariance matrix of the estimated coefficients.
cov.scaled ditto, scaled by dispersion.
correlation (only if correlation is true.) The estimated correlations of the estimated coefficients.
symbolic.cor (only if correlation is true.) The value of the argument symbolic.cor.

See Also
glm, summary.

Examples

## For examples see example(glm)

summary.lm

Summarizing Linear Model Fits

Description

summary method for class "lm".

Usage

## S3 method for class 'lm'
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)

## S3 method for class 'summary.lm'
print(x, digits = max(3, getOption("digits") - 3),
symbolic.cor = x$symbolic.cor,
signif.stars = getOption("show.signif.stars"), ...)

Arguments

object an object of class "lm", usually, a result of a call to lm.
x an object of class "summary.lm", usually, a result of a call to summary.lm.
correlation logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
digits the number of significant digits to use when printing.
symbolic.cor logical. If TRUE, print the correlations in a symbolic form (see symnum) rather than as numbers.
signif.stars logical. If TRUE, 'significance stars' are printed for each coefficient.
... further arguments passed to or from other methods.

Details

print.summary.lm tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if signif.stars is TRUE. Aliased coefficients are omitted in the returned object but restored by the print method. Correlations are printed to two decimal places (or symbolically): to see the actual correlations print summary(object)$correlation directly.
The function summary.lm computes and returns a list of summary statistics of the fitted linear model given in object, using the components (list elements) "call" and "terms" from its argument, plus

residuals the weighted residuals, the usual residuals rescaled by the square root of the weights specified in the call to lm.

coefficients a $p \times 4$ matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value. Aliased coefficients are omitted.

aliased named logical vector showing if the original coefficients are aliased.

sigma the square root of the estimated variance of the random error

\[
\hat{\sigma}^2 = \frac{1}{n - p} \sum w_i R_i^2,
\]

where $R_i$ is the $i$-th residual, residuals[i].

df degrees of freedom, a 3-vector ($p, n - p, p*$), the first being the number of non-aliased coefficients, the last being the total number of coefficients.

fstatistic (for models including non-intercept terms) a 3-vector with the value of the F-statistic with its numerator and denominator degrees of freedom.

r.squared $R^2$, the ‘fraction of variance explained by the model’,

\[
R^2 = 1 - \frac{\sum_i R_i^2}{\sum (y_i - \bar{y})^2},
\]

where $\bar{y}$ is the mean of $y_i$ if there is an intercept and zero otherwise.

adj.r.squared the above $R^2$ statistic ‘adjusted’, penalizing for higher $p$.

cov.unscaled a $p \times p$ matrix of (unscaled) covariances of the $\hat{\beta}_j$, $j = 1, \ldots, p$.

correlation the correlation matrix corresponding to the above cov.unscaled, if correlation = TRUE is specified.

symbolic.cor (only if correlation is true.) The value of the argument symbolic.cor.

na.action from object, if present there.

See Also

The model fitting function lm, summary.

Function coef will extract the matrix of coefficients with standard errors, t-statistics and p-values.

Examples

```r
###-- Continuing the lm(.) example:
coef(lm.D90) # the bare coefficients
sld90 <- summary(lm.D90 <- lm(weight ~ group -1)) # omitting intercept
sld90
coeff(sld90) # much more

### model with aliased* coefficient:
lm.D9. <- lm(weight ~ group + I(group != "Ctl"))
Sm.D9. <- summary(lm.D9.)
Sm.D9. # shows the NA NA NA NA line
stopifnot(length(cc <- coef(lm.D9.)) == 3, is.na(cc[3]),
      dim(coef(Sm.D9.)) == c(2,4), Sm.D9.$df == c(2, 18, 3))
```
Summary Method for Multivariate Analysis of Variance

Description
A summary method for class "manova".

Usage
```r
## S3 method for class 'manova'
summary(object,
         test = c("Pillai", "Wilks", "Hotelling-Lawley", "Roy"),
         intercept = FALSE, tol = 1e-7, ...)
```

Arguments
- `object`: An object of class "manova" or an aov object with multiple responses.
- `test`: The name of the test statistic to be used. Partial matching is used so the name can be abbreviated.
- `intercept`: logical. If TRUE, the intercept term is included in the table.
- `tol`: tolerance to be used in deciding if the residuals are rank-deficient: see qr.
- `...`: further arguments passed to or from other methods.

Details
The `summary.manova` method uses a multivariate test statistic for the summary table. Wilks' statistic is most popular in the literature, but the default Pillai–Bartlett statistic is recommended by Hand and Taylor (1987).

The table gives a transformation of the test statistic which has approximately an F distribution. The approximations used follow S-PLUS and SAS (the latter apart from some cases of the Hotelling–Lawley statistic), but many other distributional approximations exist: see Anderson (1984) and Krzanowski and Marriott (1994) for further references. All four approximate F statistics are the same when the term being tested has one degree of freedom, but in other cases that for the Roy statistic is an upper bound.

The tolerance `tol` is applied to the QR decomposition of the residual correlation matrix (unless some response has essentially zero residuals, when it is unscaled). Thus the default value guards against very highly correlated responses: it can be reduced but doing so will allow rather inaccurate results and it will normally be better to transform the responses to remove the high correlation.

Value
An object of class "summary.manova". If there is a positive residual degrees of freedom, this is a list with components
- `row.names`: The names of the terms, the row names of the `stats` table if present.
- `SS`: A named list of sums of squares and product matrices.
- `Eigenvalues`: A matrix of eigenvalues.
- `stats`: A matrix of the statistics, approximate F value, degrees of freedom and P value.

Otherwise components `row.names`, `SS` and `Df` (degrees of freedom) for the terms (and not the residuals).
summary.nls

Summary of Non-Linear Least-Squares Model Fits

Usage

## S3 method for class 'nls'
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)

## S3 method for class 'summary.nls'
print(x, digits = max(3,getOption("digits") - 3),
symbolic.cor = x$symbolic.cor,
signif.stars = getOption("show.signif.stars"), ...)

manova, aov

Examples

## Example on producing plastic film from Krzanowski (1998, p. 381)
tear <- c(6.5, 6.2, 5.8, 6.5, 6.5, 6.9, 7.2, 6.9, 6.1, 6.3,
6.7, 6.6, 7.2, 7.1, 6.8, 7.1, 7.0, 7.2, 7.5, 7.6)
gloss <- c(9.5, 9.9, 9.6, 9.6, 9.2, 9.1, 10.0, 9.9, 9.5, 9.4,
9.1, 9.3, 8.3, 8.4, 8.5, 9.2, 8.8, 9.7, 10.1, 9.2)
opacity <- c(4.4, 6.4, 3.0, 4.1, 0.8, 5.7, 2.0, 3.9, 1.9, 5.7,
2.8, 4.1, 3.8, 1.6, 3.4, 8.4, 5.2, 6.9, 2.7, 1.9)
Y <- cbind(tear, gloss, opacity)
rate <- gl(2,10, labels = c("Low", "High"))
additive <- gl(2, 5, length = 20, labels = c("Low", "High"))
fit <- manova(Y ~ rate * additive)
summary.aov(fit) # univariate ANOVA tables
summary(fit, test = "Wilks") # ANOVA table of Wilks' lambda
summary(fit) # same F statistics as single-df terms
Arguments

object: an object of class "nls".

x: an object of class "summary.nls", usually the result of a call to summary.nls.

correlation: logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.

digits: the number of significant digits to use when printing.

symbolic.cor: logical. If TRUE, print the correlations in a symbolic form (see symnum) rather than as numbers.

signif.stars: logical. If TRUE, ‘significance stars’ are printed for each coefficient.

...: further arguments passed to or from other methods.

Details

The distribution theory used to find the distribution of the standard errors and of the residual standard error (for t ratios) is based on linearization and is approximate, maybe very approximate.

print.summary.nls tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives ‘significance stars’ if signif.stars is TRUE.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print summary(object)$correlation directly.

Value

The function summary.nls computes and returns a list of summary statistics of the fitted model given in object, using the component “formula” from its argument, plus

residuals: the weighted residuals, the usual residuals rescaled by the square root of the weights specified in the call to nls.

coefficients: a \( p \times 4 \) matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value.

sigma: the square root of the estimated variance of the random error

\[
\hat{\sigma}^2 = \frac{1}{n - p} \sum R_i^2,
\]

where \( R_i \) is the i-th weighted residual.

df: degrees of freedom, a 2-vector \( (p, n - p) \). (Here and elsewhere \( n \) omits observations with zero weights.)

cov.unscaled: a \( p \times p \) matrix of (unscaled) covariances of the parameter estimates.

correlation: the correlation matrix corresponding to the above cov.unscaled, if correlation = TRUE is specified and there are a non-zero number of residual degrees of freedom.

symbolic.cor: (only if correlation is true.) The value of the argument symbolic.cor.

See Also

The model fitting function nls, summary.

Function coef will extract the matrix of coefficients with standard errors, t-statistics and p-values.
Summary method for Principal Components Analysis

Description

The `summary` method for class "princomp".

Usage

## S3 method for class 'princomp'
summary(object, loadings = FALSE, cutoff = 0.1, ...)

## S3 method for class 'summary.princomp'
print(x, digits = 3, loadings = x$print.loadings,
      cutoff = x$cutoff, ...)

Arguments

- `object`  an object of class "princomp", as from `princomp()`.
- `loadings` logical. Should loadings be included?
- `cutoff` numeric. Loadings below this cutoff in absolute value are shown as blank in the output.
- `x` an object of class "summary.princomp".
- `digits` the number of significant digits to be used in listing loadings.
- `...` arguments to be passed to or from other methods.

Value

object with additional components `cutoff` and `print.loadings`.

See Also

`princomp`

Examples

summary(pc.cr <- princomp(USArrests, cor = TRUE))
## The signs of the loading columns are arbitrary
print(summary(princomp(USArrests, cor = TRUE),
           loadings = TRUE, cutoff = 0.2), digits = 2)
supsmu

Friedman’s SuperSmoother

Description
Smooth the (x, y) values by Friedman’s ‘super smoother’.

Usage
supsmu(x, y, wt =, span = "cv", periodic = FALSE, bass = 0, trace = FALSE)

Arguments
x
x values for smoothing
y
y values for smoothing
wt
case weights, by default all equal
span
the fraction of the observations in the span of the running lines smoother, or "cv" to choose this by leave-one-out cross-validation.
periodic
if TRUE, the x values are assumed to be in [0, 1] and of period 1.
bass
controls the smoothness of the fitted curve. Values of up to 10 indicate increasing smoothness.
trace
logical, if true, prints one line of info “per spar”, notably useful for "cv”.

Details
supsmu is a running lines smoother which chooses between three spans for the lines. The running lines smoothers are symmetric, with k/2 data points each side of the predicted point, and values of k as 0.5 * n, 0.2 * n and 0.05 * n, where n is the number of data points. If span is specified, a single smoother with span span * n is used.

The best of the three smoothers is chosen by cross-validation for each prediction. The best spans are then smoothed by a running lines smoother and the final prediction chosen by linear interpolation.

The FORTRAN code says: “For small samples (n < 40) or if there are substantial serial correlations between observations close in x-value, then a pre-specified fixed span smoother (span > 0) should be used. Reasonable span values are 0.2 to 0.4.”

Cases with non-finite values of x, y or wt are dropped, with a warning.

Value
A list with components
x
the input values in increasing order with duplicates removed.
y
the corresponding y values on the fitted curve.

References
symnum

See Also
ppr

Examples

require(graphics)

with(cars, {
  plot(speed, dist)
  lines(supsmu(speed, dist))
  lines(supsmu(speed, dist, bass = 7), lty = 2)
})

symnum

Symbolic Number Coding

Description
Symbolically encode a given numeric or logical vector or array. Particularly useful for visualization of structured matrices, e.g., correlation, sparse, or logical ones.

Usage

symnum(x, cutpoints = c(0.3, 0.6, 0.8, 0.9, 0.95),
  symbols = if(numeric.x) c(" ", ",", ",", ",+", ",x", "B")
    else c(".", "|"),
  legend = length(symbols) >= 3,
  na = ",", eps = 1e-5, numeric.x = is.numeric(x),
  corr = missing(cutpoints) && numeric.x,
  show.max = if(corr) ",", show.min = NULL,
  abbr.colnames = has.colnames,
  lower.triangular = corr && is.numeric(x) && is.matrix(x),
  diag.lower.tri = corr && !is.null(show.max))

Arguments

x numeric or logical vector or array.
cutpoints numeric vector whose values cutpoints[j] = c_j (after augmentation, see corr below) are used for intervals.
symbols character vector, one shorter than (the augmented, see corr below) cutpoints. symbols[j] = s_j are used as ‘code’ for the (half open) interval [c_j, c_{j+1}).
When numeric.x is FALSE, i.e., by default when argument x is logical, the default is c(" ", ",") (graphical 0/1 s).
legend logical indicating if a "legend" attribute is desired.
na character or logical. How NAs are coded. If na == FALSE, NAs are coded invisibly, including the "legend" attribute below, which otherwise mentions NA coding.
eps absolute precision to be used at left and right boundary.
numeric.x logical indicating if x should be treated as numbers, otherwise as logical.
corresponds to TRUE. If TRUE, x contains correlations. The cutpoints are augmented by 0 and 1 and abs(x) is coded.

show.max logical. If TRUE, or of mode character, the maximal cutpoint is coded especially.

show.min logical. If TRUE, or of mode character, the minimal cutpoint is coded especially.

abbr.colnames logical, integer or NULL indicating how column names should be abbreviated (if they are); if NULL (or FALSE and x has no column names), the column names will all be empty, i.e., ""; otherwise if abbr.colnames is false, they are left unchanged. If TRUE or integer, existing column names will be abbreviated to abbreviate(*, minlength = abbr.colnames).

lower.triangular logical. If TRUE and x is a matrix, only the lower triangular part of the matrix is coded as non-blank.

diag.lower.tri logical. If lower.triangular and this are TRUE, the diagonal part of the matrix is shown.

Value

An atomic character object of class noquote and the same dimensions as x.

If legend is TRUE (as by default when there are more than two classes), the result has an attribute "legend" containing a legend of the returned character codes, in the form

\[ c_1 s_1 c_2 s_2 \ldots s_n c_{n+1} \]

where \( c_j = \text{cutpoints}[j] \) and \( s_j = \text{symbols}[j] \).

Note

The optional (mostly logical) arguments all try to use smart defaults. Specifying them explicitly may lead to considerably improved output in many cases.

symnum(ii, cutpoints = 2*(0:4), symbols = c(".", "-", "+", "."), show.max = TRUE)
symnum(1:12 %% 3 == 0) # --> "+" = TRUE, "." = FALSE for logical

## Pascal's Triangle modulo 2 -- odd and even numbers:
N <- 38
pascal <- t(sapply(0:N, function(n) round(choose(n, 0:N - (N-n)%/%2))))
rownames(pascal) <- rep("", 1+N) # <-- to improve "graphic"
symnum(pascal %% 2, symbols = c("", "A"), numeric.x = FALSE)

##-- Symbolic correlation matrices:
```

symnum(cor(attitude), diag.lower.tri = FALSE)
symnum(cor(attitude), abbr.colnames = NULL)
symnum(cor(attitude), abbr.colnames = FALSE)
symnum(cor(attitude), abbr.colnames = 2)

symnum(cor(rbind(1, rnorm(25), rnorm(25)^2)))
symnum(cor(matrix(rexp(30, 1), 5, 18))) # <<-- PATTERN ! --
symnum(cm1 <- cor(matrix(rnorm(90) , 5, 18))) # < White Noise SMALL n
symnum(cm1, diag.lower.tri = FALSE)
symnum(cm2 <- cor(matrix(rnorm(900), 50, 18))) # < White Noise "BIG" n
symnum(cm2, lower.triangular = FALSE)

## NA's:
Cm <- cor(matrix(rnorm(60), 10, 6)); Cm[c(3,6), 2] <- NA
symnum(Cm, show.max = NULL)

## Graphical P-values (aka "significance stars"):
pval <- rev(sort(c(outer(1:6, 10^-(1:3)))))
symp <- symnum(pval, corr = FALSE,
cutpoints = c(0, .001,.01,.05, .1, 1),
symbols = c("***","**","*","."," "))

noquote(cbind(P.val = format(pval), Signif = symp))

t.test

### Student’s t-Test

**Description**

Performs one and two sample t-tests on vectors of data.

#### Usage

t.test(x, ...)

#### Arguments

- **x**
  a (non-empty) numeric vector of data values.
- **y**
  an optional (non-empty) numeric vector of data values.
- **alternative**
  a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
- **mu**
  a number indicating the true value of the mean (or difference in means if you are performing a two sample test).
paired  a logical indicating whether you want a paired t-test.
var.equal  a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used.
conf.level  confidence level of the interval.
formula  a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs either 1 for a one-sample or paired test or a factor with two levels giving the corresponding groups. If lhs is of class "Pair" and rhs is 1, a paired test is done, see Examples.
data  an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset  an optional vector specifying a subset of observations to be used.
na.action  a function which indicates what should happen when the data contain NAs.
...  further arguments to be passed to or from methods. For the formula method, this includes arguments of the default method, but not paired.

Details

alternative = "greater" is the alternative that x has a larger mean than y. For the one-sample case: that the mean is positive.
If paired is TRUE then both x and y must be specified and they must be the same length. Missing values are silently removed (in pairs if paired is TRUE). If var.equal is TRUE then the pooled estimate of the variance is used. By default, if var.equal is FALSE then the variance is estimated separately for both groups and the Welch modification to the degrees of freedom is used.
If the input data are effectively constant (compared to the larger of the two means) an error is generated.

Value

A list with class "htest" containing the following components:

statistic  the value of the t-statistic.
parameter  the degrees of freedom for the t-statistic.
p.value  the p-value for the test.
conf.int  a confidence interval for the mean appropriate to the specified alternative hypothesis.
estimate  the estimated mean or difference in means depending on whether it was a one-sample test or a two-sample test.
null.value  the specified hypothesized value of the mean or mean difference depending on whether it was a one-sample test or a two-sample test.
stderr  the standard error of the mean (difference), used as denominator in the t-statistic formula.
alternative  a character string describing the alternative hypothesis.
meth  a character string indicating what type of t-test was performed.
data.name  a character string giving the name(s) of the data.
The Student t Distribution

Description

Density, distribution function, quantile function and random generation for the t distribution with df degrees of freedom (and optional non-centrality parameter ncp).

Usage

```r
dt(x, df, ncp, log = FALSE)
pt(q, df, ncp, lower.tail = TRUE, log.p = FALSE)
qt(p, df, ncp, lower.tail = TRUE, log.p = FALSE)
rt(n, df, ncp)
```

Arguments

- `x, q`: vector of quantiles.
- `p`: vector of probabilities.
The t distribution with \( df = \nu \) degrees of freedom has density
\[
f(x) = \frac{\Gamma((\nu + 1)/2)}{\sqrt{\pi \nu} \Gamma(\nu/2)} \left(1 + \frac{x^2}{\nu}\right)^{-(\nu+1)/2}
\]
for all real \( x \). It has mean 0 (for \( \nu > 1 \)) and variance \( \frac{\nu}{\nu - 2} \) (for \( \nu > 2 \)).

The general non-central \( t \) with parameters \( (\nu, \delta) = (df, ncp) \) is defined as the distribution of
\[
T_{\nu}(\delta) := \frac{U + \delta}{\sqrt{V/\nu}}
\]
where \( U \) and \( V \) are independent random variables, \( U \sim N(0, 1) \) and \( V \sim \chi^2_\nu \) (see Chisquare).

The most used applications are power calculations for \( t \)-tests:
Let \( T = \frac{X - \mu}{S/\sqrt{n}} \) where \( X \) is the mean and \( S \) the sample standard deviation (sd) of \( X_1, X_2, \ldots, X_n \) which are i.i.d. \( N(\mu, \sigma^2) \). Then \( T \) is distributed as non-central \( t \) with \( df = n - 1 \) degrees of freedom and non-centrality parameter \( ncp = (\mu - \mu_0)\sigma/\sqrt{n} \).

The \( t \) distribution's cumulative distribution function (cdf), \( F_{\nu}(t) \) fulfills \( F_{\nu}(t) = \frac{1}{2} I_{x}(\nu/2, 1/2) \) for \( t \leq 0 \), and \( F_{\nu}(t) = 1 - \frac{1}{2} I_{x}(\nu/2, 1/2) \), for \( t \geq 0 \), where \( x := \nu/(\nu + t^2) \), and \( I_x(a,b) \) is the incomplete beta function, in R this is \( pbeta(x, a, b) \).

Notes

Supplying \( ncp = 0 \) uses the algorithm for the non-central distribution, which is not the same algorithm used if \( ncp \) is omitted. This is to give consistent behaviour in extreme cases with values of \( ncp \) very near zero.

The code for non-zero \( ncp \) is principally intended to be used for moderate values of \( ncp \): it will not be highly accurate, especially in the tails, for large values.

Details

The \( t \) distribution is computed via an accurate formula provided by Catherine Loader (see the reference in \texttt{dbinom}).
For the non-central case of \( dt \), C code contributed by Claus Ekstrøm based on the relationship (for \( x \neq 0 \)) to the cumulative distribution.

For the central case of \( pt \), a normal approximation in the tails, otherwise via \texttt{pbeta}.

For the non-central case of \( pt \) based on a C translation of

This computes the lower tail only, so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant.

For central \( qt \), a C translation of

altered to take account of

The non-central case is done by inversion.

References

See Also

\texttt{Distributions} for other standard distributions, including \texttt{df} for the F distribution.

Examples

```r
require(graphics)

1 - pt(1:5, df = 1)
qt(.975, df = c(1:10,20,50,100,1000))

tt <- seq(0, 10, length.out = 21)
ncp <- seq(0, 6, length.out = 31)
ptn <- outer(tt, ncp, function(t, d) pt(t, df = 3, ncp = d))
t.tit <- "Non-central t - Probabilities"
image(tt, ncp, ptn, zlim = c(0,1), main = t.tit)
persp(tt, ncp, ptn, zlim = 0:1, r = 2, phi = 20,theta = 200, main = t.tit,
xlab = "t", ylab = "non-centrality parameter",
    zlab = "Pr(T <= t)"
)
plot(function(x) dt(x, df = 3, ncp = 2), -3, 11, ylim = c(0, 0.32),
    xaxs = "i")
```

## Relation between \( F_t(.) = pt(x, n) \) and \texttt{pbeta}:

```r
ptBet <- function(t, n) {
  x <- n/(n + t^2)
  r <- pb <- pbeta(x, n/2, 1/2) / 2
  pos <- t > 0
  r[pos] <- 1 - pb[pos]
```

```r
x <- seq(-5, 5, by = 1/8)
u <- 3:10
pt. <- outer(x, nu, pt)
ptB <- outer(x, nu, ptBet)
## matplot(x, pt., type = "l")
stopifnot(all.equal(pt., ptB, tolerance = 1e-15))
```

---

### Description

Plots regression terms against their predictors, optionally with standard errors and partial residuals added.

### Usage

```r
termplot(model, data = NULL, envir = environment(formula(model)),
partial.resid = FALSE, rug = FALSE,
terms = NULL, se = FALSE,
xlabs = NULL, ylabs = NULL, main = NULL,
col.term = 2, lwd.term = 1.5,
col.se = "orange", lty.se = 2, lwd.se = 1,
col.res = "gray", cex = 1, pch = par("pch"),
col.smth = "darkred", lty.smth = 2, span.smth = 2/3,
ask = dev.interactive() && nb.fig < n.tms,
use.factor.levels = TRUE, smooth = NULL, ylim = "common",
plot = TRUE, transform.x = FALSE, ...)
```

### Arguments

- **model**: fitted model object
- **data**: data frame in which variables in model can be found
- **envir**: environment in which variables in model can be found
- **partial.resid**: logical; should partial residuals be plotted?
- **rug**: add rugplots (jittered 1-d histograms) to the axes?
- **terms**: which terms to plot (default NULL means all terms); a vector passed to `predict(..., type = "terms", terms = *)`.
- **se**: plot pointwise standard errors?
- **xlabs**: vector of labels for the x axes
- **ylabs**: vector of labels for the y axes
- **main**: logical, or vector of main titles; if TRUE, the model’s call is taken as main title, NULL or FALSE mean no titles.
- **col.term, lwd.term**: color and line width for the ‘term curve’, see `lines`.
termplot

The model object must have a predict method that accepts type = "terms", e.g., glm in the stats package, coxph and survreg in the survival package.

For the partial.resid = TRUE option model must have a residuals method that accepts type = "partial", which lm and glm do.

The data argument should rarely be needed, but in some cases termplot may be unable to reconstruct the original data frame. Using na.action=na.exclude makes these problems less likely.

Nothing sensible happens for interaction terms, and they may cause errors.

The plot = FALSE option is useful when some special action is needed, e.g. to overlay the results of two different models or to plot confidence bands.

Value

For plot = FALSE, a list with one element for each plot which would have been produced. Each element of the list is a data frame with variables x, y, and optionally the pointwise standard errors se. For continuous predictors x will contain the ordered unique values and for a factor it will be a factor containing one instance of each level. The list has attribute "constant" copied from the predicted terms object.

Otherwise, the number of terms, invisibly.

For (generalized) linear models, plot.lm and predict.glm.
Examples

```r
require(graphics)

had.splines <- "package:splines" %in% search()
if(!had.splines) rs <- require(splines)
x <- 1:100
z <- factor(rep(LETTERS[1:4], 25))
y <- rnorm(100, sin(x/10)+as.numeric(z))
model <- glm(y ~ ns(x, 6) + z)
par(mfrow = c(2,2)) ## 2 x 2 plots for same model :
termplot(model, main = paste("termplot( ", deparse(model$call)," ...")
termplot(model, rug = TRUE)
termplot(model, partial.resid = TRUE, se = TRUE, main = TRUE)
termplot(model, partial.resid = TRUE, smooth = panel.smooth, span.smth = 1/4)
if(!had.splines & rs) detach("package:splines")

if(requireNamespace("MASS", quietly = TRUE)) {
hills.lm <- lm(log(time) ~ log(climb)+log(dist), data = MASS::hills)
termplot(hills.lm, partial.resid = TRUE, smooth = panel.smooth, terms = "log(dist)", main = "Original")
termplot(hills.lm, transform.x = TRUE, partial.resid = TRUE, smooth = panel.smooth, terms = "log(dist)", main = "Transformed")
}
```

terms

### Model Terms

<table>
<thead>
<tr>
<th>Model Terms</th>
</tr>
</thead>
</table>

Description

The function `terms` is a generic function which can be used to extract `terms` objects from various kinds of R data objects.

Usage

```r
terms(x, ...)
```

Arguments

- `x` object used to select a method to dispatch.
- `...` further arguments passed to or from other methods.

Details

There are methods for classes "aovlist", and "terms" "formula" (see `terms.formula`): the default method just extracts the terms component of the object, or failing that a "terms" attribute (as used by `model.frame`).

There are `print` and `labels` methods for class "terms": the latter prints the term labels (see `terms.object`).
terms.formula

Value
An object of class c("terms", "formula") which contains the terms representation of a symbolic model. See terms.object for its structure.

References

See Also
terms.object, terms.formula, lm, glm, formula.

Description
This function takes a formula and some optional arguments and constructs a terms object. The terms object can then be used to construct a model.matrix.

Usage
## S3 method for class 'formula'
terms(x, specials = NULL, abb = NULL, data = NULL, neg.out = TRUE, keep.order = FALSE, simplify = FALSE, ..., allowDotAsName = FALSE)

Arguments
x a formula.
specials which functions in the formula should be marked as special in the terms object? A character vector or NULL.
abb Not implemented in R; deprecated.
data a data frame from which the meaning of the special symbol . can be inferred. It is used only if there is a . in the formula.
neg.out Not implemented in R; deprecated.
keep.order a logical value indicating whether the terms should keep their positions. By default, when FALSE, the terms are reordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on. Effects of a given order are kept in the order specified.
simplify should the formula be expanded and simplified, the pre-1.7.0 behaviour?
... further arguments passed to or from other methods.
allowDotAsName normally . in a formula refers to the remaining variables contained in data. Exceptionally, . can be treated as a name for non-standard uses of formulae.

Details
Not all of the options work in the same way that they do in S and not all are implemented.
A terms object is returned. It is the re-ordered formula (unless keep.order = TRUE) with several attributes, see terms.object for details. In all cases variables within an interaction term in the formula are re-ordered by the ordering of the "variables" attribute, which is the order in which the variables occur in the formula.

See Also

terms, terms.object, also for examples.

terms.object Description of Terms Objects

Description

An object of class terms holds information about a model. Usually the model was specified in terms of a formula and that formula was used to determine the terms object.

Details

The object itself is simply the result of terms.formula(<formula>). It has a number of attributes and they are used to construct the model frame:

factors An integer matrix of variables by terms showing which variables appear in which terms.
  The entries are
    0 if the variable does not occur in the term,
    1 if it does occur and should be coded by contrasts, and
    2 if it occurs and should be coded via dummy variables for all levels (as when a lower-order term is missing).
  Note that variables in main effects always receive 1, even if the intercept is missing (in which case the first one should be coded with dummy variables). If there are no terms other than an intercept and offsets, this is integer(0).
term.labels A character vector containing the labels for each of the terms in the model, except for offsets. Note that these are after possible re-ordering of terms.
  Non-syntactic names will be quoted by backticks: this makes it easier to re-construct the formula from the term labels.
variables A call to list of the variables in the model.
intercept Either 0, indicating no intercept is to be fit, or 1 indicating that an intercept is to be fit.
order A vector of the same length as term.labels indicating the order of interaction for each term.
response The index of the variable (in variables) of the response (the left hand side of the formula).
  Zero, if there is no response.
offset If the model contains offset terms there is an offset attribute indicating which variable(s) are offsets
specials If a specials argument was given to terms.formula there is a specials attribute, a pairlist of vectors (one for each specified special function) giving numeric indices of the arguments of the list returned as the variables attribute which contain these special functions.
dataClasses optional. A named character vector giving the classes (as given by .MFclass) of the variables used in a fit.

predvars optional. An expression to help in computing predictions at new covariate values; see makedata.

The object has class c("terms", "formula").

Note

These objects are different from those found in S. In particular there is no formula attribute: instead the object is itself a formula. (Thus, the mode of a terms object is different.)

Examples of the specials argument can be seen in the aov and coxph functions, the latter from package survival.

See Also
terms, formula.

Examples

## use of specials (as used for gam() in packages mgcv and gam)
(tf <- terms(y ~ x + x:z + s(x), specials = "s"))
## Note that the "factors" attribute has variables as row names
## and term labels as column names, both as character vectors.
attr(tf, "specials") # index 's' variable(s)
rownames(attr(tf, "factors"))[attr(tf, "specials")$s]

## we can keep the order by
terms(y ~ x + x:z + s(x), specials = "s", keep.order = TRUE)

## Sampling Times of Time Series

time creates the vector of times at which a time series was sampled.

cycle gives the positions in the cycle of each observation.

frequency returns the number of samples per unit time and deltat the time interval between observations (see ts).

Usage

time(x, ...)
## Default S3 method:
time(x, offset = 0, ts.eps = getOption("ts.eps"), ...)

cycle(x, ...)
frequency(x, ...)
deltat(x, ...)
toeplitz

Arguments

- **x**: a univariate or multivariate time-series, or a vector or matrix.
- **offset**: can be used to indicate when sampling took place in the time unit. 0 (the default) indicates the start of the unit, 0.5 the middle and 1 the end of the interval.
- **ts.eps**: time series comparison tolerance, used in `time()` to determine if values close than `ts.eps` to an integer should be `round()`ed to it in order to preserve the “year”.
- **...**: extra arguments for future methods.

Details

These are all generic functions, which will use the `tsp` attribute of `x` if it exists. `time` and `cycle` have methods for class `ts` that coerce the result to that class.

`time()` `round()`s values close to an integer, i.e., closer than `ts.eps`, since R 4.3.0. For previous behaviour, you can call it with `ts.eps = 0`.

References

See Also

- `ts`, `start`, `tsp`, `window`.
- `date` for clock time, `system.time` for CPU usage.

Examples

```r
require(graphics)
cycle(presidents)
# a simple series plot
plot(as.vector(time(presidents)), as.vector(presidents), type = "l")
```

Description

In its simplest use, `toeplitz()` forms a symmetric Toeplitz matrix given its first column (or row).

For the general case, asymmetric and non-square Toeplitz matrices are formed either by specifying the first column and row separately,

```r
T1 <- toeplitz(col, row)
```

or by

```r
T <- toeplitz2(x, nr, nc)
```

where only one of `(nr, nc)` needs to be specified. In the latter case, the simple equivalence $T_{i,j} = x_{i-j+n_c}$ is fulfilled where $n_c = \text{ncol}(T)$.
toeplitz

Usage

toeplitz (x, r = NULL, symmetric = is.null(r))
toeplitz2(x, nrow = length(x) +1 - ncol, ncol = length(x) +1 - nrow)

Arguments

x
for toeplitz(x, *): the first column of the Toeplitz matrix; for toeplitz2(x, *) it is the upper-and-left border of the Toeplitz matrix, i.e., from top-right to bottom-left, such that $T[i,j] == x[i-j + ncol]$.

r
the first row of the target Toeplitz matrix; only needed in asymmetric cases.

symmetric
optional logical indicating if the matrix should be symmetric.

nrow, ncol
the number of rows and columns; only one needs to be specified.

Value

The $n \times m$ Toeplitz matrix $T$; for

toeplitz(): $\text{dim}(T)$ is $(n,m)$ and $m == \text{length}(x)$ and $n == m$ in the symmetric case or $n == \text{length}(r)$ otherwise.

toeplitz2(): $\text{dim}(T) == c(nrow, ncol)$.

Author(s)

A. Trapletti and Martin Maechler (speedup and asymmetric extensions)

Examples

x <- 1:5
toeplitz (x)

T2 <- toeplitz2(c(13:12, 1:5), 5, 3)# this is the same matrix:
stopifnot(identical(T., T2))

# Matrix of character (could also have logical, raw, complex ..) {also warning}:
noquote(toeplitz(letters[1:4], LETTERS[20:26]))

## A convolution/smootherr weight matrix :
m <- 17
k <- length(wts <- c(76, 99, 60, 20, 1))
n <- m-k+1
## Convolution
W <- toeplitz2(c(rep(0, m-k), wts, rep(0, m-k)), ncol=n)

## "display" nicely :
if(requireNamespace("Matrix"))
  print(Matrix::Matrix(W)) else {
    colnames(W) <- paste0(",", if(n <= 9) 1:n else c(1:9, letters[seq_len(n-9)]))
    print(W)
  
}

## scale W to have column sums 1:
W. <- W / sum(wts)
all.equal(rep(1, ncol(W.)), colSums(W.), check.attributes = FALSE)
## Visualize "mass-preserving" convolution

```r
x <- 1:n; f <- function(x) exp(-(x - .4*n)/3)^2
y <- f(x) + rep_len(3:-2, n)/10
## Smoothing convolution:
y.hat <- W. %*% y # y.hat := smoothed(y) ("mass preserving" -> longer than y)
stopifnot(length(y.hat) == m, m == n + (k-1))
plot(x,y, type="b", xlim=c(1,m)); curve(f(x), 1,n, col="gray", lty=2, add=TRUE)
lines(1:m, y.hat, col=2, lwd=3)
rbind(sum(y), sum(y.hat)) ## mass preserved
```

```r
## And, yes, convolve(y, *) does the same when called appropriately:
all.equal(c(y.hat), convolve(y, rev(wts/sum(wts)), type="open"))
```

---

ts

### Time-Series Objects

The function `ts` is used to create time-series objects. `as.ts` and `is.ts` coerce an object to a time-series and test whether an object is a time series.

#### Usage

```r
ts(data = NA, start = 1, end = numeric(), frequency = 1,
deltat = 1, ts.eps = getOption("ts.eps"),
class = if(nseries > 1) c("mts", "ts", "matrix", "array") else "ts",
names = )
as.ts(x, ...)
is.ts(x)
is.mts(x)
```

#### Arguments

- **data**: a vector or matrix of the observed time-series values. A data frame will be coerced to a numeric matrix via `data.matrix`. (See also ‘Details’.)
- **start**: the time of the first observation. Either a single number or a vector of two numbers (the second of which is an integer), which specify a natural time unit and a (1-based) number of samples into the time unit. See the examples for the use of the second form.
- **end**: the time of the last observation, specified in the same way as `start`.
- **frequency**: the number of observations per unit of time.
- **deltat**: the fraction of the sampling period between successive observations; e.g., 1/12 for monthly data. Only one of `frequency` or `deltat` should be provided.
- **ts.eps**: time series comparison tolerance. Frequencies are considered equal if their absolute difference is less than `ts.eps`.
- **class**: class to be given to the result, or none if NULL or "none". The default is "ts" for a single series, or `c("mts", "ts", "matrix", "array")` for multiple series.
- **names**: a character vector of names for the series in a multiple series: defaults to the colnames of `data`, or "Series 1", "Series 2", ....
- **x**: an arbitrary R object.
- **...**: arguments passed to methods (unused for the default method).
The function `ts` is used to create time-series objects. These are vectors or matrices which inherit from class "ts" (and have additional attributes) which represent data which has been sampled at equispaced points in time. In the matrix case, each column of the matrix data is assumed to contain a single (univariate) time series. Time series must have at least one observation, and although they need not be numeric there is very limited support for non-numeric series.

Class "ts" has a number of methods. In particular arithmetic will attempt to align time axes, and subsetting to extract subsets of series can be used (e.g., `EuStockMarkets[, "DAX"]`). However, subsetting the first (or only) dimension will return a matrix or vector, as will matrix subsetting. Subassignment can be used to replace values but not to extend a series (see `window`). There is a method for `t` that transposes the series as a matrix (a one-column matrix if a vector) and hence returns a result that does not inherit from class "ts".

Argument `frequency` indicates the sampling frequency of the time series, with the default value 1 indicating one sample in each unit time interval. For example, one could use a value of 7 for frequency when the data are sampled daily, and the natural time period is a week, or 12 when the data are sampled monthly and the natural time period is a year. Values of 4 and 12 are assumed in (e.g.) print methods to imply a quarterly and monthly series respectively. `frequency` need not be a whole number: for example, `frequency = 0.2` would imply sampling once every five time units.

`as.ts` is generic. Its default method will use the `tsp` attribute of the object if it has one to set the start and end times and frequency.

`is.ts()` tests if an object is a time series, i.e., inherits from "ts" and is of positive length.

`is.mts(x)` tests if an object `x` is a multivariate time series, i.e., fulfills `is.ts(x), is.matrix(x)` and inherits from class "mts".

`tsp`, `frequency`, `start`, `end`, `time`, `window`, `print.ts`, `plot.ts`, `is.ts`, `is.mts`, `tsp`, `frequency`, `start`, `end`, `time`, `window`, `plot.ts`, `print.ts`, the print method for time series objects; `plot.ts`, the plot method for time series objects.

For other definitions of 'time series' (e.g., time-ordered observations) see the CRAN task view at https://CRAN.R-project.org/view=TimeSeries.

Examples

```r
require(graphics)

# 2nd Quarter of 1959
print( ts(1:10, frequency = 4, start = c(1959, 2)), calendar = TRUE)
# 2nd Quarter of 1959

# Using July 1954 as start date:
gnp <- ts(csum(1 + round(rnorm(100), 2)),
           start = c(1954, 7), frequency = 12)
plot(gnp) # using 'plot.ts' for time-series plot

# Multivariate
z <- ts(matrix(rnorm(300), 100, 3), start = c(1961, 1), frequency = 12)
class(z)
is.mts(z)
```
head(z) # as "matrix"
plot(z)
plot(z, plot.type = "single", lty = 1:3)

## A phase plot:
plot(nhtemp, lag(nhtemp, 1), cex = .8, col = "blue",
    main = "Lag plot of New Haven temperatures")

---

**Methods for Time Series Objects**

**Description**

Methods for objects of class "ts", typically the result of `ts`.

**Usage**

`diff(x, lag = 1, differences = 1, ...)`

`na.omit(object, ...)`

**Arguments**

- `x`: an object of class "ts" containing the values to be differenced.
- `lag`: an integer indicating which lag to use.
- `differences`: an integer indicating the order of the difference.
- `object`: a univariate or multivariate time series.
- `...`: further arguments to be passed to or from methods.

**Details**

The `na.omit` method omits initial and final segments with missing values in one or more of the series. ‘Internal’ missing values will lead to failure.

**Value**

For the `na.omit` method, a time series without missing values. The class of object will be preserved.

**See Also**

`diff`, `na.omit`, `na.fail`, `na.contiguous`. 
**ts.plot**

*Plot Multiple Time Series*

**Description**

Plot several time series on a common plot. Unlike `plot.ts` the series can have a different time bases, but they should have the same frequency.

**Usage**

```r
ts.plot(..., gpars = list())
```

**Arguments**

- `...` one or more univariate or multivariate time series.
- `gpars` list of named graphics parameters to be passed to the plotting functions. Those commonly used can be supplied directly in `...`.

**Value**

None.

**Note**

Although this can be used for a single time series, `plot` is easier to use and is preferred.

**See Also**

`plot.ts`

**Examples**

```r
require(graphics)

ts.plot(ldeaths, mdeaths, fdeaths,
       gpars=list(xlab="year", ylab="deaths", lty=c(1:3)))
```

---

**ts.union**

*Bind Two or More Time Series*

**Description**

Bind time series which have a common frequency. `ts.union` pads with NAs to the total time coverage, `ts.intersect` restricts to the time covered by all the series.

**Usage**

```r
ts.intersect(..., dframe = FALSE)
ts.union(..., dframe = FALSE)
```
Arguments

... two or more univariate or multivariate time series, or objects which can coerced to time series.

dframe logical; if TRUE return the result as a data frame.

Details

As a special case, ... can contain vectors or matrices of the same length as the combined time series of the time series present, as well as those of a single row.

Value

A time series object if dframe is FALSE, otherwise a data frame.

See Also

cbind.

Examples

ts.union(mdeaths, fdeaths)
cbind(mdeaths, fdeaths) # same as the previous line
ts.intersect(window(mdeaths, 1976), window(fdeaths, 1974, 1978))

sales1 <- ts.union(BJsales, lead = BJsales.lead)
ts.intersect(sales1, lead3 = lag(BJsales.lead, -3))

tsdia...
Value

None. Diagnostics are plotted.

See Also

arima, StructTS, Box.test

Examples

```r
require(graphics)

fit <- arima(lh, c(1,0,0))
tsdag(fit)

## see also examples(arima)

(fit <- StructTS(log10(JohnsonJohnson), type = "BSM"))
tsdag(fit)
```

---

**tsp**

_Tsp Attribute of Time-Series-like Objects_

Description

_tsp_ returns the _tsp_ attribute (or NULL). It is included for compatibility with S version 2. _tsp<~_ sets the _tsp_ attribute. _hasTsp_ ensures _x_ has a _tsp_ attribute, by adding one if needed.

Usage

```r
tsp(x)
tsp(x) <- value
hasTsp(x)
```

Arguments

- **x**
  
  a vector or matrix or univariate or multivariate time-series.

- **value**
  
  a numeric vector of length 3 or NULL.

Details

The _tsp_ attribute gives the start time _in time units_, the end time and the frequency (the number of observations per unit of time, e.g. 12 for a monthly series).

Assignments are checked for consistency.

Assigning NULL which removes the _tsp_ attribute _and any "ts" (or "mts") class_ of _x_.

Value

An object which differs from _x_ only in the _tsp_ attribute (unless NULL is assigned).

_hasTsp_ adds, if needed, an attribute with a start time and frequency of 1 and end time _NROW_(x).
tsSmooth

References

See Also

ts, time, start.

---

**tsSmooth**  
*Use Fixed-Interval Smoothing on Time Series*

Description

Performs fixed-interval smoothing on a univariate time series via a state-space model. Fixed-interval smoothing gives the best estimate of the state at each time point based on the whole observed series.

Usage

tsSmooth(object, ...)

Arguments

- **object**: a time-series fit. Currently only class "StructTS" is supported
- **...**: possible arguments for future methods.

Value

A time series, with as many dimensions as the state space and results at each time point of the original series. (For seasonal models, only the current seasonal component is returned.)

Author(s)

B. D. Ripley

References

See Also

KalmanSmooth, StructTS.

For examples consult AirPassengers, JohnsonJohnson and Nile.
Description

Functions of the distribution of the studentized range, $R/s$, where $R$ is the range of a standard normal sample and $d f \times s^2$ is independently distributed as chi-squared with $d f$ degrees of freedom, see `pchisq`.

Usage

\begin{align*}
\text{ptukey}(q, nmeans, df, nranges = 1, lower.tail = \text{TRUE}, \text{log.p} = \text{FALSE}) \\
\text{qtukey}(p, nmeans, df, nranges = 1, lower.tail = \text{TRUE}, \text{log.p} = \text{FALSE})
\end{align*}

Arguments

- `q`: vector of quantiles.
- `p`: vector of probabilities.
- `nmeans`: sample size for range (same for each group).
- `df`: degrees of freedom for $s$ (see below).
- `nranges`: number of groups whose maximum range is considered.
- `log.p`: logical; if TRUE, probabilities $p$ are given as log($p$).
- `lower.tail`: logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

If $n_g = nranges$ is greater than one, $R$ is the maximum of $n_g$ groups of nmeans observations each.

Value

`ptukey` gives the distribution function and `qtukey` its inverse, the quantile function.

The length of the result is the maximum of the lengths of the numerical arguments. The other numerical arguments are recycled to that length. Only the first elements of the logical arguments are used.

Note

A Legendre 16-point formula is used for the integral of `ptukey`. The computations are relatively expensive, especially for `qtukey` which uses a simple secant method for finding the inverse of `ptukey`. `qtukey` will be accurate to the 4th decimal place.

Source

`qtukey` is in part adapted from Odeh and Evans (1974).
TukeyHSD

Compute Tukey Honest Significant Differences

Description

Create a set of confidence intervals on the differences between the means of the levels of a factor with the specified family-wise probability of coverage. The intervals are based on the Studentized range statistic, Tukey’s ‘Honest Significant Difference’ method.

Usage

TukeyHSD(x, which, ordered = FALSE, conf.level = 0.95, ...)

Arguments

x A fitted model object, usually an aov fit.
which A character vector listing terms in the fitted model for which the intervals should be calculated. Defaults to all the terms.
ordered A logical value indicating if the levels of the factor should be ordered according to increasing average in the sample before taking differences. If ordered is true then the calculated differences in the means will all be positive. The significant differences will be those for which the lwr end point is positive.
conf.level A numeric value between zero and one giving the family-wise confidence level to use.
... Optional additional arguments. None are used at present.
Details

This is a generic function: the description here applies to the method for fits of class "aov".

When comparing the means for the levels of a factor in an analysis of variance, a simple comparison using t-tests will inflate the probability of declaring a significant difference when it is not in fact present. This because the intervals are calculated with a given coverage probability for each interval but the interpretation of the coverage is usually with respect to the entire family of intervals.

John Tukey introduced intervals based on the range of the sample means rather than the individual differences. The intervals returned by this function are based on this Studentized range statistics.

The intervals constructed in this way would only apply exactly to balanced designs where there are the same number of observations made at each level of the factor. This function incorporates an adjustment for sample size that produces sensible intervals for mildly unbalanced designs.

If which specifies non-factor terms these will be dropped with a warning: if no terms are left this is an error.

Value

A list of class c("multicomp", "TukeyHSD"). with one component for each term requested in which. Each component is a matrix with columns diff giving the difference in the observed means, lwr giving the lower end point of the interval, upr giving the upper end point and p adj giving the p-value after adjustment for the multiple comparisons.

There are print and plot methods for class "TukeyHSD". The plot method does not accept xlab, ylab or main arguments and creates its own values for each plot.

summary(fm1 <- aov(breaks ~ wool + tension, data = warpbreaks))
TukeyHSD(fm1, "tension", ordered = TRUE)
plot(TukeyHSD(fm1, "tension"))
The Uniform Distribution

Description

These functions provide information about the uniform distribution on the interval from min to max. dunif gives the density, punif gives the distribution function qunif gives the quantile function and runif generates random deviates.

Usage

dunif(x, min = 0, max = 1, log = FALSE)
punif(q, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)
qunif(p, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)
runif(n, min = 0, max = 1)

Arguments

x, q       vector of quantiles.
p          vector of probabilities.
n          number of observations. If length(n) > 1, the length is taken to be the number required.
min, max   lower and upper limits of the distribution. Must be finite.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

If min or max are not specified they assume the default values of 0 and 1 respectively.

The uniform distribution has density

\[
f(x) = \frac{1}{max - min}
\]

for \( min \leq x \leq max \).

For the case of \( u := min == max \), the limit case of \( X \equiv u \) is assumed, although there is no density in that case and dunif will return NaN (the error condition).

runif will not generate either of the extreme values unless max = min or max-min is small compared to min, and in particular not for the default arguments.

Value

dunif gives the density, punif gives the distribution function, qunif gives the quantile function, and runif generates random deviates.

The length of the result is determined by n for runif, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.
Note

The characteristics of output from pseudo-random number generators (such as precision and periodicity) vary widely. See `.Random.seed` for more information on R’s random number generation algorithms.

References

See Also

`.Random.seed` about random number generation in R.

`Distributions` for other standard distributions.

Examples

```r
u <- runif(20)

## The following relations always hold :
punif(u) == u
dunif(u) == 1

var(runif(10000)) # ~ = 1/12 = .08333
```

Description

The function `uniroot` searches the interval from `lower` to `upper` for a root (i.e., zero) of the function `f` with respect to its first argument.

Setting `extendInt` to a non-"no" string, means searching for the correct interval = `c(lower,upper)` if `sign(f(x))` does not satisfy the requirements at the interval end points; see the ‘Details’ section.

Usage

```r
uniroot(f, interval, ..., lower = min(interval), upper = max(interval),
f.lower = f(lower, ...), f.upper = f(upper, ...),
extendInt = c("no", "yes", "downX", "upX"), check.conv = FALSE,
tol = .Machine$double.eps^0.25, maxiter = 1000, trace = 0)
```

Arguments

- `f` the function for which the root is sought.
- `interval` a vector containing the end-points of the interval to be searched for the root.
- `...` additional named or unnamed arguments to be passed to `f`
- `lower, upper` the lower and upper end points of the interval to be searched.
The same as \( f(\text{upper}) \) and \( f(\text{lower}) \), respectively. Passing these values from the caller where they are often known is more economical as soon as \( f() \) contains non-trivial computations.

**extendInt**

Character string specifying if the interval \( c(\text{lower}, \text{upper}) \) should be extended or directly produce an error when \( f() \) does not have differing signs at the endpoints. The default, "no", keeps the search interval and hence produces an error. Can be abbreviated.

**check.conv**

Logical indicating whether a convergence warning of the underlying `uniroot` should be caught as an error and if non-convergence in `maxiter` iterations should be an error instead of a warning. Can be abbreviated.

**tol**

The desired accuracy (convergence tolerance).

**maxiter**

The maximum number of iterations.

**trace**

Integer number; if positive, tracing information is produced. Higher values giving more details.

**Details**

Note that arguments after ... must be matched exactly.

Either interval or both `lower` and `upper` must be specified: the upper endpoint must be strictly larger than the lower endpoint. The function values at the endpoints must be of opposite signs (or zero), for `extendInt="no"`, the default. Otherwise, if `extendInt="yes"`, the interval is extended on both sides, in search of a sign change, i.e., until the search interval \([l, u]\) satisfies \(f(l) \cdot f(u) \leq 0\).

If it is known how \( f \) changes sign at the root \( x_0 \), that is, if the function is increasing or decreasing there, `extendInt` can (and typically should) be specified as "upX" (for "upward crossing") or "downX", respectively. Equivalently, define \( S := \pm 1 \), to require \( S = \text{sign}(f(x_0 + \epsilon)) \) at the solution. In that case, the search interval \([l, u]\) possibly is extended to be such that \( S \cdot f(l) \leq 0 \) and \( S \cdot f(u) \geq 0 \).

`uniroot()` uses Fortran subroutine `zeroin` (from Netlib) based on algorithms given in the reference below. They assume a continuous function (which then is known to have at least one root in the interval).

Convergence is declared either if \( f(x) = 0 \) or the change in \( x \) for one step of the algorithm is less than `tol` (plus an allowance for representation error in \( x \)).

If the algorithm does not converge in `maxiter` steps, a warning is printed and the current approximation is returned.

\( f \) will be called as \( f(x, \ldots) \) for a numeric value of \( x \).

The argument passed to \( f \) has special semantics and used to be shared between calls. The function should not copy it.

**Value**

A list with at least five components: `root` and `f.root` give the location of the root and the value of the function evaluated at that point. `iter` and `estim.prec` give the number of iterations used and an approximate estimated precision for `root`. (If the root occurs at one of the endpoints, the estimated precision is NA.) `init.it` contains the number of `initial extendInt` iterations if there were any and is NA otherwise. In the case of such `extendInt` iterations, `iter` contains the sum of these and the `zeroin` iterations.

Further components may be added in the future.
Source

Based on 'zeroin.c' in https://netlib.org/c/brent.shar.

polyroot for all complex roots of a polynomial; optimize, nlm.

Examples

require(utils) # for str

## some platforms hit zero exactly on the first step:
## if so the estimated precision is 2/3.
f <- function(x, a) x - a
str(xmin <- uniroot(f, c(0, 1), tol = 0.0001, a = 1/3))

## handheld calculator example: fixed point of cos(.):
uniroot(function(x) cos(x) - x, lower = -pi, upper = pi, tol = 1e-9)$root

str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2, tol = 0.0001))
str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2, tol = 1e-10))

## Find the smallest value x for which exp(x) > 0 (numerically):
r <- uniroot(function(x) 1e80*exp(x) - 1e-300, c(-1000, 0), tol = 1e-15)
str(r, digits.d = 15) # around -745, depending on the platform.

exp(r$root) # = 0, but not for r$root * 0.999...
minexp <- r$root * (1 - 10*.Machine$double.eps)
exp(minexp) # typically denormalized

###--- uniroot() with new interval extension + checking features: """"""----------

f1 <- function(x) (121 - x^2)/(x^2+1)
f2 <- function(x) exp(-x)*(x - 12)

try(uniroot(f1, c(0,10)))
try(uniroot(f2, c(0, 2)))

###-> error: f() .. end points not of opposite sign

## where as 'extendInt="yes"' simply first enlarges the search interval:
ul <- uniroot(f1, c(0,10),extendInt="yes", trace=1)
u2 <- uniroot(f2, c(0,2), extendInt="yes", trace=2)
stopifnot(all.equal(ul$root, 11, tolerance = 1e-5),
            all.equal(u2$root, 12, tolerance = 6e-6))

## The *danger* of interval extension:
## No way to find a zero of a positive function, but
## numerically, f(-|M|) becomes zero:
update <- uniroot(exp, c(0,2), extendInt="yes", trace=TRUE)

## Nonsense example (must give an error):
tools::assertCondition( uniroot(function(x) 1, 0:1, extendInt="yes"),
  "error", verbose=TRUE)

## Convergence checking :
sinc <- function(x) ifelse(x == 0, 1, sin(x)/x)
curve(sinc, -6,18); abline(h=0,v=0, lty=3, col=adjustcolor("gray", 0.8))
uniroot(sinc, c(0,5), extendInt="yes", maxiter=4) #-> "just" a warning

## now with  check.conv=TRUE, must signal a convergence error :
uniroot(sinc, c(0,5), extendInt="yes", maxiter=4, check.conv=TRUE)

### Weibull cumulative hazard (example origin, Ravi Varadhan):
cumhaz <- function(t, a, b) b * (t/b)^a
froot <- function(x, u, a, b) cumhaz(x, a, b) - u

n <- 1000
u <- -log(runif(n))
a <- 1/2
b <- 1

## Find failure times
ru <- sapply(u, function(x)
  uniroot(froot, u=x, a=a, b=b, interval= c(1.e-14, 1e04),
         extendInt="yes")$root)
ru2 <- sapply(u, function(x)
  uniroot(froot, u=x, a=a, b=b, interval= c(0.01, 1e04),
         extendInt="yes")$root)
stopifnot(all.equal(ru, ru2, tolerance = 6e-6))

r1 <- uniroot(froot, u=0.99, a=a, b=b, interval= c(0.01, 1e04),
              extendInt="up")
stopifnot(all.equal(0.99, cumhaz(r1$root, a=a, b=b)))

## An error if 'extendInt' assumes "wrong zero-crossing direction":
uniroot(froot, u=0.99, a=a, b=b, interval= c(0.1, 1e04), extendInt="down")

---

**update**

Update and Re-fit a Model Call

**Description**

update will update and (by default) re-fit a model. It does this by extracting the call stored in the object, updating the call and (by default) evaluating that call. Sometimes it is useful to call update with only one argument, for example if the data frame has been corrected.

"Extracting the call" in update() and similar functions uses getCall() which itself is a (S3) generic function with a default method that simply gets x$call.
Because of this, update() will often work (via its default method) on new model classes, either automatically, or by providing a simple getCall() method for that class.

Usage

```
update(object, ...)
## Default S3 method:
update(object, formula., ..., evaluate = TRUE)

getCall(x, ...)
```

Arguments

- `object, x` An existing fit from a model function such as `lm`, `glm` and many others.
- `formula.` Changes to the formula – see `update.formula` for details.
- `...` Additional arguments to the call, or arguments with changed values. Use name = NULL to remove the argument name.
- `evaluate` If true evaluate the new call else return the call.

Value

If `evaluate = TRUE` the fitted object, otherwise the updated call.

trt <- c(4.81,4.17,4.41,3.59,5.87,3.83,6.03,4.89,4.32,4.69)
group <- gl(2, 10, 20, labels = c("Ctl", "Trt"))
weight <- c(ctl, trt)
lm.D9 <- lm(weight ~ group)
summary(lm.D90 <- update(lm.D9, . ~ . - 1))
options(contrasts = c("contr.helmert", "contr.poly"))
update(lm.D9)
getCall(lm.D90) # "through the origin"
options(oldcon)
```
update.formula

Model Updating

Description

update.formula is used to update model formulae. This typically involves adding or dropping terms, but updates can be more general.

Usage

## S3 method for class 'formula'
update(old, new, ...)  

Arguments

old a model formula to be updated.
new a formula giving a template which specifies how to update.
... further arguments passed to or from other methods.

Details

Either or both of old and new can be objects such as length-one character vectors which can be coerced to a formula via as.formula.

The function works by first identifying the left-hand side and right-hand side of the old formula. It then examines the new formula and substitutes the lhs of the old formula for any occurrence of '.' on the left of new, and substitutes the rhs of the old formula for any occurrence of '.' on the right of new. The result is then simplified via terms.formula(simplify = TRUE).

Value

The updated formula is returned. The environment of the result is that of old.

See Also

terms, model.matrix.

Examples

update(y ~ x, . ~ . + x2) #> y ~ x + x2
update(y ~ x, log(.) ~ . ) #> log(y) ~ x
update(. ~ u+v, res ~ . ) #> res ~ u + v
**Description**

Performs an F test to compare the variances of two samples from normal populations.

**Usage**

```r
var.test(x, ...)  
## Default S3 method:
var.test(x, y, ratio = 1,
  alternative = c("two.sided", "less", "greater"),
  conf.level = 0.95, ...)
## S3 method for class 'formula'
var.test(formula, data, subset, na.action, ...)
```

**Arguments**

- `x, y` numeric vectors of data values, or fitted linear model objects (inheriting from class "lm").
- `ratio` the hypothesized ratio of the population variances of `x` and `y`.
- `alternative` a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
- `conf.level` confidence level for the returned confidence interval.
- `formula` a formula of the form `lhs ~ rhs` where `lhs` is a numeric variable giving the data values and `rhs` a factor with two levels giving the corresponding groups.
- `data` an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- `subset` an optional vector specifying a subset of observations to be used.
- `na.action` a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- `...` further arguments to be passed to or from methods.

**Details**

The null hypothesis is that the ratio of the variances of the populations from which `x` and `y` were drawn, or in the data to which the linear models `x` and `y` were fitted, is equal to `ratio`.

**Value**

A list with class "htest" containing the following components:

- `statistic` the value of the F test statistic.
- `parameter` the degrees of the freedom of the F distribution of the test statistic.
p.value the p-value of the test.
conf.int a confidence interval for the ratio of the population variances.
estimate the ratio of the sample variances of x and y.
null.value the ratio of population variances under the null.
alternative a character string describing the alternative hypothesis.
method the character string "F test to compare two variances".
data.name a character string giving the names of the data.

See Also
bartlett.test for testing homogeneity of variances in more than two samples from normal distributions; ansari.test and mood.test for two rank based (nonparametric) two-sample tests for difference in scale.

Examples
x <- rnorm(50, mean = 0, sd = 2)
y <- rnorm(30, mean = 1, sd = 1)
var.test(x, y) # Do x and y have the same variance?
var.test(lm(x ~ 1), lm(y ~ 1)) # The same.

varimax Rotation Methods for Factor Analysis

Description
These functions ‘rotate’ loading matrices in factor analysis.

Usage
varimax(x, normalize = TRUE, eps = 1e-5)
promax(x, m = 4)

Arguments
x A loadings matrix, with p rows and k < p columns
m The power used the target for promax. Values of 2 to 4 are recommended.
normalize logical. Should Kaiser normalization be performed? If so the rows of x are re-scaled to unit length before rotation, and scaled back afterwards.
eps The tolerance for stopping: the relative change in the sum of singular values.

Details
These seek a ‘rotation’ of the factors x %*% T that aims to clarify the structure of the loadings matrix. The matrix T is a rotation (possibly with reflection) for varimax, but a general linear transformation for promax, with the variance of the factors being preserved.
**Value**

A list with components

- `loadings`: The ‘rotated’ loadings matrix, \( x %*% \text{rotmat} \), of class "loadings".
- `rotmat`: The ‘rotation’ matrix.

**References**

**See Also**

- `factanal`, `Harman74.cor`.

**Examples**

```r
## varimax with normalize = TRUE is the default
fa <- factanal(~., 2, data = swiss)
varimax(loadings(fa), normalize = FALSE)
promax(loadings(fa))
```

**vcov**

*Calculate Variance-Covariance Matrix for a Fitted Model Object*

**Description**

Returns the variance-covariance matrix of the main parameters of a fitted model object. The “main” parameters of model correspond to those returned by `coef`, and typically do not contain a nuisance scale parameter (`sigma`).

**Usage**

```r
vcov(object, ...)  
## S3 method for class 'lm'
vcov(object, complete = TRUE, ...)  
## and also for '[summary.]glm' and 'mlm'  
## S3 method for class 'aov'
vcov(object, complete = FALSE, ...)  

.vcov.aliased(aliased, vc, complete = TRUE)
```
Arguments

object  
a fitted model object, typically. Sometimes also a \texttt{summary()} object of such a fitted model.

complete  
for the \texttt{aov}, \texttt{lm}, \texttt{glm}, \texttt{mlm}, and where applicable \texttt{summary.lm} etc methods: logical indicating if the full variance-covariance matrix should be returned also in case of an over-determined system where some coefficients are undefined and \texttt{coef(.)} contains NAs correspondingly. When complete = \texttt{TRUE}, \texttt{vcov()} is compatible with \texttt{coef()} also in this singular case.

...  
additional arguments for method functions. For the \texttt{glm} method this can be used to pass a dispersion parameter.

aliased  
a \texttt{logical} vector typically identical to \texttt{is.na(coef(.))} indicating which coefficients are ‘aliased’.

vc  
a variance-covariance matrix, typically “incomplete”, i.e., with no rows and columns for aliased coefficients.

Details

\texttt{vcov()} is a generic function and functions with names beginning in \texttt{vcov.} will be methods for this function. Classes with methods for this function include: \texttt{lm}, \texttt{mlm}, \texttt{glm}, \texttt{nls}, \texttt{summary.lm}, \texttt{summary.glm}, \texttt{negbin}, \texttt{polr}, \texttt{rlm} (in package \texttt{MASS}), \texttt{multinom} (in package \texttt{nnet}) \texttt{gls}, \texttt{lme} (in package \texttt{nlme}), \texttt{coxph} and \texttt{survreg} (in package \texttt{survival}).

(\texttt{vcov()} methods for summary objects allow more efficient and still encapsulated access when both \texttt{summary(mod)} and \texttt{vcov(mod)} are needed.)

\texttt{.vcov.aliased()} is an auxiliary function useful for \texttt{vcov} method implementations which have to deal with singular model fits encoded via NA coefficients: It augments a \texttt{vcov–matrix} \texttt{vc} by \texttt{NA} rows and columns where needed, i.e., when some entries of \texttt{aliased} are true and \texttt{vc} is of smaller dimension than \texttt{length(aliased)}.

Value

A matrix of the estimated covariances between the parameter estimates in the linear or non-linear predictor of the model. This should have row and column names corresponding to the parameter names given by the \texttt{coef} method.

When some coefficients of the (linear) model are undetermined and hence NA because of linearly dependent terms (or an “over specified” model), also called “aliased”, see \texttt{alias}, then since R version 3.5.0, \texttt{vcov()} (iff \texttt{complete = TRUE}, i.e., by default for \texttt{lm} etc, but not for \texttt{aov}) contains corresponding rows and columns of NAs, wherever \texttt{coef()} has always contained such NAs.

---

Weibull  

\textit{The Weibull Distribution}

Description  

Density, distribution function, quantile function and random generation for the Weibull distribution with parameters shape and scale.
Weibull

Usage

dweibull(x, shape, scale = 1, log = FALSE)
pweibull(q, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
qweibull(p, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
rweibull(n, shape, scale = 1)

Arguments

x, q
vector of quantiles.

p
vector of probabilities.

n
number of observations. If length(n) > 1, the length is taken to be the number required.

shape, scale
shape and scale parameters, the latter defaulting to 1.

log, log.p
logical; if TRUE, probabilities p are given as log(p).

lower.tail
logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The Weibull distribution with shape parameter \( a \) and scale parameter \( \sigma \) has density given by

\[
f(x) = (a/\sigma)(x/\sigma)^{a-1} \exp(-(x/\sigma)^{a})
\]
for \( x > 0 \). The cumulative distribution function is \( F(x) = 1 - \exp(-(x/\sigma)^{a}) \) on \( x > 0 \), the mean is \( E(X) = \sigma \Gamma(1 + 1/a) \), and the \( \text{Var}(X) = \sigma^2 (\Gamma(1 + 2/a) - (\Gamma(1 + 1/a))^2) \).

Value

dweibull gives the density, pweibull gives the distribution function, qweibull gives the quantile function, and rweibull generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rweibull, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

The cumulative hazard \( H(t) = -\log(1 - F(t)) \) is

\[-pweibull(t, a, b, lower = FALSE, log = TRUE)\]

which is just \( H(t) = (t/b)^a \).

Source

[dpq]weibull are calculated directly from the definitions. rweibull uses inversion.

References

weighted.mean

Description

Compute a weighted mean.

Usage

weighted.mean(x, w, ...)

## Default S3 method:
weighted.mean(x, w, ..., na.rm = FALSE)

Arguments

x

an object containing the values whose weighted mean is to be computed.

w

a numerical vector of weights the same length as x giving the weights to use for elements of x.

...            

arguments to be passed to or from methods.

na.rm

a logical value indicating whether NA values in x should be stripped before the computation proceeds.

Details

This is a generic function and methods can be defined for the first argument x: apart from the default methods there are methods for the date-time classes "POSIXct", "POSIXlt", "difftime" and "Date". The default method will work for any numeric-like object for which [, multiplication, division and sum have suitable methods, including complex vectors.

If w is missing then all elements of x are given the same weight, otherwise the weights are normalized to sum to one (if possible: if their sum is zero or infinite the value is likely to be NaN).

Missing values in w are not handled specially and so give a missing value as the result. However, zero weights are handled specially and the corresponding x values are omitted from the sum.

Value

For the default method, a length-one numeric vector.

See Also

Distributions for other standard distributions, including the Exponential which is a special case of the Weibull distribution.

Examples

x <- c(0, rlnorm(50))
all.equal(dweibull(x, shape = 1), dexp(x))
all.equal(pweibull(x, shape = 1, scale = pi), pexp(x, rate = 1/pi))
## Cumulative hazard H():
all.equal(pweibull(x, 2.5, pi, lower.tail = FALSE, log.p = TRUE),
-((x/pi)^2.5, tolerance = 1e-15)
all.equal(qweibull(x/11, shape = 1, scale = pi), qexp(x/11, rate = 1/pi))
weighted.residuals

See Also

mean

Examples

## GPA from Siegel 1994
wt <- c(5, 5, 4, 1)/15
x <- c(3.7,3.3,3.5,2.8)
xm <- weighted.mean(x, wt)

weighted.residuals Compute Weighted Residuals

Description

Computed weighted residuals from a linear model fit.

Usage

weighted.residuals(obj, drop0 = TRUE)

Arguments

obj 
R object, typically of class lm or glm.
drop0 
logical. If TRUE, drop all cases with weights == 0.

Details

Weighted residuals are based on the deviance residuals, which for a lm fit are the raw residuals \( R_i \) multiplied by \( \sqrt{w_i} \), where \( w_i \) are the weights as specified in lm’s call.

Dropping cases with weights zero is compatible with influence and related functions.

Value

Numeric vector of length \( n' \), where \( n' \) is the number of non-0 weights (drop0 = TRUE) or the number of observations, otherwise.

See Also

residuals, lm.influence, etc.

Examples

## following on from example(lm)
all.equal(weighted.residuals(lm.D9),
residuals(lm.D9))

x <- 1:10
w <- 0:9
y <- rnorm(x)
weighted.residuals(lmxy <- lm(y ~ x, weights = w))
weighted.residuals(lmxy, drop0 = FALSE)
weights  Extract Model Weights

Description
weights is a generic function which extracts fitting weights from objects returned by modeling functions.
Methods can make use of napredict methods to compensate for the omission of missing values. The default methods does so.

Usage
weights(object, ...)

Arguments
object an object for which the extraction of model weights is meaningful.
... other arguments passed to methods.

Value
Weights extracted from the object object: the default method looks for component "weights" and if not NULL calls napredict on it.

wilcox.test  Wilcoxon Rank Sum and Signed Rank Tests

Description
Performs one- and two-sample Wilcoxon tests on vectors of data; the latter is also known as 'Mann-Whitney' test.

Usage
wilcox.test(x, ...)

## Default S3 method:
wilcox.test(x, y = NULL,
alternatives = c("two.sided", "less", "greater"),
mu = 0, paired = FALSE, exact = NULL, correct = TRUE,
conf.int = FALSE, conf.level = 0.95,
The formula interface is only applicable for the 2-sample tests.

If only x is given, or if both x and y are given and paired is TRUE, a Wilcoxon signed rank test of the null that the distribution of x (in the one sample case) or of x - y (in the paired two sample case) is symmetric about mu is performed.

Otherwise, if both x and y are given and paired is FALSE, a Wilcoxon rank sum test (equivalent to the Mann-Whitney test: see the Note) is carried out. In this case, the null hypothesis is that the distributions of x and y differ by a location shift of mu and the alternative is that they differ by some other location shift (and the one-sided alternative "greater" is that x is shifted to the right of y).
By default (if exact is not specified), an exact p-value is computed if the samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

For stability reasons, it may be advisable to use rounded data or to set digits.rank = 7, say, such that determination of ties does not depend on very small numeric differences (see the example).

Optionally (if argument conf.int is true), a nonparametric confidence interval and an estimator for the pseudomedian (one-sample case) or for the difference of the location parameters \( x-y \) is computed. (The pseudomedian of a distribution \( F \) is the median of the distribution of \( (u + v)/2 \), where \( u \) and \( v \) are independent, each with distribution \( F \). If \( F \) is symmetric, then the pseudomedian and median coincide. See Hollander & Wolfe (1973), page 34.) Note that in the two-sample case the estimator for the difference in location parameters does not estimate the difference in medians (a common misconception) but rather the median of the difference between a sample from \( x \) and a sample from \( y \).

If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations. These are continuity-corrected for the interval but not the estimate (as the correction depends on the alternative).

With small samples it may not be possible to achieve very high confidence interval coverages. If this happens a warning will be given and an interval with lower coverage will be substituted.

When \( x \) (and \( y \) if applicable) are valid, the function now always returns, also in the conf.int = TRUE case when a confidence interval cannot be computed, in which case the interval boundaries and sometimes the estimate now contain NaN.

**Value**

A list with class "htest" containing the following components:

- statistic: the value of the test statistic with a name describing it.
- parameter: the parameter(s) for the exact distribution of the test statistic.
- p.value: the p-value for the test.
- null.value: the location parameter \( \mu \).
- alternative: a character string describing the alternative hypothesis.
- method: the type of test applied.
- data.name: a character string giving the names of the data.
- conf.int: a confidence interval for the location parameter. (Only present if argument conf.int = TRUE.)
- estimate: an estimate of the location parameter. (Only present if argument conf.int = TRUE.)

**Warning**

This function can use large amounts of memory and stack (and even crash \( R \) if the stack limit is exceeded) if exact = TRUE and one sample is large (several thousands or more).

**Note**

The literature is not unanimous about the definitions of the Wilcoxon rank sum and Mann-Whitney tests. The two most common definitions correspond to the sum of the ranks of the first sample with the minimum value \( m(m+1)/2 \) for a first sample of size \( m \) subtracted or not: \( R \) subtracts. It seems Wilcoxon's original paper used the unadjusted sum of the ranks but subsequent tables subtracted the minimum.
R's value can also be computed as the number of all pairs \((x[i], y[j])\) for which \(y[j]\) is not greater than \(x[i]\), the most common definition of the Mann-Whitney test.

wilcoxon.test(Ozone ~ Month, data = airquality,
   subset = Month %in% c(5, 8))

## accuracy in ties determination via 'digits.rank':
wilcoxon.test(4:2, 3:1, paired=TRUE) # Warning: cannot compute exact p-value with ties
wilcoxon.test((4:2)/10, (3:1)/10, paired=TRUE) # no ties => *no* warning
wilcoxon.test((4:2)/10, (3:1)/10, paired=TRUE, digits.rank = 9) # same ties as (4:2, 3:1)

---

Wilcoxon

Distribution of the Wilcoxon Rank Sum Statistic

Description

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon rank sum statistic obtained from samples with size \( m \) and \( n \), respectively.

Usage

\[
\begin{align*}
dwilcox & \text{x, m, n, log = FALSE} \\
pwilcox & \text{q, m, n, lower.tail = TRUE, log.p = FALSE} \\
qwilcox & \text{p, m, n, lower.tail = TRUE, log.p = FALSE} \\
rwilcox & \text{nn, m, n}
\end{align*}
\]

Arguments

- **x, q**: vector of quantiles.
- **p**: vector of probabilities.
- **nn**: number of observations. If \( \text{length(nn)} > 1 \), the length is taken to be the number required.
- **m, n**: numbers of observations in the first and second sample, respectively. Can be vectors of positive integers.
- **log, log.p**: logical; if TRUE, probabilities \( p \) are given as \( \log(p) \).
- **lower.tail**: logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

This distribution is obtained as follows. Let \( x \) and \( y \) be two random, independent samples of size \( m \) and \( n \). Then the Wilcoxon rank sum statistic is the number of all pairs \((x[i], y[j])\) for which \( y[j] \) is not greater than \( x[i] \). This statistic takes values between 0 and \( m \times n \), and its mean and variance are \( m \times n / 2 \) and \( m \times n \times (m + n + 1) / 12 \), respectively.

If any of the first three arguments are vectors, the recycling rule is used to do the calculations for all combinations of the three up to the length of the longest vector.
Value

dwilcox gives the density, p wilcox gives the distribution function, q wilcox gives the quantile function, and r wilcox generates random deviates.
The length of the result is determined by nn for r wilcox, and is the maximum of the lengths of the numerical arguments for the other functions.
The numerical arguments other than nn are recycled to the length of the result. Only the first elements of the logical arguments are used.

Warning

These functions can use large amounts of memory and stack (and even crash R if the stack limit is exceeded and stack-checking is not in place) if one sample is large (several thousands or more).

Note

S-PLUS used a different (but equivalent) definition of the Wilcoxon statistic: see wilcox.test for details.

Author(s)

Kurt Hornik

Source

These ("d","p","q") are calculated via recursion, based on c wilcox(k, m, n), the number of choices with statistic k from samples of size m and n, which is itself calculated recursively and the results cached. Then d wilcox and p wilcox sum appropriate values of c wilcox, and q wilcox is based on inversion.

r wilcox generates a random permutation of ranks and evaluates the statistic. Note that it is based on the same C code as sample(), and hence is determined by .Random.seed, notably from RNGkind(sample.kind = ..) which changed with R version 3.6.0.

See Also

wilcox.test to calculate the statistic from data, find p values and so on.

Distributions for standard distributions, including dsignrank for the distribution of the one-sample Wilcoxon signed rank statistic.

Examples

require(graphics)
x <- -1:(4*6 + 1)
fx <- d wilcox(x, 4, 6)
Fx <- p wilcox(x, 4, 6)

layout(rbind(1,2), widths = 1, heights = c(3,2))
plot(x, fx, type = "h", col = "violet",
main = "Probabilities (density) of Wilcoxon-Statist.(n=6, m=4)"
plot(x, Fx, type = "s", col = "blue",
main = "Distribution of Wilcoxon-Statist.(n=6, m=4)"
abline(h = 0:1, col = "gray20", lty = 2)
layout(1) # set back
N <- 200
hist(U <- rwilcox(N, m = 4, n = 6), breaks = 0:25 - 1/2,
    border = "red", col = "pink", sub = paste("N =", N))
mtext("N * f(x), f() = true \"density\"", side = 3, col = "blue")
lines(x, N*fx, type = "h", col = "blue", lwd = 2)
points(x, N*fx, cex = 2)

## Better is a Quantile-Quantile Plot
qqplot(U, qw <- qwilcox((1:N - 1/2)/N, m = 4, n = 6),
    main = paste("Q-Q-Plot of empirical and theoretical quantiles",
               "Wilcoxon Statistic. (m=4, n=6)", sep = "\n"))
n <- as.numeric(names(print(tU <- table(U))))
text(n+.2, n+.5, labels = tU, col = "red")

window

Description

window is a generic function which extracts the subset of the object x observed between the times
start and end. If a frequency is specified, the series is then re-sampled at the new frequency.

Usage

window(x, ...)
## S3 method for class 'ts'
window(x, ...)
## Default S3 method:
window(x, start = NULL, end = NULL,
    frequency = NULL, deltat = NULL, extend = FALSE, ts.eps = getOption("ts.eps"), ...)

window(x, ...) <- value
## S3 replacement method for class 'ts'
window(x, start, end, frequency, deltat, ...) <- value

Arguments

x  a time-series (or other object if not replacing values).
start  the start time of the period of interest.
end  the end time of the period of interest.
frequency, deltat  the new frequency can be specified by either (or both if they are consistent).
extend  logical. If true, the start and end values are allowed to extend the series. If
false, attempts to extend the series give a warning and are ignored.
ts.eps  time series comparison tolerance. Frequencies are considered equal if their ab-
solute difference is less than ts.eps and boundaries (length-1 versions of start
and end) are checked with fuzz ts.eps/frequency(x).
...  further arguments passed to or from other methods.
value  replacement values.
Details

The start and end times can be specified as for ts. If there is no observation at the new start or end, the immediately following (start) or preceding (end) observation time is used.

The replacement function has a method for ts objects, and is allowed to extend the series (with a warning). There is no default method.

Value

The value depends on the method. window.default will return a vector or matrix with an appropriate tsp attribute.

window.ts differs from window.default only in ensuring the result is a ts object.

If extend = TRUE the series will be padded with NAs if needed.

References

window(presidents, 1944, c(1979,2), extend = TRUE)

pres <- window(presidents, 1945, c(1949,4)) # values in the 1940's
window(pres, 1945.25, 1945.50) <- c(60, 70)
window(pres, 1944, 1944.75) <- 0 # will generate a warning
window(pres, c(1945,4), c(1949,4), frequency = 1) <- 85:89
pres

xtabs

Cross Tabulation

Description

Create a contingency table (optionally a sparse matrix) from cross-classifying factors, usually contained in a data frame, using a formula interface.

Usage

xtabs(formula = ~., data = parent.frame(), subset, sparse = FALSE, na.action, na.rm = FALSE, addNA = FALSE, exclude = if(!addNA) c(NA, NaN), drop.unused.levels = FALSE)

### S3 method for class 'xtabs'
print(x, na.print = "", ...)
Arguments

formula: a formula object with the cross-classifying variables (separated by +) on the right-hand side (or an object which can be coerced to a formula). Interactions are not allowed. On the left-hand side, one may optionally give a vector or a matrix of counts; in the latter case, the columns are interpreted as corresponding to the levels of a variable. This is useful if the data have already been tabulated, see the examples below.

data: an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset: an optional vector specifying a subset of observations to be used.

sparse: logical specifying if the result should be a sparse matrix, i.e., inheriting from sparseMatrix. Only works for two factors (since there are no higher-order sparse array classes yet).

na.action: a function which indicates what should happen when the variables in formula (or subset) contain NAs. Defaults to na.pass, so na.rm and addNA, respectively, control the handling of missing values for the two sides of the formula. Using na.omit removes any incomplete cases.

na.rm: logical: should missing values on the left-hand side of the formula be treated as zero when computing the sum?

addNA: logical indicating if NAs in the factors should get a separate level and be counted, using addNA(*, ifany=TRUE). This has no effect if na.action = na.omit.

exclude: a vector of values to be excluded when forming the set of levels of the classifying factors.

drop.unused.levels: a logical indicating whether to drop unused levels in the classifying factors. If this is FALSE and there are unused levels, the table will contain zero marginals, and a subsequent chi-squared test for independence of factors will not work.

x: an object of class "xtabs".

na.print: character string (or NULL) indicating how NA are printed. The default ("") does not show NAs clearly, and na.print = "NA" maybe advisable instead.

...: further arguments passed to or from other methods.

Details

There is a summary method for contingency table objects created by table or xtabs(*, sparse = FALSE), which gives basic information and performs a chi-squared test for independence of factors (note that the function chisq.test currently only handles 2-d tables).

If a left-hand side is given in formula, its entries are simply summed over the cells corresponding to the right-hand side; this also works if the LHS does not give counts.

For variables in formula which are factors, exclude must be specified explicitly; the default exclusions will not be used.

In R versions before 3.4.0, e.g., when na.action = na.pass, sometimes zeroes (0) were returned instead of NAs.

In R versions before 4.4.0, when !addNA as by default, the default na.action was na.omit, effectively treating missing counts as zero.
Value

By default, when `sparse = FALSE`, a contingency table in array representation of S3 class c("xtabs", "table"), with a "call" attribute storing the matched call.

When `sparse = TRUE`, a sparse numeric matrix, specifically an object of S4 class `dgTMatrix` from package `Matrix`.

See Also

`table` for traditional cross-tabulation, and `as.data.frame.table` which is the inverse operation of xtabs (see the DF example below).

`sparseMatrix` on sparse matrices in package `Matrix`.

Examples

```r
## 'esoph' has the frequencies of cases and controls for all levels of ## the variables 'agegp', 'alcgp', and 'tobgp'.
xtabs(cbind(ncases, ncontrols) ~ ., data = esoph)
## Output is not really helpful ... flat tables are better:
ftable(xtabs(cbind(ncases, ncontrols) ~ ., data = esoph))
## In particular if we have fewer factors ...  
ftable(xtabs(cbind(ncases, ncontrols) ~ agegp, data = esoph))

## This is already a contingency table in array form. 
DF <- as.data.frame(UCBAdmissions)
## Now 'DF' is a data frame with a grid of the factors and the counts 
## in variable 'Freq'.
DF
## Nice for taking margins ...
xtabs(Freq ~ Gender + Admit, DF)
## And for testing independence ...
summary(xtabs(Freq ~ ., DF))

## with NA's
DN <- DF; DN[cbind(6:9, c(1:2,4,1))] <- NA
DN # 'Freq' is missing only for (Rejected, Female, B)
(xtNA <- xtabs(Freq ~ Gender + Admit, DN)) # NA prints 'invisibly'
print(xtNA, na.print = "NA") # show NA's better
xtabs(Freq ~ Gender + Admit, DN, na.rm = TRUE) # ignore missing Freq
## Use addNA = TRUE to tabulate missing factor levels:
xtabs(Freq ~ Gender + Admit, DN, addNA = TRUE)
xtabs(Freq ~ Gender + Admit, DN, addNA = TRUE, na.rm = TRUE)
## na.action = na.omit removes all rows with NAs right from the start:
xtabs(Freq ~ Gender + Admit, DN, na.action = na.omit)

## Create a nice display for the warp break data.
warpbreaks$replicate <- rep_len(1:9, 54)
ftable(xtabs(breaks ~ wool + tension + replicate, data = warpbreaks))

### ---- Sparse Examples ----
if(require("Matrix")) withAutoprint({
## similar to "nlme"s 'ergoStool'
  d.ergo <- data.frame(Type = paste0("T", rep(1:4, 9+4)),
                        Subj = gl(9, 4, 36+4))
  xtabs(~ Type + Subj, data = d.ergo) # 4 replicates each
})
```
set.seed(15) # a subset of cases:
xtabs(~ Type + Subj, data = d.ergo[sample(36, 10), ], sparse = TRUE)

## Hypothetical two-level setup:
inner <- factor(sample(letters[1:25], 100, replace = TRUE))
inout <- factor(sample(LETTERS[1:5], 25, replace = TRUE))
fr <- data.frame(inner = inner, outer = inout[as.integer(inner)])
xtabs(~ inner + outer, fr, sparse = TRUE)
Chapter 11

The stats4 package

---

**Description**

Statistical Functions using S4 classes.

**Details**

This package contains functions and classes for statistics using the S version 4 class system.

The methods currently support maximum likelihood (function `mle()` returning class "mle"), including methods for `logLik` for use with `AIC`.

**Author(s)**

R Core Team and contributors worldwide

Maintainer: R Core Team <R-core@r-project.org>

---

**Methods**

**signature(object = "ANY")**

Generic function: see `coef`.

**signature(object = "mle")**

Extract the full coefficient vector (including any fixed coefficients) from the fit.

**signature(object = "summary.mle")**

Extract the coefficient vector and standard errors from the summary of the fit.

---

1825
Methods

signature(object = "ANY") Generic function: see confint.
signature(object = "mle") First generate profile and then confidence intervals from the profile.
signature(object = "profile.mle") Generate confidence intervals based on likelihood profile.

Description

Extract the maximized log-likelihood from "mle" objects.

Methods

signature(object = "ANY") Generic function: see logLik.
signature(object = "mle") Extract log-likelihood from the fit.

Note

The mle method does not know about the number of observations unless nobs was specified on the call and so may not be suitable for use with BIC.
## Arguments

- **minuslogl**: Function to calculate negative log-likelihood.
- **start**: Named list of vectors or single vector. Initial values for optimizer. By default taken from the default arguments of `minuslogl`.
- **optim**: Optimizer function. (Experimental)
- **method**: Optimization method to use. See `optim`.
- **fixed**: Named list of vectors or single vector. Parameter values to keep fixed during optimization.
- **nobs**: Optional integer: the number of observations, to be used for e.g. computing BIC.
- **lower, upper**: Named lists of vectors or single vectors. Bounds for `optim`, if relevant.
- **...**: Further arguments to pass to `optim`.

## Details

The `optim` optimizer is used to find the minimum of the negative log-likelihood. An approximate covariance matrix for the parameters is obtained by inverting the Hessian matrix at the optimum. By default, `optim` from the `stats` package is used; other optimizers need to be plug-compatible, both with respect to arguments and return values.

The function `minuslogl` should take one or several arguments, each of which can be a vector. The optimizer optimizes a function which takes a single vector argument, containing the concatenation of the arguments to `minuslogl`, removing any values that should be held fixed. This function internally unpacks the argument vector, inserts the fixed values and calls `minuslogl`.

The vector arguments `start`, `fixed`, `upper`, and `lower`, can be given in both packed and unpacked form, either as a single vector or as a list of vectors. In the latter case, you only need to specify those list elements that are actually affected. For vector arguments, including those inside lists, use a default marker for those values that you don’t want to set: `NA` for `fixed` and `start`, and `+Inf`, `-Inf` for `upper`, and `lower`.

## Value

An object of class `mle-class`.

## Note

Notice that the `ml1` argument should calculate -log L (not -2 log L). It is for the user to ensure that the likelihood is correct, and that asymptotic likelihood inference is valid.

## See Also

- `mle-class`

## Examples

```r
## Avoid printing to unwarranted accuracy
od <- options(digits = 5)

## Simulated EC50 experiment with count data
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)

## Easy one-dimensional MLE:
```
nLL <- function(lambda) -sum(stats::dpois(y, lambda, log = TRUE))
fit0 <- mle(nLL, start = list(lambda = 5), nobs = NROW(y))
## sanity check --- notice that "nobs" must be input
## (not guaranteed to be meaningful for any likelihood)
stopifnot(nobs(fit0) == length(y))

# For 1D, this is preferable:
fit1 <- mle(nLL, start = list(lambda = 5), nobs = NROW(y),
           method = "Brent", lower = 1, upper = 20)
## This needs a constrained parameter space: most methods will accept NA
ll <- function(ymax = 15, xhalf = 6) {
  if(ymax > 0 && xhalf > 0)
    -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
  else NA
}
(fit <- mle(ll, nobs = length(y)))

## Alternative using bounds on optimization
ll2 <- function(ymax = 15, xhalf = 6)
  -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
mle(ll2, lower = rep(0, 2))

AIC(fit)
BIC(fit)

summary(fit)
logLik(fit)
vcov(fit)
plot(profile(fit), absVal = FALSE)
confint(fit)

## Use bounded optimization
## The lower bounds are really > 0,
## but we use >=0 to stress-test profiling
(fit2 <- mle(ll2, lower = c(0, 0)))
plot(profile(fit2), absVal = FALSE)

## A better parametrization:
ll3 <- function(lymax = log(15), lxhalf = log(6))
  -sum(stats::dpois(y, lambda = exp(lymax)/(1+x/exp(lxhalf)), log = TRUE))
(fit3 <- mle(ll3))
plot(profile(fit3), absVal = FALSE)
exp(confint(fit3))

# Regression tests for bounded cases (this was broken in R 3.x)
fit4 <- mle(ll, lower = c(0, 4)) # has max on boundary
confint(fit4)

## direct check that fixed= and constraints work together
mle(ll, lower = c(0, 4), fixed=list(ymax=23)) # has max on boundary

## Linear regression using MLE
x <- 1:10
```r
y <- c(0.48, 2.24, 2.22, 5.15, 4.64, 5.53, 7, 8.8, 7.67, 9.23)

LM_mll <- function(formula, data = environment(formula))
{
  y <- model.response(model.frame(formula, data))
  X <- model.matrix(formula, data)
  b0 <- numeric(NCOL(X))
  names(b0) <- colnames(X)
  function(b=b0, sigma=1)
    -sum(dnorm(y, X %*% b, sigma, log=TRUE))
}

mll <- LM_mll(y ~ x)

summary(lm(y~x)) # for comparison -- notice variance bias in MLE
summary(mle(mll, lower=c(-Inf,-Inf, 0.01))))
summary(mle(mll, lower=list(sigma = 0.01)))) # # alternative specification

confint(mle(mll, lower=list(sigma = 0.01)))
plot(profile(mle(mll, lower=list(sigma = 0.01))))

Binom_mll <- function(x, n)
{
  force(x); force(n) ## beware lazy evaluation
  function(p=.5) -dbinom(x, n, p, log=TRUE)
}

## Likelihood functions for different x.
## This code goes wrong, if force(x) is not used in Binom_mll:

curve(Binom_mll(0, 10)(p), xname="p", ylim=c(0, 10))

mll_list <- list(10)
for (x in 1:10)
  mll_list[[x]] <- Binom_mll(x, 10)
for (mll in mll_list)
  curve(mll(p), xname="p", add=TRUE)

mll <- Binom_mll(4,10)
mle(mll, lower = 1e-16, upper = 1-1e-16) # limits must be inside (0,1)

## Boundary case: This works, but fails if limits are set closer to 0 and 1
mll <- Binom_mll(0, 10)
mle(mll, lower=.005, upper=.995)

## Not run:
## We can use limits closer to the boundaries if we use the
## drop-in replacement optimr() from the optimx package.

mle(mll, lower = 1e-16, upper = 1-1e-16, optim=optimx::optimr)

## End(Not run)

options(od)
```
Class "mle" for Results of Maximum Likelihood Estimation

Description
This class encapsulates results of a generic maximum likelihood procedure.

Objects from the Class
Objects can be created by calls of the form new("mle", ...), but most often as the result of a call to mle.

Slots
- call: Object of class "language". The call to mle.
- coef: Object of class "numeric". Estimated parameters.
- fullcoef: Object of class "numeric". Full parameter set of fixed and estimated parameters.
- fixed: Object of class "numeric". Fixed parameter values (NA for non-fixed parameters).
- vcov: Object of class "matrix". Approximate variance-covariance matrix.
- min: Object of class "numeric". Minimum value of objective function.
- details: a "list", as returned from optim.
- minuslogl: Object of class "function". The negative loglikelihood function.
- nobs: "integer" of length one. The number of observations (often NA, when not set in call explicitly).
- method: Object of class "character". The optimization method used.

Methods
- confint signature(object = "mle"): Confidence intervals from likelihood profiles.
- logLik signature(object = "mle"): Extract maximized log-likelihood.
- profile signature(fitted = "mle"): Likelihood profile generation.
- nobs signature(object = "mle"): Number of observations, here simply accessing the nobs slot mentioned above.
- show signature(object = "mle"): Display object briefly.
- summary signature(object = "mle"): Generate object summary.
- update signature(object = "mle"): Update fit.
- vcov signature(object = "mle"): Extract variance-covariance matrix.
plot-methods  
Methods for Function plot in Package stats4

Description
Plot profile likelihoods for "mle" objects.

Usage

```
## S4 method for signature 'profile.mle,missing'
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100, nseg = 50,
    absVal = TRUE, ...)
```

Arguments
- `x`: an object of class "profile.mle"
- `levels`: levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually `conf` is used instead of giving `levels` explicitly.
- `conf`: a numeric vector of confidence levels for profile-based confidence intervals on the parameters.
- `nseg`: an integer value giving the number of segments to use in the spline interpolation of the profile t curves.
- `absVal`: a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t. Defaults to `TRUE`.
- `...`: other arguments to the `plot` function can be passed here.

Methods
- `signature(x = "ANY", y = "ANY")` Generic function: see `plot`.
- `signature(x = "profile.mle", y = "missing")` Plot likelihood profiles for `x`.

profile-methods  
Methods for Function profile in Package stats4

Description
Profile likelihood for "mle" objects.

Usage

```
## S4 method for signature 'mle'
profile(fitted, which = 1:p, maxsteps = 100, alpha = 0.01,
    zmax = sqrt(qchisq(1 - alpha, 1L)), del = zmax/5,
    trace = FALSE, ...)
```
Arguments

- `fitted`: Object to be profiled.
- `which`: Optionally select subset of parameters to profile.
- `maxsteps`: Maximum number of steps to bracket `zmax`.
- `alpha`: Significance level corresponding to `zmax`, based on a Scheffe-style multiple testing interval. Ignored if `zmax` is specified.
- `zmax`: Cutoff for the profiled value of the signed root-likelihood.
- `del`: Initial stepsize on root-likelihood scale.
- `trace`: Logical. Print intermediate results.
- `...`: Currently unused.

Details

The profiling algorithm tries to find an approximately evenly spaced set of at least five parameter values (in each direction from the optimum) to cover the root-likelihood function. Some care is taken to try and get sensible results in cases of high parameter curvature. Notice that it may not always be possible to obtain the cutoff value, since the likelihood might level off.

Value

An object of class "profile.mle", see "profile.mle-class".

Methods

- `signature(fitted = "ANY")`: Generic function: see `profile`.
- `signature(fitted = "mle")`: Profile the likelihood in the vicinity of the optimum of an "mle" object.

Profile.mle-class

Class "profile.mle"; Profiling information for "mle" object

Description

Likelihood profiles along each parameter of likelihood function

Objects from the Class

Objects can be created by calls of the form `new("profile.mle", ...)`, but most often by invoking `profile` on an "mle" object.

Slots

- `profile`: Object of class "list". List of profiles, one for each requested parameter. Each profile is a data frame with the first column called `z` being the signed square root of the -2 log likelihood ratio, and the others being the parameters with names prefixed by `par.vals`.
- `summary`: Object of class "summary.mle". Summary of object being profiled.
Methods

confint signature(object = "profile.mle"): Use profile to generate approximate confidence intervals for parameters.

plot signature(x = "profile.mle", y = "missing"): Plot profiles for each parameter.

See Also

mle, mle-class, summary.mle-class

Description

Show objects of classes mle and summary.mle

Methods

signature(object = "mle") Print simple summary of mle object. Just the coefficients and the call.

signature(object = "summary.mle") Shows call, table of coefficients and standard errors, and $-2 \log L$.

summary-methods Methods for Function summary in Package stats4

Description

Summarize objects

Methods

signature(object = "ANY") Generic function

signature(object = "mle") Generate a summary as an object of class "summary.mle", containing estimates, asymptotic SE, and value of $-2 \log L$. 
summary.mle-class

Class "summary.mle", Summary of "mle" Objects

Description

Extract of "mle" object

Objects from the Class

Objects can be created by calls of the form `new("summary.mle", ...), but most often by invoking `summary` on an "mle" object. They contain values meant for printing by `show`.

Slots

call: Object of class "language" The call that generated the "mle" object.

coeff: Object of class "matrix". Estimated coefficients and standard errors

m2logL: Object of class "numeric". Minus twice the log likelihood.

Methods

`show` signature(object = "summary.mle"): Pretty-prints object

`coef` signature(object = "summary.mle"): Extracts the contents of the coef slot

See Also

`summary`, `mle`, `mle-class`

update-methods

Methods for Function `update` in Package `stats4`

Description

Update "mle" objects.

Usage

```r
## S4 method for signature 'mle'
update(object, ..., evaluate = TRUE)
```

Arguments

- `object`: An existing fit.
- `...`: Additional arguments to the call, or arguments with changed values. Use `name = NULL` to remove the argument name.
- `evaluate`: If true evaluate the new call else return the call.
Methods

signature(object = "ANY") Generic function: see update.

signature(object = "mle") Update a fit.

Examples

x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 8, 5, 4, 8)
ll <- function(ymax = 15, xhalf = 6)
    -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
fit <- mle(ll)
## note the recorded call contains ..1, a problem with S4 dispatch
update(fit, fixed = list(xhalf = 3))

Description

Extract the approximate variance-covariance matrix from "mle" objects.

Methods

signature(object = "ANY") Generic function: see vcov.

signature(object = "mle") Extract the estimated variance-covariance matrix for the estimated parameters (if any).
Chapter 12

The tcltk package

**tcltk-package**  
*Tcl/Tk Interface*

**Description**

Interface and language bindings to Tcl/Tk GUI elements.

**Details**

This package provides access to the platform-independent Tcl scripting language and Tk GUI elements. See TkWidgets for a list of supported widgets, TkWidgetcmds for commands to work with them, and references in those files for more.

The Tcl/Tk documentation is in the system man pages.

For a complete list of functions, use `ls("package:tcltk")`.

Note that Tk will not be initialized if there is no DISPLAY variable set, but Tcl can still be used. This is most useful to allow the loading of a package which depends on tcltk in a session that does not actually use it (e.g., during installation).

**Author(s)**

Maintainer: R Core Team <R-core@r-project.org>

---

**TclInterface**  
*Low-level Tcl/Tk Interface*

**Description**

These functions and variables provide the basic glue between R and the Tcl interpreter and Tk GUI toolkit. Tk windows may be represented via R objects. Tcl variables can be accessed via objects of class tclVar and the C level interface to Tcl objects is accessed via objects of class tclObj.
### Usage

```
.Tcl(...) 
.Tcl.objv(objv) 
.Tcl.args(...) 
.Tcl.args.objv(...) 
.Tcl.callback(...) 
.Tk.ID(win) 
.Tk.newwin(ID) 
.Tk.subwin(parent) 
.TkRoot 
.TkUp

tkdestroy(win)
is.tkwin(x)

tclvalue(x)
tclvalue(x) <- value

tclVar(init = "")
## S3 method for class 'tclVar'
as.character(x, ...)
## S3 method for class 'tclVar'
tclvalue(x)
## S3 replacement method for class 'tclVar'
tclvalue(x) <- value

tclArray()
## S3 method for class 'tclArray'
x[[...]]
## S3 replacement method for class 'tclArray'
x[[...]] <- value
## S3 method for class 'tclArray'
x$i
## S3 replacement method for class 'tclArray'
x$i <- value

## S3 method for class 'tclArray'
names(x)
## S3 method for class 'tclArray'
length(x)

tclObj(x)
tclObj(x) <- value
## S3 method for class 'tclVar'
tclObj(x) 
## S3 replacement method for class 'tclVar'
tclObj(x) <- value

as.tclObj(x, drop = FALSE)
is.tclObj(x)

## S3 method for class 'tclObj'
```
as.character(x, ...)  
## S3 method for class 'tclObj'
as.integer(x, ...)   
## S3 method for class 'tclObj'
as.double(x, ...)   
## S3 method for class 'tclObj'
as.logical(x, ...)  
## S3 method for class 'tclObj'
as.raw(x, ...)      
## S3 method for class 'tclObj'
tclvalue(x)

## Default S3 method:
tclvalue(x)
## Default S3 replacement method:
tclvalue(x) <- value

tclVersion()

Arguments

objv     a named vector of Tcl objects
win      a window structure
x        an object
i        character or (unquoted) name
drop     logical. Indicates whether a single-element vector should be made into a simple
         Tcl object or a list of length one
value    For tclvalue assignments, a character string. For tclObj assignments, an ob-
         ject of class tclObj
ID       a window ID
parent   a window which becomes the parent of the resulting window
path     path to a directory containing Tcl packages
package  a Tcl package name
warn     logical. Warn if not found?
...      Additional arguments. See below.
init     initialization value

Details

Many of these functions are not intended for general use but are used internally by the commands
that create and manipulate Tk widgets and Tcl objects. At the lowest level .Tcl sends a command
as a text string to the Tcl interpreter and returns the result as an object of class tclObj (see below).
A newer variant .Tcl.objv accepts arguments in the form of a named list of tclObj objects.
.Tcl.args converts an R argument list of tag = value pairs to the Tcl -option value style, thus
enabling a simple translation between the two languages. To send a value with no preceding option
flag to Tcl, just use an untagged argument. In the rare case one needs an option with no subsequent
value tag = NULL can be used. Most values are just converted to character mode and inserted in the command string, but window objects are passed using their ID string, and callbacks are passed via the result of Tcl.Callback. Tags are converted to option flags simply by prepending a - .Tcl.args.objv serves a similar purpose as .Tcl.args but produces a list of tclObj objects suitable for passing to .Tcl.objv. The names of the list are converted to Tcl option style internally by .Tcl.objv.

Callbacks can be either atomic callbacks handled by .Tcl.Callback or expressions. An expression is treated as a list of atomic callbacks, with the following exceptions: if an element is a name, it is first evaluated in the callers frame, and likewise if it is an explicit function definition; the break expression is translated directly to the Tcl counterpart. .Tcl.Callback converts R functions and unevaluated calls to Tcl command strings. The argument must be either a function closure or an object of mode "call" followed by an environment. The return value in the first case is of the form R_call 0x408b94d4 in which the hexadecimal number is the memory address of the function. In the second case it will be of the form R_call_lang 0x8a95904 0x819bfd0. For expressions, a sequence of similar items is generated, separated by semicolons.

.Tcl.args takes special precautions to ensure that functions or calls will continue to exist at the specified address by assigning the callback into the relevant window environment (see below).

Tk windows are represented as objects of class tkwin which are lists containing a ID field and an env field which is an R environments, enclosed in the global environment. The value of the ID field is identical to the Tk window name. The env environment contains a parent variable and a num.subwin variable. If the window obtains sub-windows and callbacks, they are added as variables to the environment. .TkRoot is the top window with ID "."; this window is not displayed in order to avoid ill effects of closing it via window manager controls. The parent variable is undefined for .TkRoot.

.Tk.ID extracts the ID of a window, .Tk.newwin creates a new window environment with a given ID and .Tk.subwin creates a new window which is a sub-window of a given parent window.

.TkUp is a logical flag to indicate whether the Tk widget system is active; if FALSE, only the Tcl interpreter is available.

tkdestroy destroys a window and also removes the reference to a window from its parent.

is.tkwin can be used to test whether a given object is a window environment.

tclVar creates a new Tcl variable and initializes it to init. An R object of class tclVar is created to represent it. Using as.character on the object returns the Tcl variable name. Accessing the Tcl variable from R is done using the tclvalue function, which can also occur on the left-hand side of assignments. If tclvalue is passed an argument which is not a tclVar object, then it will assume that it is a character string explicitly naming global Tcl variable. Tcl variables created by tclVar are uniquely named and automatically unset by the garbage collector when the representing object is no longer in use.

tclArray creates a new Tcl array and initializes it to the empty array. An R object of class tclArray and inheriting from class tclVar is created to represent it. You can access elements of the Tcl array using indexing with [[ ] or $, which also allow replacement forms. Notice that Tcl arrays are associative by nature and hence unordered; indexing with a numeric index i refers to the element with the name as.character(i). Multiple indices are pasted together separated by commas to form a single name. You can query the length and the set of names in an array using methods for length and names, respectively; these cannot meaningfully be set so assignment forms exist only to print an error message.

It is possible to access Tcl’s ‘dual-ported’ objects directly, thus avoiding parsing and deparsing of their string representation. This works by using objects of class tclobj. The string representation of such objects can be extracted (but not set) using tclvalue and conversion to vectors of mode "character", "double", "integer", "logical", and "raw" is performed using the standard coercion functions as.character, etc. Conversely, such vectors can be converted using as.tclobj.
There is an ambiguity as to what should happen for length one vectors, controlled by the drop argument; there are cases where the distinction matters to Tcl, although mostly it treats them equivalently. Notice that tclvalue and as.character differ on an object whose string representation has embedded spaces, the former is sometimes to be preferred, in particular when applied to the result of tclread, tkgetOpenFile, and similar functions. The as.raw method returns a raw vector or a list of raw vectors and can be used to return binary data from Tcl.

The object behind a tclVar object is extracted using tclObj(x) which also allows an assignment form, in which the right hand side of the assignment is automatically converted using as.tclObj.

There is a print method for tclObj objects; it prints '<Tcl>' followed by the string representation of the object. Notice that as.character on a tclVar object is the name of the corresponding Tcl variable and not the value.

Tcl packages can be loaded with tclRequire; it may be necessary to add the directory where they are found to the Tcl search path with addTclPath. The return value is a class "tclObj" object if it succeeds, or FALSE if it fails (when a warning is issued). To see the current search path as an R character vector, use:

```r
strsplit(tclvalue('auto_path'), " ")[1]
```

The Tcl version (including patch level) is returned as a character string (such as "8.6.3").

Note

Strings containing unbalanced braces are currently not handled well in many circumstances.

TkWidgets, TkCommands, TkWidgetcmds.

capabilities("tcltk") to see if Tcl/Tk support was compiled into this build of R.

Examples

tclVersion()
.Tcl("format "%s
" Hello, World!"")

f <- function() cat("HI!\n")
.Tcl.callback(f)
.Tcl.args(text = "Push!", command = f) # NB: Different address

xyzzy <- tclVar(7913)
tclvalue(xyzzy)
tclvalue(xyzzy) <- "foo"
as.character(xyzzy)
tcl("set", as.character(xyzzy))

## Not run:
## These cannot be run by example() but should be OK when pasted
## into an interactive R session with the tcltk package loaded
top <- tktoplevel() # a Tk widget, see Tk-widgets
top$env = top$env, all.names = TRUE)

## End(Not run)
tclServiceMode

Allow Tcl events to be serviced or not

Description

This function controls or reports on the Tcl service mode, i.e., whether Tcl will respond to events.

Usage

tclServiceMode(on = NULL)

Arguments

on (logical) Whether event servicing is turned on.

Details

If called with on == NULL (the default), no change is made.

Note that this blocks all Tcl/Tk activity, including for widgets from other packages. It may be better to manage mapping of windows individually.

Value

The value of the Tcl service mode before the call.

Examples

## see demo(tkcanvas) for an example
oldmode <- tclServiceMode(FALSE)
# Do some work to create a nice picture.
# Nothing will be displayed until...
tclServiceMode(oldmode)
## another idea is to use tkwm.withdraw() ... tkwm.deiconify()
Usage

tclopen(...)             
tcloclose(...)           
tclputs(...)             
tclread(...)             
```

### Arguments
- **x**  
  A window object
- **value**  
  For `tktitle` assignments, a character string.
- **...**  
  Handled via `.Tcl.args`

### Details
`tcl` provides a generic interface to calling any Tk or Tcl command by simply running `.Tcl.args.objv` on the argument list and passing the result to `.Tcl.objv`. Most of the other commands simply call `tcl` with a particular first argument and sometimes also a second argument giving the subcommand.

`tktitle` and its assignment form provides an alternate interface to Tk's `wm title`

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. With a few exceptions, the pattern is that Tk subcommands like `pack configure` are converted to function names like `tkpack.configure`, and Tcl subcommands are like `tclfile.dir`. 
### tkpager

**Page file using Tk text widget**

**Description**

This plugs into `file.show`, showing files in separate windows.

**Usage**

```
tkpager(file, header, title, delete.file)
```

**Arguments**

- `file` character vector containing the names of the files to be displayed
- `header` headers to use for each file
- `title` common title to use for the window(s). Pasted together with the `header` to form actual window title.
- `delete.file` logical. Should file(s) be deleted after display?

**Note**

The "\b_" string used for underlining is currently quietly removed. The font and background colour are currently hardcoded to Courier and gray90.

**See Also**

- `file.show`
tkProgressBar

Progress Bars via Tk

Description

Put up a Tk progress bar widget.

Usage

tkProgressBar(title = "R progress bar", label = "", 
               min = 0, max = 1, initial = 0, width = 300)

getTkProgressBar(pb)
setTkProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'tkProgressBar'
close(con, ...)

Arguments

title, label character strings, giving the window title and the label on the dialog box respectively.
min, max (finite) numeric values for the extremes of the progress bar.
initial, value initial or new value for the progress bar.
width the width of the progress bar in pixels: the dialog box will be 40 pixels wider (plus frame).
pb, con an object of class "tkProgressBar".
... for consistency with the generic.

Details

tkProgressBar will display a widget containing a label and progress bar.
setTkProgressBar will update the value and for non-NULL values, the title and label (provided there was one when the widget was created). Missing (NA) and out-of-range values of value will be (silently) ignored.
The progress bar should be closed when finished with.

This will use the ttk::progressbar widget for Tk version 8.5 or later, otherwise R’s copy of BWidget’s progressbar.

Value

For tkProgressBar an object of class "tkProgressBar".
For getTkProgressBar and setTkProgressBar, a length-one numeric vector giving the previous value (invisibly for setTkProgressBar).

See Also

txtProgressBar
Examples

```r
pb <- tkProgressBar("test progress bar", "Some information in %", 0, 100, 50)
Sys.sleep(0.5)
u <- c(0, sort(runif(20, 0, 100)), 100)
for(i in u) {
  Sys.sleep(0.1)
  info <- sprintf("%d%% done", round(i))
  setTkProgressBar(pb, i, sprintf("test (%s)", info), info)
}
Sys.sleep(5)
close(pb)
```

tkStartGUI  
<Tcl/Tk GUI startup>

Description

Starts up the Tcl/Tk GUI

Usage

```r
tkStartGUI()
```

Details

Starts a GUI console implemented via a Tk text widget. This should probably be called at most once per session. Also redefines the file pager (as used by `help()`) to be the Tk pager.

Note

`tkStartGUI()` saves its evaluation environment as `.GUIenv`. This means that the user interface elements can be accessed in order to extend the interface. The three main objects are named `Term`, `Menu`, and `Toolbar`, and the various submenus and callback functions can be seen with `ls(envir = .GUIenv)`.

Peter Dalgaard

TkWidgetcmds  
<Tk widget commands>

Description

These functions interface to Tk widget commands.
Usage

tkactivate(widget, ...)
tkadd(widget, ...)
tkaddtag(widget, ...)
tkbbox(widget, ...)
tkcanvasx(widget, ...)
tkcanvasy(widget, ...)
tkcget(widget, ...)
tkcompare(widget, ...)
tkconfigure(widget, ...)
tkcoords(widget, ...)
tkcreate(widget, ...)
tkcurselection(widget, ...)
tkdchars(widget, ...)
tkdebug(widget, ...)
tkdelete(widget, ...)
tkdelta(widget, ...)
tkdeselect(widget, ...)
tkdlineinfo(widget, ...)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>widget</td>
<td>The widget this applies to</td>
</tr>
<tr>
<td>...</td>
<td>Handled via .Tcl.args</td>
</tr>
</tbody>
</table>

Details

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. Except for a few exceptions, the pattern is that Tcl widget commands possibly with subcommands like .a.b selection clear are converted to function names like tkselection.clear and the widget is given as the first argument.
TkWidgets

Examples

```r
## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
tkpack(txt.w <- tktext(tt))
tkinsert(txt.w, "0.0", "plot(1:10)"

# callback function
eval.txt <- function() eval(str2lang(tclvalue(tkget(txt.w, "0.0", "end"))))
tkpack(but.w <- tbbutton(tt, text = "Submit", command = eval.txt))

## Try pressing the button, edit the text and when finished:
tkdestroy(tt)

## End(Not run)
```

---

TkWidgets

Tk widgets

Description

Create Tk widgets and associated R objects.

Usage

```r
tkwidgit(parent, type, ...)
tkbutton(parent, ...)
tkcanvas(parent, ...)
tkcheckbutton(parent, ...)
tkentry(parent, ...)
ttkentry(parent, ...)
tkframe(parent, ...)
tklabel(parent, ...)
tklistbox(parent, ...)
tkmenu(parent, ...)
tkmenubutton(parent, ...)
tkmessage(parent, ...)
tkradiobutton(parent, ...)
tkscale(parent, ...)
tkscrollbar(parent, ...)
tktext(parent, ...)
tkttoplevel(parent = .TkRoot, ...)
```
ttkbutton(parent, ...)
ttkcheckbutton(parent, ...)
ttkcombobox(parent, ...)
ttkframe(parent, ...)
ttklabel(parent, ...)
ttklabeledframe(parent, ...)
ttkmenubutton(parent, ...)
ttknotebook(parent, ...)
ttkpanedwindow(parent, ...)
ttkprogressbar(parent, ...)
ttkradiobutton(parent, ...)
ttkscrollbar(parent, ...)
ttkseparator(parent, ...)
ttksizegrip(parent, ...)
ttkspinbox(parent, ...)
ttktreeview(parent, ...)

Arguments

parent Parent of widget window.
type string describing the type of widget desired.
... handled via .Tcl.args.

Details

These functions create Tk widgets. tkwidget creates a widget of a given type, the others simply call tkwidget with the respective type argument.

The functions starting ttk are for the themed widget set for Tk 8.5 or later. A tutorial can be found at https://tkdocs.com/.

It is not possible to describe the widgets and their arguments in full. Please refer to the Tcl/Tk documentation.

See Also

TclInterface, TkCommands, TkWidgetcmds

Examples

## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
label.widget <- tklabel(tt, text = "Hello, World!")
button.widget <- tkbutton(tt, text = "Push",
                        command = function()cat("OW!\n"))
tkpack(label.widget, button.widget) # geometry manager
                      # see Tk-commands

## Push the button and then...

tkdestroy(tt)
## test for themed widgets

```r
if(as.character(tcl("info", "tclversion")) >= "8.5") {
  # make use of themed widgets
  # list themes
  themes <- as.character(tcl("ttk::style", "theme", "names"))
  themes
  # select a theme -- for pre-XP windows
  # tcl("ttk::style", "theme", "use", "winnative")
tcl("ttk::style", "theme", "use", themes[1])
} else {
  # use Tk 8.0 widgets
}
```

## End(Not run)

---

tk_choose.dir

### Choose a Folder Interactively

#### Description

Use a Tk widget to choose a directory interactively.

#### Usage

```r
tk_choose.dir(default = "", caption = "Select directory")
```

#### Arguments

- `default`: which directory to show initially.
- `caption`: the caption on the selection dialog.

#### Value

A length-one character vector, character NA if ‘Cancel’ was selected.

#### See Also

- `tk_choose.files`

#### Examples

```r
if (interactive()) tk_choose.dir(getwd(), "Choose a suitable folder")
```
tk_choose.files  
Choose a List of Files Interactively

Description

Use a Tk file dialog to choose a list of zero or more files interactively.

Usage

```r
tk_choose.files(default = "", caption = "Select files",
                  multi = TRUE, filters = NULL, index = 1)
```

Arguments

- **default**: which filename to show initially.
- **caption**: the caption on the file selection dialog.
- **multi**: whether to allow multiple files to be selected.
- **filters**: two-column character matrix of filename filters.
- **index**: unused.

Details

Unlike `file.choose`, `tk_choose.files` will always attempt to return a character vector giving a list of files. If the user cancels the dialog, then zero files are returned, whereas `file.choose` would signal an error.

The format of `filters` can be seen from the example. File patterns are specified via extensions, with "*" meaning any file, and "" any file without an extension (a filename not containing a period). (Other forms may work on specific platforms.) Note that the way to have multiple extensions for one file type is to have multiple rows with the same name in the first column, and that whether the extensions are named in the file chooser widget is platform-specific. The format may change before release.

Value

A character vector giving zero or more file paths.

Note

A bug in Tk 8.5.0–8.5.4 prevented multiple selections being used.

See Also

`file.choose`, `tk_choose.dir`

Examples

```r
Filters <- matrix(c("R code", ".R", "R code", ".s",
                    "Text", ".txt", "All files", "*"),
                   4, 2, byrow = TRUE)
Filters
if(interactive()) tk_choose.files(filter = Filters)
```
tk_messageBox  

Tk Message Box

Description

An implementation of a generic message box using Tk.

Usage

tk_messageBox(type = c("ok", "okcancel", "yesno", "yesnocancel",  
               "retrycancel", "abortretryignore"),  
               message, caption = "", default = "", ...)

Arguments

type character. The type of dialog box. It will have the buttons implied by its name.  
Can be abbreviated.

message character. The information field of the dialog box.

caption the caption on the widget displayed.

default character. The name of the button to be used as the default.

... additional named arguments to be passed to the Tk function of this name. An  
example is icon = "warning".

Value

A character string giving the name of the button pressed.

See Also

tkmessageBox for a ‘raw’ interface.

tk_select.list Select Items from a List

Description

Select item(s) from a character vector using a Tk listbox.

Usage

tk_select.list(choices, preselect = NULL, multiple = FALSE,  
               title = NULL)

Arguments

choices a character vector of items.

preselect a character vector, or NULL. If non-null and if the string(s) appear in the list, the  
item(s) are selected initially.

multiple logical: can more than one item be selected?

title optional character string for window title, or NULL for no title.
Details

This is a version of \texttt{select.list} implemented as a Tk list box plus OK and Cancel buttons. There will be a scrollbar if the list is too long to fit comfortably on the screen.

The dialog box is modal, so a selection must be made or cancelled before the R session can proceed. Double-clicking on an item is equivalent to selecting it and then clicking OK.

If Tk is version 8.5 or later, themed widgets will be used.

Value

A character vector of selected items. If \texttt{multiple} is false and no item was selected (or Cancel was used), "" is returned. If \texttt{multiple} is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

See Also

\texttt{select.list} (a text version except on Windows and the macOS GUI), \texttt{menu} (whose graphics = TRUE mode uses this on most Unix-alikes).
Chapter 13

The tools package

tools-package  Tools for Package Development

Description
Tools for package development, administration and documentation.

Details
This package contains tools for manipulating R packages and their documentation.
For a complete list of functions, use library(help = "tools").

Author(s)
Kurt Hornik and Friedrich Leisch
Maintainer: R Core Team <R-core@r-project.org>

.print.via.format  Printing Utilities

Description
.print.via.format is a “prototype” print() method, useful, at least as a start, by a simple

   print.<myS3class> <- .print.via.format

Usage
.print.via.format(x, ...)

Arguments
x  object to be printed.
... optional further arguments, passed to format.
Value

x, invisibly (by invisible()), as print methods should.

See Also

The print generic; its default method print.default (used for many basic implicit classes such as "numeric", "character" and arrays of them, lists etc).

Examples

## The function is simply defined as
function (x, ...) {
  writelines(format(x, ...))
  invisible(x)
}
## is used for simple print methods in R, and as prototype for new methods.

---

**add_datalist**

Add a ‘datalist’ File to a Source Package

Description

The data() command with no arguments lists all the datasets available via data in attached packages, and to do so a per-package list is installed. Creating that list at install time can be slow for packages with huge datasets, and can be expedited by a supplying ‘data/datalist’ file.

Usage

add_datalist(pkgpath, force = FALSE, small.size = 1024^2)

Arguments

pkgpath The path to a (source) package.
force logical: can an existing ‘data/datalist’ file be over-written?
small.size number: a ‘data/datalist’ file is created only if the total size of the data files is larger than small.size bytes.

Details

R CMD build will call this function to add a data list to packages with 1MB or more of file in the ‘data’ directory.

It can also be also helpful to give a ‘data/datalist’ file in packages whose datasets have many dependencies, including loading the packages itself (and maybe others).

See Also

data.

The ‘Writing R Extensions’ manual.
assertCondition

assertCondition

Asserting Error Conditions

Description
When testing code, it is not sufficient to check that results are correct, but also that errors or warnings are signalled in appropriate situations. The functions described here provide a convenient facility for doing so. The three functions check that evaluating the supplied expression produces an error, a warning or one of a specified list of conditions, respectively. If the assertion fails, an error is signalled.

Usage

assertError(expr, classes = "error", verbose = FALSE)
assertWarning(expr, classes = "warning", verbose = FALSE)
assertCondition(expr, ..., .exprString = , verbose = FALSE)

Arguments

expr an unevaluated R expression which will be evaluated via tryCatch(expr, ...).
classes,... character strings corresponding to the classes of the conditions that would satisfy the assertion; e.g., "error" or "warning". If none are specified, any condition will satisfy the assertion. See the details section.
.exprString The string to be printed corresponding to expr. By default, the actual expr will be deparsed. Will be omitted if the function is supplied with the actual expression to be tested. If assertCondition() is called from another function, with the actual expression passed as an argument to that function, supply the deparsed version.
verbose If TRUE, a message is printed when the condition is satisfied.

Details

assertCondition() uses the general condition mechanism to check all the conditions generated in evaluating expr. The occurrence of any of the supplied condition classes among these satisfies the assertion regardless of what other conditions may be signalled.
assertError() is a convenience function for asserting errors; it calls assertCondition().
assertWarning() asserts that a warning will be signalled, but not an error, whereas assertCondition(expr, "warning") will be satisfied even if an error follows the warning. See the examples.

Value
If the assertion is satisfied, a list of all the condition objects signalled is returned, invisibly. See conditionMessage for the interpretation of these objects. Note that all conditions signalled during the evaluation are returned, whether or not they were among the requirements.

Author(s)
John Chambers and Martin Maechler
See Also

stop, warning; signalCondition, tryCatch.

Examples

```r
assertError(sqrt("abc"))
assertWarning(matrix(1:8, 4,3))

assertCondition(""-1") # ok, any condition would satisfy this

try( assertCondition(sqrt(2), "warning") )
## .. Failed to get warning in evaluating sqrt(2)
assertCondition(sqrt("abc"), "error") # ok
try( assertCondition(sqrt("abc"), "warning") ) # -> error: had no warning
   assertCondition(sqrt("abc"), "error")
   ## identical to assertError() call above

assertCondition(matrix(1:5, 2,3), "warning")
try( assertCondition(matrix(1:8, 4,3), "error") )
## .. Failed to get expected error ....

## either warning or worse:
assertCondition(matrix(1:8, 4,3), "error","warning") # OK
assertCondition(matrix(1:8, 4,3), "warning") # OK

## when both are signalled:
ff <- function() { warning("my warning"); stop("my error") }
assertCondition(ff(), "warning")
   ## but assertWarning does not allow an error to follow
try(assertWarning(ff()))
   assertCondition(ff(), "error") # ok
assertCondition(ff(), "error", "warning") # ok (quietly, catching warning)

## assert that assertC..() does not assert [and use *one* argument only]
assertCondition( assertCondition(sqrt(2), "warning") )
assertCondition( assertCondition(sqrt("abc"), "warning"), "error")
assertCondition( assertCondition(matrix(1:8, 4,3), "error"), "error")
```

Description

This function defines and registers styles for rendering bibentry objects into ’Rd’ format, for later conversion to text, HTML, etc.

Usage

```r
bibstyle(style, envir, ...., .init = FALSE, .default = TRUE)
getBibstyle(all = FALSE)
```
Arguments

- `style` A character string naming the style.
- `envir` (optional) An environment holding the functions to implement the style.
- `...` Named arguments to add to the environment.
- `.init` Whether to initialize the environment from the default style "JSS".
- `.default` Whether to set the specified style as the default style.
- `all` Whether to return the names of all registered styles.

Details

Rendering of `bibentry` objects may be done using routines modelled after those used by BibTeX. This function allows environments to be created and manipulated to contain those routines.

There are two ways to create a new style environment. The easiest is to set `.init = TRUE`, in which case the environment will be initialized with a copy of the default "JSS" environment. (This style is modelled after the ‘jss.bst’ style used by the *Journal of Statistical Software*.) Alternatively, the `envir` argument can be used to specify a completely new style environment.

To find the name of the default style, use `getBibstyle()`. To retrieve an existing style without setting it as the default, use `bibstyle(style, .default = FALSE)`. To modify an existing style, specify `style` and some named entries via `. ...`. (Modifying the default "JSS" style is discouraged.) Setting `style` to `NULL` or leaving it missing will retrieve the default style, but modifications will not be allowed.

At a minimum, the environment should contain routines to render each of the 12 types of bibliographic entry supported by `bibentry` as well as several other routines described below. The former must be named `formatArticle`, `formatBook`, `formatInbook`, `formatIncollection`, `formatInProceedings`, `formatManual`, `formatMastersthesis`, `formatMisc`, `formatPhdthesis`, `formatProceedings`, `formatTechreport` and `formatUnpublished`. Each of these takes one argument, a single `unclass`ed entry from the `bibentry` vector passed to the renderer, and should produce a single element character vector (possibly containing newlines).

The other routines are as follows. `sortKeys`, a function to produce a sort key to sort the entries, is passed the original `bibentry` vector and should produce a sortable vector of the same length to define the sort order. Finally, the optional function `cite` should have the same argument list as `utils::cite`, and should produce a citation to be used in text.

The `format` method for “bibentry” objects adds a field named “.index” to each entry after sorting and before formatting. This is a 1-based index within the complete object that can be used in styles that require numbering. Although the "JSS" style doesn’t use numbers, it includes a `fmtPrefix()` stub function that may be used to display them. See the example below.

Value

`bibstyle` returns the environment which has been selected or created.

`getBibstyle` returns the name of the default style, or all style names.

Author(s)

Duncan Murdoch

bibstyle("unsorted", sortKeys = function(refs) seq_along(refs), 
    fmtPrefix = function(paper) paste0("[", paper$.index, 
        "]", 
    .init = TRUE)
print(refs, .bibstyle = "unsorted")
```

Description

**Build One Vignette**

This is the workhorse of R CMD Sweave.

Usage

```r
buildVignette(file, dir = ".", weave = TRUE, latex = TRUE, tangle = TRUE, 
    quiet = TRUE, clean = TRUE, keep = character(), 
    engine = NULL, buildPkg = NULL, encoding, ...)
```

Arguments

- `file` character; the vignette source file.
- `dir` character; the working directory in which the intermediate and output files will be produced.
- `weave` logical; should weave be run?
- `latex` logical; should `texi2pdf` be run if weaving produces a `.tex` file?
- `tangle` logical; should tangle be run?
- `quiet` logical; run in quiet mode?
- `clean` logical; whether to remove some newly created, often intermediate, files. See details below.
buildVignettes

keep  a list of file names to keep in any case when cleaning. Note that “target” files are kept anyway.

engine NULL or character; name of vignette engine to use. Overrides any ‘\VignetteEngine{}’ markup in the vignette.

buildPkg NULL or a character vector; optional packages in which to find the vignette engine.

encoding  the encoding to assume for the file. If not specified, it will be read if possible from the file’s contents. Note that if the vignette is part of a package, buildVignettes reads the package’s encoding from the ‘DESCRIPTION’ file but this function does not.

...  Additional arguments passed to weave and tangle.

Details

This function determines the vignette engine for the vignette (default utils::Sweave), then weaves and/or tangles the vignette using that engine. Finally, if clean is TRUE, newly created intermediate files (non “targets”, where these depend on the engine, etc, and not any in keep) will be deleted. If clean is NA, and weave is true, newly created intermediate output files (e.g., ‘.tex’) will not be deleted even if a ‘.pdf’ file has been produced from them.

If buildPkg is specified, those packages will be loaded before the vignette is processed and will be used as the default packages in the search for a vignette engine, but an explicitly specified package in the vignette source (e.g., using ‘\VignetteEngine{utils::Sweave}’ to specify the Sweave engine in the utils package) will override it. In contrast, if the engine argument is given, it will override the vignette source.

Value

A character vector naming the files that have been produced.

Author(s)

Henrik Bengtsson and Duncan Murdoch

See Also

buildVignettes for building all vignettes in a package.
Usage

buildVignettes(package, dir, lib.loc = NULL, quiet = TRUE,
    clean = TRUE, tangle = FALSE, skip = NULL,
    ser_elibs = NULL)

pkgVignettes(package, dir, subdirs = NULL, lib.loc = NULL,
    output = FALSE, source = FALSE, check = FALSE)

Arguments

package a character string naming an installed package. If given, vignette source files are by default looked for in subdirectory ‘doc’.
dir a character string specifying the path to a package’s root source directory. If given, vignette source files are by default looked for in subdirectory ‘vignettes’.
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
quiet logical. Weave and run texi2pdf in quiet mode.
clean Remove all files generated by the build, even if there were copies there before.
tangle logical. Do tangling as well as weaving.
skip a character vector of names of vignettes (without file extension, matching the names returned from pkgVignettes) which should be skipped, or TRUE to skip those with unavailable ‘\VignetteDepends’ (from vignetteInfo).
ser_elibs For use from R CMD check.
subdirs a character vector of subdirectories of dir in which to look for vignettes. The first which exists is used. Defaults to “doc” if package is supplied, otherwise “vignettes”.
output logical indicating if the output filenames for each vignette should be returned (in component outputs).
source logical indicating if the tangled output filenames for each vignette should be returned (in component sources).
check logical. If TRUE, check whether all files that have vignette-like filenames have an identifiable vignette engine. This may be a false positive if a file is not a vignette but has a filename matching a pattern defined by one of the vignette engines.

details

buildVignettes is used by R CMD build and R CMD check to (re-)build vignette outputs from their sources.

As from R 3.4.1, both of these functions ignore files that are listed in the ‘.Rbuildignore’ file in dir.

Value

buildVignettes is called for its side effect of creating the outputs of all vignettes, and if tangle = TRUE, extracting the R code.

pkgVignettes returns an object of class ”pkgVignettes” if a vignette directory is found, otherwise NULL.
Examples

```r
gVigns <- pkgVignettes("grid")
str(gVigns)
```

---

## Conversion Tables between Character Sets

### Description

`charset_to_Unicode` is a matrix of Unicode code points with columns for the common 8-bit encodings.

`Adobe_glyphs` is a data frame which gives Adobe glyph names for Unicode code points. It has two character columns, "adobe" and "unicode" (a 4-digit hex representation).

### Usage

```r
charset_to_Unicode
Adobe_glyphs
```

### Details

`charset_to_Unicode` is an integer matrix of class `c("noquote", "hexmode")` so prints in hexadecimal. The mappings are those used by `libiconv`: there are differences in the way quotes and minus/hyphen are mapped between sources (and the postscript encoding files use a different mapping).

`Adobe_glyphs` includes all the Adobe glyph names which correspond to single Unicode characters. It is sorted by Unicode code point and within a point alphabetically on the glyph (there can be more than one name for a Unicode code point). The data are in the file `R_HOME/share/encodings/Adobe_glyphlist`.

### Examples

```r
## find Adobe names for ISOLatin2 chars.
latin2 <- charset_to_Unicode[, "ISOLatin2"]
aUnicode <- as.hexmode(paste0("0x", Adobe_glyphs$unicode))
keep <- aUnicode %in% latin2
aUnicode <- aUnicode[keep]
aAdobe <- Adobe_glyphs[keep, 1]
## first match
aLatin2 <- aAdobe[match(latin2, aUnicode)]
## all matches
bLatin2 <- lapply(1:256, function(x) aAdobe[aUnicode == latin2[x]])
format(bLatin2, justify = "none")
```
checkFF

Check Foreign Function Calls

Description

Performs checks on calls to compiled code from R code. Currently only checks whether the interface functions such as `.C` and `.Fortran` are called with a "NativeSymbolInfo" first argument or with argument `PACKAGE` specified, which is highly recommended to avoid name clashes in foreign function calls.

Usage

```r
checkFF(package, dir, file, lib.loc = NULL, 
registration = FALSE, check_DUP = FALSE, 
verbose = getOption("verbose"))
```

Arguments

- **package**: a character string naming an installed package. If given, the installed R code of the package is checked.
- **dir**: a character string specifying the path to a package's root source directory. This should contain the subdirectory 'R' (for R code). Only used if `package` is not given.
- **file**: the name of a file containing R code to be checked. Used if neither `package` nor `dir` are given.
- **lib.loc**: a character vector of directory names of R libraries, or `NULL`. The default value of `NULL` corresponds to all libraries currently known. The specified library trees are used to search for `package`.
- **registration**: a logical. If `TRUE`, checks the registration information on the call (if available).
- **check_DUP**: a logical. If `TRUE`, `.C` and `.Fortran` calls with `DUP = FALSE` are reported.
- **verbose**: a logical. If `TRUE`, additional diagnostics are printed (and the result is returned invisibly).

Details

Note that we can only check if the name argument is a symbol or a character string, not what class of object the symbol resolves to at run-time.

If the package has a namespace which contains a `useDynLib` directive, calls in top-level functions in the package are not reported as their symbols will be preferentially looked up in the DLL named in the first `useDynLib` directive.

This checks that calls with `PACKAGE` specified are to the same package, and reports separately those which are in base packages and those which are in other packages (and if those packages are specified in the 'DESCRIPTION' file).

Value

An object of class "checkFF".

There are `format` and `print` methods to display the information contained in such objects.
checkMD5sums

See Also

.C..Fortran;Foreign.

Examples

# order is pretty much random
checkFF(package = "stats", verbose = TRUE)

checkMD5sums

Check and Create MD5 Checksum Files

Description

checkMD5sums checks the files against a file ‘MD5’.

Usage

checkMD5sums(package, dir)

Arguments

package the name of an installed package
dir the path to the top-level directory of an installed package.

Details

The file ‘MD5’ which is created is in a format which can be checked by md5sum -c MD5 if a suitable command-line version of md5sum is available. (For Windows, one is supplied in the bundle at https://cran.r-project.org/bin/windows/Rtools/.)

If dir is missing, an installed package of name package is searched for.

The private function tools:::.installMD5sums is used to create MD5 files in the Windows build.

Value

checkMD5sums returns a logical, NA if there is no ‘MD5’ file to be checked.

md5sum
checkPoFiles

Check Translation Files for Inconsistent Format Strings

Description

These functions compare formats embedded in English messages with translated strings to check for consistency. checkPoFile checks one file, while checkPoFiles checks all files for specified or all languages.

Usage

checkPoFile(f, strictPlural = FALSE)
checkPoFiles(language, dir = ".")

Arguments

f  a character string giving a single filepath.
strictPlural  whether to compare formats of singular and plural forms in a strict way.
language  a character string giving a language code, or a ‘regexp’ (regular expression), to match languages in dir. Use "" to denote all languages in the dir path.
dir  a path to a directory in which to check files.

Details

Part of R’s internationalization depends on translations of messages in ‘.po’ files. In these files an ‘English’ message taken from the R sources is followed by a translation into another language. Many of these messages are format strings for C or R sprintf and related functions. In these cases, the translation must give a compatible format or an error will be generated when the message is displayed.

The rules for compatibility differ between C and R in several ways. C supports several conversions not supported by R, namely c, u, p, n. It is allowed in C’s sprintf() function to have more arguments than are needed by the format string, but in R the counts must match exactly. R requires types of arguments to match, whereas C will do the display whether it makes sense or not.

These functions compromise on the testing as follows. The additional formats allowed in C are accepted, and all differences in argument type or count are reported. As a consequence some reported differences are not errors.

If the strictPlural argument is TRUE, then argument lists must agree exactly between singular and plural forms of messages; if FALSE, then translations only need to match one or the other of the two forms. When checkPoFiles calls checkPoFile, the strictPlural argument is set to TRUE for files with names starting ‘R-’, and to FALSE otherwise.

Items marked as ‘fuzzy’ in the ‘.po’ file are not processed (as they are ignored by the message compiler).

If a difference is found, the translated string is checked for variant percent signs (e.g., the wide percent sign "\uFF05"). Such signs will not be recognized as format specifiers, and are likely to be errors.

Value

Both functions return an object of S3 class "check_po_files". A print method is defined for this class to display a report on the differences.
checkRd

Author(s)
Duncan Murdoch

References
See the GNU gettext manual for the `.po` file format:

See Also
update_pkg_po() which calls checkPoFile(): xgettext, sprintf.

Examples
```r
## Not run:
checkPoFiles("de", "/path/to/R/src/directory")
## End(Not run)
```

checkRd  Check an Rd Object

Description
Check an help file or the output of the parse_Rd function.

Usage
```r
checkRd(Rd, defines = .Platform$OS.type, stages = "render",
        unknownOK = TRUE, listOK = TRUE, ..., def_enc = FALSE)
```

Arguments
- **Rd**: a filename or Rd object to use as input.
- **defines**: string(s) to use in #ifdef tests.
- **stages**: at which stage ("build", "install", or "render") should \Sexpr macros be executed? See the notes below.
- **unknownOK**: unrecognized macros are treated as errors if FALSE, otherwise warnings.
- **listOK**: unnecessary non-empty braces (e.g., around text, not as an argument) are treated as errors if FALSE, otherwise warnings ("Lost braces").
- **...**: additional parameters to pass to parse_Rd when Rd is a filename. One that is often useful is encoding.
- **def_enc**: logical: has the package declared an encoding, so tests for non-ASCII text are suppressed?
checkRd performs consistency checks on an Rd file, confirming that required sections are present, etc.

It accepts a filename for an Rd file, and will use `parse_Rd` to parse it before applying the checks. If so, warnings from `parse_Rd` are collected, together with those from the internal function `prepare_Rd`, which does the `#ifdef` and `\Sexpr` processing, drops sections that would not be rendered or are duplicated (and should not be) and removes empty sections.

An Rd object is passed through `prepare_Rd`, but it may already have been (and installed Rd objects have).

Warnings are given a ‘level’: those from `prepare_Rd` have level 0. These include:

- `\Sexpr` expects R code; found …
- Unprocessed ’stage’ macro from stage-stage `\Sexpr`
- All text must be in a section
- Only one tag name section is allowed: the first will be used
- `docType` type is unrecognized
- Section name is unrecognized and will be dropped
- Dropping empty section name

checkRd itself can show:

- Tag tag name not recognized
- Unrecognized format: …
- `\tabular` format must be simple text
- Unrecognized `\tabular` format: …
- Only n columns allowed in this table
- Tag tag name is invalid in a block name block
- `\method` not valid outside a code block
- Tag `\method` is only valid in `\usage`
- Tag `\dontrun` is only valid in `\examples`
- Invalid email address: …
- Invalid URL: …
- `\name` should not contain !, | or @
- `\item` in block name must have non-empty label
- Empty section tag name
- `\name` should only contain printable ASCII characters
- Non-ASCII contents without declared encoding
- Non-ASCII contents in second part of `\enc`
- Escaped LaTeX specials: …
- Lost braces …
- Tag `\ldots` is invalid in a code block
- `\title` should not end in a period

and variations with `\method` replaced by `\S3method` or `\S4method`, `\dontrun` replaced by `\donttest`, `\dontdiff` or `\dontshow`, and `\title` replaced by `\section` or `\subsection` name.

“Lost braces” are uprated to warning level -1 when they match common markup mistakes, e.g., `\code{text}` rendered as `\texttt{text}` due to the missing backslash escape for the macro name.

Note that both `prepare_Rd` and `checkRd` have tests for an empty section: that in `checkRd` is stricter (essentially that nothing is output).
checkRdaFiles

Value

This may fail through an R error, but otherwise warnings are collected as returned as an object of class "checkRd", a character vector of messages. This class has a print method which only prints unique messages, and has argument minlevel that can be used to select only more serious messages. (This is set to -1 in R CMD check.) Possible fatal errors are those from !unknownOK or !listOK, from invalid \if or \ifelse conditions, from running the parser (e.g., a non-existent file, unclosed quoted string, non-ASCII input without a specified encoding, an invalid value for an \Sexpr option), or from prepare_Rd (multiple Rdversion declarations, invalid \encoding or \docType or \name sections, and missing or duplicate \name or \title sections), including errors from parsing/running code from \Sexpr macros (if covered by stages).

parse_Rd, Rd2HTML.

Examples

## parsed Rd from the installed version of _this_ help file
d <- Rd_db("tools")[["checkRd.Rd"]]
d
stopifnot(length(checkRd(d)) == 0) # there should be no issues

## make up \tabular issues
bad <- r"\name{bad}\title{bad}\description{\tabular{p}{1 \tab 2}}"
(res <- checkRd(parse_Rd(textConnection(bad))))
stopifnot(length(res) > 0)
Arguments

paths      A character vector of paths to save files. If this specifies a single directory, it is taken to refer to all `.rda` and `.RData` files in that directory.
compress, compression_level
          Type and level of compression: see save. Values of compress can be abbreviated.
version    The format to be used when re-saving: see save.

Details

compress = "auto" asks R to choose the compression and ignores compression_level. It will try "gzip", "bzip2" and if the "gzip" compressed size is over 10Kb, "xz" and choose the smallest compressed file (but with a 10% bias towards "gzip"). This can be slow.

For back-compatibility, version = NULL is interpreted to mean version 2: however version-3 files will only be saved as version 3.

Value

For checkRdaFiles, a data frame with rows names paths and columns

size      numeric: file size in bytes, NA if the file does not exist.
ASCII     logical: true for save(ASCII = TRUE), NA if the format is not that of an R save file.
compress  character: type of compression. One of "gzip", "bzip2", "xz", "none" or "unknown" (which means that if this is an R save file it is from a later version of R).
version    integer: positive with the version(s) of the save(), see there on which versions have been default in which versions of R, and NA for non-Rda files.

Examples

```r
## Not run:
## from a package top-level source directory
paths <- sort(Sys.glob(c("data/*.rda", "data/*.RData")))
(res <- checkRdaFiles(paths))
## pick out some that may need attention
bad <- is.na(res$ASCII) | res$ASCII | (res$size > 1e4 & res$compress == "none")
res[bad, ]
## End(Not run)
```

checkTnF                Check R Packages or Code for T/F

Description

Checks the specified R package or code file for occurrences of T or F, and gathers the expression containing these. This is useful as in R T and F are just variables which are set to the logicals TRUE and FALSE by default, but are not reserved words and hence can be overwritten by the user. Hence, one should always use TRUE and FALSE for the logicals.
Usage

checkTnF(package, dir, file, lib.loc = NULL)

Arguments

package a character string naming an installed package. If given, the installed R code and the examples in the documentation files of the package are checked. R code installed as an image file cannot be checked.
dir a character string specifying the path to a package’s root source directory. This must contain the subdirectory ‘R’ (for R code), and should also contain ‘man’ (for documentation). Only used if package is not given. If used, the R code files and the examples in the documentation files are checked.
file the name of a file containing R code to be checked. Used if neither package nor dir are given.
lib.loc a character vector of directory names of \texttt{R} libraries, or \texttt{NULL}. The default value of \texttt{NULL} corresponds to all libraries currently known. The specified library trees are used to search for package.

Value

An object of class "checkTnF" which is a list containing, for each file where occurrences of \texttt{T} or \texttt{F} were found, a list with the expressions containing these occurrences. The names of the list are the corresponding file names.

There is a \texttt{print} method for nicely displaying the information contained in such objects.

checkVignettes Check Package Vignettes

Description

Check all vignettes of a package by running \texttt{Sweave} (or other custom weave function) and/or \texttt{Stangle} (or other custom tangle function) on them. All R source code files found after the tangling step are \texttt{source}ed to check whether all code can be executed without errors.

Usage

checkVignettes(package, dir, lib.loc = NULL, 
tangle = TRUE, weave = TRUE, latex = FALSE, 
workdir = c("tmp", "src", "cur"), 
keepfiles = FALSE)

Arguments

package a character string naming an installed package. If given, vignette source files are looked for in subdirectory ‘doc’.
dir a character string specifying the path to a package’s root source directory. If given, vignette source files are looked for in subdirectory ‘vignettes’.
lib.loc a character vector of directory names of \texttt{R} libraries, or \texttt{NULL}. The default value of \texttt{NULL} corresponds to all libraries currently known. The specified library trees are used to search for package.
tangle  Perform a tangle and source the extracted code?
weave  Perform a weave?
llatex logical: if weave and latex are TRUE and there is no ‘Makefile’ in the vignettes directory, run the intermediate ‘.tex’ outputs from weaving through texi2pdf.
workdir  Directory used as working directory while checking the vignettes. If “tmp” then a temporary directory is created, this is the default. If “src” then the directory containing the vignettes itself is used, if “cur” then the current working directory of R is used.
keepfiles  Delete files in the temporary directory? This option is ignored when workdir != “tmp”.

details
This function first uses pkgVignettes to find the package vignettes, and in particular their vignette engines (see vignetteEngine).
If tangle is true, it then runs Stangle (or other custom tangle function provided by the engine) to produce (one or more) R code files from each vignette, then sources each code file in turn.
If weave is true, the vignettes are run through Sweave (or other custom weave function provided by the engine). If latex is also true and there is no ‘Makefile’ in the vignettes directory, texi2pdf is run on the intermediate ‘.tex’ files from weaving for those vignettes which did not give errors in the previous steps.

value
An object of class "checkVignettes", which is a list with the error messages found during the tangle, source, weave and latex steps. There is a print method for displaying the information contained in such objects.

check_packages_in_dir  Check Source Packages and Their Reverse Dependencies

description
Check source packages in a given directory, optionally with their reverse dependencies.

usage
check_packages_in_dir(dir,
  pfiles = Sys.glob("*.tar.gz"),
  check_args = character(),
  check_args_db = list(),
  reverse = NULL,
  check_env = character(),
  xvfb = FALSE,
  Ncpus = getOption("Ncpus", 1L),
  clean = TRUE,
  install_args = list(),
  parallel_args = list(),
  ...)

Arguments

dir  a character string giving the path to the directory with the source `.tar.gz` files to be checked.
pfiles (optional) character vector of tarball files to be checked. Useful for choosing a subset of the `*.tar.gz` files in dir.
check_args a character vector with arguments to be passed to R CMD check, or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively.
check_args_db a named list of character vectors with arguments to be passed to R CMD check, with names the respective package names.
reverse a list with names partially matching "repos", "which", or "recursive", giving the repositories to use for locating reverse dependencies (a subset ofgetOption("repos"), the default), the types of reverse dependencies (default: c("Depends", "Imports", "LinkingTo"), with shorthands "most" and "all" as for package_dependencies), and indicating whether to also check reverse dependencies of reverse dependencies and so on (default: FALSE), or NULL (default), in which case no reverse dependencies are checked.
check_env a character vector of name=value strings to set environment variables for checking, or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively.
xvfb a logical indicating whether to perform checking inside a virtual framebuffer X server (Unix only), or a character vector of Xvfb options for doing so.
Ncpus the number of parallel processes to use for parallel installation and checking.
clean a logical indicating whether to remove the downloaded reverse dependency sources.
install_args list of arguments to be passed to underlying install.packages call.
parallel_args list of arguments to be passed to underlying calls of parLapply (on Windows) or mclapply (on other OS).
... passed to readLines, e.g. for reading log files produced in a different encoding; currently not used by check_packages_in_dir.
all a logical indicating whether to also summarize the reverse dependencies checked.
full a logical indicating whether to also give details for checks with non-ok results, or summarize check example timings (if available).
which see package_dependencies.

old a character string giving the path to the directory of a previous check_packages_in_dir run.

outputs a logical indicating whether to analyze changes in the outputs of the checks performed, or only (default) the status of the checks.

sources a logical indicating whether to also investigate the changes in the source files checked (default: FALSE).

logs a character vector with the paths of `00check.log` to analyze. Only used if dir was not given.

drop_ok a logical indicating whether to drop checks with 'ok' status, or a character vector with the 'ok' status tags to drop. The default corresponds to tags 'OK', 'NONE' and 'SKIPPED'.

Details

check_packages_in_dir allows to conveniently check source package `.tar.gz` files in the given directory dir, along with their reverse dependencies as controlled by reverse.

The "which" component of reverse can also be a list, in which case reverse dependencies are obtained for each element of the list and the corresponding element of the "recursive" component of reverse (which is recycled as needed).

If needed, the source `.tar.gz` files of the reverse dependencies to be checked as well are downloaded into dir (and removed at the end if clean is true). Next, all packages (additionally) needed for checking are installed to the 'Library' subdirectory of dir. Then, all `.tar.gz` files are checked using the given arguments and environment variables, with outputs and messages to files in the 'Outputs' subdirectory of dir. The `*.Rcheck` directories with the check results of the reverse dependencies are renamed by prefixing their base names with 'rdepends_'.

Results and timings can conveniently be summarized using summarize_check_packages_in_dir_results and summarize_check_packages_in_dir_timings, respectively.

Installation and checking is performed in parallel if Ncpus is greater than one: this will use mclapply on Unix and parLapply on Windows.

check_packages_in_dir returns an object inheriting from class "check_packages_in_dir" which has print and summary methods.

check_packages_in_dir_changes allows to analyze the effect of changing (some of) the sources. With dir and old the paths to the directories with the new and old sources, respectively, and the corresponding check results, possible changes in the check results can conveniently be analyzed as controlled via options outputs and sources. The changes object returned can be subscripted according to change in severity from the old to the new results by using one of "==", "!="", "<", "<="", ">" or ">=" as row index.

check_packages_in_dir_details analyzes check log files to obtain check details as a data frame which can be used for further processing, providing check name, status and output for every check performed and not dropped according to status tag (via variables Check, Status and Output, respectively).

Environment variable `_R_CHECK_ELAPSED_TIMEOUT_` can be used to set a limit on the elapsed time of each check run. See the ‘R Internals’ manual for how the value is interpreted and for other environment variables which can be used for finer-grained control on timeouts within a check run.

Note

This functionality is still experimental: interfaces may change in future versions.
Examples

```r
## Not run:
## Check packages in dir without reverse dependencies:
check_packages_in_dir(dir)
## Check packages in dir and their reverse dependencies using the
## defaults (all repositories in getOption("repos"), all "strong"
## reverse dependencies, no recursive reverse dependencies):
check_packages_in_dir(dir, reverse = list())
## Check packages in dir with their reverse dependencies from CRAN,
## using all strong reverse dependencies and reverse suggests:
check_packages_in_dir(dir,
    reverse = list(repos = getOption("repos")\["CRAN"],
        which = "most"))
## Check packages in dir with their reverse dependencies from CRAN,
## using '--as-cran' for the former but not the latter:
check_packages_in_dir(dir,
    check_args = c("--as-cran", ""),
    reverse = list(repos = getOption("repos")\["CRAN"]))
## End(Not run)
```

### Description

Find inconsistencies between actual and documented ‘structure’ of R objects in a package. codoc compares names and optionally also corresponding positions and default values of the arguments of functions. codocClasses and codocData compare slot names of S4 classes and variable names of data sets, respectively.

### Usage

```r
codoc(package, dir, lib.loc = NULL,
       use.values = NULL, verbose = getOption("verbose"))
codocClasses(package, lib.loc = NULL)
codocData(package, lib.loc = NULL)
```

### Arguments

- **package**: a character string naming an installed package.
- **dir**: a character string specifying the path to a package’s root source directory. This must contain the subdirectories ‘man’ with R documentation sources (in Rd format) and ‘R’ with R code. Only used if package is not given.
- **lib.loc**: a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
- **use.values**: if FALSE, do not use function default values when comparing code and docs. Otherwise, compare all default values if TRUE, and only the ones documented in the usage otherwise (default).
- **verbose**: a logical. If TRUE, additional diagnostics are printed.
Details

The purpose of codoc is to check whether the documented usage of function objects agrees with their formal arguments as defined in the R code. This is not always straightforward, in particular as the usage information for methods to generic functions often employs the name of the generic rather than the method.

The following algorithm is used. If an installed package is used, it is loaded (unless it is the base package), after possibly detaching an already loaded version of the package. Otherwise, if the sources are used, the R code files of the package are collected and sourced in a new environment. Then, the usage sections of the Rd files are extracted and parsed ‘as much as possible’ to give the formals documented. For interpreted functions in the code environment, the formals are compared between code and documentation according to the values of the argument use.values.

If a package has a namespace both exported and unexported objects are checked, as well as registered S3 methods. (In the unlikely event of differences the order is exported objects in the package, registered S3 methods and finally objects in the namespace and only the first found is checked.)

Currently, the R documentation format has no high-level markup for the basic ‘structure’ of classes and data sets (similar to the usage sections for function synopses). Variable names for data frames in documentation objects obtained by suitably editing ‘templates’ created by prompt are recognized by codocData and used provided that the documentation object is for a single data frame (i.e., only has one alias). codocClasses analogously handles slot names for classes in documentation objects obtained by editing shells created by promptClass. Help files named ‘pkgname-defunct.Rd’ for the appropriate pkgname are checked more loosely, as they may have undocumented arguments.

Value

codoc returns an object of class "codoc". Currently, this is a list which, for each Rd object in the package where an inconsistency was found, contains an element with a list of the mismatches (which in turn are lists with elements code and docs, giving the corresponding arguments obtained from the function’s code and documented usage).

codocClasses and codocData return objects of class "codocClasses" and "codocData", respectively, with a structure similar to class "codoc".

There are print methods for nicely displaying the information contained in such objects.

Note

The default for use.values has been changed from FALSE to NULL, for R versions 1.9.0 and later.

undoc, QC

compactPDF

Compact PDF Files

Description

Re-save PDF files (especially vignettes) more compactly. Support function for R CMD build --compact-vignettes.
compactPDF

Usage

compactPDF(paths,
    qpdf = Sys.which(Sys.getenv("R_QPDF", "qpdf")),
    gs_cmd = Sys.getenv("R_GSCMD", ""),
    gs_quality = Sys.getenv("GS_QUALITY", "none"),
    gs_extras = character(),
    verbose = FALSE)

## S3 method for class 'compactPDF'
format(x, ratio = 0.9, diff = 1e4, ...)

Arguments

paths       A character vector of paths to PDF files, or a length-one character vector naming
da directory, when all `.pdf` files in that directory will be used.
qpdf        Character string giving the path to the qpdf command. If empty, qpdf will not
be used.
gs_cmd      Character string giving the path to the GhostScript executable, if that is to be
used. On Windows this is the path to `gswin32c.exe` or `gswin64c.exe`. If "" (the default),
the function will try to find a platform-specific path to GhostScript
where required.
gs_quality  A character string indicating the quality required: the options are "none" (so
GhostScript is not used), "printer" (300dpi), "ebook" (150dpi) and "screen"
(72dpi). Can be abbreviated.
gs_extras   An optional character vector of further options to be passed to GhostScript.
verbose     logical or non-negative integer indicating if and how much of the compression
utilities' output should be shown.
x           An object of class "compactPDF".
ratio, diff Limits for reporting: files are only reported whose sizes are reduced both by a
factor of ratio and by diff bytes.
...         Further arguments to be passed to or from other methods.

Details

This by default makes use of qpdf, available from https://qpdf.sourceforge.io/ (including as
a Windows binary) and included with the CRAN macOS distribution of R. If gs_cmd is non-empty
and gs_quality != "none", GhostScript will used first, then qpdf if it is available. If gs_quality
!= "none" and gs_cmd is "", an attempt will be made to find a GhostScript executable.

qpdf and/or gs_cmd are run on all PDF files found, and those which are reduced in size by at least
10% and 10Kb are replaced.

The strategy of our use of qpdf is to (losslessly) compress both PDF streams and objects. GhostScript
compresses streams and more (including downsampling and compressing embedded
images) and consequently is much slower and may lose quality (but can also produce much smaller
PDF files). However, quality "ebook" is perfectly adequate for screen viewing and printing on laser
printers.

Where PDF files are changed they will become PDF version 1.5 files: these have been supported by
Acrobat Reader since version 6 in 2003, so this is very unlikely to cause difficulties.

Stream compression is what most often has large gains. Most PDF documents are generated with
object compression, but this does not seem to be the default for MiKTeX's pdflatex. For some
PDF files (and especially package vignettes), using GhostScript can dramatically reduce the space taken by embedded images (often screenshots).

Where both GhostScript and qpdf are selected (when `gs_quality != "none"` and both executables are found), they are run in that order and the size reductions apply to the total compression achieved.

**Value**

An object of class `c("compactPDF", "data.frame")`. This has two columns, the old and new sizes in bytes for the files that were changed.

There are `format` and `print` methods: the latter passes ... to the format method, so will accept `ratio` and `diff` arguments.

**Note**

The external tools used may change in future releases.

Frequently, updates to GhostScript have produced better compression (up to several times better), so if possible use the latest version available.

**See Also**

`resaveRdaFiles`.

For other tools to compact PDF files, see the ‘Writing R Extensions’ manual.

---

**CRANtools**

**CRAN Package Repository Tools**

**Description**

Tools for obtaining information about current packages in the CRAN package repository, and their check status.

**Usage**

```r
CRAN_package_db()
CRAN_check_results(flavors = NULL)
CRAN_check_details(flavors = NULL)
CRAN_check_issues()
summarize_CRAN_check_status(packages,
                            results = NULL,
                            details = NULL,
                            issues = NULL)
```

**Arguments**

- `packages` a character vector of package names.
- `flavors` a character vector of CRAN check flavor names, or `NULL` (default), corresponding to all available flavors.
- `results` the return value of `CRAN_check_results()` (default), or a subset of this.
- `details` the return value of `CRAN_check_details()` (default), or a subset of this.
- `issues` the return value of `CRAN_check_issues()` (default), or a subset of this.
Details

`CRAN_package_db()` returns a data frame with character columns containing most `DESCRIPTION` metadata for the current packages in the CRAN package repository, including in particular the Description and Maintainer information not provided by `utils::available.packages()`.

`CRAN_check_results()` returns a data frame with the basic CRAN package check results including timings, with columns Package, Flavor and Status giving the package name, check flavor, and overall check status, respectively.

`CRAN_check_details()` returns a data frame inheriting from class "check_details" (which has useful print and format methods) with details on the check results, providing check name, status and output for every non-OK check (via columns Check, Status and Output, respectively). Packages with all-OK checks are indicated via a * Check wildcard name and OK Status.

`CRAN_check_issues()` returns a character frame with additional check issues (including the memory-access check results made available from [https://www.stats.ox.ac.uk/pub/bdr/memtests/](https://www.stats.ox.ac.uk/pub/bdr/memtests/)) as a character frame with variables Package, Version, kind (an identifier for the issue) and href (a URL with information on the issue).

Value

See ‘Details’. Note that the results are collated on CRAN: currently this is done in a locale which sorts aAbB ....

Which CRAN?

The main functions access a CRAN mirror specified by the environment variable `R_CRAN_WEB`, defaulting to one specified in the "repos" option. Otherwise the entry in the 'repositories' file (see `setRepositories`) is used: if that specifies ‘@CRAN@’ (the default) or does not contain an entry for CRAN then [https://CRAN.R-project.org](https://CRAN.R-project.org) is used.

The mirror to be used is reported by `utils::findCRANmirror("web")`.

Note that these functions access parts of CRAN under 'web/contrib' and 'web/packages' so if you have specified a mirror of just 'src/contrib' for installing packages you will need to set `R_CRAN_WEB` to point to a full mirror.

Internal functions `CRAN_aliases_db`, `CRAN_archive_db`, `CRAN_current_db` and `CRAN_rdxrefs_db` (used by `R CMD check`) use `R_CRAN_SRC` rather than `R_CRAN_WEB`.

Examples

```r
## This can be rather slow with a non-local CRAN mirror
## and might fail (slowly) without Internet access in that case.

set.seed(11)  # but the packages chosen will change as soon as CRAN does.

pdb <- CRAN_package_db()
dim(pdb)
## DESCRIPTION fields included:
colnames(pdb)
## Summarize publication dates:
summary(as.Date(pdb$Published))
## Summarize numbers of packages according to maintainer:
summary(lengths(split(pdb$Package, pdb$Maintainer)))
## Packages with 'LASSO' in their Description:
pdb$Package[grepl("LASSO", pdb$Description)]

results <- CRAN_check_results()
```
## Available variables:
names(results)
## Tabulate overall check status according to flavor:
with(results, table(Flavor, Status))

details <- CRAN_check_details()
## Available variables:
names(details)
## Tabulate checks according to their status:
tab <- with(details, table(Check, Status))
## Inspect some installation problems:
bad <- subset(details,
   (Check == "whether package can be installed") &
   (Status != "OK")))
## Show a random sample of up to 6
head(bad[sample(seq_len(NROW(bad)), NROW(bad)), ])

issues <- CRAN_check_issues()
head(issues)
## Show counts of issues according to kind:
table(issues[, "kind"])

## Summarize CRAN check status for 10 randomly-selected packages
## (reusing the information already read in):
pos <- sample(seq_len(NROW(pdb)), 10L)
summarize_CRAN_check_status(pdb[pos, "Package"],
   results, details, issues)

delimMatch

### Delimited Pattern Matching

**Description**
Match delimited substrings in a character vector, with proper nesting.

**Usage**
delimMatch(x, delim = c("",""), syntax = "Rd")

**Arguments**
- **x**
a character vector.
- **delim**
a character vector of length 2 giving the start and end delimiters. Future versions might allow for arbitrary regular expressions.
- **syntax**
currently, always the string "Rd" indicating Rd syntax (i.e., ‘%’ starts a comment extending till the end of the line, and ‘\’ escapes). Future versions might know about other syntax, perhaps via 'syntax tables' allowing to flexibly specify comment, escape, and quote characters.

**Value**
An integer vector of the same length as x giving the starting position (in characters) of the first match, or −1 if there is none, with attribute "match.length" giving the length (in characters) of the matched text (or −1 for no match).
See Also

regexpr for ‘simple’ pattern matching.

Examples

```r
x <- c("\value{foo}", "function(bar)"
delimMatch(x)
delimMatch(x, c("(", ")"))
```

---

**dependsOnPkgs**  
*Find Reverse Dependencies*

**Description**

Find ‘reverse’ dependencies of packages, that is those packages which depend on this one, and (optionally) so on recursively.

**Usage**

```r
dependsOnPkgs(pkgs,  
dependencies = "strong",  
recursive = TRUE, lib.loc = NULL,  
installed =  
utils::installed.packages(lib.loc, fields = "Enhances"))
```

**Arguments**

- `pkgs`: a character vector of package names.
- `dependencies`: a character vector listing the types of dependencies, a subset of c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances"). Character string "all" is shorthand for that vector, character string "most" for the same vector without "Enhances", character string "strong" (default) for the first three elements of that vector.
- `recursive`: logical: should reverse dependencies of reverse dependencies (and so on) be included?
- `lib.loc`: a character vector of R library trees, or NULL for all known trees (see `.libPaths`).
- `installed`: a result of calling `installed.packages`.

**Value**

A character vector of package names, which does not include any from `pkgs`.

**See Also**

`package_dependencies()` to get the regular ("forward") dependencies of a package.

**Examples**

```r
## there are few dependencies in a vanilla R installation:  
## lattice may not be installed  
dependsOnPkgs("lattice")
```
encoded_text_to_latex  Translate non-ASCII Text to \LaTeX{} Escapes

**Description**

Translate non-ASCII characters in text to \LaTeX{} escape sequences.

**Usage**

```r
encoded_text_to_latex(x, 
  encoding = c("latin1", "latin2", "latin9", 
  "UTF-8", "utf8"))
```

**Arguments**

- `x` a character vector.
- `encoding` the encoding to be assumed. "latin9" is officially ISO-8859-15 or Latin-9, but known as latin9 to \LaTeX{}'s `inputenc` package.

**Details**

Non-ASCII characters in `x` are replaced by an appropriate \LaTeX{} escape sequence, or `?` if there is no appropriate sequence.

Even if there is an appropriate sequence, it may not be supported by the font in use. Hyphen is mapped to `\-`.

**Value**

A character vector of the same length as `x`.

**See Also**

`iconv`

**Examples**

```r
x <- "fran\xE7ais"
encoded_text_to_latex(x, "latin1")
## Not run:
## create a tex file to show the upper half of 8-bit charsets
x <- rawToChar(as.raw(160:255), multiple = TRUE)
(x <- matrix(x, ncol = 16, byrow = TRUE))
xx <- x
xx[] <- encoded_text_to_latex(x, "latin1") # or latin2 or latin9
xx <- apply(xx, 1, paste, collapse = "&")
con <- file("test-encoding.tex", "w")
header <- c("\documentclass{article}",
  "\usepackage[T1]{fontenc}",
  "\usepackage{Rd}",
  "\begin{document}",
  "\HeaderA{test}{test}",[test],
```
Utilities for listing files, and manipulating file paths.

**Usage**

- `file_ext(x)
- `file_ext_as_absolute(x)
- `file_path_sans_ext(x, compression = FALSE)

```r
list_files_with_exts(dir, exts, all.files = FALSE, full.names = TRUE)
list_files_with_type(dir, type, all.files = FALSE, full.names = TRUE, OS_subdirs = .OS_type())
```

**Arguments**

- `x` character vector giving file paths.
- `compression` logical: should compression extension `.gz`, `.bz2` or `.xz` be removed first?
- `dir` a character string with the path name to a directory.
- `exts` a character vector of possible file extensions (excluding the leading dot).
- `all.files` a logical. If FALSE (default), only visible files are considered; if TRUE, all files are used.
full.names a logical indicating whether the full paths of the files found are returned (default), or just the file names.

type a character string giving the `type` of the files to be listed, as characterized by their extensions. Currently, possible values are "code" (R code), "data" (data sets), "demo" (demos), "docs" (R documentation), and "vignette" (vignettes).

OS_subdirs a character vector with the names of OS-specific subdirectories to possibly include in the listing of R code and documentation files. By default, the value of the environment variable R_OSTYPE, or if this is empty, the value of .Platform$OS.type, is used.

Details

file_ext returns the file (name) extensions (excluding the leading dot). (Only purely alphanumeric extensions are recognized.)

file_path_as_absolute turns a possibly relative file path absolute, performing tilde expansion if necessary. This is a wrapper for normalizePath. Currently, x must be a single existing path.

file_path_sans_ext returns the file paths without extensions (and the leading dot). (Only purely alphanumeric extensions are recognized.)

list_files_with_exts returns the paths or names of the files in directory `dir` with extension matching one of the elements of `exts`. Note that by default, full paths are returned, and that only visible files are used.

list_files_with_type returns the paths of the files in `dir` of the given `type`, as determined by the extensions recognized by R. When listing R code and documentation files, files in OS-specific subdirectories are included if present according to the value of `OS_subdirs`. Note that by default, full paths are returned, and that only visible files are used.

See Also

file.path, file.info, list.files

Examples

dir <- file.path(R.home(), "library", "stats")
list_files_with_exts(file.path(dir, "demo"), "R")
list_files_with_type(file.path(dir, "demo"), "demo") # the same
file_path_sans_ext(list.files(file.path(R.home("modules"))))

Description

Find a GhostScript executable in a cross-platform way.

Usage

find_gs_cmd(gs_cmd = "")

Arguments

gs_cmd The name, full or partial path of a GhostScript executable.
Details

The details differ by platform.

On a Unix-alike, the GhostScript executable is usually called gs. The name (and possibly path) of the command is taken first from argument gs_cmd then from the environment variable R_GSCMD and default gs. This is then looked for on the system path and the value returned if a match is found.

On Windows, the name of the command is taken from argument gs_cmd then from the environment variables R_GSCMD and GSC. If neither of those produces a suitable command name, gswin64c and gswin32c are tried in turn. In all cases the command is looked for on the system PATH.

Note that on Windows (and some other OSes) there are separate GhostScript executables to display Postscript/PDF files and to manipulate them: this function looks for the latter.

Value

A character string giving the full path to a GhostScript executable if one was found, otherwise an empty string.

Examples

## Not run:
## Suppose a Solaris system has GhostScript 9.00 on the path and
## 9.07 in /opt/csw/bin. Then one might set
Sys.setenv(R_GSCMD = "/opt/csw/bin/gs")

## End(Not run)

getVignetteInfo  Get Information on Installed Vignettes

Description

This function gets information on installed vignettes.

Usage

getVignetteInfo(package = NULL, lib.loc = NULL, all = TRUE)

Arguments

package Which package to look in, or NULL for all packages.
lib.loc Which library to look in.
all Whether to search all installed packages, or just attached packages.

Value

A matrix with columns

Package the name of the package
Dir the directory where the package is installed
Topic the name of the vignette
File the base filename of the source of the vignette
**HTMLheader**

<table>
<thead>
<tr>
<th>Title</th>
<th>the title of the vignette</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td>the tangled R source from the vignette</td>
</tr>
<tr>
<td>PDF</td>
<td>the PDF or HTML file for display</td>
</tr>
</tbody>
</table>

**Note**

The last column of the result is named PDF for historical reasons, but it may contain a filename of a PDF or HTML document.

**See Also**

`pkgVignettes` is a similar function that can work on an uninstalled package.

**Examples**

```r
getVignetteInfo("grid")
```

---

**Description**

This function generates the standard HTML header used on R help pages.

**Usage**

```r
HTMLheader(title = "R", logo = TRUE, up = NULL, 
           top = file.path(Rhome, "doc/html/index.html"), 
           Rhome = ",
           css = file.path(Rhome, "doc/html/R.css"), 
           headerTitle = paste("R:\", title), 
           outputEncoding = "UTF-8")
```

**Arguments**

- `title`: The title to display and use in the HTML headers. Should have had any HTML escaping already done.
- `logo`: Whether to display the R logo after the title.
- `up`: Which page (if any) to link to on the “up” button.
- `top`: Which page (if any) to link to on the “top” button.
- `Rhome`: A relative path to the R home directory. See the ‘Details’.
- `css`: The relative URL for the Cascading Style Sheet.
- `headerTitle`: The title used in the headers.
- `outputEncoding`: The declared encoding for the whole page.

**Details**

The up and top links should be relative to the current page. The Rhome path default works with dynamic help; for static help, a relative path (e.g., ‘../..’) to it should be used.
Value

A character vector containing the lines of an HTML header which can be used to start a page in the R help system.

Examples

cat(HTMLheader("This is a sample header"), sep="\n")

Description

Compute relative file paths for URLs to other package's installed HTML documentation.

Usage

findHTMLlinks(pkgDir = "", lib.loc = NULL, level = 0:2)

Arguments

pkgDir the top-level directory of an installed package. The default indicates no package.
lib.loc character vector describing the location of R library trees to scan: the default indicates .libPaths().
level Which level(s) to include.

Details

findHTMLlinks tries to resolve links from one help page to another. It uses in decreasing priority

- The package in pkgDir: this is used when converting HTML help for that package (level 0).
- The base and recommended packages (level 1).
- Other packages found in the library trees specified by lib.loc in the order of the trees and alphabetically within a library tree (level 2).

Value

A named character vector of file paths, relative to the 'html' directory of an installed package. So these are of the form "./././somepkg/html/sometopic.html".

Author(s)

Duncan Murdoch, Brian Ripley
loadRdMacros

Load User-defined Rd Help System Macros

Description

Loads macros from an `.Rd` file, or from several `.Rd` files contained in a package.

Usage

loadRdMacros(file, macros = TRUE)
loadPkgRdMacros(pkgdir, macros = NULL)

Arguments

file  A file in Rd format containing macro definitions.
macros optionally, a previous set of macro definitions, in the format expected by the parse_Rd macros argument. loadPkgRdMacros loads the system Rd macros by default.

pkgdir  The base directory of a source package or an installed package.

Details

The Rd files parsed by these functions should contain only macro definitions; a warning will be issued if anything else other than comments or white space is found.

The macros argument may be a filename of a base set of macros, or the result of a previous call to loadRdMacros or loadPkgRdMacros in the same session. These results should be assumed to be valid only within the current session.

The loadPkgRdMacros function first looks for an "RdMacros" entry in the package ‘DESCRIPTION’ file. If present, it should contain a comma-separated list of other package names; their macros will be loaded before those of the current package. It will then look in the current package for `.Rd` files in the ‘man/macros’ or ‘help/macros’ subdirectories, and load those.

Value

These functions each return an environment containing objects with the names of the newly defined macros from the last file processed. The parent environment will be macros from the previous file, and so on. The first file processed will have emptyenv() as its parent.

Author(s)

Duncan Murdoch

References

See the ‘Writing R Extensions’ manual for the syntax of Rd files, or https://developer.r-project.org/parseRd.pdf for a technical discussion.

See Also

parse_Rd
Examples

```r
f <- tempfile()
writeLines(r"(
\newcommand{\Rlogo}{
  \ifhtml{\figure{Rlogo.svg}(options: width=100 alt="R logo")}
  \iflatex{\figure{Rlogo.pdf}(options: width=0.5in)}
}
)\)", f)
m <- loadRdMacros(f)
ls(m)
ls(parent.env(m))
ls(parent.env(parent.env(m)))
parse_Rd(textConnection(r"(\Rlogo)"), fragment = TRUE, macros = m)
```

makevars

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Determine the location of the user and site specific ‘Makevars’ files for customizing package compilation.</td>
</tr>
</tbody>
</table>

Usage

```r
makevars_user()
makevars_site()
```

Details

Package maintainers can use these functions to employ user and site specific compilation settings also for compilations not using R’s mechanisms (in particular, custom compilations in subdirectories of ‘src’), e.g., by adding configure code calling R with `cat(tools::makevars_user())` or `cat(tools::makevars_site())`, and if non-empty passing this with ‘-f’ to custom Make invocations.

Value

A character string with the path to the user or site specific ‘Makevars’ file, or an empty character vector if there is no such file.

See Also

Section ‘Customizing package compilation’ in the ‘R Installation and Administration’ manual.

Examples

```r
makevars_user()
makevars_site()
```
**make_translations_pkg**  
*Package the Current Translations in the R Sources*

**Description**

A utility for R Core members to prepare a package of updated translations.

**Usage**

```r
code
make_translations_pkg(srcdir, outDir = ".", append = "-1")
```

**Arguments**

- `srcdir`: The R source directory.
- `outDir`: The directory into which to place the prepared package.
- `append`: The suffix for the package version number, e.g. ‘3.0.0-1’ will be the default in R 3.0.0.

**Details**

This extracts the translations in a current R source distribution and packages them as a source package called translations which can be distributed on CRAN and installed by `update.packages`. This allows e.g. the translations shipped in R 3.x.y to be updated to those currently in ‘R-patched’, even by a user without administrative privileges.

The package has a ‘Depends’ field which restricts it to versions ‘3.x.*’ for a single x.

---

**matchConcordance**  
*Concordance between source and target lines*

**Description**

The Rd parser records locations in ‘.Rd’ files from which components of the file are read. Output generators Rd2HTML and Rd2latex can output information about these locations as “concordances” between source and output lines.

matchConcordance converts from output locations to source locations. The “Rconcordance” method of as.character produces strings to embed in output files, and the default method of as.Rconcordance converts these back to objects that can be interpreted by matchConcordance.

**Usage**

```r
code
matchConcordance(linenum, concordance)
## S3 method for class 'Rconcordance'
as.character(x, targetfile = ".", ...)
as.Rconcordance(x, ...)
followConcordance(concordance, prevConcordance)
```
matchConcordance

Arguments

linenum
One or more line numbers being queried.

concordance
The concordance data for the file containing the lines: an object of class
"Rconcordance".

prevConcordance
A concordance object retrieved from the current file.

targetfile
The output filename.

x
The object to convert: for as.character, an "Rconcordance" object; for
as.concordance, a character vector which contains as.character output, typ-
ically in comments.

... Further arguments passed to other methods.

Details

The correspondence between target lines and source lines in Rd file conversion is not one to one. Often a single source line can lead to the generation of multiple output lines, and sometimes more than one source line triggers output on the same output line.

matchConcordance converts from target lines to source lines. This can be used to help in understanding how particular output lines depend on the source, e.g. when an error is found in the output file. When more than one line contributes to the output, the last one will be returned.

The "Rconcordance" method of as.character converts a concordance object to strings suitable for embedding (e.g. in comments) in an output file.

The default method of as.Rconcordance searches for strings matching the pattern of as.character.Rconcordance output, then converts those lines back to a single concordance.

followConcordance is used when a file is transformed more than once. The first transformation records a concordance in the file which is read as prevConcordance. followConcordance chains this with the current concordance, relating the final result to the original source.

There are 3 kinds of objects used to hold concordances.

Objects of class "activeConcordance" are internal to tools; they are used by Rd2HTML and Rd2latex while building the output file and saving links to the source file.

Objects of class "Rconcordance" are visible to users. They are list objects with the following three fields:

offset
The number of lines of output before the first one corresponding to this concordance.

srcLine
For each line of output after the offset, the corresponding input file line number. There may be more lines of output than the length of srcLine, in which case nothing can be inferred about the source of those lines.

srcFile
A vector of filenames of length 1 or the same length as srcLine giving the source file(s) for each output line.

Concordance strings are produced by the "Rconcordance" method of as.character; they are simply character vectors encoding the concordance data. The default method of the as.concordance generic function converts them to "Rconcordance" objects.

Value

matchConcordance returns a character array with one row per input linenum entry and two columns, "srcFile" and "srcLine".
For the "Rconcordance" method of `as.character`, a character vector used (e.g. in `Sweave`) to embed the concordance in a file.

For `as.concordance`, an "Rconcordance" object, or `NULL` if no concordance strings are found.

---

### md5sum

**Compute MD5 Checksums**

**Description**

Compute the 32-byte MD5 hashes of one or more files.

**Usage**

```r
md5sum(files)
```

**Arguments**

- `files` character. The paths of file(s) whose contents are to be hashed.

**Details**

A MD5 ‘hash’ or ‘checksum’ or ‘message digest’ is a 128-bit summary of the file contents represented by 32 hexadecimal digits. Files with different MD5 sums are different: only very exceptionally (and usually with the intent to deceive) are those with the same sums different.

On Windows all files are read in binary mode (as the `md5sum` utilities there do): on other OSes the files are read in the default mode (almost always text mode where there is more than one).

MD5 sums are used as a check that R packages have been unpacked correctly and not subsequently accidentally modified.

**Value**

A character vector of the same length as files, with names equal to files (possibly expanded). The elements will be `NA` for non-existent or unreadable files, otherwise a 32-character string of hexadecimal digits.

**Source**

The underlying C code was written by Ulrich Drepper and extracted from a 2001 release of glibc.

**See Also**

`checkMD5sums`
package_dependencies  Computations on the Dependency Hierarchy of Packages

Description
Find (recursively) dependencies or reverse dependencies of packages.

Usage
package_dependencies(packages = NULL, db = NULL, which = "strong",
recursive = FALSE, reverse = FALSE,
verbose = getOption("verbose"))

Arguments
packages a character vector of package names.
db character matrix as from available.packages() (with the default NULL the results of this call) or data frame variants thereof. Alternatively, a package database like the one available from https://cran.r-project.org/web/packages/packages.rds.
which a character vector listing the types of dependencies, a subset of c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances"). Character string "all" is shorthand for that vector, character string "most" for the same vector without "Enhances", character string "strong" (default) for the first three elements of that vector.
recursive a logical indicating whether (reverse) dependencies of (reverse) dependencies (and so on) should be included, or a character vector like which indicating the type of (reverse) dependencies to be added recursively.
reverse logical: if FALSE (default), regular dependencies are calculated, otherwise reverse dependencies.
verbose logical indicating if output should monitor the package search cycles.

Value
Named list with one element for each package in argument packages, each consists of a character vector naming the (recursive) (reverse) dependencies of that package.

For given packages which are not found in the db, NULL entries are returned, as opposed to character(0) entries which indicate no dependencies.

See Also
dependsOnPkgs.
Examples

myPkgs <- c("MASS", "Matrix", "KernSmooth", "class", "cluster", "codetools")
pdb <- available.packages(repos = findCRANmirror("web"))

system.time(
  dep1 <- package_dependencies(myPkgs, db = pdb) # all arguments at default
  ) # very fast
utils::str(dep1, vec.len=10)

system.time( ## reverse dependencies, recursively --- takes much longer:
  deps <- package_dependencies(myPkgs, db = pdb, which = "most",
                               recursive = TRUE, reverse = TRUE)
  ) # seen ~ 10 seconds

lengths(deps) # 2020-05-03: all are 16053, but codetools with 16057

## install.packages(dependencies = TRUE) installs 'most' dependencies
## and the strong recursive dependencies of these: these dependencies
## can be obtained using 'which = "most"' and 'recursive = "strong"'.
## To illustrate on the first packages with non-missing Suggests:
packages <- pdb[head(which(!is.na(pdb[, "Suggests"])), "Package")
package_dependencies(packages, db = pdb,
  which = "most", recursive = "strong")

package_native_routine_registration_skeleton

Write Skeleton for Adding Native Routine Registration to a Package

Description

Write a skeleton for adding native routine registration to a package.

Usage

package_native_routine_registration_skeleton(dir, con = stdout(),
  align = TRUE, character_only = TRUE, include_declarations = TRUE)

Arguments

dir
  Top-level directory of a package.

con
  Connection on which to write the skeleton: can be specified as a file path.

align
  Logical: should the registration tables be lined up in three columns each?

character_only
  Logical: should only .NAME arguments specified by character strings (and not as
  names of R objects nor expressions) be extracted?

include_declarations
  Logical: should the output include declarations (also known as 'prototypes') for
  the registered routines?
Details

Registration is described in section ‘Registering native routines’ of ‘Writing R Extensions’. This function produces a skeleton of the C code which needs to be added to enable registration, conventionally as file ‘src/init.c’ or appended to the sole C file of the package.

This function examines the code in the ‘R’ directory of the package for calls to .C, .Fortran, .Call and .External and creates registration information for those it can make sense of. If the number of arguments used cannot be determined it will be recorded as -1: such values should be corrected.

Optionally the skeleton will include declarations for the registered routines: they should be checked against the C/Fortran source code, not least as the number of arguments is taken from the R code. For .Call and .External calls they will often suffice, but for .C and .Fortran calls the ‘void *’ arguments would ideally be replaced by the actual types. Otherwise declarations need to be included (they may exist earlier in that file if appending to a file, or in a header file which can be included in ‘init.c’).

The default value of character_only is appropriate when working on a package without any existing registration: character_only = FALSE can be used to suggest updates for a package which has been extended since registration. For the default value, if .NAME values are found which are not character strings (e.g. names or expressions) this is noted via a comment in the output.

Packages which used the earlier form of creating R objects for native symbols via additional arguments in a useDynLib directive will probably most easily be updated to use registration with character_only = FALSE.

If an entry point is used with different numbers of arguments in the package’s R code, an entry in the table (and optionally, a declaration) is made for each number, and a comment placed in the output. This needs to be resolved: only .External calls can have a variable number of arguments, which should be declared as -1.

A surprising number of CRAN packages had calls in R code to native routines not included in the package, which will lead to a ‘loading failed’ error during package installation when the registration C code is added.

Calls which do not name a routine such as .Call(...) will be silently ignored.

Value

None: the output is written to the connection con.

Extracting C/C++ prototypes

There are several tools available to extract function declarations from C or C++ code.

For C code one can use cproto (https://invisible-island.net/cproto/cproto.html; Windows executables are available), for example

```
cproto -I/path/to/R/include -e *.c
```

ctags (commonly distributed with the OS) covers C and C++, using something like

```
ctags -x *.c
```

to list all function usages. (The ‘Exuberant’ version allows a lot more control.)
Extracting Fortran prototypes

gfortran 9.2 and later can extract C prototypes for Fortran subroutines with a special flag:

    gfortran -c -fc-prototypes-external file.f

although ironically not for functions declared bind(C).

Note

This only examines the ‘R’ directory: it will not find e.g. `.Call` calls used directly in examples, tests etc.

Static code analysis is used to find the .C etc calls: it will find those in parts of the R code ‘commented out’ by inclusion in if(FALSE) { ... }. On the other hand, it will fail to find the entry points in constructs like

    .Call(if(int) "rle_i" else "rle_d", i, force)

and does not know the value of variables in calls like

    .Call (cfun, ...)  
    .Call(..., PACKAGE="sparseLTSEigen")

(but if character_only is false, will extract the first as "cfun"). Calls which have not been fully resolved will be noted via comments in the output file.

Call to entry points in other packages will be ignored if they have an explicit (character string) PACKAGE argument.

See Also

    package.skeleton.

Examples

```r
## Not run:  
## with a completed splines/DESCRIPTION file,  
tools::package_native_routine_registration_skeleton('splines',,,FALSE)
## produces
#include <R.h>
#include <Rinternals.h>
#include <stdlib.h> // for NULL
#include <R_ext/Rdynload.h>

/* FIXME:  
  Check these declarations against the C/Fortran source code.  
  */
/* .Call calls */
extern SEXP spline_basis(SEXP, SEXP, SEXP, SEXP);
extern SEXP spline_value(SEXP, SEXP, SEXP, SEXP);

**parseLatex**  
*Experimental Functions to Work with LaTeX Code*

**Description**

The `parseLatex` function parses LaTeX source, producing a structured object; `deparseLatex` reverses the process. The `latexToUtf8` function takes a LaTeX object, and processes a number of different macros to convert them into the corresponding UTF-8 characters.

**Usage**

```r
defparseLatex(x, dropBraces = FALSE)
latexToUtf8(x)
```

**Arguments**

- `text` A character vector containing LaTeX source code.
- `filename` A filename to use in syntax error messages.
- `verbose` If TRUE, print debug error messages.
- `verbatim` A character vector containing the names of LaTeX environments holding verbatim text.
- `verb` A character vector containing LaTeX macros that should be assumed to hold verbatim text.
- `x` A "LaTeX" object.
- `dropBraces` Drop unnecessary braces when displaying a "LaTeX" object.

**Details**

The parser does not recognize all legal LaTeX code, only relatively simple examples. It does not associate arguments with macros, that needs to be done after parsing, with knowledge of the definitions of each macro. The main intention for this function is to process simple LaTeX code used in bibliographic references, not fully general LaTeX documents.
Verbose text is allowed in three forms: the \verb macro (with single character delimiters), environments whose names are listed in the \verbatim argument, and other macros (with brace delimiters) whose names are listed in the \verb argument.

Value

The \texttt{parseLatex()} function returns a recursive object of class "\LaTeX". Each of the entries in this object will have a "latex_tag" attribute identifying its syntactic role.

The \texttt{deparseLatex()} function returns a single element character vector, possibly containing embedded newlines.

The \texttt{latexToUtf8()} function returns a modified version of the "\LaTeX" object that was passed to it.

Author(s)

Duncan Murdoch

Examples

\begin{verbatim}
latex <- parseLatex("fran\c{c}ais")
deparseLatex(latexToUtf8(latex))
\end{verbatim}

\begin{verbatim}
\textbf{parse_Rd} \hspace{1cm} \textit{Parse an Rd File}
\end{verbatim}

Description

This function reads an R documentation (Rd) file and parses it, for processing by other functions.

Usage

\begin{verbatim}
parse_Rd(file, srcfile = NULL, encoding = "unknown",
        verbose = FALSE, fragment = FALSE, warningCalls = TRUE,
        macros = file.path(R.home("share"), "Rd", "macros", "system.Rd"),
        permissive = FALSE)
## S3 method for class 'Rd'
print(x, deparse = FALSE, ...)
## S3 method for class 'Rd'
as.character(x, deparse = FALSE, ...)
\end{verbatim}

Arguments

\begin{verbatim}
file \hspace{2cm} A filename or text-mode connection. At present filenames work best.
srcfile \hspace{2cm} NULL, or a "srcfile" object. See the ‘Details’ section.
encoding \hspace{2cm} Encoding to be assumed for input strings.
verbose \hspace{2cm} Logical indicating whether detailed parsing information should be printed.
fragment \hspace{2cm} Logical indicating whether file represents a complete Rd file, or a fragment.
warningCalls \hspace{2cm} Logical: should parser warnings include the call?
macros \hspace{2cm} Filename or environment from which to load additional macros, or a logical value. See the Details below.
\end{verbatim}
parse_Rd

permissive Logical indicating that unrecognized macros should be treated as text with no warning.
x An object of class Rd.
deparse If TRUE, attempt to reinstate the escape characters so that the resulting characters will parse to the same object.

... Further arguments to be passed to or from other methods.

Details

This function parses ‘Rd’ files according to the specification given in https://developer.r-project.org/parseRd.pdf.

It generates a warning for each parse error and attempts to continue parsing. In order to continue, it is generally necessary to drop some parts of the file, so such warnings should not be ignored.

Files without a marked encoding are by default assumed to be in the native encoding. An alternate default can be set using the encoding argument. All text in files is translated to the UTF-8 encoding in the parsed object.

As from R version 3.2.0, User-defined macros may be given in a separate file using ‘\newcommand’ or ‘\renewcommand’. An environment may also be given: it would be produced by loadRdMacros, loadPkgRdMacros, or by a previous call to parse_Rd. If a logical value is given, only the default built-in macros will be used; FALSE indicates that no "macros" attribute will be returned with the result.

The permissive argument allows text to be parsed that is not completely in Rd format. Typically it would be LaTeX code, used in an Rd fragment, e.g. in a bibentry. With permissive = TRUE, this will be passed through as plain text. Since parse_Rd doesn’t know how many arguments belong in LaTeX macros, it will guess based on the presence of braces after the macro; this is not infallible.

Value

parse_Rd returns an object of class "Rd". The internal format of this object is subject to change. The as.character() and print() methods defined for the class return character vectors and print them, respectively.

Unless macros = FALSE, the object will have an attribute named "macros", which is an environment containing the macros defined in file, in a format that can be used for further parse_Rd calls in the same session. It is not guaranteed to work if saved to a file and reloaded in a different session.

Rd2HTML for the converters that use the output of parse_Rd().
pkg2HTML  

Rd Converters

Description

Generate a single-page HTML reference manual from the Rd sources contained in an installed or source R package.

Usage

pkg2HTML(package, dir = NULL, lib.loc = NULL, outputEncoding = "UTF-8", stylesheet = file.path(R.home("doc"), "html", "R-nav.css"), hooks = list(pkg_href = function(pkg) sprintf("%s.html", pkg)), texmath = getOption("help.htmlmath"), prism = TRUE, out = NULL, toc_entry = c("title", "name"), ...
Rhtml = FALSE, mathjax_config = file.path(R.home("doc"), "html", "mathjax-config.js"), include_description = TRUE)

Arguments

package  a character string, typically giving the name of an installed package. Can also be a file path or URL pointing to a source tarball (this feature is experimental).
dir  character string giving the path to a directory containing an installed or source package.
lib.loc  a character vector describing the location of R library trees to search through, or NULL. Passed on to find.package and Rd_db.
outputEncoding  character string; see Rd2HTML.
stylesheet  character string giving URL containing CSS style information.
hooks  A list of functions controlling details of output. Currently the only component used is pkg_href, which is used to determine the output HTML file path given a package name as input.
texmath  character string controlling math rendering library to be used, either "katex" or "mathjax". The default is to use "katex", unless the package appears to use the mathjaxr package in at least one of its documentation files. The support for MathJax is experimental and may not work well.
prism  logical flag controlling code highlighting, as described in Rd2HTML.
out  a filename or connection object to which to write the output. The default out = "" is equivalent to out = stdout().
toc_entry  Determines whether the entry for a help page in the table of contents is the name of the help page or its title.
...  additional arguments, passed on to Rd2HTML. The stages argument, if specified, is passed on to Rd_db.
pskill

logical: whether the output is intended to be a Rhtml file that can be processed using \texttt{knitr}. If \texttt{TRUE}, the examples section is wrapped inside a \texttt{rcode} block.

\texttt{mathjax_config} character string giving path of file containing configuration instructions for \texttt{mathjax}. Relevant only if \texttt{texmath = "mathjax"}.

\texttt{include_description} logical flag indicating whether the output should begin with the contents of the \texttt{DESCRIPTION} file.

Details

The \texttt{pkg2HTML} function is intended to produce a single-page HTML reference manual for a given package, with links to other packages. The URLs of links to external packages are controlled by the provided hooks.

The handling of \texttt{\Sexpr-s} are necessarily incomplete, but can be controlled to some extent by specifying the \texttt{stages} argument. Best results are likely for installed packages.

Value

The name of the output file (invisibly).

pkg2HTML("tools", out = tempfile(fileext = ".html")) |> browseURL()
\end{verbatim}

---

\textbf{pskill} \hspace{1cm} \textit{Kill a Process}

Description

pskill sends a signal to a process, usually to terminate it.

Usage

\begin{verbatim}
pskill(pid, signal = SIGTERM)
\end{verbatim}

\texttt{SIGHUP} \hspace{1cm} \texttt{SIGINT} \hspace{1cm} \texttt{SIGQUIT} \hspace{1cm} \texttt{SIGKILL} \hspace{1cm} \texttt{SIGTERM} \hspace{1cm} \texttt{SIGSTOP} \hspace{1cm} \texttt{SIGTSTP}
Arguments

pid  positive integers: one or more process IDs as returned by `Sys.getpid`

signal  integer, most often one of the symbolic constants.

Details

Signals are a C99 concept, but only a small number are required to be supported (of those listed, only SIGINT and SIGTERM). They are much more widely used on POSIX operating systems (which should define all of those listed here), which also support a kill system call to send a signal to a process, most often to terminate it. Function `pskill` provides a wrapper: it silently ignores invalid values of its arguments, including zero or negative pids.

In normal use on a Unix-alike, Ctrl-C sends SIGINT, Ctrl-\ sends SIGQUIT and Ctrl-Z sends SIGTSTP: that and SIGSTOP suspend a process which can be resumed by SIGCONT.

The signals are small integers, but the actual numeric values are not standardized (and most do differ between OSes). The `SIG*` objects contain the appropriate integer values for the current platform (or `NA_INTEGER` if the signal is not defined).

Only SIGINT and SIGTERM will be defined on Windows, and `pskill` will always use the Windows system call `TerminateProcess`.

Value

A logical vector of the same length as `pid`, TRUE (for success) or FALSE, invisibly.

See Also

Package `parallel` has several means to launch child processes which record the process IDs.

`psnice`

Examples

```r
## Not run:
pskill(c(237, 245), SIGKILL)
## End(Not run)
```

`psnice`  
*Get or Set the Priority (Niceness) of a Process*

Description

Get or set the ‘niceness’ of the current process, or one or more other processes.

Usage

`psnice(pid = Sys.getpid(), value = NA_integer_)`
Arguments

pid  positive integers: the process IDs of one of more processes: defaults to the R session process.

value  The niceness to be set, or NA for an enquiry.

Details

POSIX operating systems have a concept of process priorities, usually from 0 to 39 (or 40) with 20 being a normal priority and (somewhat confusingly) larger numeric values denoting lower priority. To add to the confusion, there is a ‘niceness’ value, the amount by which the priority numerically exceeds 20 (which can be negative). Processes with high niceness will receive less CPU time than those with normal priority. On some OSes, processes with niceness +19 are only run when the system would otherwise be idle.

On many OSes utilities such as top report the priority and not the niceness. Niceness is used by the utility ‘/usr/bin/renice’: ‘/usr/bin/nice’ (and /usr/bin/renice -n) specifies an increment in niceness.

Only privileged users (usually super-users) can lower the niceness.

Windows has a slightly different concept of ‘priority classes’. We have mapped the idle priority to niceness 19, ‘below normal’ to 15, normal to 0, ‘above normal’ to -5 and ‘realtime’ to -10. Unlike Unix-alikes, a non-privileged user can increase the priority class on Windows (but using ‘realtime’ is inadvisable).

Value

An integer vector of previous niceness values, NA if unknown for any reason.

See Also

Various functions in package parallel create child processes whose priority may need to be changed. pskill.

QC Checks for R Code and/or Documentation

Description

Functions for performing various quality control (QC) checks on R code and documentation, notably on R packages.

Usage

  checkDocFiles  (package, dir, lib.loc = NULL, chkInternal = NULL)
  checkDocStyle (package, dir, lib.loc = NULL)
  checkReplaceFuns(package, dir, lib.loc = NULL)
  checkS3methods (package, dir, lib.loc = NULL)
  checkRdContents (package, dir, lib.loc = NULL, chkInternal = NULL)

  langElts
  nonS3methods(package)
Arguments

package a character string naming an installed package.

dir a character string specifying the path to a package’s root source (or installed in some cases) directory. This should contain the subdirectories ‘R’ (for R code) and ‘man’ with R documentation sources (in Rd format). Only used if package is not given.

lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.

chkInternal logical indicating if Rd files marked with keyword internal should be checked as well. If NULL (default), these are checked “specially”, ignoring missing documentation of arguments.

Details

checkDocFiles checks, for all Rd files in a package, whether all arguments shown in the usage sections of the Rd file are documented in its arguments section. It also reports duplicated entries in the arguments section, and ‘over-documented’ arguments which are given in the arguments section but not in the usage.

checkDocStyle investigates how (S3) methods are shown in the usages of the Rd files in a package. It reports the methods shown by their full name rather than using the Rd method markup for indicating S3 methods. Earlier versions of R also reported about methods shown along with their generic, which typically caused problems for the documentation of the primary argument in the generic and its methods. With \method now being expanded in a way that class information is preserved, joint documentation is no longer necessarily a problem. (The corresponding information is still contained in the object returned by checkDocStyle.)

checkReplaceFuns checks whether replacement functions or S3/S4 replacement methods in the package R code have their final argument named value.

checkS3methods checks whether all S3 methods defined in the package R code have all arguments of the corresponding generic, with positional arguments of the generics in the same positions for the method. As an exception, the first argument of a formula method may be called formula even if this is not the name used by the generic. The rules when ... is involved are subtle: see the source code. Functions recognized as S3 generics are those with a call to UseMethod in their body, internal S3 generics (see InternalMethods), and S3 group generics (see Math). Possible dispatch under a different name is not taken into account. The generics are sought first in the given package, then (if given an installed package) in the package imports, and finally the namespace environment for the base package.

checkRdContents() checks Rd content, e.g., whether arguments of functions in the usage section have non empty descriptions.

nonS3methods(package) returns a character vector with the names of the functions in package which ‘look’ like S3 methods, but are not. Using package = NULL returns all known examples.

langElts is a character vector of names of “language elements” of R. These are implemented as “very primitive” functions (no argument list; print()ing as .Primitive("name")).

If using an installed package, the checks needing access to all R objects of the package will load the package (unless it is the base package), after possibly detaching an already loaded version of the package.
Value

The functions return objects of class the same as the respective function names containing the information about problems detected. There are print methods for nicely displaying the information contained in such objects.

Rcmd R CMD Interface

Description

Invoke R CMD tools from within R.

Usage

Rcmd(args, ...)

Arguments

args a character vector of arguments to R CMD.
... arguments to be passed to system2.

Details

Provides a portable convenience interface to the R CMD mechanism by invoking the corresponding system commands (using the version of R currently used) via system2.

Value

See section “Value” in system2.

Rd2HTML Rd Converters

Description

These functions take the output of parse_Rd(), an Rd object, and produce a help page from it. As they are mainly intended for internal use, their interfaces are subject to change.

Usage

Rd2HTML(Rd, out = "", package = "", defines = .Platform$OS.type, Links = NULL, Links2 = NULL, stages = "render", outputEncoding = "UTF-8", dynamic = FALSE, no_links = FALSE, fragment = FALSE, stylesheet = if (dynamic) "/doc/html/R.css" else "R.css", texmath = getOption("help.htmlmath"), concordance = FALSE, standalone = TRUE, hooks = list(),
Rd2HTML

\begin{verbatim}
toc = isTRUE(getOption("help.htmltoc")),
Rhtml = FALSE,
...

Rd2txt(Rd, out = "", package = "", defines = .Platform$OS.type,
stages = "render", outputEncoding = "",
fragment = FALSE, options, ...)

Rd2latex(Rd, out = "", defines = .Platform$OS.type,
stages = "render", outputEncoding = "UTF-8",
fragment = FALSE, ..., writeEncoding = TRUE,
concordance = FALSE)

Rd2ex(Rd, out = "", defines = .Platform$OS.type,
stages = "render", outputEncoding = "UTF-8",
commentDontrun = TRUE, commentDonttest = FALSE, ...)
\end{verbatim}

Arguments

Rd a filename or Rd object to use as input.
out a filename or connection object to which to write the output. The default out = "" is equivalent to out = stdout().
package the package to list in the output.
defines string(s) to use in \#ifdef tests.
stages at which stage ("build", "install", or "render") should Sexpr macros be executed? See the notes below.
outputEncoding see the ‘Encodings’ section below.
dynamic logical: set links for render-time resolution by dynamic help system.
no_links logical: suppress hyperlinks to other help topics. Used by R CMD Rdconv.
fragment logical: should fragments of Rd files be accepted? See the notes below.
styleSheet character: a URL for a stylesheet to be used in the header of the HTML output page.
texmath character: controls how mathematics in \eqn and \deqn commands are typeset in HTML output. Useful values are "katex" (default) and "mathjax" to use KaTeX or MathJax respectively, otherwise basic substitutions are used. May be ignored under certain circumstances, e.g., if the help page already uses macros from the mathjaxr package.
concordance Whether concordance data should be embedded in the output file and attached to the return value.
standalone logical: whether the output is intended to be a standalone HTML file. If FALSE, the header and footer are omitted, so that the output can be combined with other fragments.
hooks A list of functions controlling details of output. Currently the only component used is pkg_href, which is used by pkg2HTML to determine the output HTML file path given a package name as input.
toc logical: whether the HTML output should include a table of contents. Ignored unless standalone = TRUE.
Rhtml logical: whether the output is intended to be a Rhtml file that can be processed using \texttt{knitr}. If TRUE, the examples section is wrapped inside a rcode block.
Links, Links2
NULL or a named (by topics) character vector of links, as returned by findHTML\_links.

options
An optional named list of options to pass to Rd2txt\_options.

writeEncoding
Should \texttt{\textbackslash{}inputencoding} lines be written in the file for non-ASCII encodings?

commentDontrun
Should \texttt{\textbackslash{}dontrun} sections be commented out?

commentDonttest
Should \texttt{\textbackslash{}donttest} sections be commented out?

Details
These functions convert help documents: Rd2HTML produces HTML, Rd2txt produces plain text, Rd2latex produces LaTeX. Rd2ex extracts the examples in the format used by \texttt{example} and \texttt{R} utilities.

Each of the functions accepts a filename for an Rd file, and will use parse\_Rd to parse it before applying the conversions or checks.

The difference between arguments Link and Link2 is that links are looked in them in turn, so lazy-evaluation can be used to only do a second-level search for links if required.

Before R 3.6.0, the default for Rd2latex was output\_Encoding = "ASCII", including using the second option of \texttt{\textbackslash{}enc} markup, because \LaTeX{} versions did not provide enough coverage of UTF-8 glyphs for a long time.

Rd2txt will format text paragraphs to a width determined by width, with appropriate margins. The default is to be close to the rendering in versions of R < 2.10.0.

Rd2txt will use directional quotes (see \texttt{sQuote}) if option "useFancyQuotes" is true (usually the default, see \texttt{sQuote}) and the current encoding is UTF-8.

Various aspects of formatting by Rd2txt are controlled by the options argument, documented with the Rd2txt\_options function. Changes made using options are temporary, those made with Rd2txt\_options are persistent.

When fragment = \texttt{TRUE}, the Rd file will be rendered with no processing of \texttt{\Sexpr} elements or conditional defines using \texttt{#ifdef} or \texttt{#ifndef}. Normally a fragment represents text within a section, but if the first element of the fragment is a section macro, the whole fragment will be rendered as a series of sections, without the usual sorting.

Value
These functions are executed mainly for the side effect of writing the converted help page. Their value is the name of the output file (invisibly). For Rd2latex, the output name is given an attribute "latex\_Encoding" giving the encoding of the file in a form suitable for use with the \LaTeX{} \texttt{\textbackslash{}inputenc} package. For Rd2HTML with standalone = \texttt{FALSE}, an attribute "info" gives supplementary information such as the contents of the name and title fields. This is currently experimental, and the details are subject to change.

For Rd2HTML and Rd2latex with concordance = \texttt{TRUE}, a "concordance" attribute is added, containing an \texttt{Rconcordance} object.

Encodings
Rd files are normally intended to be rendered on a wide variety of systems, so care must be taken in the encoding of non-ASCII characters. In general, any such encoding should be declared using the 'encoding' section for there to be any hope of correct rendering.
For output, the `outputEncoding` argument will be used: `outputEncoding = ""` will choose the native encoding for the current system.

If the text cannot be converted to the `outputEncoding`, byte substitution will be used (see `iconv`): `Rd2latex` and `Rd2ex` give a warning.

**Note**

The `\Sexpr` macro includes R code that will be executed at one of three times: build time (when a package’s source code is built into a tarball), install time (when the package is installed or built into a binary package), and render time (when the man page is converted to a readable format).

For example, this man page was:

1. built on 2024-04-24 at 08:24:52,
2. installed on 2024-04-24 at 08:24:52, and
3. rendered on 2024-04-24 at 11:00:52.

## Simulate rendering of this (installed) page in HTML and text format
Rd <- Rd_db("tools")[["Rd2HTML.Rd"]]
outfile <- tempfile(fileext = ".html")
Rd2HTML(Rd, outfile, package = "tools") |> browseURL()

outfile <- tempfile(fileext = ".txt")
Rd2txt(Rd, outfile, package = "tools") |> file.show()
```

---

### `Rd2txt_options`

*Set Formatting Options for Text Help*

**Description**

This function sets various options for displaying text help.

**Usage**

`Rd2txt_options(...)`
Arguments

... A list containing named options, or options passed as individual named arguments. See below for currently defined ones.

Details

This function persistently sets various formatting options for the Rd2txt function which is used in displaying text format help. Currently defined options are:

- **width** (default 80): The width of the output page.
- **minIndent** (default 10): The minimum indent to use in a list.
- **extraIndent** (default 4): The extra indent to use in each level of nested lists.
- **sectionIndent** (default 5): The indent level for a section.
- **sectionExtra** (default 2): The extra indentation for each nested section level.
- **itemBullet** (default "* ", with the asterisk replaced by a Unicode bullet in UTF-8 and most Windows locales): The symbol to use as a bullet in itemized lists.
- **enumFormat**: A function to format item numbers in enumerated lists.
- **showURLs** (default FALSE): Whether to show URLs when expanding \href tags.
- **code_quote** (default TRUE): Whether to render \code and similar with single quotes.
- **underline_titles** (default TRUE): Whether to render section titles with underlines (via backspacing).

Value

If called with no arguments, returns all option settings in a list. Otherwise, it changes the named settings and invisibly returns their previous values.

Rd2txt_options()["minIndent"]
Rd2txt_options(saveOpts)
stopifnot(identical(Rd2txt_options(), saveOpts))
```
Rdiff

Difference R Output Files

Description

Given two R output files, compute differences ignoring headers, footers and some other differences.

Usage

Rdiff(from, to, useDiff = FALSE, forEx = FALSE, nullPointers = TRUE, Log = FALSE)

Arguments

from, to    filepaths to be compared
useDiff    should diff be used to compare results? Overridden to false if the command is not available.
forEx      logical: extra pruning for '-Ex.Rout' files to exclude headers and footers of examples, code and results for "--timings", etc.
nullPointers logical: should the displayed addresses of pointers be set to 0x00000000 before comparison?
Log         logical: should the returned value include a log of differences found?

Details

The R startup banner and any timing information from R CMD BATCH are removed from both files, together with lines about loading packages. UTF-8 fancy quotes (see sQuote) and on Windows, Windows' so-called 'smart quotes', are mapped to a simple quote. Addresses of environments, compiled bytecode and other exotic types expressed as hex addresses (e.g., '<environment: 0x12345678>') are mapped to 0x00000000. The files are then compared line-by-line. If there are the same number of lines and useDiff is false, a simple diff -b-like display of differences is printed (which ignores trailing spaces and differences in numbers of consecutive spaces), otherwise diff -bw is called on the edited files. (This tries to ignore all differences in whitespace: note that flag '-w' is not required by POSIX but is supported by GNU, Solaris and FreeBSD versions – macOS uses an old GNU version.)

There is limited support for comparing PDF files produced by pdf(compress = FALSE), mainly for use in make check – this requires a diff command and useDiff = TRUE.

Mainly for use in examples and tests, text from marker '>` # IGNORE_RDIFF_BEGIN' up to (but not including) `>` # IGNORE_RDIFF_END' is ignored.

Value

If Log is true, a list with components status (see below) and out, a character vector of descriptions of differences, possibly of zero length.

Otherwise, a status indicator (invisibly), 0L if and only if no differences were found.

See Also

The shell script run as R CMD Rdiff, which uses useDiff = TRUE.
Rdindex

Rdindex

1913

Generate Index from Rd Files

Description
Print a 2-column index table with names and titles from given R documentation files to a given
output file or connection. The titles are nicely formatted between two column positions (typically
25 and 72, respectively).
Usage
Rdindex(RdFiles, outFile = "", type = NULL,
width = 0.9 * getOption("width"), indent = NULL)
Arguments
RdFiles

a character vector specifying the Rd files to be used for creating the index, either
by giving the paths to the files, or the path to a single directory with the sources
of a package.

outFile

a connection, or a character string naming the output file to print to. "" (the
default) indicates output to the console.

type

a character string giving the documentation type of the Rd files to be included in
the index, or NULL (the default). The type of an Rd file is typically specified via
the \docType tag; if type is "data", Rd files whose only keyword is datasets
are included as well.

width

a positive integer giving the target column for wrapping lines in the output.

indent

a positive integer specifying the indentation of the second column. Must not be
greater than width/2, and defaults to width/3.

Details
If a name is not a valid alias, the first alias (or the empty string if there is none) is used instead.

RdTextFilter

Select Text in an Rd File

Description
This function blanks out all non-text in an Rd file, for spell checking or other uses.
Usage
RdTextFilter(ifile, encoding = "unknown", keepSpacing = TRUE,
drop = character(), keep = character(),
macros = file.path(R.home("share"), "Rd", "macros", "system.Rd"))


Arguments

ifile
An input file specified as a filename or connection, or an "Rd" object from parse_Rd.

encoding
An encoding name to pass to parse_Rd.

keepSpacing
Whether to try to leave the text in the same lines and columns as in the original file.

drop
Additional sections of the Rd to drop.

keep
Sections of the Rd file to keep.

macros
Macro definitions to assume when parsing. See parse_Rd.

Details

This function parses the Rd file, then walks through it, element by element. Items with tag "TEXT" are kept in the same position as they appeared in the original file, while other parts of the file are replaced with blanks, so a spell checker such as aspell can check only the text and report the position in the original file. (If keepSpacing is FALSE, blank filling will not occur, and text will not be output in its original location.)

By default, the tags \$S3method, \$S4method, \command, \docType, \email, \encoding, \file, \keyword, \link, \linkS4class, \method, \pkg, and \var are skipped. Additional tags can be skipped by listing them in the drop argument; listing tags in the keep argument will stop them from being skipped. It is also possible to keep any of the c("RCODE", "COMMENT", "VERB") tags, which correspond to R-like code, comments, and verbatim text respectively, or to drop "TEXT".

Value

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Rd file.

Note

The filter attempts to merge text elements into single words when markup in the Rd file is used to highlight just the start of a word.

Author(s)

Duncan Murdoch

See Also

aspell, for which this is an acceptable filter.
Description

Utilities for computing on the information in Rd objects.

Usage

Rd_db(package, dir, lib.loc = NULL, stages = "build")

Arguments

package a character string naming an installed package.
dir a character string specifying the path to a package’s root source directory. This should contain the subdirectory ‘man’ with R documentation sources (in Rd format). Only used if package is not given.
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
stages if dir is specified and the database is being built from source, which stages of \Sexpr processing should be processed?

Details

Rd_db builds a simple database of all Rd objects in a package, as a list of the results of running parse_Rd on the Rd source files in the package and processing platform conditionals and some \Sexpr macros.

See Also

parse_Rd

Examples

```r
## Build the Rd db for the (installed) base package.
db <- Rd_db("base")

## Keyword metadata per Rd object.
keywords <- lapply(db, tools:::.Rd_get_metadata, "keyword")
## Tabulate the keyword entries.
kw_table <- sort(table(unlist(keywords)))
## The 5 most frequent ones:
rev(kw_table)[1 : 5]
## The "most informative" ones:
kw_table[kw_table == 1]

## Concept metadata per Rd file.
concepts <- lapply(db, tools:::.Rd_get_metadata, "concept")
## How many files already have \concept metadata?
sum(sapply(concepts, length) > 0)
## How many concept entries altogether?
length(unlist(concepts))
```
**read.00Index**  
*Read 00Index-style Files*

**Description**

Read item/description information from ‘00Index’-like files. Such files are description lists rendered in tabular form, and currently used for the ‘INDEX’ and ‘demo/00Index’ files of add-on packages.

**Usage**

```
read.00Index(file)
```

**Arguments**

- **file**
  
  the name of a file to read data values from. If the specified file is "", then input is taken from the keyboard (in this case input can be terminated by a blank line). Alternatively, `file` can be a connection, which will be opened if necessary, and if so closed at the end of the function call.

**Value**

A character matrix with 2 columns named "Item" and "Description" which hold the items and descriptions.

**See Also**

- `formatDL` for the inverse operation of creating a 00Index-style file from items and their descriptions.

---

**showNonASCII**  
*Pick Out Non-ASCII Characters*

**Description**

This function prints elements of a character vector which contain non-ASCII bytes, printing such bytes as a escape like ‘<fc>’.

**Usage**

```
showNonASCII(x)
showNonASCIIfile(file)
```

**Arguments**

- **x**
  
  a character vector.

- **file**
  
  path to a file.
**Details**

This was originally written to help detect non-portable text in files in packages.

It prints all elements of \( x \) which contain non-ASCII characters, preceded by the element number and with non-ASCII bytes highlighted via `iconv(sub = "byte")`.

However, this rendering depends on `iconv(to = "ASCII")` failing to convert, and macOS 14 no longer does so reliably so for example permille (`'\u2030'`) is rendered as `o/oo`.

**Value**

The elements of \( x \) containing non-ASCII characters will be returned invisibly.

**Examples**

```r
out <- c(
  "fran\xE7ais: test of showNonASCII():",
  "\n\details{",
  " This is a good line",
  " This has an \xfcmlaut in it.",
  " OK again.",
  "}")

f <- tempfile()
cat(out, file = f, sep = "\n")

showNonASCIIfile(f)
unlink(f)
```

---

**Description**

This function starts the internal help server, so that HTML help pages are rendered when requested.

**Usage**

```r
startDynamicHelp(start = TRUE)
```

**Arguments**

- **start** logical: whether to start or shut down the dynamic help system. If NA, the server is started if not already running.

**Details**

This function starts the internal HTTP server, which runs on the loopback interface (`'127.0.0.1'`). If options(`"help.ports"`) is set to a vector of non-zero integer values, `startDynamicHelp` will try those ports in order; otherwise, it tries up to 10 random ports to find one not in use. It can be disabled by setting the environment variable `R_DISABLE_HTTPD` to a non-empty value or options(`"help.ports"`) to 0.

`startDynamicHelp` is called by functions that need to use the server, so would rarely be called directly by a user.
Note that `options(help_type = "html")` must be set to actually make use of HTML help, although it might be the default for an `R` installation.

If the server cannot be started or is disabled, `help.start` will be unavailable and requests for HTML help will give text help (with a warning).

The browser in use does need to be able to connect to the loopback interface: occasionally it is set to use a proxy for HTTP on all interfaces, which will not work – the solution is to add an exception for `"127.0.0.1"`.

**Value**

The chosen port number is returned invisibly (which will be 0 if the server has been stopped).

**See Also**

`help.start` and `help(help_type = "html")` will attempt to start the HTTP server if required. `Rd2HTML` is used to render the package help pages.

---

### Description

This function blanks out code chunks and Noweb markup in an Sweave input file, for spell checking or other uses.

### Usage

```r
SweaveTeXFilter(ifile, encoding = "unknown")
```

### Arguments

- `ifile`: Input file or connection.
- `encoding`: Text encoding to pass to `readLines`.

### Details

This function blanks out all Noweb markup and code chunks from an Sweave input file, leaving behind the LaTeX source, so that a LaTeX-aware spelling checker can check it and report errors in their original locations.

### Value

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Sweave input file.

### Author(s)

Duncan Murdoch

### See Also

`aspell`, for which this is used with `filter = "Sweave"`. 
Test Installed Packages

Description

These functions allow an installed package to be tested, or all base and recommended packages.

Usage

```r
testInstalledPackage(pkg, lib.loc = NULL, outDir = ".",
                     types = c("examples", "tests", "vignettes"),
                     srcdir = NULL, Ropts = "", ...)

testInstalledPackages(outDir = ".", errorsAreFatal = TRUE,
                      scope = c("both", "base", "recommended"),
                      types = c("examples", "tests", "vignettes"),
                      srcdir = NULL, Ropts = "", ...)

testInstalledBasic(scope = c("basic", "devel", "both", "internet", "all"),
                    outDir = file.path(R.home(), "tests"),
                    testSrcdir = getTestSrcdir(outDir))

standard_package_names()
```

Arguments

- **pkg**: name of an installed package.
- **lib.loc**: library path(s) in which to look for the package. See `library`.
- **outDir**: the directory into which to write the output files: this should already exist. The default, "." is the current working directory. Often a subdirectory is preferable.
- **types**: type(s) of tests to be done.
- **srcdir**: Optional directory to look for .save files.
- **Ropts**: Additional options such as `-d valgrind` to be passed to `R CMD BATCH` when running examples or tests.
- **errorsAreFatal**: logical: should testing terminate at the first error?
- **scope**: a string indicating which set(s) should be tested. "both" includes "basic" and "devel"; "all" adds "internet". Can be abbreviated.
- **...**: additional arguments use when preparing the files to be run, e.g. `commentDontrun` and `commentDonttest`.
- **testSrcdir**: optional directory where the test R scripts are found.

Details

The `testInstalledPackage()` tests depend on having the package example files installed (which is the default).

If package-specific tests are found in a ‘tests’ directory they can be tested: these are not installed by default, but will be if `R CMD INSTALL --install-tests` was used. Finally, the R code in any vignettes can be extracted and tested.
The package-specific tests are run in a ‘pkg-tests’ subdirectory of ‘outDir’, and leave their output there.

testInstalledBasic runs the basic tests, if installed or inside testSrcdir. This should be run with LC_COLLATE=C set: the function tries to set this but it may not work on all OSes. For non-English locales it may be desirable to set environment variables LANGUAGE to ‘en’ and LC_TIME to ‘C’ to reduce the number of differences from reference results.

Except on Windows, if the environment variable TEST_MC_CORES is set to an integer greater than one, testInstalledPackages will run the package tests in parallel using its value as the maximum number of parallel processes.

The package-specific tests for the base and recommended packages are not normally installed, but make install-tests is provided to do so (as well as the basic tests).

Value

Invisibly 0L for success, 1L for failure.

standard_package_names() returns a list with components named

base a character vector with the ‘base’ package names.
recommended a character vector with the ‘Recommended’ package names in historical order.

Examples

```r
str(stPkgs <- standard_package_names())
## consistency of packageDescription and standard_package_names :
(pNms <- unlist(stPkgs, FALSE))
(prio <- sapply(as.vector(pNms), packageDescription, fields = "Priority"))
stopifnot(identical(unname(prio),
   sub("[0-9]+$", '', names(pNms)))))
```

---

texi2dvi

**Compile LaTeX Files**

**Description**

Run latex/pdflatex, makeindex and bibtex until all cross-references are resolved to create a DVI or a PDF file.

**Usage**

texi2dvi(file, pdf = FALSE, clean = FALSE, quiet = TRUE,
texi2dvi = getOption("texi2dvi"),
texinputs = NULL, index = TRUE)

texi2pdf(file, clean = FALSE, quiet = TRUE,
texi2dvi = getOption("texi2dvi"),
texinputs = NULL, index = TRUE)
Arguments

- **file** character string. Name of the \LaTeX source file.
- **pdf** logical. If TRUE, a PDF file is produced instead of the default DVI file (\texttt{texi2dvi} command line option '--pdf').
- **clean** logical. If TRUE, all auxiliary files created during the conversion are removed.
- **quiet** logical. No output unless an error occurs.
- **texi2dvi** character string (or NULL). Script or program used to compile a TeX file to DVI or PDF. The default (selected by "" or "texi2dvi" or NULL) is to look for a program or script named \texttt{texi2dvi} on the path and otherwise emulate the script with system2 calls (which can be selected by the value "emulation"). See also 'Details'.
- **texinputs** NULL or a character vector of paths to add to the \LaTeX and BibTeX input search paths.
- **index** logical: should indices be prepared?

Details

texi2pdf is a wrapper for the common case of \texttt{texi2dvi(pdf = TRUE)}.

Despite the name, this is used in \texttt{R} to compile \LaTeX files, specifically those generated from vignettes and by the \texttt{Rd2pdf} script (used for package reference manuals). It ensures that the \texttt{'R_HOME/share/texmf'} directory is in the TEXINPUTS path, so \texttt{R} style files such as \texttt{Sweave.sty} and \texttt{Rd.sty} will be found. The TeX search path used is first the existing TEXINPUTS setting (or the current directory if unset), then elements of argument texinputs, then \texttt{'R_HOME/share/texmf'} and finally the default path. Analogous changes are made to BIBINPUTS and BSTINPUTS settings.

The default option for \texttt{texi2dvi} is set from environment variable \texttt{R_TEXI2DVICMD}, and the default for that is set from environment variable \texttt{TEXI2DVI} or if that is unset, from a value chosen when \texttt{R} is configured.

A shell script \texttt{texi2dvi} is part of GNU’s \texttt{texinfo}. Several issues have been seen with released versions, so if yours does not work correctly try \texttt{R_TEXI2DVICMD=emulation}.

Occasionally indices contain special characters which cause indexing to fail (particularly when using the 'hyperref' \LaTeX package) even on valid input. The argument index = FALSE is provided to allow package manuals to be made when this happens: it uses emulation.

Value

Invisible NULL. Used for the side effect of creating a DVI or PDF file in the current working directory (and maybe other files, especially if clean = FALSE).

Note

There are various versions of the \texttt{texi2dvi} script on Unix-alikes and quite a number of bugs have been seen, some of which this \texttt{R} wrapper works around.

One that was present with \texttt{texi2dvi} version 4.8 (as supplied by macOS) is that it will not work correctly for paths which contain spaces, nor if the absolute path to a file would contain spaces.

The three possible approaches all have their quirks. For example the Unix-alike \texttt{texi2dvi} script removes ancillary files that already exist but the other two approaches do not (and may get confused by such files).

Where supported (\texttt{texi2dvi 5.0} and later; \texttt{texify.exe} from MiKTeX), option ‘--max-iterations=20’ is used to avoid infinite retries.
The emulation mode supports `quiet = TRUE` from R 3.2.3 only. Currently `clean = TRUE` only cleans up in this mode if the conversion was successful—this gives users a chance to examine log files in the event of error.

All the approaches should respect the values of environment variables `LATEX`, `PDFLATEX`, `MAKEINDEX` and `BIBTEX` for the full paths to the corresponding commands.

Author(s)

Originally Achim Zeileis but largely rewritten by R-core.

toHTML

Display an Object in HTML

description

This generic function generates a complete HTML page from an object.

Usage

toHTML(x, ...)  
## S3 method for class 'packageIQR'  
toHTML(x, ...)  
## S3 method for class 'news_db'  
toHTML(x, ...)  

Arguments

x An object to display.
...

Optional parameters for methods; the "packageIQR" and "news_db" methods pass these to `HTMLheader`.

Value

A character vector to display the object x. The "packageIQR" method is designed to display lists in the R help system.

See Also

`HTMLheader`

Examples

cat(toHTML(demo(package = "base")), sep = "\n")
## Deprecated Objects in Package tools

### Description

(Currently none)

The functions or variables listed here are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

### See Also

[Deprecated, Defunct](#)

---

## toRd

Generic Function to Convert Object to a Fragment of Rd Code

### Description

Methods for this function render their associated classes as a fragment of Rd code, which can then be rendered into text, HTML, or LaTeX.

### Usage

```r
toRd(obj, ...)  
## S3 method for class 'bibentry'

## S3 method for class 'bibentry'

## S3 method for class 'bibentry'

## S3 method for class 'bibentry'
```

### Arguments

- `obj`  
  The object to be rendered.

- `style`  
  The style to be used in converting a `bibentry` object.

- `...`  
  Additional arguments used by methods.

### Details

See [bibstyle](#) for a discussion of styles. The default `style = NULL` value gives the default style.

### Value

Returns a character vector containing a fragment of Rd code that could be parsed and rendered. The default method converts `obj` to mode character, then escapes any Rd markup within it. The `bibentry` method converts an object of that class to markup appropriate for use in a bibliography.
**toTitleCase**  
*Convert Titles to Title Case*

**Description**
Convert a character vector to title case, especially package titles.

**Usage**
toTitleCase(text)

**Arguments**
- **text**
  a character vector.

**Details**
This is intended for English text only.
No definition of ‘title case’ is universally accepted: all agree that ‘principal’ words are capitalized and common words like ‘for’ are not, but not which words fall into each category.
Generally words in all capitals are left alone: this implementation knows about conventional mixed-case words such as ‘LaTeX’ and ‘OpenBUGS’ and a few technical terms which are not usually capitalized such as ‘jar’ and ‘xls’. However, unknown technical terms will be capitalized unless they are single words enclosed in single quotes: names of packages and libraries should be quoted in titles.

**Value**
A character vector of the same length as text, without names.

---

**undoc**  
*Find Undocumented Objects*

**Description**
Finds the objects in a package which are undocumented, in the sense that they are visible to the user (or data objects or S4 classes provided by the package), but no documentation entry exists.

**Usage**
undoc(package, dir, lib.loc = NULL)

**Arguments**
- **package**
a character string naming an installed package.
- **dir**
a character string specifying the path to a package’s root source directory. This must contain the subdirectory ‘man’ with R documentation sources (in Rd format), and at least one of the ‘R’ or ‘data’ subdirectories with R code or data objects, respectively.
- **lib.loc**
a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
**update_PACKAGES**

**Update Existing PACKAGES Files**

**Description**
Update an existing repository by reading the PACKAGES file, retaining entries which are still valid, removing entries which are no longer valid, and only processing built package tarballs which do not match existing entries.

Update PACKAGES can be much faster than write_PACKAGES for small-moderate changes to large repository indexes, particularly in non-strict mode (see Details).

**Usage**

```r
update_PACKAGES(dir = ".", fields = NULL, type = c("source", "mac.binary", "win.binary"), verbose.level = as.integer(dryrun), latestOnly = TRUE, addFiles = FALSE, rds_compress = "xz", strict = TRUE, dryrun = FALSE)
```

**Arguments**

- **dir**
  - see write_PACKAGES.
- **fields**
  - see write_PACKAGES.
- **type**
  - see write_PACKAGES.
- **verbose.level**
  - one of \{0, 1, 2\}, the level of informative messages displayed throughout the process. Defaults to 0 if dryrun is FALSE (the default) and 1 otherwise. See Details for more information.
- **latestOnly**
  - see write_PACKAGES.
- **addFiles**
  - see write_PACKAGES.
- **rds_compress**
  - see write_PACKAGES.
- **strict**
  - see write_PACKAGES.
- **dryrun**
  - see write_PACKAGES.
addFiles  see write_PACKAGES.

dirs_compressed see write_PACKAGES.

strict  logical. Should “strict mode” be used when checking existing PACKAGES entries. See Details. Defaults to TRUE.

dryrun  logical. Should the updates to existing PACKAGES files be computed but NOT applied. Defaults to FALSE.

Details

Throughout this section, package tarball is defined to mean any archive file in dir whose name can be interpreted as ‘package_version.ext’ – with ext the appropriate extension for built packages of type type – (or that is pointed to by the File field of an existing PACKAGES entry). Novel package tarballs are those which do not match an existing PACKAGES file entry.

update_PACKAGES calls directly down to write_PACKAGES with a warning (and thus all package tarballs will be processed), if any of the following conditions hold:

- type is “win.binary” and strict is TRUE (no MD5 checksums are included in win.binary PACKAGES files)
- No PACKAGES file exists under dir
- A PACKAGES file exists under dir but is empty
- fields is not NULL and one or more specified fields are not present in the existing PACKAGES file

update_PACKAGES avoids (re)processing package tarballs in cases where a PACKAGES file entry already exists and appears to remain valid. The logic for detecting still-valid entries is as follows:

Any package tarball which was last modified more recently than the existing PACKAGES file is considered novel; existing PACKAGES entries appearing to correspond to such tarballs are always considered stale and replaced by newly generated ones. Similarly, all PACKAGES entries that do not correspond to any package tarball found in dir are considered invalid and are excluded from the resulting updated PACKAGES files.

When strict is TRUE, PACKAGES entries that match a package tarball (by package name and version) are confirmed via MD5 checksum; only those that pass are retained as valid. All novel package tarballs are fully processed by the standard machinery underlying write_PACKAGES and the resulting entries are added. Finally, if latestOnly is TRUE, package-version pruning is performed across the entries.

When strict is FALSE, package tarballs are assumed to encode correct metadata in their filenames. PACKAGES entries which appear to match a package tarball are retained as valid (No MD5 checksum testing occurs). If latestOnly is TRUE, package-version pruning is performed across the full set of retained entries and novel package tarballs before the processing of the novel tarballs, at significant computational and time savings in some situations. After the optional pruning, any relevant novel package tarballs are processed via the standard machinery and added to the set of retained entries.

In both cases, after the above process concludes, entries are sorted alphabetically by the string concatenation of Package and Version. This should match the entry order write_PACKAGES outputs.

The fields within the entries are ordered as follows: canonical fields - i.e., those appearing as columns when available.packages is called on a CRAN mirror - appear first in their canonical order, followed by any non-canonical fields.

After entry and field reordering, the final database of PACKAGES entries is written to all three PACKAGES files, overwriting the existing versions.
When `verbose.level` is 0, no extra messages are displayed to the user. When it is 1, detailed information about what is happening is conveyed via messages, but underlying machinery from `write_PACKAGES` is invoked with `verbose = FALSE`. Behavior when `verbose.level` is 2 is identical to `verbose.level` 1 with the exception that underlying machinery from `write_PACKAGES` is invoked with `verbose = TRUE`, which will individually list every processed tarball.

**Note**

While both strict and non-strict modes can offer speedups when updating small percentages of large repositories, non-strict mode is *much* faster and is recommended in situations where the assumption it makes about tarballs’ filenames encoding accurate information is safe.

**Note**

Users should expect significantly smaller speedups over `write_PACKAGES` in the type == "win.binary" case on at least some operating systems. This is due to `write_PACKAGES` being significantly faster in this context, rather than `update_PACKAGES` being slower.

**Author(s)**

Gabriel Becker (adapted from previous, related work by him in the `switchr` package which is copyright Genentech, Inc.)

**See Also**

`write_PACKAGES`

**Examples**

```r
## Not run:
write_PACKAGES("c:/myFolder/myRepository") # on Windows
update_PACKAGES("c:/myFolder/myRepository") # on Windows
write_PACKAGES("/pub/RWin/bin/windows/contrib/2.9",
  type = "win.binary") # on Linux
update_PACKAGES("/pub/RWin/bin/windows/contrib/2.9",
  type = "win.binary") # on Linux

## End(Not run)
```

**update_pkg_po**

Prepare Translations for a Package

**Description**

Prepare the ‘po’ directory of a package and optionally compile and install the translations.

**Usage**

```r
update_pkg_po(pkgdir, pkg = NULL, version = NULL,
  pot_make = TRUE, mo_make = TRUE,
  verbose =getOption("verbose"),
  mergeOpt = ",", copyright, bugs)
```
update_pkg_po

Arguments

pkgdir
The path to the package directory.

pkg
The package name: if NULL it is read from the package’s ‘DESCRIPTION’ file.

version
The package version: if NULL it is read from the package’s ‘DESCRIPTION’ file.

pot_make, mo_make
logicals indicating if a new ‘*.pot’ file or new binary translations ‘*.mo’ should be (re)created.

verbose
logical indicating if extra information about the updating process should be printed to the console.

Details

This performs a series of steps to prepare or update messages in the package:

- If the package sources do not already have a ‘po’ directory, one is created.
- xgettext2pot is called to create/update a file ‘po/R-pkgname.pot’ containing the translatable messages in the package.
- All existing files in directory po with names ‘R-lang.po’ are updated from ‘R-pkgname.pot’. checkPoFile is called on the updated file, and if there are no problems the file is compiled and installed under ‘inst/po’.
- In a UTF-8 locale, a ‘translation’ ‘en@quot.po’ is created with UTF-8 directional quotes, compiled and installed under ‘inst/po’.
- The remaining steps are done only if file ‘po/pkgnamel.pot’ already exists. The ‘src/*.{c,cc,cpp,m,mm}’ files in the package are examined to create a file ‘po/pkgnamel.pot’ containing the translatable messages in the C/C++ files. If there is a src/windows directory, files within it are also examined.
- All existing files in directory po with names ‘lang.po’ are updated from ‘pkgnamel.pot’. checkPoFile is called on the updated file, and if there are no problems the file is compiled and installed under ‘inst/po’.
- In a UTF-8 locale, a ‘translation’ ‘en@quot.po’ is created with UTF-8 directional quotes, compiled and installed under ‘inst/po’.

Note that C/C++ messages are not automatically prepared for translation as they need to be explicitly marked for translation in the source files. Once that has been done, create an empty file ‘po/pkgnamel.pot’ in the package sources and run this function again.

pkg = "base" is special (and for use by R developers only): the C files are not in the package directory but in the main sources.

System requirements

This function requires the following tools from the GNU gettext-tools: xgettext, msgmerge, msgfmt, msginit and msgconv. These are part of most Linux distributions and easily compiled from the sources on Unix-alikes (including macOS). Pre-compiled versions for Windows are available in https://www.stats.ox.ac.uk/pub/Rtools/goodies/gettext-tools.zip.

It will probably not work correctly for en@quot translations except in a UTF-8 locale, so these are skipped elsewhere.
userdir

R User Directories

Description

Directories for storing R-related user-specific data, configuration and cache files.

Usage

R_user_dir(package, which = c("data", "config", "cache"))

Arguments

package a character string giving the name of an R package
which a character string indicating the kind of file(s) of interest. Can be abbreviated.

Details

For desktop environments using X Windows, the freedesktop.org project (formerly X Desktop Group, XDG) developed the XDG Base Directory Specification (https://specifications.freedesktop.org/basedir-spec) for standardizing the location where certain files should be placed. CRAN package rappdirs provides these general locations with appropriate values for all platforms for which R is available.

R_user_dir specializes the general mechanism to R package specific locations for user files, by providing package specific subdirectories inside a ‘R’ subdirectory inside the “base” directories appropriate for user-specific data, configuration and cache files (see the examples), with the intent that packages will not interfere if they work within their respective subdirectories.

The locations of these base directories can be customized via the specific environment variables R_USER_DATA_DIR, R_USER_CONFIG_DIR and R_USER_CACHE_DIR. If these are not set, the general XDG-style environment variables XDG_DATA_HOME, XDG_CONFIG_HOME and XDG_CACHE_HOME are used if set, and otherwise, defaults appropriate for the R platform in use are employed.

Examples

R_user_dir("FOO", "cache")

## Create one, platform agnostically, must work if <normal> :
(Rdb <- R_user_dir("base"))
if(newD <- !dir.exists(Rdb)) # should work user specifically:
  newD <- dir.create(Rdb, recursive=TRUE)
dir(Rdb) # typically empty
if(newD) unlink(Rdb) # cleaning up

list.files(R_user_dir("grid"), full.names = TRUE)
Description

Vignettes are normally processed by Sweave, but package writers may choose to use a different engine (e.g., one provided by the knitr, noweb or R.rsp packages). This function is used by those packages to register their engines, and internally by R to retrieve them.

Usage

vignetteEngine(name, weave, tangle, pattern = NULL, package = NULL, aspell = list())

Arguments

name the name of the engine.
weave a function to convert vignette source files to PDF/HTML or intermediate LaTeX output.
tangle a function to convert vignette source files to R code.
pattern a regular expression pattern for the filenames handled by this engine, or NULL for the default pattern.
package the package registering the engine. By default, this is the package calling vignetteEngine.
aspell a list with element names filter and/or control giving the respective arguments to be used when spell checking the text in the vignette source file with aspell.

Details

If weave is missing, vignetteEngine will return the currently registered engine matching name and package.

If weave is NULL, the specified engine will be deleted.

Other settings define a new engine. The weave and tangle functions must be defined with argument lists compatible with function(file, ...). Currently the ... arguments may include logical argument quiet and character argument encoding; others may be added in future. These are described in the documentation for Sweave and Stangle.

The weave and tangle functions should return the filename of the output file that has been produced. Currently the weave function, when operating on a file named `<name><pattern>` must produce a file named `<name>.[.](tex|pdf|html)`. The `.tex` files will be processed by pdflatex to produce `.pdf` output for display to the user; the others will be displayed as produced. The tangle function must produce a file named `<name>.[rRsS]` containing the executable R code from the vignette. The tangle function may support a split = TRUE argument, and then it should produce files named `<name>.*.[rRsS]`.

The pattern argument gives a regular expression to match the extensions of files which are to be processed as vignette input files. If set to NULL, the default pattern `"[.][RrSs](nw|tex)$"` is used.
vignetteInfo

Value

If the engine is being deleted, NULL. Otherwise a list containing components

name The name of the engine
package The name of its package
pattern The pattern for vignette input files
weave The weave function
tangle The tangle function

Author(s)

Duncan Murdoch and Henrik Bengtsson.

Sweave and the ’Writing R Extensions’ manual.

Examples

str(vignetteEngine("Sweave"))

vignetteInfo

Basic Information about a Vignette

Description

Extract metadata from a vignette source file.

Usage

vignetteInfo(file)

Arguments

file file name of the vignette.

Value

A list with the following character components:

file the basename of the file.
title the vignette title from ’\VignetteIndexEntry’, possibly an empty string.
depends a vector of package dependencies from ’\VignetteDepends’, possibly of length 0.
keywords a vector of keywords from ’\VignetteKeyword’, possibly of length 0.
engine the vignetteEngine, such as ”utils::Sweave” or ”knitr::knitr”.

See Also

package_dependencies for recursive dependencies.
Examples

```r
gridEx <- system.file("doc", "grid.Rnw", package = "grid")
vi <- vignetteInfo(gridEx)
str(vi)
```

write_PACKAGES

Generate PACKAGES Files

Description

Generate ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files for a repository of source or Mac/Windows binary packages.

Usage

```r
write_PACKAGES(dir = ".", fields = NULL,
type = c("source", "mac.binary", "win.binary"),
verbose = FALSE, unpacked = FALSE, subdirs = FALSE,
latestOnly = TRUE, addFiles = FALSE, rds_compress = "xz",
validate = FALSE)
```

Arguments

- **dir**: Character vector describing the location of the repository (directory including source or binary packages) to generate the ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files from and write them to.
- **fields**: a character vector giving the fields to be used in the ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files in addition to the default ones, or NULL (default). The default corresponds to the fields needed by `available.packages`: "Package", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "OS_type", "License" and "Archs", and those fields will always be included, plus the file name in field "File" if `addFiles = TRUE` and the path to the subdirectory in field "Path" if subdirectories are used.
- **type**: Type of packages: currently source ‘.tar.{gz,bz2,xz}’ archives, and macOS or Windows binary (‘.tgz’ or ‘.zip’, respectively) packages are supported. Defaults to "win.binary" on Windows and to "source" otherwise.
- **verbose**: logical. Should packages be listed as they are processed?
- **unpacked**: a logical indicating whether the package contents are available in unpacked form or not (default).
- **subdirs**: either logical (to indicate if subdirectories should be included, recursively) or a character vector of names of subdirectories to include (which are not recursed).
- **latestOnly**: logical: if multiple versions of a package are available should only the latest version be included?
- **addFiles**: logical: should the filenames be included as field ‘File’ in the ‘PACKAGES’ file.
- **rds_compress**: The type of compression to be used for ‘PACKAGES.rds’: see `saveRDS`. The default is the one found to give maximal compression, and is as used on CRAN.
- **validate**: a logical indicating whether ‘DESCRIPTION’ files should be validated, and the corresponding packages skipped in case this finds problems.
Details

write_PACKAGES scans the named directory for R packages, extracts information from each package's 'DESCRIPTION' file, and writes this information into the 'PACKAGES', 'PACKAGES.gz' and 'PACKAGES.rds' files, where the first two represent the information in DCF format, and the third serializes it via saveRDS.

Including non-latest versions of packages is only useful if they have less constraining version requirements, so for example latestOnly = FALSE could be used for a source repository when 'foo_1.0' depends on 'R >= 2.15.0' but 'foo_0.9' is available which depends on 'R >= 2.11.0'.

Support for repositories with subdirectories and hence for subdirs != FALSE depends on recording a "Path" field in the 'PACKAGES' files.

Support for more general file names (e.g., other types of compression) via a "File" field in the 'PACKAGES' files can be used by download.packages. If the file names are not of the standard form, use addFiles = TRUE.

type = "win.binary" uses unz connections to read all 'DESCRIPTION' files contained in the (zipped) binary packages for Windows in the given directory dir, and builds files 'PACKAGES', 'PACKAGES.gz' and 'PACKAGES.rds' files from this information.

For a remote repository there is a tradeoff between download speed and time spent by available.packages processing the downloaded file(s). For large repositories it is likely to be beneficial to use rds_compress = "xz".

Value

Invisibly returns the number of packages described in the resulting 'PACKAGES', 'PACKAGES.gz' and 'PACKAGES.rds' files. If 0, no packages were found and no files were written.

Note

Processing `.tar.gz` archives to extract the 'DESCRIPTION' files is quite slow.

This function can be useful on other OSes to prepare a repository to be accessed by Windows machines, so type = "win.binary" should work on all OSes.

Author(s)

Uwe Ligges and R-core.

See Also

See read.dcf and write.dcf for reading 'DESCRIPTION' files and writing the 'PACKAGES' and 'PACKAGES.gz' files. See update_PACKAGES for efficiently updating existing 'PACKAGES' and 'PACKAGES.gz' files.

Examples

## Not run:
write_PACKAGES("c:/myFolder/myRepository") # on Windows
write_PACKAGES("/pub/RWin/bin/windows/contrib/2.9",
    type = "win.binary") # on Linux

## End(Not run)
xgettext  
Extract Translatable Messages from R Files in a Package

Description

For each file in the ‘R’ directory (including system-specific subdirectories) of a source package, extract the unique arguments passed to these “message generating” calls:

for xgettext(): to stop, warning, message, packageStartupMessage, gettext and gettextf.
for xngettext(): to ngettext.

xgettext2pot() calls both xgettext() and then xngettext().

Usage

xgettext(dir, verbose = FALSE, asCall = TRUE)
xgettext(dir, verbose = FALSE)
xgettext2pot(dir, potFile, name = "R", version, bugs)

Arguments

dir  
the directory of a source package, i.e., with a `./R` sub directory.

verbose  
logical: should each file be listed as it is processed?

asCall  
logical: if TRUE each argument is converted to string and returned whole, otherwise the string literals within each argument are extracted (recursively). See Examples.

potFile  
name of po template file to be produced. Defaults to ‘R-pkgname.pot’ where pkgname is the basename of ‘dir’.

name, version, bugs
as recorded in the template file: version defaults the version number of the currently running R, and bugs to "bugs.r-project.org".

Details

Leading and trailing white space (space, tab and linefeed (aka newline, i.e., \n)) is removed for all the calls extracted by xgettext(), see ‘Description’ above, as it is by the internal code that passes strings for translation.

We look to see if the matched functions were called with domain = NA. If so, when asCall is true, the whole call is omitted. Note that a call might contain a nested call to gettext (or warning, etc.) whose strings would be visible if asCall is false.

xgettext2pot calls xgettext and then xngettext, and writes a PO template file (to potFile) for use with the GNU Gettext tools. This ensures that the strings for simple translation are unique in the file (as GNU Gettext requires), but does not do so for ngettext calls (and the rules are not stated in the Gettext manual, but msgfmt complains if there is duplication between the sets.).

If applied to the base package, this also looks in the ‘.R’ files in ‘R_HOME/share/R’.
Value

For `xgettext`, a list of objects of class "xgettext" (which has a print method), one per source file that contains potentially translatable strings.

For `xngettext`, a list of objects of class "xngettext", which are themselves lists of length-2 character vectors.

See Also

`update_pkg_po()` which calls `xgettext2pot()`.

Examples

```r
## Not run: ## in a source-directory build (not typical!) of R;
## otherwise, download and unpack the R sources, and replace
## R.home() by "<my_path_to_source_R>" :
xgettext(file.path(R.home(), "src", "library", "splines"))

## End(Not run)

## Create source package-like <tmp>/R/foo.R and get text from it:
tmpPkg <- tempdir()
tmpRDir <- file.path(tmpPkg, "R")
dir.create(tmpRDir, showWarnings = FALSE)
fnChar <- paste(sep = "\n",
        "foo <- function(x) {
          " if (x < -1) stop('too small')",
          " # messages unduplicated (not so for ngettext)
          " if (x < -0.5) stop('too small')",
          " if (x < 0) {
            " warning(",
            "   'sqrt(x) is', sqrt(as.complex(x))",",
            "   ', which may be too small'",",
            " )",
            " }
          " # calls with domain=NA are skipped",
          " if (x == 0) cat(gettext('x is 0\n', domain=NA))",
          " # gettext strings may be ignored due to 'outer' domain=NA",
          " if (x > 10) warning('x is ', gettextf('%2f', x), domain=NA)",
          " # using a custom condition class",
          " if (x == 42),
          " stop(errorCondition(gettext('needs Deep Thought'), class='myError'))",
          " x",
          " })
        }
      )
writeLines(fnChar, con = file.path(tmpRDir, "foo.R"))

## [1]: suppressing (tmpfile) name to make example Rdiff-able
xgettext(tmpPkg, asCall=TRUE)[[1]] # default; shows calls
xgettext(tmpPkg, asCall=FALSE)[[1]] # doesn't ; but then ' %.2f'
unlink(tmpRDir, recursive=TRUE)
```

adist

Approximate String Distances

Description

Compute the approximate string distance between character vectors. The distance is a generalized
Levenshtein (edit) distance, giving the minimal possibly weighted number of insertions, deletions
and substitutions needed to transform one string into another.

Usage

`adist(x, y = NULL, costs = NULL, counts = FALSE, fixed = TRUE,
       partial = !fixed, ignore.case = FALSE, useBytes = FALSE)`
Arguments

x  a character vector. Long vectors are not supported.
y  a character vector, or NULL (default) indicating taking x as y.
costs  a numeric vector or list with names partially matching ‘insertions’, ‘deletions’ and ‘substitutions’ giving the respective costs for computing the Levenshtein distance, or NULL (default) indicating using unit cost for all three possible transformations.
counts  a logical indicating whether to optionally return the transformation counts (numbers of insertions, deletions and substitutions) as the "counts" attribute of the return value.
fixed  a logical. If TRUE (default), the x elements are used as string literals. Otherwise, they are taken as regular expressions and partial = TRUE is implied (corresponding to the approximate string distance used by agrep with fixed = FALSE).
partial  a logical indicating whether the transformed x elements must exactly match the complete y elements, or only substrings of these. The latter corresponds to the approximate string distance used by agrep (by default).
ignore.case  a logical. If TRUE, case is ignored for computing the distances.
useBytes  a logical. If TRUE distance computations are done byte-by-byte rather than character-by-character.

Details

The (generalized) Levenshtein (or edit) distance between two strings s and t is the minimal possibly weighted number of insertions, deletions and substitutions needed to transform s into t (so that the transformation exactly matches t). This distance is computed for partial = FALSE, currently using a dynamic programming algorithm (see, e.g., https://en.wikipedia.org/wiki/Levenshtein_distance) with space and time complexity $O(mn)$, where $m$ and $n$ are the lengths of $s$ and $t$, respectively. Additionally computing the transformation sequence and counts is $O(\max(m,n))$.

The generalized Levenshtein distance can also be used for approximate (fuzzy) string matching, in which case one finds the substring of t with minimal distance to the pattern s (which could be taken as a regular expression, in which case the principle of using the leftmost and longest match applies), see, e.g., https://en.wikipedia.org/wiki/Approximate_string_matching. This distance is computed for partial = TRUE using ‘tre’ by Ville Laurikari (https://github.com/laurikari/tre) and corresponds to the distance used by agrep. In this case, the given cost values are coerced to integer.

Note that the costs for insertions and deletions can be different, in which case the distance between s and t can be different from the distance between t and s.

Value

A matrix with the approximate string distances of the elements of x and y, with rows and columns corresponding to x and y, respectively.

If counts is TRUE, the transformation counts are returned as the "counts" attribute of this matrix, as a 3-dimensional array with dimensions corresponding to the elements of x, the elements of y, and the type of transformation (insertions, deletions and substitutions), respectively. Additionally, if partial = FALSE, the transformation sequences are returned as the "trafos" attribute of the return value, as character strings with elements ‘M’, ‘I’, ‘D’ and ‘S’ indicating a match, insertion, deletion and substitution, respectively. If partial = TRUE, the offsets (positions of the first and last element)
of the matched substrings are returned as the "offsets" attribute of the return value (with both offsets − 1 in case of no match).

See Also

\texttt{agrep} for approximate string matching (fuzzy matching) using the generalized Levenshtein distance.

Examples

\begin{verbatim}
adist("kitten", "sitting")
## To see the transformation counts for the Levenshtein distance:
drop(attr(adist("kitten", "sitting", counts = TRUE), "counts"))
## To see the transformation sequences:
attr(adist(c("kitten", "sitting"), counts = TRUE), "trafos")

## Cf. the examples for agrep:
adist("lasy", "1 lazy 2")
## For a "partial approximate match" (as used for agrep):
adist("lasy", "1 lazy 2", partial = TRUE)
\end{verbatim}
**Description**

`apropos()` returns a character vector giving the names of objects in the search list matching (as a regular expression) what.

`find()` returns where objects of a given name can be found.

**Usage**

```r
apropos(what, where = FALSE, ignore.case = TRUE, dot_internals = FALSE, mode = "any")
```

```r
find(what, mode = "any", numeric = FALSE, simple.words = TRUE)
```

**Arguments**

- **what** character string. For `simple.words = FALSE` the name of an object; otherwise a regular expression to match object names against.
- **where**, **numeric** a logical indicating whether positions in the search list should also be returned
- **ignore.case** logical indicating if the search should be case-insensitive, `TRUE` by default.
- **dot_internals** logical indicating if the search result should show `base` internal objects, `FALSE` by default.
- **mode** character; if not "any", only objects whose `mode` equals `mode` are searched.
- **simple.words** logical; if `TRUE`, the `what` argument is only searched as a whole word.

**Details**

If `mode != "any"` only those objects which are of mode `mode` are considered.

`find` is a different user interface for a similar task to `apropos`. By default (`simple.words == TRUE`), only whole names are matched. Unlike `apropos`, matching is always case-sensitive.

Unlike the default behaviour of `ls`, names which begin with a `.` are included, but base ‘internal’ objects are included only when `dot_internals` is true.

**Value**

For `apropos`, a character vector sorted by name. For `where = TRUE` this has names giving the (numerical) positions on the search path.

For `find`, either a character vector of environment names or (for `numeric = TRUE`) a numerical vector of positions on the search path with names the names of the corresponding environments.

**Author(s)**

Originally, Kurt Hornik and Martin Maechler (May 1997).
aregexec

Approximate String Match Positions

Description

Determine positions of approximate string matches.

Usage

aregexec(pattern, text, max.distance = 0.1, costs = NULL,
         ignore.case = FALSE, fixed = FALSE, useBytes = FALSE)
Arguments

pattern  a non-empty character string or a character string containing a regular expression (for fixed = FALSE) to be matched. Coerced by `as.character` to a string if possible.

text    character vector where matches are sought. Coerced by `as.character` to a character vector if possible.

max.distance    maximum distance allowed for a match. See `agrep`.

costs    cost of transformations. See `agrep`.

ignore.case    a logical. If TRUE, case is ignored for computing the distances.

fixed    If TRUE, the pattern is matched literally (as is). Otherwise (default), it is matched as a regular expression.

useBytes    a logical. If TRUE comparisons are byte-by-byte rather than character-by-character.

Details

`aregexec` provides a different interface to approximate string matching than `agrep` (along the lines of the interfaces to exact string matching provided by `regexec` and `grep`).

Note that by default, `agrep` performs literal matches, whereas `aregexec` performs regular expression matches.

See `agrep` and `adist` for more information about approximate string matching and distances.

Comparisons are byte-by-byte if `pattern` or any element of `text` is marked as "bytes".

Value

A list of the same length as `text`, each element of which is either −1 if there is no match, or a sequence of integers with the starting positions of the match and all substrings corresponding to parenthesized subexpressions of `pattern`, with attribute "match.length" an integer vector giving the lengths of the matches (or −1 for no match).

See Also

`regmatches` for extracting the matched substrings.

Examples

```r
## Cf. the examples for agrep.
x <- c("1 lazy", "1", "1 LAZY")
aregexec("laysy", x, max.distance = 2)
aregexec("(lay)(sy)", x, max.distance = 2)
aregexec("(lay)(sy)", x, max.distance = 2, ignore.case = TRUE)
m <- aregexec("(lay)(sy)", x, max.distance = 2)
regmatches(x, m)
```
**arrangeWindows**

Rearrange Windows on MS Windows

**Description**

This function allows you to tile or cascade windows, or to minimize or restore them (on Windows, i.e. when `.Platform$OS.type == "windows"`). This may include windows not “belonging” to R.

**Usage**

`arrangeWindows(action, windows, preserve = TRUE, outer = FALSE)`

**Arguments**

- **action**
  - a character string, the action to perform on the windows. The choices are `c("vertical", "horizontal", "cascade", "minimize", "restore")` with default "vertical"; see the 'Details' for the interpretation. Abbreviations may be used.

- **windows**
  - a list of window handles, by default produced by `getWindowsHandles()`.

- **preserve**
  - If TRUE, when tiling preserve the outer boundary of the collection of windows; otherwise make them as large as will fit.

- **outer**
  - This argument is only used in MDI mode. If TRUE, tile the windows on the system desktop. Otherwise, tile them within the MDI frame.

**Details**

The actions are as follows:

- "vertical" Tile vertically.
- "horizontal" Tile horizontally.
- "cascade" Cascade the windows.
- "minimize" Minimize all of the windows.
- "restore" Restore all of the windows to normal size (not minimized, not maximized).

The tiling and cascading are done by the standard Windows API functions, but unlike those functions, they will apply to all of the windows in the windows list.

By default, windows is set to the result of `getWindowsHandles()` (with one exception described below). This will select windows belonging to the current R process. However, if the global environment contains a variable named `.arrangeWindowsDefaults`, it will be used as the argument list instead. See the `getWindowsHandles` man page for a discussion of the optional arguments to that function.

When `action = "restore"` is used with `windows` unspecified, `minimized = TRUE` is added to the argument list of `getWindowsHandles` so that minimized windows will be restored.

In MDI mode, by default tiling and cascading will happen within the R GUI frame. However, if `outer = TRUE`, tiling is done on the system desktop. This will generally not give desirable results if any R child windows are included within `windows`. 
Value

This function is called for the side effect of arranging the windows. The list of window handles is returned invisibly.

Note

This is only available on Windows.

Author(s)

Duncan Murdoch

See Also

getWindowsHandles

Examples

## Not run: ## Only available on Windows:
arrangeWindows("v")
# This default is useful only in SDI mode: it will tile any Firefox window along with the R windows
.arrangeWindowsDefaults <- list(c("R", "all"), pattern = c("", "Firefox"))
arrangeWindows("v")

## End(Not run)

---

**askYesNo**

*Ask a Yes/No Question*

Description

askYesNo provides a standard way to ask the user a yes/no question. It provides a way for front-ends to substitute their own dialogs.

Usage

```r
askYesNo(msg, default = TRUE,
prompts = getOption("askYesNo", gettext(c("Yes", "No", "Cancel"))),
...)
```

Arguments

- `msg` The prompt message for the user.
- `default` The default response.
- `prompts` Any of: a character vector containing 3 prompts corresponding to return values of TRUE, FALSE, or NA, or a single character value containing the prompts separated by / characters, or a function to call.
- `...` Additional parameters, ignored by the default function.
aspell

Details

askYesNo will accept case-independent partial matches to the prompts. If no response is given the value of default will be returned; if a non-empty string that doesn’t match any of the prompts is entered, an error will be raised.

If a function or single character string naming a function is given for prompts, it will be called as fn(msg = msg, default = default, prompts = prompts, ...). On Windows, the GUI uses the unexported utils:::askYesNoWinDialog function for this purpose.

If strings (or a string such as "Y/N/C") are given as prompts, the choices will be mapped to lowercase for the non-default choices, and left as-is for the default choice.

Value

TRUE for yes, FALSE for no, and NA for cancel.

See Also

readline for more general user input.

Examples

if (interactive())
  askYesNo("Do you want to use askYesNo?")

aspell

Spell Check Interface

Description

Spell check given files via Aspell, Hunspell or Ispell.

Usage

aspell(files, filter, control = list(), encoding = "unknown",
       program = NULL, dictionaries = character())

Arguments

files a character vector with the names of files to be checked.
filter an optional filter for processing the files before spell checking, given as either a function (with formals ifile and encoding), or a character string specifying a built-in filter, or a list with the name of a built-in filter and additional arguments to be passed to it. See Details for available filters. If missing or NULL, no filtering is performed.
control a list or character vector of control options for the spell checker.
encoding the encoding of the files. Recycled as needed.
program a character string giving the name (if on the system path) or full path of the spell check program to be used, or NULL (default). By default, the system path is searched for aspell, hunspell and ispell (in that order), and the first one found is used.
dictionaries a character vector of names or file paths of additional R level dictionaries to use. Elements with no path separator specify R system dictionaries (in subdirectory ‘share/dictionaries’ of the R home directory). The file extension (currently, only ‘.rds’) can be omitted.

Details

The spell check programs employed must support the so-called Ispell pipe interface activated via command line option ‘-a’. In addition to the programs, suitable dictionaries need to be available. See http://aspell.net, https://hunspell.github.io/ and https://www.cs.hmc.edu/~geoff/ispell.html, respectively, for obtaining the Aspell, Hunspell and (International) Ispell programs and dictionaries.

On Windows, Aspell is available via MSYS2. One should use a non-Cygwin version, e.g. package mingw-w64-x86_64-aspell. The version built against the Cygwin runtime (package aspell) requires Unix line endings in files and Unix-style paths, which is incompatible with aspell().

The currently available built-in filters are “Rd” (corresponding to RdTextFilter, with additional argument ignore allowing to give regular expressions for parts of the text to be ignored for spell checking), “Swave” (corresponding to SweaveTeXFilter), “R”, “pot”, “dcf” and “md”.

Filter “R” is for R code and extracts the message string constants in calls to message, warning, stop, packageStartupMessage, gettext, gettextf, and ngettext (the unnamed string constants for the first five, and fmt and msg1/msg2 string constants, respectively, for the latter two).

Filter “pot” is for message string catalog ‘.pot’ files. Both have an argument ignore allowing to give regular expressions for parts of message strings to be ignored for spell checking: e.g., using “[^\t]*[^\t:[:punct:]]” ignores all text inside single quotes.

Filter “dcf” is for files in Debian Control File format. The fields to keep can be controlled by argument keep (a character vector with the respective field names). By default, ‘Title’ and ‘Description’ fields are kept.

Filter “md” is for files in Markdown format (‘.md’ and ‘.Rmd’ files), and needs packages commonmark and xml2 to be available.

The print method for the objects returned by aspell has an indent argument controlling the indentation of the positions of possibly misspelled words. The default is 2; Emacs users may find it useful to use an indentation of 0 and visit output in grep-mode. It also has a verbose argument: when this is true, suggestions for replacements are shown as well.

It is possible to employ additional R level dictionaries. Currently, these are files with extension ‘.rds’ obtained by serializing character vectors of word lists using saveRDS. If such dictionaries are employed, they are combined into a single word list file which is then used as the spell checker’s personal dictionary (option ‘-p’): hence, the default personal dictionary is not used in this case.

Value

A data frame inheriting from aspell (which has a useful print method) with the information about possibly misspelled words.

References

See Also

aspell-utils for utilities for spell checking packages.
Examples

```r
## Not run:
## To check all Rd files in a directory, (additionally) skipping the
## \references sections.
files <- Sys.glob("*.Rd")
aspell(files, filter = list("Rd", drop = "\references"))

## To check all Sweave files
files <- Sys.glob(c("*.Rnw", "*.Smw", "*.rnw", "*.snw"))
aspell(files, filter = "Sweave", control = "--t")

## To check all Texinfo files (Aspell only)
files <- Sys.glob("*.texi")
aspell(files, control = "--mode=texinfo")

## End(Not run)

## List the available R system dictionaries.
Sys.glob(file.path(R.home("share"), "dictionaries", "*.rds"))
```

aspell-utils  
Spell Check Utilities

Description

Utilities for spell checking packages via Aspell, Hunspell or Ispell.

Usage

```r
aspell_package_Rd_files(dir,
drop = c("\abbr", "\acronym", "\author", "\references"),
control = list(), program = NULL,
dictionaries = character())  
aspell_package_vignettes(dir,
control = list(), program = NULL,
dictionaries = character())  
aspell_package_R_files(dir, ignore = character(), control = list(),
program = NULL, dictionaries = character())  
aspell_package_C_files(dir, ignore = character(), control = list(),
program = NULL, dictionaries = character())  
aspell_write_personal_dictionary_file(x, out, language = "en",
program = NULL)
```

Arguments

dir        a character string specifying the path to a package’s root directory.
drop       a character vector naming additional Rd sections to drop when selecting text via RdTextFilter.
control    a list or character vector of control options for the spell checker.
program a character string giving the name (if on the system path) or full path of the spell check program to be used, or NULL (default). By default, the system path is searched for aspell, hunspell and ispell (in that order), and the first one found is used.

dictionaries a character vector of names or file paths of additional R level dictionaries to use. See aspell.

ignore a character vector with regular expressions to be replaced by blanks when filtering the message strings.

x a character vector, or the result of a call to aspell().

out a character string naming the personal dictionary file to write to.

language a character string indicating a language as used by Aspell.

Details

Functions aspell_package_Rd_files, aspell_package_vignettes, aspell_package_R_files and aspell_package_C_files perform spell checking on the Rd files, vignettes, R files, and C-level messages of the package with root directory dir. They determine the respective files, apply the appropriate filters, and run the spell checker.

See aspell for details on filters.

The C-level message string are obtained from the `po/PACKAGE.pot` message catalog file, with `PACKAGE` the basename of dir. See the section on ‘C-level messages’ in ‘Writing R Extensions’ for more information.

When using Aspell, the vignette checking skips parameters and/or options of commands `\Sexpr`, `\citet`, `\code`, `\pkg`, `\proglang` and `\samp` (in addition to the what the Aspell TeX/LaTeX filter skips by default). Further commands can be skipped by adding `--add-tex-command` options to the control argument. E.g., to skip both option and parameter of `\mycmd`, add `--add-tex-command='mycmd op'`.

Suitable values for control, program, dictionaries, drop and ignore can also be specified using a package defaults file which should go as `.aspell` subdirectory of dir, and provides defaults via assignments of suitable named lists, e.g.,

```r
test <- list(control = "--add-tex-command='mycmd op'")
```

for vignettes (when using Aspell) and similarly assigning to Rd_files, R_files and C_files for Rd files, R files and C level message defaults.

Maintainers of packages using both English and American spelling will find it convenient to pass control options `--master=en_US` and `--add-extra-dicts=en_GB` to Aspell and control options `--d en_US, en_GB` to Hunspell (provided that the corresponding dictionaries are installed).

Older versions of R had no support for R level dictionaries, and hence provided the function aspell_write_personal_dictionary_file to create (spell check) program-specific personal dictionary files from words to be accepted. The new mechanism is to use R level dictionaries, i.e., `.rds` files obtained by serializing character vectors of such words using saveRDS. For such dictionaries specified via the package defaults mechanism, elements with no path separator can be R system dictionaries or dictionaries in the `.aspell` subdirectory.

aspell
available.packages  List Available Packages at CRAN-like Repositories

Description

available.packages returns a matrix of details corresponding to packages currently available at one or more repositories. The current list of packages is downloaded over the internet (or copied from a local mirror).

Usage

available.packages(contriburl = contrib.url(repos, type), method, fields = NULL, type = getOption("pkgType"), filters = NULL, repos = getOption("repos"), ignore_repo_cache = FALSE, max_repo_cache_age, quiet = TRUE, ...)

Arguments

contriburl  URL(s) of the 'contrib' sections of the repositories. Specify this argument only if your repository mirror is incomplete, e.g., because you mirrored only the 'contrib' section.

method  download method, see download.file.

type  character string, indicate which type of packages: see install.packages. If type = "both" this will use the source repository.

fields  a character vector giving the fields to extract from the 'PACKAGES' file(s) in addition to the default ones, or NULL (default). Unavailable fields result in NA values.

filters  a character vector or list or NULL (default). See 'Details'.

repos  character vector, the base URL(s) of the repositories to use.

ignore_repo_cache  logical. If true, the repository cache is never used (see 'Details').

max_repo_cache_age  any cached values older than this in seconds will be ignored. See 'Details'.

quiet  logical, passed to download.file(); change only if you know what you are doing.

...  allow additional arguments to be passed from callers (which might be arguments to future versions of this function). Currently these are all passed to download.file().

Details

The list of packages is either copied from a local mirror (specified by a 'file:///' URI) or downloaded. If downloaded and ignore_repo_cache is false (the default), the list is cached for the R session in a per-repository file in tempdir() with a name like

repos_http%3a%2f%2fcran.r-project.org%2fsrc%2fcontrib.rds
The cached values are renewed when found to be too old, with the age limit controlled via argument max_repo_cache_age. This defaults to the current value of the environment variable R_AVAILABLE_PACKAGES_CACHE_CONTROL_MAX_AGE, or if unset, to 3600 (one hour).

By default, the return value includes only packages whose version and OS requirements are met by the running version of R, and only gives information on the latest versions of packages.

Argument filters can be used to select which of the packages on the repositories are reported. It is called with its default value (NULL) by functions such as install.packages: this value corresponds to getOption("available_packages_filters") and to c("R_version", "OS_type", "subarch", "duplicates") if that is unset or set to NULL.

The built-in filters are

"R_version" Exclude packages whose R version requirements are not met.

"OS_type" Exclude packages whose OS requirement is incompatible with this version of R: that is exclude Windows-only packages on a Unix-alike platform and vice versa.

"subarch" For binary packages, exclude those with compiled code that is not available for the current sub-architecture, e.g. exclude packages only compiled for 32-bit Windows on a 64-bit Windows R.

"duplicates" Only report the latest version where more than one version is available, and only report the first-named repository (in contriburl) with the latest version if that is in more than one repository.

"license/FOSS" Include only packages for which installation can proceed solely based on packages which can be verified as Free or Open Source Software (FOSS, e.g., https://en.wikipedia.org/wiki/FOSS) employing the available license specifications. Thus both the package and any packages that it depends on to load need to be known to be FOSS.

Note that this does depend on the repository supplying license information.

"license/restricts_use" Include only packages for which installation can proceed solely based on packages which are known not to restrict use.

"CRAN" Use CRAN versions in preference to versions from other repositories (even if these have a higher version number). This needs to be applied before the default "duplicates" filter, so cannot be used with add = TRUE.

If all the filters are from this set, then they can be specified as a character vector; otherwise filters should be a list with elements which are character strings, user-defined functions or add = TRUE (see below).

User-defined filters are functions which take a single argument, a matrix of the form returned by available.packages, and return a matrix consisting of a subset of the rows of the argument.

The special ‘filter’ add = TRUE appends the other elements of the filter list to the default filters.

Value

A character matrix with one row per package, row names the package names and column names including "Package", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "File" and "Repository". Additional columns can be specified using the fields argument.

Where provided by the repository, fields "OS_type", "License", "License_is_FOSS", "License_restricts_use", "Archs", "MD5sum" and "NeedsCompilation" are reported for use by the filters and package management tools, including install.packages.
The 'R Installation and Administration' manual for how to set up a repository.

Examples

## Count package licenses
db <- available.packages(repos = findCRANmirror("web"), filters = "duplicates")
table(db[,"License"])

## Use custom filter function to only keep recommended packages
## which do not require compilation
available.packages(repos = findCRANmirror("web"),
  filters = list(
    add = TRUE,
    function (db) db[db[,"Priority"] %in% "recommended" &
      db[,"NeedsCompilation"] == "no", ]
  ))

## Not run:
## Restrict install.packages() (etc) to known-to-be-FOSS packages
options(available_packages_filters =
  c("R_version", "OS_type", "subarch", "duplicates", "license/FOSS"))
## or
options(available_packages_filters = list(add = TRUE, "license/FOSS"))

## Give priority to released versions on CRAN, rather than development
## versions on R-Forge etc.
options(available_packages_filters =
  c("R_version", "OS_type", "subarch", "CRAN", "duplicates"))

## End(Not run)
Details

Use R CMD BATCH --help to be reminded of the usage.

By default, the input commands are printed along with the output. To suppress this behavior, add options(echo = FALSE) at the beginning of infile, or use option '--no-echo'.

The infile can have end of line marked by LF or CRLF (but not just CR), and files with an incomplete last line (missing end of line (EOL) mark) are processed correctly.

A final expression `proc.time()` will be executed after the input script unless the latter calls `q(runLast = FALSE)` or is aborted. This can be suppressed by the option '--no-timing'.

Additional options can be set by the environment variable R_BATCH_OPTIONS: these come after the default options (see the description of the options argument) and before any options given on the command line.

Note

On Unix-alikes only: Unlike Splus BATCH, this does not run the R process in the background. In most shells,

```
R CMD BATCH [options] infile [outfile] &
```

will do so.

bibentry

Bibliography Entries

Description

Functionality for representing and manipulating bibliographic information in enhanced BibTeX style.

Usage

```
bibentry(bibtype, textVersion = NULL, header = NULL, footer = NULL, 
        key = NULL, ..., other = list(), 
        mheader = NULL, mfooter = NULL)
```

```
## S3 method for class 'bibentry'
print(x, style = "text", .bibstyle, 
      bibtex = length(x) <= getOption("citation.bibtex.max", 1), 
      ...)```

```
## S3 method for class 'bibentry'
format(x, style = "text", .bibstyle = NULL, 
       bibtex = length(x) <= 1, 
       citMsg = missing(bibtex), 
       sort = FALSE, macros = NULL, ...)
```

```
## S3 method for class 'bibentry'
sort(x, decreasing = FALSE, .bibstyle = NULL, drop = FALSE, ...)
```
## S3 method for class 'citation'
print(x, style = "citation", ...)
## S3 method for class 'citation'
format(x, style = "citation", ...)
## S3 method for class 'bibentry'
toBibtex(object, escape = FALSE, ...)

### Arguments

- **bibtype**: a character string with a BibTeX entry type. See [Entry Types](#) for details.
- **textVersion**: a character string with a text representation of the reference to optionally be employed for printing. It is recommended to leave this unspecified if `format(x, style = "text")` works correctly. Only if special LaTeX macros (e.g., math formatting) or special characters (e.g., with accents) are necessary, a *textVersion* should be provided.
- **header**: a character string with optional header text.
- **footer**: a character string with optional footer text.
- **key**: a character string giving the citation key for the entry.
- **...**: for `bibentry`: arguments of the form `tag=value` giving the fields of the entry, with *tag* and *value* the name and value of the field, respectively. Arguments with empty values are dropped. Field names are case-insensitive. See [Entry Fields](#) for details.
- **x**: an object inheriting from class "bibentry".
- **style**: an optional character string specifying the print style. If present, must be a unique abbreviation (with case ignored) of the available styles, see [Details](#).
- **decreasing**: logical, passed to `order` indicating the sort direction.
- **.bibstyle**: a character string naming a bibliography style, see `bibstyle`.
- **bbibtex**: logical indicating if BibTeX code should be given additionally; currently applies only to `style = "citation"`. The default for the `print()` method depends on the number of (bib) entries and `getOption("citation.bibtex.max")` (which itself is 1 by default). For example, to see no BibTeX at all, you can change the default by `options(citation.bibtex.max = 0)`.
- **citMsg**: logical indicating if a "message" should be added (to the footer) about how to get BibTeX code when `bibtex` is false and `style = "citation"`.
- **sort**: logical indicating if bibentries should be sorted, using `bibstyle(.bibstyle)$sortKeys(x)`.
- **macros**: a character string or an object with already loaded Rd macros, see [Details](#).
drop logical used as $x[\ldots, \text{drop}=\text{drop}]$ inside the sort() method.

object an object inheriting from class "bibentry".

escape a logical indicating whether non-ASCII characters should be translated to LaTeX escape sequences.

Details

The bibentry objects created by bibentry can represent an arbitrary positive number of references. One can use c() to combine bibentry objects, and hence in particular build a multiple reference object from single reference ones. Alternatively, one can use bibentry to directly create a multiple reference object by specifying the arguments as lists of character strings.

The print method for bibentry objects is based on a corresponding format method and provides a choice between seven different styles: plain text (style "text"), BibTeX ("bibtex"), a mixture of plain text and BibTeX as traditionally used for citations ("citation"), HTML ("html"), \LaTeX\ ("latex"), R code ("R"), and a simple copy of the textVersion elements (style "textVersion"). The "text", "html" and "latex" styles make use of the \bibstyle function for rendering the bibentry into (intermediate) Rd format. The Rd format uses markup commands documented in the \texttt{Rd format} section of the \texttt{Writing R Extensions} manual, e.g. \texttt{\bold}. In addition, one can use the macros argument to provide additional (otherwise unknown, presumably LaTeX-style) Rd macros, either by giving the path to a file with Rd macros to be loaded via loadRdMacros, or an object with macros already loaded. Note that the "latex" result may contain commands from the \LaTeX\ style file \texttt{Rd.sty} shipped with \texttt{R}; put \texttt{\usepackage{Rd}} in the preamble of a \LaTeX\ document to make these available when compiling, e.g. with texi2pdf.

When printing bibentry objects in citation style, a header/footer for each item can be displayed as well as a mheader/mfooter for the whole vector of references.

For formatting as R code, a choice between giving a character vector with one bibentry() call for each bibentry (as commonly used in \texttt{CITATION} files), or a character string with one collapsed call, obtained by combining the individual calls with c() if there is more than one bibentry. This can be controlled by passing the argument collapse=FALSE (default) or TRUE, respectively, to the format() method. (Printing in R style always collapses to a single call.)

It is possible to subscript bibentry objects by their keys (which are used for character subscripts if the names are NULL).

There is also a toBibtex method for direct conversion to BibTeX.

As of R 4.3.0, there is also a transform method which allows to directly use the current fields, see the examples.

Value

bibentry produces an object of class "bibentry".

Entry Types

bibentry creates "bibentry" objects, which are modeled after BibTeX entries. The entry should be a valid BibTeX entry type, e.g.,

\textbf{Article}: An article from a journal or magazine.

\textbf{Book}: A book with an explicit publisher.

\textbf{InBook}: A part of a book, which may be a chapter (or section or whatever) and/or a range of pages.

\textbf{InCollection}: A part of a book having its own title.
**InProceedings**: An article in a conference proceedings.

**Manual**: Technical documentation like a software manual.

**Misc**: Use this type when nothing else fits.

**PhdThesis**: A PhD thesis.

**Proceedings**: The proceedings of a conference.

**TechReport**: A report published by a school or other institution, usually numbered within a series.

**Unpublished**: A document having an author and title, but not formally published.

**Entry Fields**

The ... argument of `bibentry` can be any number of BibTeX fields, including

- **address**: The address of the publisher or other type of institution.
- **author**: The name(s) of the author(s), either as a `person` object, or as a character string which `as.person` correctly coerces to such.
- **booktitle**: Title of a book, part of which is being cited.
- **chapter**: A chapter (or section or whatever) number.
- **editor**: Name(s) of editor(s), same format as author.
- **institution**: The publishing institution of a technical report.
- **journal**: A journal name.
- **note**: Any additional information that can help the reader. The first word should be capitalized.
- **number**: The number of a journal, magazine, technical report, or of a work in a series.
- **pages**: One or more page numbers or range of numbers.
- **publisher**: The publisher’s name.
- **school**: The name of the school where a thesis was written.
- **series**: The name of a series or set of books.
- **title**: The work’s title.
- **url**: A URL for the reference. (If the URL is an expanded DOI, we recommend to use the ‘doi’ field with the unexpanded DOI instead.)
- **volume**: The volume of a journal or multi-volume book.
- **year**: The year of publication.

**See Also**

`person`
Examples

```r
## R reference
rref <- bibentry(
  bibtype = "Manual",
  title = "R: A Language and Environment for Statistical Computing",
  author = person("R Core Team"),
  organization = "R Foundation for Statistical Computing",
  address = "Vienna, Austria",
  year = 2014,
  url = "https://www.R-project.org/"
)

## Different printing styles
print(rref)
print(rref, style = "bibtex")
print(rref, style = "citation")
print(rref, style = "html")
print(rref, style = "latex")
print(rref, style = "R")

## References for boot package and associated book
bref <- c(
  bibentry(
    bibtype = "Manual",
    title = "boot: Bootstrap R (S-PLUS) Functions",
    author = c(
      person("Angelo", "Canty", role = "aut",
      comment = "S original"),
      person(c("Brian", "D."), "Ripley", role = c("aut", "trl", "cre"),
      comment = "R port, author of parallel support",
      email = "ripley@stats.ox.ac.uk")
    ),
    year = "2012",
    note = "R package version 1.3-4",
    url = "https://CRAN.R-project.org/package=boot",
    key = "boot-package"
  ),
  bibentry(
    bibtype = "Book",
    title = "Bootstrap Methods and Their Applications",
    author = as.person("Anthony C. Davison [aut], David V. Hinkley [aut]")",
    year = "1997",
    publisher = "Cambridge University Press",

    isbn = "0-521-57391-2",
    url = "http://statwww.epfl.ch/davison/BMA/",
    key = "boot-book"
  )
)

## Combining and subsetting
c(rref, bref)
bref[2]
bref["boot-book"]

## Extracting fields
```
bref$author
bref[1]$author

## Field names are case-insensitive
rref$Year
rref$Year <- R.version$year
stopifnot(identical(rref$year, R.version$year))

## Convert to BibTeX
toBibtex(bref)

## Transform
transform(rref, address = paste0(address, ", Europe"))

## BibTeX reminder message (in case of >= 2 refs):
print(bref, style = "citation")

## Format in R style
## One bibentry() call for each bibentry:
writeLines(paste(format(bref, "R"), collapse = "\n\n"))
## One collapsed call:
writeLines(format(bref, "R", collapse = TRUE))

---

browseEnv  

### Browse Objects in Environment

#### Description

The `browseEnv` function opens a browser with list of objects currently in `sys.frame()` environment.

#### Usage

```r
browseEnv(envir = .GlobalEnv, pattern,
          excludepatt = "^last\.\\.warning",
          html = .Platform$GUI != "AQUA",
          expanded = TRUE, properties = NULL,
          main = NULL, debugMe = FALSE)
```

#### Arguments

- **envir**
  - an **environment** the objects of which are to be browsed.
- **pattern**
  - a **regular expression** for object subselection is passed to the internal `ls()` call.
- **excludepatt**
  - a regular expression for **dropping** objects with matching names.
- **html**
  - is used to display the workspace on a HTML page in your favorite browser. The default except when running from `R.app` on macOS.
- **expanded**
  - whether to show one level of recursion. It can be useful to switch it to `FALSE` if your workspace is large. This option is ignored if `html` is set to `FALSE`.
- **properties**
  - a named list of global properties (of the objects chosen) to be showed in the browser; when `NULL` (as per default), user, date, and machine information is used.
browseURL

**Description**

Load URL into an HTML Browser.

**Usage**

```r
browseURL(url, browser = getOption("browser"),
           encodeIfNeeded = FALSE)
```

**Details**

Very experimental code: displays a static HTML page on all platforms except Rd on macOS.

Only allows one level of recursion into object structures.

It can be generalized. See sources for details. Most probably, this should rather work through using the `tkWidget` package (from https://www.bioconductor.org).

**See Also**

`str`, `ls`.

**Examples**

```r
if(interactive()) {
  ## create some interesting objects:
  ofa <- ordered(4:1)
  ex1 <- expression(1+ 0:9)
  ex3 <- expression(u, v, 1+ 0:9)
  example(factor, echo = FALSE)
  example(table, echo = FALSE)
  example(ftable, echo = FALSE)
  example(lm, echo = FALSE, ask = FALSE)
  example(str, echo = FALSE)

  ## and browse them:
  browseEnv()

  ## a (simple) function's environment:
  af12 <- approxfun(1:2, 1:2, method = "const")
  browseEnv(envir = environment(af12))
}
```
Arguments

url a non-empty character string giving the URL to be loaded. Some platforms also accept file paths.

browser a non-empty character string giving the name of the program to be used as the HTML browser. It should be in the PATH, or a full path specified. Alternatively, an R function to be called to invoke the browser.

Under Windows NULL is also allowed (and is the default), and implies that the file association mechanism will be used.

encodeIfNeeded Should the URL be encoded by URLencode before passing to the browser? This is not needed (and might be harmful) if the browser program/function itself does encoding, and can be harmful for 'file:///' URLs on some systems and for 'http:///' URLs passed to some CGI applications. Fortunately, most URLs do not need encoding.

Details

On Unix-alikes: The default browser is set by option "browser", in turn set by the environment variable R_BROWSER which is by default set in file ‘$R_HOME/etc/Renviron’ to a choice made manually or automatically when R was configured. (See Startup for where to override that default value.) To suppress showing URLs altogether, use the value "false".

On many platforms it is best to set option "browser" to a generic program/script and let that invoke the user's choice of browser. For example, on macOS use open and on many other Unix-alikes use xdg-open.

If browser supports remote control and R knows how to perform it, the URL is opened in any already-running browser or a new one if necessary. This mechanism currently is available for browsers which support the "-remote openURL(...)" interface (which includes Mozilla and Opera), Galeon, KDE konqueror (via kfmclient) and the GNOME interface to Mozilla. (Firefox has dropped support, but defaults to using an already-running browser.) Note that the type of browser is determined from its name, so this mechanism will only be used if the browser is installed under its canonical name.

Because "-remote" will use any browser displaying on the X server (whatever machine it is running on), the remote control mechanism is only used if DISPLAY points to the local host. This may not allow displaying more than one URL at a time from a remote host.

It is the caller's responsibility to encode url if necessary (see URLencode).

To suppress showing URLs altogether, set browser = "false".

The behaviour for arguments url which are not URLs is platform-dependent. Some platforms accept absolute file paths; fewer accept relative file paths.

On Windows: The default browser is set by option "browser", in turn set by the environment variable R_BROWSER if that is set, otherwise to NULL. To suppress showing URLs altogether, use the value "false".

Some browsers have required ': ' be replaced by ' | ' in file paths: others do not accept that. All seem to accept \ as a path separator even though the RFC1738 standard requires '/'.

To suppress showing URLs altogether, set browser = "false".

URL schemes

Which URL schemes are accepted is platform-specific: expect 'http://', 'https://' and 'ftp://' to work, but 'mailto:' may or may not (and if it does may not use the user's preferred email client). However, modern browsers are unlikely to handle 'ftp://'/

For the 'file:///' scheme the format accepted (if any) can depend on both browser and OS.
## Examples

```r
## Not run:
## for KDE users who want to open files in a new tab
options(browser = "kfmclient newTab")

browseURL("https://www.r-project.org")

## On Windows-only, something like
browseURL("file://d:/R/R-2.5.1/doc/html/index.html",
        browser = "C:/Program Files/Mozilla Firefox/firefox.exe")

## End(Not run)
```

### browseVignettes

**List Vignettes in an HTML Browser**

#### Description

List available vignettes in an HTML browser with links to PDF, LaTeX/Noweb source, and (tangled) R code (if available).

#### Usage

```r
browseVignettes(package = NULL, lib.loc = NULL, all = TRUE)
```

#### Arguments

- **package**: a character vector with the names of packages to search through, or NULL in which "all" packages (as defined by argument all) are searched.
- **lib.loc**: a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.
- **all**: logical; if TRUE search all available packages in the library trees specified by lib.loc, and if FALSE, search only attached packages.
- **x**: Object of class browseVignettes.
- **...**: Further arguments, ignored by the print method.

#### Details

Function browseVignettes returns an object of the same class; the print method displays it as an HTML page in a browser (using `browseURL`).

#### See Also

- `browseURL`
- `vignette`
## Examples

```r
## List vignettes from all *attached* packages
browseVignettes(all = FALSE)

## List vignettes from a specific package
browseVignettes("grid")
```

## Description

Invokes an editor or email program to write a bug report or opens a web page for bug submission. Some standard information on the current version and configuration of R are included automatically.

### Usage

```r
bug.report(subject = "", address, 
            file = "R.bug.report", package = NULL, lib.loc = NULL,
            ...)  
```

### Arguments

- **subject**: Subject of the email.
- **address**: Recipient’s email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed).
- **file**: Filename to use (if needed) for setting up the email.
- **package**: Optional character vector naming a single package which is the subject of the bug report.
- **lib.loc**: A character vector describing the location of R library trees in which to search for the package, or NULL. The default value of NULL corresponds to all libraries currently known.
- ...**: Additional named arguments such as method and ccaddress to pass to `create.post`.

### Details

If package is NULL or a base package, this opens the R bugs tracker at [https://bugs.r-project.org/](https://bugs.r-project.org/).

If package is specified, it is assumed that the bug report is about that package, and parts of its ‘DESCRIPTION’ file are added to the standard information. If the package has a non-empty BugReports field in the ‘DESCRIPTION’ file specifying the URL of a webpage, that URL will be opened using `browseURL`, otherwise an email directed to the package maintainer will be generated using `create.post`. If there is any other form of BugReports field or a Contact field, this is examined as it may provide a preferred email address.

### Value

Nothing useful.
When is there a bug?

If \( R \) executes an illegal instruction, or dies with an operating system error message that indicates a problem in the program (as opposed to something like “disk full”), then it is certainly a bug.

Taking forever to complete a command can be a bug, but you must make certain that it was really \( R \)'s fault. Some commands simply take a long time. If the input was such that you KNOW it should have been processed quickly, report a bug. If you don’t know whether the command should take a long time, find out by looking in the manual or by asking for assistance.

If a command you are familiar with causes an \( R \) error message in a case where its usual definition ought to be reasonable, it is probably a bug. If a command does the wrong thing, that is a bug. But be sure you know for certain what it ought to have done. If you aren’t familiar with the command, or don’t know for certain how the command is supposed to work, then it might actually be working right. Rather than jumping to conclusions, show the problem to someone who knows for certain.

Finally, a command’s intended definition may not be best for statistical analysis. This is a very important sort of problem, but it is also a matter of judgement. Also, it is easy to come to such a conclusion out of ignorance of some of the existing features. It is probably best not to complain about such a problem until you have checked the documentation in the usual ways, feel confident that you understand it, and know for certain that what you want is not available. The mailing list r-devel@r-project.org is a better place for discussions of this sort than the bug list.

If you are not sure what the command is supposed to do after a careful reading of the manual this indicates a bug in the manual. The manual’s job is to make everything clear. It is just as important to report documentation bugs as program bugs.

If the online argument list of a function disagrees with the manual, one of them must be wrong, so report the bug.

How to report a bug

When you decide that there is a bug, it is important to report it and to report it in a way which is useful. What is most useful is an exact description of what commands you type, from when you start \( R \) until the problem happens. Always include the version of \( R \), machine, and operating system that you are using; type `version` in \( R \) to print this. To help us keep track of which bugs have been fixed and which are still open please send a separate report for each bug.

The most important principle in reporting a bug is to report FACTS, not hypotheses or categorizations. It is always easier to report the facts, but people seem to prefer to strain to posit explanations and report them instead. If the explanations are based on guesses about how \( R \) is implemented, they will be useless; we will have to try to figure out what the facts must have been to lead to such speculations. Sometimes this is impossible. But in any case, it is unnecessary work for us.

For example, suppose that on a data set which you know to be quite large the command `data.frame(x, y, z, monday, tuesday)` never returns. Do not report that `data.frame()` fails for large data sets. Perhaps it fails when a variable name is a day of the week. If this is so then when we got your report we would try out the `data.frame()` command on a large data set, probably with no day of the week variable name, and not see any problem. There is no way in the world that we could guess that we should try a day of the week variable name.

Or perhaps the command fails because the last command you used was a method that had a bug causing \( R \)’s internal data structures to be corrupted and making the `data.frame()` command fail from then on. This is why we need to know what other commands you have typed (or read from your startup file).

It is very useful to try and find simple examples that produce apparently the same bug, and somewhat useful to find simple examples that might be expected to produce the bug but actually do not. If you want to debug the problem and find exactly what caused it, that is wonderful. You should still report the facts as well as any explanations or solutions.
Invoking R with the ‘--vanilla’ option may help in isolating a bug. This ensures that the site profile and saved data files are not read.

A bug report can be generated using the function bug.report(). For reports on R this will open the Web page at https://bugs.r-project.org/: for a contributed package it will open the package’s bug tracker Web page or help you compose an email to the maintainer.

Bug reports on contributed packages should not be sent to the R bug tracker: rather make use of the package argument.

---

capture.output

Send Output to a Character String or File

Description

Evaluates its arguments with the output being returned as a character string or sent to a file. Related to sink similarly to how with is related to attach.

Usage

capture.output(..., file = NULL, append = FALSE,
  type = c("output", "message"), split = FALSE)

Arguments

... Expressions to be evaluated.

file A file name or a connection, or NULL to return the output as a character vector. If the connection is not open, it will be opened initially and closed on exit.

append logical. If file a file name or unopened connection, append or overwrite?

type, split are passed to sink(), see there.

Details

It works via sink(<file connection>) and hence the R code in dots must not interfere with the connection (e.g., by calling closeAllConnections()).

An attempt is made to write output as far as possible to file if there is an error in evaluating the expressions, but for file = NULL all output will be lost.

Messages sent to stderr() (including those from message, warning and stop) are captured by type = "message". Note that this can be “unsafe” and should only be used with care.
Value

A character string (if file = NULL), or invisible NULL.

See Also

sink, textConnection

Examples

```r
require(stats)
glmout <- capture.output(summary(glm(case ~ spontaneous+induced,
           data = infert, family = binomial())))

glmout[1:5]
capture.output(1+1, 2+2)
capture.output([1+1; 2+2])
```

## Not run: ## on Unix-alike with a2ps available
```
op <- options(useFancyQuotes=FALSE)
pdf <- pipe("a2ps -o - | ps2pdf - tempout.pdf", "w")
capture.output(example(glm), file = pdf)
close(pdf); options(op); system("evince tempout.pdf ")
```

## End(Not run)

---

changedFiles

Detect which Files Have Changed

Description

fileSnapshot takes a snapshot of a selection of files, recording summary information about each. changedFiles compares two snapshots, or compares one snapshot to the current state of the file system. The snapshots need not be the same directory; this could be used to compare two directories.

Usage

```r
fileSnapshot(path = ".", file.info = TRUE, timestamp = NULL,
            md5sum = FALSE, digest = NULL, full.names = length(path) > 1,
            ...

changedFiles(before, after, path = before$path, timestamp = before$timestamp,
             check.file.info = c("size", "isdir", "mode", "mtime"),
             md5sum = before$md5sum, digest = before$digest,
             full.names = before$full.names, ...
```

## S3 method for class 'fileSnapshot'
```
print(x, verbose = FALSE, 
```

## S3 method for class 'changedFiles'
```
print(x, verbose = FALSE, 
```
changedFiles

Arguments

path character vector; the path(s) to record.
file.info logical; whether to record file.info values for each file.
timestamp character string or NULL; the name of a file to write at the time the snapshot is taken. This gives a quick test for modification, but may be unreliable; see the Details.
md5sum logical; whether MD5 summaries of each file should be taken as part of the snapshot.
digest a function or NULL; a function with header function(filename) which will take a vector of filenames and produce a vector of values of the same length, or a matrix with that number of rows.
full.names logical; whether full names (as in list.files) should be recorded. Must be TRUE if length(path) > 1.
... additional parameters to pass to list.files to control the set of files in the snapshots.
before,after objects produced by fileSnapshot; two snapshots to compare. If after is missing, a new snapshot of the current file system will be produced for comparison, using arguments recorded in before as defaults.
check.file.info character vector; which columns from file.info should be compared.
x the object to print.
verbose logical; whether to list all data when printing.

Details

The fileSnapshot function uses list.files to obtain a list of files, and depending on the file.info, md5sum, and digest arguments, records information about each file.

The changedFiles function compares two snapshots.

If the timestamp argument to fileSnapshot is length 1, a file with that name is created. If it is length 1 in changedFiles, the file_test function is used to compare the age of all files common to both before and after to it. This test may be unreliable: it compares the current modification time of the after files to the timestamp; that may not be the same as the modification time when the after snapshot was taken. It may also give incorrect results if the clock on the file system holding the timestamp differs from the one holding the snapshot files.

If the check.file.info argument contains a non-empty character vector, the indicated columns from the result of a call to file.info will be compared.

If md5sum is TRUE, fileSnapshot will call the tools::md5sum function to record the 32 byte MD5 checksum for each file, and changedFiles will compare the values. The digest argument allows users to provide their own digest function.

Value

fileSnapshot returns an object of class “fileSnapshot”. This is a list containing the fields

info a data frame whose rownames are the filenames, and whose columns contain the requested snapshot data
path the normalized path from the call
timestamp, file.info, md5sum, digest, full.names
a record of the other arguments from the call
args other arguments passed via ... to list.files.

changedFiles produces an object of class "changedFiles". This is a list containing
added, deleted, changed, unchanged
character vectors of filenames from the before and after snapshots, with obvious meanings
changes a logical matrix with a row for each common file, and a column for each com-
parison test. TRUE indicates a change in that test.

print methods are defined for each of these types. The print method for "fileSnapshot" objects
displays the arguments used to produce them, while the one for "changedFiles" displays the
added, deleted and changed fields if non-empty, and a submatrix of the changes matrix containing
all of the TRUE values.

Author(s)

Duncan Murdoch, using suggestions from Karl Millar and others.

file.info, file_test, md5sum.

Examples

# Create some files in a temporary directory
dir <- tempfile()
dir.create(dir)
writeBin(1L, file.path(dir, "file1"))
writeBin(2L, file.path(dir, "file2"))
dir.create(file.path(dir, "dir"))

# Take a snapshot
snapshot <- fileSnapshot(dir, timestamp = tempfile("timestamp"), md5sum=TRUE)

# Change one of the files.
writeBin(3L:4L, file.path(dir, "file2"))

# Display the detected changes. We may or may not see mtime change...
changedFiles(snapshot)
changedFiles(snapshot)$changes

---

charClass  Character Classification

Description

An interface to the (C99) wide character classification functions in use.

Usage

charClass(x, class)
**charClass**

**Arguments**

- **x**  
  Either a UTF-8-encoded length-1 character vector or an integer vector of Unicode points (or a vector coercible to integer).

- **class**  
  A character string, one of those given in the ‘Details’ section.

**Details**

The classification into character classes is platform-dependent. The classes are determined by internal tables on Windows and (optionally but by default) on macOS and AIX.

The character classes are interpreted as follows:

- **"alnum"**  
  Alphabetic or numeric.

- **"alpha"**  
  Alphabetic.

- **"blank"**  
  Space or tab.

- **"cntrl"**  
  Control characters.

- **"digit"**  
  Digits 0-9.

- **"graph"**  
  Graphical characters (printable characters except whitespace).

- **"lower"**  
  Lower-case alphabetic.

- **"print"**  
  Printable characters.

- **"punct"**  
  Punctuation characters. Some platforms treat all non-alphanumeric graphical characters as punctuation.

- **"space"**  
  Whitespace, including tabs, form and line feeds and carriage returns. Some OSes include non-breaking spaces, some exclude them.

- **"upper"**  
  Upper-case alphabetic.

- **"xdigit"**  
  Hexadecimal character, one of 0-9A-Fa-f.

Alphabetic characters contain all lower- and upper-case ones and some others (for example, those in ‘title case’).

Whether a character is printable is used to decide whether to escape it when printing – see the help for `print.default`.

If `x` is a character string it should either be ASCII or declared as UTF-8 – see `Encoding`.

charClass was added in R 4.1.0. A less direct way to examine character classes which also worked in earlier versions is to use something like `grep(\"[:print:]\", intToUtf8(x))` – however, the regular-expression code might not use the same classification functions as printing and on macOS used not to.

**Value**

A logical vector of the length the number of characters or integers in `x`.

**Note**

Non-ASCII digits are excluded by the C99 standard from the class "digit": most platforms will have them as alphabetic.

It is an assumption that the system’s wide character classification functions are coded in Unicode points, but this is known to be true for all recent platforms.

The classification may depend on the locale even on one platform.

See Also

Character classes are used in regular expressions.

The OS’s man pages for iswctype and wctype.

Examples

```r
x <- c(48:70, 32, 0xa0) # Last is non-breaking space
cl <- c("alnum", "alpha", "blank", "digit", "graph", "punct", "upper", "xdigit")
X <- lapply(cl, function(y) charClass(x,y)); names(X) <- cl
X <- as.data.frame(X); row.names(X) <- sQuote(intToUtf8(x, multiple = TRUE))
X

charClass("ABC123", "alpha")
## Some accented capital Greek characters
(x <- "\u0386\u0388\u0389")
charclass(x, "upper")

## How many printable characters are there? (Around 280,000 in Unicode 13.)
## There are 2^21-1 possible Unicode points (most not yet assigned).
pr <- charClass(1:0x1fffff, "print")
table(pr)
```

choose.dir

Choose a Folder Interactively on MS Windows

Description

Use a Windows shell folder widget to choose a folder interactively.

Usage

```r
choose.dir(default = "", caption = "Select folder")
```

Arguments

- `default`: which folder to show initially.
- `caption`: the caption on the selection dialog.

Details

This brings up the Windows shell folder selection widget. With the default `default = ""`, ‘My Computer’ (or similar) is initially selected.

To workaround a bug, on Vista and later only folders under ‘Computer’ are accessible via the widget.

Value

A length-one character vector, character `NA` if ‘Cancel’ was selected.

Note

This is only available on Windows.
choose.files

See Also

choose.files (on Windows) and file.choose (on all platforms).

Examples

```r
if (interactive() & & .Platform$OS.type == "windows")
  choose.dir(getwd(), "Choose a suitable folder")
```

choose.files

Choose a List of Files Interactively on MS Windows

Description

Use a Windows file dialog to choose a list of zero or more files interactively.

Usage

```r
choose.files(default = ",", caption = "Select files",
            multi = TRUE, filters = Filters,
            index = nrow(Filters))
```

Filters

Arguments

- `default`: which filename to show initially
- `caption`: the caption on the file selection dialog
- `multi`: whether to allow multiple files to be selected
- `filters`: a matrix of filename filters (see Details)
- `index`: which row of filters to use by default

Details

Unlike file.choose, choose.files will always attempt to return a character vector giving a list of files. If the user cancels the dialog, then zero files are returned, whereas file.choose would signal an error. choose.dir chooses a directory.

Windows file dialog boxes include a list of ‘filters’, which allow the file selection to be limited to files of specific types. The filters argument to choose.files allows the list of filters to be set. It should be an n by 2 character matrix. The first column gives, for each filter, the description the user will see, while the second column gives the mask(s) to select those files. If more than one mask is used, separate them by semicolons, with no spaces. The index argument chooses which filter will be used initially.

Filters is a matrix giving the descriptions and masks for the file types that R knows about. Print it to see typical formats for filter specifications. The examples below show how particular filters may be selected.

If you would like to display files in a particular directory, give a fully qualified file mask (e.g., "c:\\*.*") in the default argument. If a directory is not given, the dialog will start in the current directory the first time, and remember the last directory used on subsequent invocations.

There is a buffer limit on the total length of the selected filenames: it is large but this function is not intended to select thousands of files, when the limit might be reached.
chooseBioCmirror

Description

Interact with the user to choose a Bioconductor mirror.

Usage

```r
chooseBioCmirror(graphics = getOption("menu.graphics"), ind = NULL, local.only = FALSE)
```

Arguments

- **graphics** Logical. If true, use a graphical list: on Windows or the macOS GUI use a list box, and on a Unix-alike use a Tk widget if package `tcltk` and an X server are available. Otherwise use a text menu.
- **ind** Optional numeric value giving which entry to select.
- **local.only** Logical, try to get most recent list from the Bioconductor master or use file on local disk only.

Details

This sets the option "BioC_mirror": it is used before a call to `setRepositories`. The out-of-the-box default for that option is NULL, which currently corresponds to the mirror [https://bioconductor.org](https://bioconductor.org).

The ‘Bioconductor (World-wide)’ ‘mirror’ is a network of mirrors providing reliable world-wide access; other mirrors may provide faster access on a geographically local scale.

`ind` chooses a row in `
R_HOME/doc/BioC_mirrors.csv`, by number.

Value

None: this function is invoked for its side effect of updating options("BioC_mirror").
chooseCRANmirror

Select a CRAN Mirror

Description

Interact with the user to choose a CRAN mirror.

Usage

chooseCRANmirror(graphics = getOption("menu.graphics"), ind = NULL, 
local.only = FALSE)

getCRANmirrors(all = FALSE, local.only = FALSE)

Arguments

graphics Logical. If true, use a graphical list: on Windows or the macOS GUI use a list box, and on a Unix-alike use a Tk widget if package tcltk and an X server are available. Otherwise use a text menu.

ind Optional numeric value giving which entry to select.

all Logical, get all known mirrors or only the ones flagged as OK.

local.only Logical, try to get most recent list from the CRAN master or use file on local disk only.

Details

A list of mirrors is stored in file ‘R_HOME/doc/CRAN_mirrors.csv’, but first an on-line list of current mirrors is consulted, and the file copy used only if the on-line list is inaccessible.

chooseCRANmirror is called by a Windows GUI menu item and by contrib.url if it finds the initial dummy value of options("repos").

HTTPS mirrors with mirroring over ssh will be offered in preference to other mirrors (which are listed in a sub-menu).

ind chooses a row in the list of current mirrors, by number. It is best used with local.only = TRUE and row numbers in ‘R_HOME/doc/CRAN_mirrors.csv’.

Value

None for chooseCRANmirror(), this function is invoked for its side effect of updating options("repos").

getCRANmirrors() returns a data frame with mirror information.

See Also

setRepositories, findCRANmirror, chooseBioCmirror, contrib.url.
citation

Citing R and R Packages in Publications

Description

How to cite R and R packages in publications.

Usage

citation(package = "base", lib.loc = NULL, auto = NULL)

readCitationFile(file, meta = NULL)
citHeader(...)
citFooter(...)

Arguments

package a character string with the name of a single package. An error occurs if more than one package name is given.

lib.loc a character vector with path names of R libraries, or the directory containing the source for package, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.

auto a logical indicating whether the default citation auto-generated from the package ‘DESCRIPTION’ metadata should be used or not, or NULL (default), indicating that a ‘CITATION’ file is used if it exists, or an object of class "packageDescription" with package metadata (see below).

file a file name.

meta a list of package metadata as obtained by packageDescription, or NULL (the default).

... character strings (which will be pasted).

Details

The R core development team and the very active community of package authors have invested a lot of time and effort in creating R as it is today. Please give credit where credit is due and cite R and R packages when you use them for data analysis.

Execute function citation() for information on how to cite the base R system in publications. If the name of a non-base package is given, the function either returns the information contained in the ‘CITATION’ file of the package (using readCitationFile with meta equal to packageDescription(package, lib.loc)) or auto-generates citation information from the ‘DESCRIPTION’ file.

Packages can use an ‘Authors@R’ field in their ‘DESCRIPTION’ to provide (R code giving) a person object with a refined, machine-readable description of the package “authors” (in particular specifying their precise roles). Only those with an author role will be included in the auto-generated citation.

If the object returned by citation() contains only one reference, the associated print method shows both a text version and a BibTeX entry for it. If a package has more than one reference then only the text versions are shown. This threshold is controlled by
The `CITATION` file of an R package should be placed in the ‘inst’ subdirectory of the package source. The file is an R source file and may contain arbitrary R commands including conditionals and computations. Function `readCitationFile()` is used by `citation()` to extract the information in ‘CITATION’ files. The file is sourced by the R parser in a temporary environment and all resulting bibliographic objects (specifically, inheriting from "bibentry") are collected. These are typically produced by one or more `bibentry()` calls, optionally preceded by a `citHeader()` and followed by a `citFooter()` call. One can include an auto-generated package citation in the ‘CITATION’ file via `citation(auto = meta)`.

`readCitationFile` makes use of the Encoding element (if any) of `meta` to determine the encoding of the file.

**Value**

An object of class "citation", inheriting from class "bibentry"; see there, notably for the `print` and `format` methods.

`citHeader` and `citFooter` return an empty "bibentry" storing “outer” header/footer text for the package citation.

**See Also**

`bibentry`

**Examples**

```r
## the basic R reference
citation()

## extract the BibTeX entry from the return value
x <- citation()
toBibtex(x)

## references for a package
citation("lattice")
citation("lattice", auto = TRUE)  # request the Manual-type reference
citation("foreign")

## a CITATION file with more than one bibentry:
file.show(system.file("CITATION", package="mgcv"))
cm <- citation("mgcv")
cm # header, text references, plus "reminder" about getting BibTeX
print(cm, bibtex = TRUE) # each showing its bibtex code

## a CITATION file including citation(auto = meta)
file.show(system.file("CITATION", package="nlme"))
citation("nlme")
```
c\cite{author}

\begin{description}
\item[Description] Cite a bibentry object in text. The \cite{} function uses the \cite{} function from the default \texttt{bibstyle} if present, or \citeNatbib{} if not. \citeNatbib{} uses a style similar to that used by the \LaTeX\ package \texttt{natbib}.
\item[Usage] 
\begin{verbatim}
cite(keys, bib, ...) 
citeNatbib(keys, bib, textual = FALSE, before = NULL, after = NULL, 
mode = c("authoryear", "numbers", "super"), 
abbreviate = TRUE, longnamesfirst = TRUE, 
bibpunct = c("(", ",", ";", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",")
previous)
\end{verbatim}
\item[Arguments] 
\begin{description}
\item[keys] A character vector of keys of entries to cite. May contain multiple keys in a single entry, separated by commas.
\item[bib] A \texttt{"bibentry"} object containing the list of documents in which to find the keys.
\item[... ] Additional arguments to pass to the \cite{} function for the default style.
\item[textual] Produce a "textual" style of citation, i.e. what \texttt{\cite{author}} would produce in \LaTeX{}.
\item[before] Optional text to display before the citation.
\item[after] Optional text to display after the citation.
\item[mode] The "mode" of citation.
\item[abbreviate] Whether to abbreviate long author lists.
\item[longnamesfirst] If abbreviate == \texttt{TRUE}, whether to leave the first citation long.
\item[bibpunct] A vector of punctuation to use in the citation, as used in \texttt{natbib}. See the Details section.
\item[previous] A list of keys that have been previously cited, to be used when abbreviate == \texttt{TRUE} and longnamesfirst == \texttt{TRUE}
\end{description}
\item[Details] Argument names are chosen based on the documentation for the \LaTeX\ \texttt{natbib} package. See that documentation for the interpretation of the bibpunct entries.
\begin{enumerate}
\item The left delimiter.
\item The right delimiter.
\item The separator between references within a citation.
\item An indicator of the "mode": \texttt{"n"} for numbers, \texttt{"s"} for superscripts, anything else for author-year.
\item Punctuation to go between the author and year.
\end{enumerate}
\end{description}
6. Punctuation to go between years when authorship is suppressed.

Note that if `mode` is specified, it overrides the mode specification in `bibpunct[4]`. Partial matching is used for `mode`.

The defaults for `citeNatbib` have been chosen to match the JSS style, and by default these are used in `cite`. See `bibstyle` for how to set a different default style.

**Value**

A single element character string is returned, containing the citation.

**Author(s)**

Duncan Murdoch

**Examples**

```r
### R reference
rref <- bibentry(
  bibtype = "Manual",
  title = "R: A Language and Environment for Statistical Computing",
  author = person("R Core Team"),
  organization = "R Foundation for Statistical Computing",
  address = "Vienna, Austria",
  year = 2013,
  url = "https://www.R-project.org/",
  key = "R"
)

### References for boot package and associated book
bref <- c(
  bibentry(
    bibtype = "Manual",
    title = "boot: Bootstrap R (S-PLUS) Functions",
    author = c(
      person("Angelo", "Canty", role = "aut",
        comment = "S original"),
      person(c("Brian", "D."), "Ripley", role = c("aut", "trl", "cre"),
        comment = "R port, author of parallel support",
        email = "ripley@stats.ox.ac.uk")
    ),
    year = "2012",
    note = "R package version 1.3-4",
    url = "https://CRAN.R-project.org/package=boot",
    key = "boot-package"
  ),
  bibentry(
    bibtype = "Book",
    title = "Bootstrap Methods and Their Applications",
    author = as.person("Anthony C. Davison [aut], David V. Hinkley [aut]")
  )
)
```
citEntry

Bibliography Entries (Older Interface)

Description

Old interface providing functionality for specifying bibliographic information in enhanced BibTeX style. Since R 2.14.0 this has been superseded by bibentry.

Usage

citEntry(entry, textVersion = NULL, header = NULL, footer = NULL, ...)

Arguments

- **entry**: a character string with a BibTeX entry type. See section Entry Types in bibentry for details.
- **textVersion**: a character string with a text representation of the reference to optionally be employed for printing.
- **header**: a character string with optional header text.
- **footer**: a character string with optional footer text.
- ... for citEntry, arguments of the form tag=value giving the fields of the entry, with tag and value the name and value of the field, respectively. See section Entry Fields in bibentry for details.

Value

citEntry produces an object of class "bibentry".

See Also

citation for more information about citing R and R packages and 'CITATION' files; bibentry for the newer functionality for representing and manipulating bibliographic information.
Read/Write to/from the Clipboard in MS Windows

Description
Transfer text between a character vector and the Windows clipboard in MS Windows (only).

Usage
getClipboardFormats(numeric = FALSE)
readClipboard(format = 13, raw = FALSE)
writeClipboard(str, format = 13)

Arguments
numeric logical: should the result be in human-readable form (the default) or raw numbers?
format an integer giving the desired format.
raw should the value be returned as a raw vector rather than as a character vector?
str a character vector or a raw vector.

Details
The Windows clipboard offers data in a number of formats: see e.g. https://docs.microsoft.com/en-gb/windows/desktop/dataxchg/clipboard-formats.
The standard formats include

Applications normally make data available in one or more of these and possibly additional private formats. Use `raw = TRUE` to read binary formats, `raw = FALSE` (the default) for text formats. The current codepage is used to convert text to Unicode text, and information on that is contained in the CF_LOCALE format. (Take care if you are running R in a different locale from Windows. It is...
close.socket

```r
close.socket(socket, ...)```

**Arguments**

- `socket` a socket object
- `...` further arguments passed to or from other methods.

**Value**

logical indicating success or failure

**Author(s)**

Thomas Lumley
Generate all combinations of the elements of x taken m at a time. If x is a positive integer, returns all combinations of the elements of seq(x) taken m at a time. If argument FUN is not NULL, applies a function given by the argument to each point. If simplify is FALSE, returns a list; otherwise returns an array, typically a matrix. ... are passed unchanged to the FUN function, if specified.

Usage
combn(x, m, FUN = NULL, simplify = TRUE, ...)

Arguments
- x: vector source for combinations, or integer n for x <- seq_len(n).
- m: number of elements to choose.
- FUN: function to be applied to each combination; default NULL means the identity, i.e., to return the combination (vector of length m).
- simplify: logical indicating if the result should be simplified to an array (typically a matrix); if FALSE, the function returns a list. Note that when simplify = TRUE as by default, the dimension of the result is simply determined from FUN(1st combination) (for efficiency reasons). This will badly fail if FUN(u) is not of constant length.
- ...: optionally, further arguments to FUN.

Details
Factors x are accepted.

Value
A list or array, see the simplify argument above. In the latter case, the identity dim(combn(n, m)) == c(m, choose(n, m)) holds.

Author(s)
Scott Chasalow wrote the original in 1994 for S; R package combinat and documentation by Vince Carey <stvjc@channing.harvard.edu>; small changes by the R core team, notably to return an array in all cases of simplify = TRUE, e.g., for combn(5,5).

compareVersion

compareVersion

Compare Two Package Version Numbers

Description

Compare two package version numbers to see which is later.

Usage

compareVersion(a, b)

Arguments

a, b

Character strings representing package version numbers.

Details

R package version numbers are of the form x.y-z for integers x, y and z, with components after x optionally missing (in which case the version number is older than those with the components present).

Value

0 if the numbers are equal, -1 if b is later and 1 if a is later (analogous to the C function strcmp).

See Also

package_version, library, packageStatus.
Examples

```r
compareVersion("1.0", "1.0-1")
compareVersion("7.2-0", "7.1-12")
```

**Description**

Compile given source files so that they can subsequently be collected into a shared object using `R CMD SHLIB` or an executable program using `R CMD LINK`. Not available on Windows.

**Usage**

```r
R CMD Compile [options] srcfiles
```

**Arguments**

- `srcfiles` A list of the names of source files to be compiled. Currently, C, C++, Objective C, Objective C++ and Fortran are supported; the corresponding files should have the extensions `.c`, `.cc` (or `.cpp`), `.m`, `.mm` (or `.M`), `.f` and `.f90` or `.f95`, respectively.
- `options` A list of compile-relevant settings, or for obtaining information about usage and version of the utility.

**Details**

`R CMD SHLIB` can both compile and link files into a shared object: since it knows what run-time libraries are needed when passed C++, Fortran and Objective C(++) sources, passing source files to `R CMD SHLIB` is more reliable.

Objective C and Objective C++ support is optional and will work only if the corresponding compilers were available at R configure time: their main usage is on macOS.

Compilation arranges to include the paths to the R public C/C++ headers.

As this compiles code suitable for incorporation into a shared object, it generates PIC code: that might occasionally be undesirable for the main code of an executable program.

This is a make-based facility, so will not compile a source file if a newer corresponding `.o` file is present.

**Note**

Some binary distributions of R have `COMPILE` in a separate bundle, e.g. an R-devel RPM. This is not available on Windows.

contrib.url

Find Appropriate Paths in CRAN-like Repositories

Description

contrib.url adds the appropriate type-specific path within a repository to each URL in repos.

Usage

contrib.url(repos, type = getOption("pkgType"))

Arguments

repos character vector, the base URL(s) of the repositories to use.

type character string, indicating which type of packages: see install.packages.

Details

If type = "both" this will use the source repository.

Value

A character vector of the same length as repos.

See Also

setRepositories to set options("repos"), the most common value used for argument repos.
available.packages, download.packages, install.packages.

The 'R Installation and Administration' manual for how to set up a repository.

count.fields

Count the Number of Fields per Line

Description

count.fields counts the number of fields, as separated by sep, in each of the lines of file read.

Usage

count.fields(file, sep = "", quote = "\"", skip = 0,
         blank.lines.skip = TRUE, comment.char = "]")
Arguments

- **file**: a character string naming an ASCII data file, or a connection, which will be opened if necessary, and if so closed at the end of the function call.
- **sep**: the field separator character. Values on each line of the file are separated by this character. By default, arbitrary amounts of whitespace can separate fields.
- **quote**: the set of quoting characters
- **skip**: the number of lines of the data file to skip before beginning to read data.
- **blank.lines.skip**: logical: if TRUE blank lines in the input are ignored.
- **comment.char**: character: a character vector of length one containing a single character or an empty string.

Details

This used to be used by `read.table` and can still be useful in discovering problems in reading a file by that function.

For the handling of comments, see `scan`.

Consistent with `scan`, `count.fields` allows quoted strings to contain newline characters. In such a case the starting line will have the field count recorded as `NA`, and the ending line will include the count of all fields from the beginning of the record.

Value

A vector with the numbers of fields found.

See Also

- `read.table`

Examples

```r
fil <- tempfile()
cat("NAME", "1:John", "2:Paul", file = fil, sep = "\n")
count.fields(fil, sep = ":")
unlink(fil)
```

create.post **Ancillary Function for Preparing Emails and Postings**

Description

An ancillary function used by `bug.report` and `help.request` to prepare emails for submission to package maintainers or to R mailing lists.

Usage

```r
create.post(instructions = character(), description = "post",
            subject = "",
            method = getOption("mailer"),
            address = "the relevant mailing list",
            ccaddress = getOption("ccaddress", ""),
            filename = "R.post", info = character())
```
Arguments

instructions  Character vector of instructions to put at the top of the template email.
description  Character string: a description to be incorporated into messages.
subject  Subject of the email. Optional except for the "mailx" method.
method  Submission method, one of "none", "mailto", "gnudoit", "ess" or (Unix only) "mailx". See ‘Details’.
address  Recipient’s email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed).
ccaddress  Optional email address for copies with the "mailx" and "mailto" methods. Use ccaddress = "" for no copy.
filename  Filename to use for setting up the email (or storing it when method is "none" or sending mail fails).
info  character vector of information to include in the template email below the 'please do not edit the information below' line.

Details

What this does depends on the method. The function first creates a template email body.

none  A file editor (see file.edit) is opened with instructions and the template email. When this returns, the completed email is in file file ready to be read/pasted into an email program.

mailto  This opens the default email program with a template email (including address, Cc: address and subject) for you to edit and send.

This works where default mailers are set up (usual on macOS and Windows, and where xdg-open is available and configured on other Unix-alikes: if that fails it tries the browser set by R_BROWSER).

This is the ‘factory-fresh’ default method.

mailx (Unix-alikes only.) A file editor (see file.edit) is opened with instructions and the template email. When this returns, it is mailed using a Unix command line mail utility such as mailx, to the address (and optionally, the Cc: address) given.

gnudoit  An (X)emacs mail buffer is opened for the email to be edited and sent: this requires the gnudoit program to be available. Currently subject is ignored.

ess  The body of the template email is sent to stdout.

Value

Invisible NULL.

See Also

bug.report, help.request.
Data sets

Description

Loads specified data sets, or list the available data sets.

Usage

```
data(..., list = character(), package = NULL, lib.loc = NULL, 
    verbose = getOption("verbose"), envir = .GlobalEnv, 
    overwrite = TRUE)
```

Arguments

- `...` literal character strings or names.
- `list` a character vector.
- `package` a character vector giving the package(s) to look in for data sets, or `NULL`. By default, all packages in the search path are used, then the ‘data’ subdirectory (if present) of the current working directory.
- `lib.loc` a character vector of directory names of R libraries, or `NULL`. The default value of `NULL` corresponds to all libraries currently known.
- `verbose` a logical. If `TRUE`, additional diagnostics are printed.
- `envir` the environment where the data should be loaded.
- `overwrite` logical: should existing objects of the same name in `envir` be replaced?

Details

Currently, four formats of data files are supported:

1. files ending `.R` or `.r` are `source()`d in, with the R working directory changed temporarily to the directory containing the respective file. (`data` ensures that the `utils` package is attached, in case it had been run via `utils::data`.)
2. files ending `.RData` or `.rda` are `load()`ed.
3. files ending `.tab`, `.txt` or `.TXT` are read using `read.table(..., header = TRUE, as.is=FALSE)`, and hence result in a data frame.
4. files ending `.csv` or `.CSV` are read using `read.table(..., header = TRUE, sep = ";", as.is=FALSE)`, and also result in a data frame.

If more than one matching file name is found, the first on this list is used. (Files with extensions `.txt`, `.tab` or `.csv` can be compressed, with or without further extension `.gz`, `.bzip2` or `.xz`.)

The data sets to be loaded can be specified as a set of character strings or names, or as the character vector `list`, or as both.

For each given data set, the first two types (`.R` or `.r`, and `.RData` or `.rda` files) can create several variables in the load environment, which might all be named differently from the data set. The third and fourth types will always result in the creation of a single variable with the same name (without extension) as the data set.
If no data sets are specified, \texttt{data} lists the available data sets. For each package, it looks for a data index in the ‘Meta’ subdirectory or, if this is not found, scans the ‘data’ subdirectory for data files using \texttt{list_files_with_type}. The information about available data sets is returned in an object of class "packageIQR". The structure of this class is experimental. Where the datasets have a different name from the argument that should be used to retrieve them the index will have an entry like \tt{beaver1 (beavers)} which tells us that dataset \tt{beaver1} can be retrieved by the call \texttt{data(beavers)}.

If \tt{lib.loc} and \tt{package} are both \tt{NULL} (the default), the data sets are searched for in all the currently loaded packages then in the ‘data’ directory (if any) of the current working directory.

If \tt{lib.loc = NULL} but \tt{package} is specified as a character vector, the specified package(s) are searched for first amongst loaded packages and then in the default libraries (see \texttt{.libPaths}).

If \tt{lib.loc} is specified (and not \tt{NULL}), packages are searched for in the specified libraries, even if they are already loaded from another library.

To just look in the ‘data’ directory of the current working directory, set \tt{package = character(0)} (and \tt{lib.loc = NULL}, the default).

**Value**

A character vector of all data sets specified (whether found or not), or information about all available data sets in an object of class "packageIQR" if none were specified.

**Good practice**

There is no requirement for \texttt{data(foo)} to create an object named \tt{foo} (nor to create one object), although it much reduces confusion if this convention is followed (and it is enforced if datasets are lazy-loaded).

\texttt{data()} was originally intended to allow users to load datasets from packages for use in their examples, and as such it loaded the datasets into the workspace \texttt{.GlobalEnv}. This avoided having large datasets in memory when not in use: that need has been almost entirely superseded by lazy-loading of datasets.

The ability to specify a dataset by name (without quotes) is a convenience: in programming the datasets should be specified by character strings (with quotes).

Use of \texttt{data} within a function without an \texttt{envir} argument has the almost always undesirable side-effect of putting an object in the user’s workspace (and indeed, of replacing any object of that name already there). It would almost always be better to put the object in the current evaluation environment by \texttt{data(\ldots, envir = environment())}. However, two alternatives are usually preferable, both described in the ‘Writing R Extensions’ manual.

- For sets of data, set up a package to use lazy-loading of data.
- For objects which are system data, for example lookup tables used in calculations within the function, use a file ‘\texttt{R/sysdata.rda}’ in the package sources or create the objects by \texttt{R} code at package installation time.

A sometimes important distinction is that the second approach places objects in the namespace but the first does not. So if it is important that the function sees \texttt{mytable} as an object from the package, it is system data and the second approach should be used. In the unusual case that a package uses a lazy-loaded dataset as a default argument to a function, that needs to be specified by ::, e.g., \texttt{survival::survexp.us}.
**Warning**

This function creates objects in the `envir` environment (by default the user’s workspace) replacing any which already existed. `data("foo")` can silently create objects other than `foo`: there have been instances in published packages where it created/replaced `.Random.seed` and hence change the seed for the session.

**Note**

One can take advantage of the search order and the fact that a `.R` file will change directory. If raw data are stored in `mydata.txt` then one can set up `mydata.R` to read `mydata.txt` and pre-process it, e.g., using `transform()`. For instance one can convert numeric vectors to factors with the appropriate labels. Thus, the `.R` file can effectively contain a metadata specification for the plaintext formats.

**See Also**

`help` for obtaining documentation on data sets, `save` for creating the second (`.rda`) kind of data, typically the most efficient one.

The ‘Writing R Extensions’ manual for considerations in preparing the ‘data’ directory of a package.

**Examples**

```r
require(utils)
data() # list all available data sets
try(data(package = "rpart"), silent = TRUE) # list the data sets in the rpart package
data(USArrests, "VADeaths") # load the data sets 'USArrests' and 'VADeaths'
## Not run: ## Alternatively
ds <- c("USArrests", "VADeaths"); data(list = ds)
## End(Not run)
help(USArrests) # give information on data set 'USArrests'
```

---

**dataentry**  
*Spreadsheet Interface for Entering Data*

**Description**

A spreadsheet-like editor for entering or editing data.

**Usage**

```r
data.entry(..., Modes = NULL, Names = NULL)
dataentry(data, modes)
de(..., Modes = list(), Names = NULL)
```

**Arguments**

- `...`  
  A list of variables: currently these should be numeric or character vectors or list containing such vectors.
- `Modes`  
  The modes to be used for the variables.
- `Names`  
  The names to be used for the variables.
data A list of numeric and/or character vectors.

modes A list of length up to that of data giving the modes of (some of) the variables. list() is allowed.

Details

The data entry editor is only available on some platforms and GUIs. Where available it provides a means to visually edit a matrix or a collection of variables (including a data frame) as described in the Notes section.

data.entry has side effects, any changes made in the spreadsheet are reflected in the variables. Function de and the internal functions de.ncols, de.setup and de.restore are designed to help achieve these side effects. If the user passes in a matrix, \( \mathbf{X} \) say, then the matrix is broken into columns before dataentry is called. Then on return the columns are collected and glued back together and the result assigned to the variable \( \mathbf{X} \). If you don’t want this behaviour use dataentry directly.

The primitive function is dataentry. It takes a list of vectors of possibly different lengths and modes (the second argument) and opens a spreadsheet with these variables being the columns. The columns of the data entry window are returned as vectors in a list when the spreadsheet is closed.

dc.ncols counts the number of columns which are supplied as arguments to data.entry. It attempts to count columns in lists, matrices and vectors. dc.setup sets things up so that on return the columns can be regrouped and reassigned to the correct name. This is handled by dc.restore.

Value

de and dataentry return the edited value of their arguments. data.entry invisibly returns a vector of variable names but its main value is its side effect of assigning new version of those variables in the user’s workspace.

Resources

The data entry window responds to X resources of class R_dataentry. Resources foreground, background and geometry are utilized.

Note

The details of interface to the data grid may differ by platform and GUI. The following description applies to the X11-based implementation under Unix.

You can navigate around the grid using the cursor keys or by clicking with the (left) mouse button on any cell. The active cell is highlighted by thickening the surrounding rectangle. Moving to the right or down will scroll the grid as needed: there is no constraint to the rows or columns currently in use.

There are alternative ways to navigate using the keys. Return and (keypad) Enter and LineFeed all move down. Tab moves right and Shift-Tab move left. Home moves to the top left.

PageDown or Control-F moves down a page, and PageUp or Control-B up by a page. End will show the last used column and the last few rows used (in any column).

Using any other key starts an editing process on the currently selected cell: moving away from that cell enters the edited value whereas Esc cancels the edit and restores the previous value. When the editing process starts the cell is cleared. In numerical columns (the default) only letters making up a valid number (including -.eE) are accepted, and entering an invalid edited value (such as blank) enters NA in that cell. The last entered value can be deleted using the BackSpace or Del(ete) key. Only a limited number of characters (currently 29) can be entered in a cell, and if necessary only
the start or end of the string will be displayed, with the omissions indicated by > or <. (The start is shown except when editing.)

Entering a value in a cell further down a column than the last used cell extends the variable and fills the gap (if any) by NAs (not shown on screen).

The column names can only be selected by clicking in them. This gives a popup menu to select the column type (currently Real (numeric) or Character) or to change the name. Changing the type converts the current contents of the column (and converting from Character to Real may generate NAs.) If changing the name is selected the header cell becomes editable (and is cleared). As with all cells, the value is entered by moving away from the cell by clicking elsewhere or by any of the keys for moving down (only).

New columns are created by entering values in them (and not by just assigning a new name). The mode of the column is auto-detected from the first value entered: if this is a valid number it gives a numeric column. Unused columns are ignored, so adding data in var5 to a three-column grid adds one extra variable, not two.

The Copy button copies the currently selected cell: paste copies the last copied value to the current cell, and right-clicking selects a cell and copies in the value. Initially the value is blank, and attempts to paste a blank value will have no effect.

Control-L will refresh the display, recalculating field widths to fit the current entries.

In the default mode the column widths are chosen to fit the contents of each column, with a default of 10 characters for empty columns. you can specify fixed column widths by setting option de.cellwidth to the required fixed width (in characters). (set it to zero to return to variable widths). The displayed width of any field is limited to 600 pixels (and by the window width).

vi, edit: edit uses dataentry to edit data frames.

Examples

# call data entry with variables x and y
## Not run: data.entry(x, y)

decall

Debug a Call

Description

Set or unset debugging flags based on a call to a function. Takes into account S3/S4 method dispatch based on the classes of the arguments in the call.

Usage

decall(call, once = FALSE)
undeccall(call)

Arguments

call An R expression calling a function. The called function will be debugged. See Details.

once logical; if TRUE, debugging only occurs once, as via debugonce. Defaults to FALSE
**debugger**

**Details**

ddebugcall debugs the non-generic function, S3 method or S4 method that would be called by evaluating call. Thus, the user does not need to specify the signature when debugging methods. Although the call is actually to the generic, it is the method that is debugged, not the generic, except for non-standard S3 generics (see `isS3stdGeneric`).

**Value**
ddebugcall invisibly returns the debugged call expression.

**Note**

Non-standard evaluation is used to retrieve the call (via `substitute`). For this reason, passing a variable containing a call expression, rather than the call expression itself, will not work.

**See Also**
ddebug for the primary debugging interface

**Examples**

```r
## Not run:
## Evaluate call after setting debugging
##
f <- factor(1:10)
res <- eval(debugcall(summary(f)))
## End(Not run)
```

---

**Post-Mortem Debugging**

**Description**

Functions to dump the evaluation environments (frames) and to examine dumped frames.

**Usage**

```r
dump.frames(dumpto = "last.dump", to.file = FALSE, include.GlobalEnv = FALSE)
debugger(dump = last.dump)
limitedLabels(value, maxwidth =getOption("width") - 5L)
```

**Arguments**

- `dumpto` a character string. The name of the object or file to dump to.
- `to.file` logical. Should the dump be to an R object or to a file?
- `include.GlobalEnv` logical indicating if a copy of the `.GlobalEnv` environment should be included in addition to the `sys.frames()`. Will be particularly useful when used in a batch job.
**debugger**

**dump**

an R dump object created by `dump.frames`.

**value**

a list of calls to be formatted, e.g., for user menus.

**maxwidth**

optional length to which to trim the result of `limitedLabels()`; values smaller than 40 or larger than 1000 are winsorized.

### Details

To use post-mortem debugging, set the option `error` to be a call to `dump.frames`. By default this dumps to an R object `last.dump` in the workspace, but it can be set to dump to a file (a dump of the object produced by a call to `save`). The dumped object contain the call stack, the active environments and the last error message as returned by `geterrmessage`.

When dumping to file, `dumpTo` gives the name of the dumped object and the file name has `'.rda'` appended.

A dump object of class "dump.frames" can be examined by calling `debugger`. This will give the error message and a list of environments from which to select repeatedly. When an environment is selected, it is copied and the `browser` called from within the copy. Note that not all the information in the original frame will be available, e.g. promises which have not yet been evaluated and the contents of any ... argument.

If `dump.frames` is installed as the error handler, execution will continue even in non-interactive sessions. See the examples for how to dump and then quit.

`limitedLabels(v)` takes a list of calls whose elements may have a `srcref` attribute and returns a vector that pastes a formatted version of those attributes onto the formatted version of the elements, all finally `strtrim()`ed to `maxwidth`.

### Value

Invisible `NULL`.

### Note

Functions such as `sys.parent` and `environment` applied to closures will not work correctly inside `debugger`.

If the error occurred when computing the default value of a formal argument the debugger will report “recursive default argument reference” when trying to examine that environment.

Of course post-mortem debugging will not work if R is too damaged to produce and save the dump, for example if it has run out of workspace.

### References

### See Also

`browser` for the actions available at the Browse prompt.

`options` for setting `error` options; `recover` is an interactive debugger working similarly to `debugger` but directly after the error occurs.
Examples

```r
## Not run:
options(error = quote(dump.frames("testdump", TRUE)))

f <- function() {
  g <- function() stop("test dump.frames")
  g()
}
f()  # will generate a dump on file "testdump.rda"
options(error = NULL)

## possibly in another R session
load("testdump.rda")
debugger(testdump)
Available environments had calls:
1: f()
2: g()
3: stop("test dump.frames")

Enter an environment number, or 0 to exit
Selection: 1
Browsing in the environment with call:
f()
Called from: debugger.look(ind)
Browse[1]> ls()
[1] "g"
Browse[1]> g
function() stop("test dump.frames")
<environment: 759818>
Browse[1]>
Available environments had calls:
1: f()
2: g()
3: stop("test dump.frames")

Enter an environment number, or 0 to exit
Selection: 0

## A possible setting for non-interactive sessions
options(error = quote({dump.frames(to.file = TRUE); q(status = 1)}))

## End(Not run)
```

demo

**Demonstrations of R Functionality**

demo is a user-friendly interface to running some demonstration R scripts. demo() gives the list of available topics.

**Usage**

demo(topic, package = NULL, lib.loc = NULL,
character.only = FALSE, verbose =getOption("verbose"),
type = c("console", "html"), echo = TRUE,
ask =getOption("demo.ask"),
encoding =getOption("encoding"))

Arguments

- **topic**: the topic which should be demonstrated, given as a name or literal character string, or a character string, depending on whether character.only is FALSE (default) or TRUE. If omitted, the list of available topics is displayed.
- **package**: a character vector giving the packages to look into for demos, or NULL. By default, all packages in the search path are used.
- **lib.loc**: a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
- **character.only**: logical; if TRUE, use topic as character string.
- **verbose**: a logical. If TRUE, additional diagnostics are printed.
- **type**: character: whether to show output in the console or a browser (using the dynamic help system). The latter is honored only in interactive sessions and if the knitr package is installed. Several other arguments are silently ignored in that case, including lib.loc.
- **echo**: a logical. If TRUE, show the R input when sourcing.
- **ask**: a logical (or "default") indicating if devAskNewPage(ask = TRUE) should be called before graphical output happens from the demo code. The value "default" (the factory-fresh default) means to ask if echo == TRUE and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the demo code. If this is evaluated to TRUE and the session is interactive, the user is asked to press RETURN to start.
- **encoding**: See source. If the package has a declared encoding, that takes preference.

Details

If no topics are given, demo lists the available demos. For type = "console", the corresponding information is returned in an object of class "packageIQR".

See Also

- source and devAskNewPage which are called by demo. example to run code in the Examples section of help pages.

Examples

demo() # for attached packages

## All available demos:
demo(package = .packages(all.available = TRUE))

## Display a demo, pausing between pages
demo(lm.glm, package = "stats", ask = TRUE)
## Display it without pausing
demo(lm.glm, package = "stats", ask = FALSE)

## Not run:
ch <- "scoping"
demo(ch, character = TRUE)

## End(Not run)

## Find the location of a demo
system.file("demo", "lm.glm.R", package = "stats")

### DLL.version

**DLL Version Information on MS Windows**

**Description**

On MS Windows only, return the version of the package and the version of R used to build the DLL, if available.

**Usage**

DLL.version(path)

**Arguments**

- **path** character vector of length one giving the complete path to the DLL.

**Value**

If the DLL does not exist, NULL.

A character vector of length two, giving the DLL version and the version of R used to build the DLL. If the information is not available, the corresponding string is empty.

**Note**

This is only available on Windows.

**Examples**

```r
if(.Platform$OS.type == "windows") withAutoprint(
  DLL.version(file.path(R.home("bin"), "R.dll"))
  DLL.version(file.path(R.home(), "library/stats/libs", .Platform$r_arch, "stats.dll"))
)
```
download.file

**Download File from the Internet**

**Description**

This function can be used to download a file from the Internet.

**Usage**

```r
download.file(url, destfile, method, quiet = FALSE, mode = "w",
               cacheOK = TRUE,
               extra =getOption("download.file.extra"),
               headers = NULL, ...)
```

**Arguments**

- `url` a character string (or longer vector for the "libcurl" method) naming the URL of a resource to be downloaded.
- `destfile` a character string (or vector, see the `url` argument) with the file path where the downloaded file is to be saved. Tilde-expansion is performed.
- `method` Method to be used for downloading files. Current download methods are "internal", "libcurl", "wget", "curl" and "wininet" (Windows only), and there is a value "auto": see 'Details' and 'Note'. The method can also be set through the option "download.file.method": see `options()`.
- `quiet` If TRUE, suppress status messages (if any), and the progress bar.
- `mode` character. The mode with which to write the file. Useful values are "w", "wb" (binary), "a" (append) and "ab". Not used for methods "wget" and "curl". See also 'Details', notably about using "wb" for Windows.
- `cacheOK` logical. Is a server-side cached value acceptable?
- `extra` character vector of additional command-line arguments for the "wget" and "curl" methods.
- `headers` named character vector of additional HTTP headers to use in HTTP[S] requests. It is ignored for non-HTTP[S] URLs. The User-Agent header taken from the `HTTPUserAgent` option (see `options`) is automatically used as the first header.
- `...` allow additional arguments to be passed, unused.

**Details**

The function `download.file` can be used to download a single file as described by `url` from the internet and store it in `destfile`.

The `url` must start with a scheme such as 'http://', 'https://' or 'file://'. Which methods support which schemes varies by R version, but `method = "auto"` will try to find a method which supports the scheme.

For `method = "auto"` (the default) currently the "internal" method is used for 'file:///' URLs and "libcurl" for all others.
Support for method "libcurl" was optional on Windows prior to R 4.2.0: use `capabilities("libcurl")` to see if it is supported on an earlier version. It uses an external library of that name (https://curl.se/libcurl/) against which R can be compiled.

When method "libcurl" is used, there is support for simultaneous downloads, so `url` and `destfile` can be character vectors of the same length greater than one (but the method has to be specified explicitly and not via "auto"). For a single URL and `quiet = FALSE` a progress bar is shown in interactive use.

Nowadays the "internal" method only supports the ‘file://’ scheme (for which it is the default). On Windows the "wininet" method currently supports ‘file://’ and (but deprecated with a warning) ‘http://’ and ‘https://’ schemes.

For methods "wget" and "curl" a system call is made to the tool given by method, and the respective program must be installed on your system and be in the search path for executables. They will block all other activity on the R process until they complete: this may make a GUI unresponsive.

`cacheOK = FALSE` is useful for ‘http://’ and ‘https://’ URLs: it will attempt to get a copy directly from the site rather than from an intermediate cache. It is used by `available.packages`.

The "libcurl" and "wget" methods follow ‘http://’ and ‘https://’ redirections to any scheme they support. (For method "curl" use argument `extra = "-L"`.) To disable redirection in `wget`, use `extra = "--max-redirect=0"`.) The "wininet" method supports some redirections but not all. (For method "libcurl", messages will quote the endpoint of redirections.)

See `url` for how ‘file://’ URLs are interpreted, especially on Windows. The "internal" and "wininet" methods do not percent-decode, but the "libcurl" and "curl" methods do: method "wget" does not support them.

Most methods do not percent-encode special characters such as spaces in URLs (see `URLencode`), but it seems the "wininet" method does.

The remaining details apply to the "wininet" and "libcurl" methods only.

The timeout for many parts of the transfer can be set by the option `timeout` which defaults to 60 seconds. This is often insufficient for downloads of large files (50MB or more) and so should be increased when `download.file` is used in packages to do so. Note that the user can set the default timeout by the environment variable `R_DEFAULT_INTERNET_TIMEOUT` in recent versions of R, so to ensure that this is not decreased packages should use something like

```r
options(timeout = max(300, getOption("timeout")))
```

(It is unrealistic to require download times of less than 1s/MB.)

The level of detail provided during transfer can be set by the `quiet` argument and the `internet.info` option: the details depend on the platform and scheme. For the "libcurl" method values of the option less than 2 give verbose output.

A progress bar tracks the transfer platform-specifically:

**On Windows** If the file length is known, the full width of the bar is the known length. Otherwise the initial width represents 100 Kbytes and is doubled whenever the current width is exceeded. (In non-interactive use this uses a text version. If the file length is known, an equals sign represents 2% of the transfer completed: otherwise a dot represents 10Kb.)

**On a Unix-alike** If the file length is known, an equals sign represents 2% of the transfer completed: otherwise a dot represents 10Kb.

The choice of binary transfer (`mode = "wb"` or "ab") is important on Windows, since unlike Unix-alikes it does distinguish between text and binary files and for text transfers changes "\n" line endings to "\r\n" (aka "CRLF").
On Windows, if mode is not supplied (`missing()`) and url ends in one of `.gz`, `.bz2`, `.xz`, `.tgz`, `.zip`, `.tar', `.rda', `.rds', `.RData' or `.pdf`, `mode = "wb"` is set so that a binary transfer is done to help unwary users.

Code written to download binary files must use `mode = "wb"` (or "ab"), but the problems incurred by a text transfer will only be seen on Windows.

**Value**

An (invisible) integer code, 0 for success and non-zero for failure. For the "wget" and "curl" methods this is the status code returned by the external program. The "internal" method can return 1, but will in most cases throw an error.

What happens to the destination file(s) in the case of error depends on the method and R version. Currently the "internal", "wininet" and "libcurl" methods will remove the file if the URL is unavailable except when `mode` specifies appending when the file should be unchanged.

**Setting Proxies**

For the Windows-only method "wininet", the 'Internet Options' of the system are used to choose proxies and so on; these are set in the Control Panel and are those used for system browsers.

For the "libcurl" and "curl" methods, proxies can be set via the environment variables `http_proxy` or `ftp_proxy`. See [https://curl.se/libcurl/c/libcurl-tutorial.html](https://curl.se/libcurl/c/libcurl-tutorial.html) for further details.

**Secure URLs**

Methods which access ‘https://’ and (where supported) ‘ftps://’ URLs should try to verify the site certificates. This is usually done using the CA root certificates installed by the OS (although we have seen instances in which these got removed rather than updated). For further information see [https://curl.se/docs/sslcerts.html](https://curl.se/docs/sslcerts.html).

On Windows with `method = "libcurl"`, the CA root certificates are provided by the OS when R was linked with `libcurl` with Schannel enabled, which is the current default in Rtools. This can be verified by checking that `libcurlVersion()` returns a version string containing "Schannel". If it does not, for verification to be on the environment variable `CURL_CA_BUNDLE` must be set to a path to a certificate bundle file, usually named ‘ca-bundle.crt’ or ‘curl-ca-bundle.crt’. (This is normally done automatically for a binary installation of R, which installs ‘R_HOME/etc/curl-ca-bundle.crt’ and sets `CURL_CA_BUNDLE` to point to it if that environment variable is not already set.) For an updated certificate bundle, see [https://curl.se/docs/sslcerts.html](https://curl.se/docs/sslcerts.html). Currently one can download a copy from [https://raw.githubusercontent.com/bagder/ca-bundle/master/ca-bundle.crt](https://raw.githubusercontent.com/bagder/ca-bundle/master/ca-bundle.crt) and set `CURL_CA_BUNDLE` to the full path to the downloaded file.

On Windows with `method = "libcurl"`, when R was linked with `libcurl` with Schannel enabled, the connection fails if it cannot be established that the certificate has not been revoked. Some MITM proxies present particularly in corporate environments do not work with this behavior. It can be changed by setting environment variable `R_LIBCURL_SSL_REVOKE_BEST_EFFORT` to TRUE, with the consequence of reducing security.

Note that the root certificates used by R may or may not be the same as used in a browser, and indeed different browsers may use different certificate bundles (there is typically a build option to choose either their own or the system ones).
**Good practice**

Setting the method should be left to the end user. Neither of the wget nor curl commands is widely available: you can check if one is available via `Sys.which`, and should do so in a package or script.

If you use `download.file` in a package or script, you must check the return value, since it is possible that the download will fail with a non-zero status but not an R error.

The supported methods do change: method libcurl was introduced in R 3.2.0 and was optional on Windows until R 4.2.0 – use `capabilities("libcurl")` in a program to see if it is available.

### ‘ftp://’ URLs

Most modern browsers do not support such URLs, and ‘https://’ ones are much preferred for use in R. ‘ftps://’ URLs have always been rare, and are nowadays even less supported.

It is intended that R will continue to allow such URLs for as long as libcurl does, but as they become rarer this is increasingly untested. What ‘protocols’ the version of libcurl being used supports can be seen by calling `libcurlVersion()`.

These URLs are accessed using the FTP protocol which has a number of variants. One distinction is between ‘active’ and ‘(extended) passive’ modes: which is used is chosen by the client. The "libcurl" method uses passive mode which was almost universally used by browsers before they dropped support altogether.

**Note**

Files of more than 2GB are supported on 64-bit builds of R; they may be truncated on some 32-bit builds.

Methods "wget" and "curl" are mainly for historical compatibility but provide may provide capabilities not supported by the "libcurl" or "wininet" methods.

Method "wget" can be used with proxy firewalls which require user/password authentication if proper values are stored in the configuration file for wget.

**wget** ([https://www.gnu.org/software/wget/](https://www.gnu.org/software/wget/)) is commonly installed on Unix-alikes (but not macOS). Windows binaries are available from MSYS2 and elsewhere.

**curl** ([https://curl.se/](https://curl.se/)) is installed on macOS and increasingly commonly on Unix-alikes. Windows binaries are available at that URL.

**See Also**

- `options` to set the HTTPUserAgent, timeout and internet.info options used by some of the methods.
- `url` for a finer-grained way to read data from URLs.
- `url.show, available.packages, download.packages` for applications.

Contributed packages **RCurl** and **curl** provide more comprehensive facilities to download from URLs.
download.packages  Download Packages from CRAN-like Repositories

Description

These functions can be used to automatically compare the version numbers of installed packages with the newest available version on the repositories and update outdated packages on the fly.

Usage

```r
download.packages(pkgs, destdir, available = NULL, 
repos = getOption("repos"), 
contriburl = contrib.url(repos, type), 
method, type = getOption("pkgType"), ...)
```

Arguments

- `pkgs` character vector of the names of packages whose latest available versions should be downloaded from the repositories.
- `destdir` directory where downloaded packages are to be stored.
- `available` an object as returned by `available.packages` listing packages available at the repositories, or NULL which makes an internal call to `available.packages`.
- `repos` character vector, the base URL(s) of the repositories to use, i.e., the URL of the CRAN master such as “https://cran.r-project.org” or ones of its mirrors, “https://cloud.r-project.org”.
- `contriburl` URL(s) of the contrib sections of the repositories. Use this argument only if your repository mirror is incomplete, e.g., because you burned only the ‘contrib’ section on a CD. Overrides argument `repos`.
- `method` Download method, see `download.file`.
- `type` character string, indicate which type of packages: see `install.packages` and ‘Details’.
- `...` additional arguments to be passed to `download.file` and `available.packages`.

Details

download.packages takes a list of package names and a destination directory, downloads the newest versions and saves them in `destdir`. If the list of available packages is not given as argument, it is obtained from repositories. If a repository is local, i.e. the URL starts with “file:”, then the packages are not downloaded but used directly. Both “file:” and “file:///” are allowed as prefixes to a file path. Use the latter only for URLs: see `url` for their interpretation. (Other forms of ‘file://’ URLs are not supported.)

For `download.packages`, `type = "both"` looks at source packages only.

Value

A two-column matrix of names and destination file names of those packages successfully downloaded. If packages are not available or there is a problem with the download, suitable warnings are given.
See Also

available.packages, contrib.url.

The main use is by install.packages.

See download.file for how to handle proxies and other options to monitor file transfers.

The ‘R Installation and Administration’ manual for how to set up a repository.

Description

Invoke a text editor on an R object.

Usage

edit(name, ...)  # Default S3 method:
edit(name = NULL, file = "", title = NULL,  
editor = getOption("editor"), ...)  

vi(name = NULL, file = "")
emacs(name = NULL, file = "")
pico(name = NULL, file = "")
xemacs(name = NULL, file = "")
xedit(name = NULL, file = "")

Arguments

name

file

title

editor

Further details and examples can be found at:

Details

edit invokes the text editor specified by editor with the object name to be edited. It is a generic  
function, currently with a default method and one for data frames and matrices.

data.entry can be used to edit data, and is used by edit to edit matrices and data frames on  
systems for which data.entry is available.
It is important to realize that edit does not change the object called name. Instead, a copy of name is made and it is that copy which is changed. Should you want the changes to apply to the object name you must assign the result of edit to name. (Try fix if you want to make permanent changes to an object.)

In the form edit(name), edit deparses name into a temporary file and invokes the editor editor on this file. Quitting from the editor causes file to be parsed and that value returned. Should an error occur in parsing, possibly due to incorrect syntax, no value is returned. Calling edit(), with no arguments, will result in the temporary file being reopened for further editing.

Note that deparsing is not perfect, and the object recreated after editing can differ in subtle ways from that deparsed: see dput and .deparseOpts. (The deparse options used are the same as the defaults for dump.) Editing a function will preserve its environment. See edit.data.frame for further changes that can occur when editing a data frame or matrix.

Currently only the internal editor in Windows makes use of the title option; it displays the given name in the window header.

Note

The functions vi, emacs, pico, xemacs, xedit rely on the corresponding editor being available and being on the path. This is system-dependent.

See Also

edit.data.frame, data.entry, fix.

Examples

## Not run:
# use xedit on the function mean and assign the changes
mean <- edit(mean, editor = "xedit")

# use vi on mean and write the result to file mean.out
vi(mean, file = "mean.out")

## End(Not run)
Arguments

- **name**: A data frame or (numeric, logical or character) matrix.
- **factor.mode**: How to handle factors (as integers or using character levels) in a data frame. Can be abbreviated.
- **edit.row.names**: Logical. Show the row names (if they exist) be displayed as a separate editable column? It is an error to ask for this on a matrix with NULL row names.
- ... further arguments passed to or from other methods.

Details

At present, this only works on simple data frames containing numeric, logical or character vectors and factors, and numeric, logical or character matrices. Any other mode of matrix will give an error, and a warning is given when the matrix has a class (which will be discarded).

Data frame columns are coerced on input to character unless numeric (in the sense of `is.numeric`), logical or factor. A warning is given when classes are discarded. Special characters (tabs, non-printing ASCII, etc.) will be displayed as escape sequences.

Factors columns are represented in the spreadsheet as either numeric vectors (which are more suitable for data entry) or character vectors (better for browsing). After editing, vectors are padded with NA to have the same length and factor attributes are restored. The set of factor levels can not be changed by editing in numeric mode; invalid levels are changed to NA and a warning is issued. If new factor levels are introduced in character mode, they are added at the end of the list of levels in the order in which they encountered.

It is possible to use the data-editor’s facilities to select the mode of columns to swap between numerical and factor columns in a data frame. Changing any column in a numerical matrix to character will cause the result to be coerced to a character matrix. Changing the mode of logical columns is not supported.

For a data frame, the row names will be taken from the original object if edit.row.names = FALSE and the number of rows is unchanged, and from the edited output if edit.row.names = TRUE and there are no duplicates. (If the row.names column is incomplete, it is extended by entries like row223.) In all other cases the row names are replaced by seq(length = nrows).

For a matrix, colnames will be added (of the form col7) if needed. The rownames will be taken from the original object if edit.row.names = FALSE and the number of rows is unchanged (otherwise NULL), and from the edited output if edit.row.names = TRUE. (If the row.names column is incomplete, it is extended by entries like row223.)

Editing a matrix or data frame will lose all attributes apart from the row and column names.

Value

The edited data frame or matrix.

Note

- `fix(dataframe)` works for in-place editing by calling this function.
- If the data editor is not available, a dump of the object is presented for editing using the default method of `edit`.
- At present the data editor is limited to 65535 rows.

Peter Dalgaard
Description

Run all the \proglang{R} code from the \textbf{Examples} part of \proglang{R}’s online help topic \texttt{topic}, with possible exceptions due to \texttt{\dontrun}, \texttt{\dontshow}, and \texttt{\donttest} tags, see `Details' below.

Usage

\begin{verbatim}
example(topic, package = NULL, lib.loc = NULL,
        character.only = FALSE, give.lines = FALSE, local = FALSE,
        type = c("console", "html"), echo = TRUE,
        verbose =getOption("verbose"),
        setRNG = FALSE, ask =getOption("example.ask"),
        prompt.prefix = abbreviate(topic, 6),
        catch.aborts = FALSE,
        run.dontrun = FALSE, run.donttest = interactive())
\end{verbatim}

Arguments

- \texttt{topic} name or literal character string: the online \texttt{help} topic the examples of which should be run.
- \texttt{package} a character vector giving the package names to look into for the topic, or \texttt{NULL} (the default), when all packages on the \texttt{search} path are used.
- \texttt{lib.loc} a character vector of directory names of \proglang{R} libraries, or \texttt{NULL}. The default value of \texttt{NULL} corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
- \texttt{character.only} a logical indicating whether \texttt{topic} can be assumed to be a character string.
- \texttt{give.lines} logical: if true, the \texttt{lines} of the example source code are returned as a character vector.
- \texttt{local} logical: if \texttt{TRUE} evaluate locally, if \texttt{FALSE} evaluate in the workspace.
- \texttt{type} character: whether to show output in the console or a browser (using the dynamic help system). The latter is honored only in interactive sessions and if the \pkg{knitr} package is installed. Several other arguments are silently ignored in that case, including \texttt{setRNG} and \texttt{lib.loc}.
- \texttt{echo} logical; if \texttt{TRUE}, show the \proglang{R} input when sourcing.
- \texttt{verbose} logical; if \texttt{TRUE}, show even more when running example code.
setRNG logical or expression; if not FALSE, the random number generator state is saved, then initialized to a specified state, the example is run and the (saved) state is restored. setRNG = TRUE sets the same state as \texttt{R CMD check} does for running a package’s examples. This is currently equivalent to \texttt{setRNG = \{RNGkind("default", "default", "default"); set.seed(1)}.

ask logical (or "default") indicating if \texttt{devAskNewPage(ask = TRUE)} should be called before graphical output happens from the example code. The value "default" (the factory-fresh default) means to ask if echo is true and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the example code.

prompt.prefix character; prefixes the prompt to be used if echo is true (as it is by default).

catch.aborts logical, passed on to \texttt{source()}, indicating that "abort"ing errors should be caught.

run.dontrun logical indicating that \texttt{\dontrun} should be ignored, i.e., do run the enclosed code.

run.donttest logical indicating that \texttt{\donttest} should be ignored, i.e., do run the enclosed code.

Details

If \texttt{lib.loc} is not specified, the packages are searched for amongst those already loaded, then in the libraries given by \texttt{.libPaths()}. If \texttt{lib.loc} is specified, packages are searched for only in the specified libraries, even if they are already loaded from another library. The search stops at the first package found that has help on the topic.

An attempt is made to load the package before running the examples, but this will not replace a package loaded from another location.

If \texttt{local = TRUE} objects are not created in the workspace and so not available for examination after \texttt{example} completes: on the other hand they cannot overwrite objects of the same name in the workspace.

As detailed in the ‘Writing R Extensions’ manual, the author of the help page can tag parts of the examples with the following exception rules:

\texttt{\dontrun} encloses code that should not be run.

\texttt{\dontshow} encloses code that is invisible on help pages, but will be run both by the package checking tools, and the \texttt{example()} function. This was previously \texttt{\testonly}, and that form is still accepted.

\texttt{\donttest} encloses code that typically should be run, but not during package checking. The default \texttt{run.donttest = interactive()} leads \texttt{example()} use in other help page examples to skip \texttt{\donttest} sections appropriately.

The additional \texttt{\dontdiff} tag (in R \(\geq 4.4.0\)) produces special comments in the code run by \texttt{example} (for \texttt{Rdiff}-based testing of example output), but does not affect which code is run or displayed on the help page.

Value

The value of the last evaluated expression, unless \texttt{give.lines} is true, where a \texttt{character} vector is returned.

Author(s)

Martin Maechler and others
file.edit

Edit One or More Files

Description

Edit one or more files in a text editor.

Usage

file.edit(..., title = file, editor = getOption("editor"),
    fileEncoding = "")

Arguments

... one or more character vectors containing the names of the files to be displayed. These will be tilde-expanded: see path.expand.

    title the title to use in the editor; defaults to the filename.

    editor the text editor to be used, usually as a character string naming (or giving the path to) the text editor you want to use. See ‘Details’.

    fileEncoding the encoding to assume for the file: the default is to assume the native encoding. See the ‘Encoding’ section of the help for file.

Examples

example(InsectSprays)
## force use of the standard package 'stats':
example("smooth", package = "stats", lib.loc = .Library)

## set RNG *before* example as when R CMD check is run:

r1 <- example(quantile, setRNG = TRUE)
x1 <- rnorm(1)
u <- runif(1)
## identical random numbers
r2 <- example(quantile, setRNG = TRUE)
x2 <- rnorm(1)
stopifnot(identical(r1, r2))
## but x1 and x2 differ since the RNG state from before example()
## differs and is restored!
x1; x2

## Exploring examples code:
## How large are the examples of "lm...()" functions?
lmex <- sapply(apropos("^lm", mode = "function"),
    example, character.only = TRUE, give.lines = TRUE)
lengths(lmex)
Details

The behaviour of this function is very system-dependent. Currently files can be opened only one at a time on Unix; on Windows, the internal editor allows multiple files to be opened, but has a limit of 50 simultaneous edit windows.

The `title` argument is used for the window caption in Windows, and is currently ignored on other platforms.

Any error in re-encoding the files to the native encoding will cause the function to fail.

The default for `editor` is system-dependent. On Windows it defaults to "internal", the script editor, and in the macOS GUI the document editor is used whatever the value of `editor`. On Unix the default is set from the environment variables `EDITOR` or `VISUAL` if either is set, otherwise `vi` is used.

`editor` can also be an R function, in which case it is called with the arguments `name`, `file`, and `title`. Note that such a function will need to independently implement all desired functionality.

On Windows, UTF-8-encoded paths not valid in the current locale can be used.

`files`, `file.show`, `edit`, `fix`,

Examples

```r
## Not run:
# open two R scripts for editing
file.edit("script1.R", "script2.R")

## End(Not run)
```

file_test

Shell-style Tests on Files

Description

Utility for shell-style file tests.

Usage

```r
file_test(op, x, y)
```

Arguments

- `op` a character string specifying the test to be performed. Unary tests (only `x` is used) are "-f" (existence and not being a directory), "-d" (existence and directory), "-L" or "-h" (existence and symbolic link), "-x" (executable as a file or searchable as a directory), "-w" (writable) and "-r" (readable). Binary tests are "-nt" (strictly newer than, using the modification dates) and "-ot" (strictly older than): in both cases the test is false unless both files exist.

- `x`, `y` character vectors giving file paths.
**Details**

‘Existence’ here means being on the file system and accessible by the `stat` system call (or a 64-bit extension) – on a Unix-alike this requires execute permission on all of the directories in the path that leads to the file, but no permissions on the file itself.

For the meaning of "-x" on Windows see `file.access`.

**See Also**

`file.exists` which only tests for existence (test -e on some systems) but not for not being a directory.

`file.path, file.info`

**Examples**

```r
dir <- file.path(R.home(), "library", "stats")
file_test("-d", dir)
file_test("-nt", file.path(dir, "R"), file.path(dir, "demo"))
```

---

**Description**

Find out if a CRAN mirror has been selected for the current session.

**Usage**

```r
findCRANmirror(type = c("src", "web"))
```

**Arguments**

- `type`  
  Is the mirror to be used for package sources or web information?

**Details**

Find out if a CRAN mirror has been selected for the current session. If so, return its URL else return "https://CRAN.R-project.org".

The mirror is looked for in several places:

- The value of the environment variable R_CRAN_SRC or R_CRAN_WEB (depending on `type`), if set.
- An entry in `getOption("repos")` named ‘CRAN’ which is not the default ‘"@CRAN@"’.
- The ‘CRAN’ URL entry in the ‘repositories’ file (see `setRepositories`), if it is not the default ‘"@CRAN@"’.

The two types allow for partial local CRAN mirrors, for example those mirroring only the package sources where `getOption("repos")` might point to the partial mirror and R_CRAN_WEB point to a full (remote) mirror.
findLineNum

Find the Location of a Line of Source Code, or Set a Breakpoint There

Description

These functions locate objects containing particular lines of source code, using the information saved when the code was parsed with `keep.source = TRUE`.

Usage

```r
findLineNum(srcfile, line, nameonly = TRUE, 
            envir = parent.frame(), lastenv)
```

```r
setBreakpoint(srcfile, line, nameonly = TRUE, 
              envir = parent.frame(), lastenv, verbose = TRUE, 
              tracer, print = FALSE, clear = FALSE, ...)
```

Arguments

- `srcfile` The name of the file containing the source code.
- `line` The line number within the file. See Details for an alternate way to specify this.
- `nameonly` If TRUE (the default), we require only a match to `basename(srcfile)`, not to the full path.
- `envir` Where do we start looking for function objects?
- `lastenv` Where do we stop? See the Details.
- `verbose` Should we print information on where breakpoints were set?
- `tracer` An optional `tracer` function to pass to `trace`. By default, a call to `browser` is inserted.
- `print` The `print` argument to pass to `trace`.
- `clear` If TRUE, call `untrace` rather than `trace`.
- `...` Additional arguments to pass to `trace`.

Value

A character string.

See Also

`setRepositories`, `chooseCRANmirror`

Examples

```r
c(findCRANmirror("src"), findCRANmirror("web"))
Sys.setenv(R_CRAN_WEB = "https://cloud.r-project.org")
c(findCRANmirror("src"), findCRANmirror("web"))
```
Details

The `findLineNum` function searches through all objects in environment `envir`, its parent, grandparent, etc., all the way back to `lastenv`.

`lastenv` defaults to the global environment if `envir` is not specified, and to the root environment `emptyenv()` if `envir` is specified. (The first default tends to be quite fast, and will usually find all user code other than S4 methods; the second one is quite slow, as it will typically search all attached system libraries.)

For convenience, `envir` may be specified indirectly: if it is not an environment, it will be replaced with `environment(envir)`.

`setBreakpoint` is a simple wrapper function for `trace` and `untrace`. It will set or clear breakpoints at the locations found by `findLineNum`.

`srcfile` is normally a filename entered as a character string, but it may be a "srcfile" object, or it may include a suffix like "filename.R#nn", in which case the number `nn` will be used as a default value for `line`.

As described in the description of the `where` argument on the man page for `trace`, the R package system uses a complicated scheme that may include more than one copy of a function in a package. The user will typically see the public one on the search path, while code in the package will see a private one in the package namespace. If you set `envir` to the environment of a function in the package, by default `findLineNum` will find both versions, and `setBreakpoint` will set the breakpoint in both. (This can be controlled using `lastenv`; e.g., `envir = environment(foo), lastenv = globalenv()` will find only the private copy, as the search is stopped before seeing the public copy.)

S version 4 methods are also somewhat tricky to find. They are stored with the generic function, which may be in the `base` or other package, so it is usually necessary to have `lastenv = emptyenv()` in order to find them. In some cases transformations are done by R when storing them and `findLineNum` may not be able to find the original code. Many special cases, e.g. methods on primitive generics, are not yet supported.

Value

`findLineNum` returns a list of objects containing location information. A `print` method is defined for them.

`setBreakpoint` has no useful return value; it is called for the side effect of calling `trace` or `untrace`.

Duncan Murdoch

See Also

`trace`

Examples

```r
## Not run:
# Find what function was defined in the file mysource.R at line 100:
findLineNum("mysource.R#100")

# Set a breakpoint in both copies of that function, assuming one is in the
# same namespace as myfunction and the other is on the search path
```
setBreakpoint("mysource.R#100", envir = myfunction)

## End(Not run)

---

**fix**  
*Fix an Object*

**Description**

`fix` invokes `edit` on `x` and then assigns the new (edited) version of `x` in the user’s workspace.

**Usage**

`fix(x, ...)`

**Arguments**

- `x`: the name of an R object, as a name or a character string.
- `...`: arguments to pass to editor: see `edit`.

**Details**

The name supplied as `x` need not exist as an R object, in which case a function with no arguments and an empty body is supplied for editing.

Editing an R object may change it in ways other than are obvious: see the comment under `edit`. See `edit.data.frame` for changes that can occur when editing a data frame or matrix.

**See Also**

`edit.edit.data.frame`

**Examples**

```r
## Not run:
## Assume 'my.fun' is a user defined function:
fix(my.fun)
## now my.fun is changed
## Also,
fix(my.data.frame) # calls up data editor
fix(my.data.frame, factor.mode="char") # use of ...
## End(Not run)
```
flush.console  Flush Output to a Console

Description

This does nothing except on console-based versions of R. On the macOS and Windows GUIs, it ensures that the display of output in the console is current, even if output buffering is on.

Usage

flush.console()

format  Format Unordered and Ordered Lists

Description

Format unordered (itemize) and ordered (enumerate) lists.

Usage

formatUL(x, label = "*", offset = 0,
       width = 0.9 *getOption("width"))
formatOL(x, type = "arabic", offset = 0, start = 1,
       width = 0.9 *getOption("width"))

Arguments

x            a character vector of list items.
label        a character string used for labelling the items.
offset       a non-negative integer giving the offset (indentation) of the list.
width        a positive integer giving the target column for wrapping lines in the output.
type         a character string specifying the 'type' of the labels in the ordered list. If "arabic" (default), arabic numerals are used. For "Alph" or "alph", single upper or lower case letters are employed (in this case, the number of the last item must not exceed 26). Finally, for "Roman" or "roman", the labels are given as upper or lower case roman numerals (with the number of the last item maximally 3999). type can be given as a unique abbreviation of the above, or as one of the HTML style tokens "1" (arabic), "A"/"a" (alphabetic), or "I"/"i" (roman), respectively.
start        a positive integer specifying the starting number of the first item in an ordered list.

Value

A character vector with the formatted entries.
## A simpler recipe.

```r
x <- c("Mix dry ingredients thoroughly.",
       "Pour in wet ingredients.",
       "Mix for 10 minutes.",
       "Bake for one hour at 300 degrees.")
## Format and output as an unordered list.
writeLines(formatUL(x))
## Format and output as an ordered list.
writeLines(formatOL(x))
## Ordered list using lower case roman numerals.
writeLines(formatOL(x, type = "i"))
## Ordered list using upper case letters and some offset.
writeLines(formatOL(x, type = "A", offset = 5))
```

---

### getAnywhere

**Retrieve an R Object, Including from a Namespace**

#### Description

These functions locate all objects with name matching their argument, whether visible on the search path, registered as an S3 method or in a namespace but not exported. `getAnywhere()` returns the objects and `argsAnywhere()` returns the arguments of any objects that are functions.

#### Usage

```r
getAnywhere(x)
argsAnywhere(x)
```

#### Arguments

- `x` a character string or name.

#### Details

These functions look at all loaded namespaces, whether or not they are associated with a package on the search list.

They do not search literally “anywhere”: for example, local evaluation frames and namespaces that are not loaded will not be searched.

Where functions are found as registered S3 methods, an attempt is made to find which namespace registered them. This may not be correct, especially if namespaces have been unloaded.
Value

For `getAnywhere()` an object of class “getAnywhere”. This is a list with components

- **name**: the name searched for
- **objs**: a list of objects found
- **where**: a character vector explaining where the object(s) were found
- **visible**: logical: is the object visible
- **dups**: logical: is the object identical to one earlier in the list.

In computing whether objects are identical, their environments are ignored.

Normally the structure will be hidden by the `print` method. There is a `[]` method to extract one or more of the objects found.

For `argsAnywhere()` one or more argument lists as returned by `args`.

See Also

- `getS3method` to find the method which would be used: this might not be the one of those returned by `getAnywhere` since it might have come from a namespace which was unloaded or be registered under another name.
- `get`, `getFromNamespace`, `args`

Examples

```r
getAnywhere("format.dist")
getAnywhere("simpleLoess") # not exported from stats
argsAnywhere(format.dist)
```

### Description

Utility functions to access and replace the non-exported functions in a namespace, for use in developing packages with namespaces.

They should not be used in production code (except perhaps `assignInMyNamespace`, but see the ‘Note’).

### Usage

```r
getFromNamespace(x, ns, pos = -1, envir = as.environment(pos))
assignInNamespace(x, value, ns, pos = -1, envir = as.environment(pos))
assignInMyNamespace(x, value)
fixInNamespace(x, ns, pos = -1, envir = as.environment(pos), ...)
```
Arguments

- **x**: an object name (given as a character string).
- **value**: an R object.
- **ns**: a namespace, or character string giving the namespace.
- **pos**: where to look for the object: see `get`.
- **envir**: an alternative way to specify an environment to look in.
- **...**: arguments to pass to the editor: see `edit`.

Details

`assignInMyNamespace` is intended to be called from functions within a package, and chooses the namespace as the environment of the function calling it.

The namespace can be specified in several ways. Using, for example, `ns = "stats"` is the most direct, but a loaded package can be specified via any of the methods used for `get`: `ns` can also be the environment printed as `<namespace:foo>`.

`getFromNamespace` is similar to (but predates) the `:::` operator: it is more flexible in how the namespace is specified.

`fixInNamespace` invokes `edit` on the object named `x` and assigns the revised object in place of the original object. For compatibility with `fix`, `x` can be unquoted.

Value

`getFromNamespace` returns the object found (or gives an error).

`assignInNamespace`, `assignInMyNamespace` and `fixInNamespace` are invoked for their side effect of changing the object in the namespace.

Warning

`assignInNamespace` should not be used in final code, and will in future throw an error if called from a package. Already certain uses are disallowed.

Note

`assignInNamespace`, `assignInMyNamespace` and `fixInNamespace` change the copy in the namespace, but not any copies already exported from the namespace, in particular an object of that name in the package (if already attached) and any copies already imported into other namespaces. They are really intended to be used *only* for objects which are not exported from the namespace. They do attempt to alter a copy registered as an S3 method if one is found.

They can only be used to change the values of objects in the namespace, not to create new objects.

`get`, `fix`, `getS3method`
getParseData

Get Detailed Parse Information from Object

Description

If the "keep.source" option is TRUE, R’s parser will attach detailed information on the object it has parsed. These functions retrieve that information.

Usage

getParseData(x, includeText = NA)
getParseText(parseData, id)

Arguments

x an expression returned from parse, or a function or other object with source reference information
includeText logical; whether to include the text of parsed items in the result
parseData a data frame returned from getParseData
id a vector of item identifiers whose text is to be retrieved

Details

In version 3.0.0, the R parser was modified to include code written by Romain Francois in his parser package. This constructs a detailed table of information about every token and higher level construct in parsed code. This table is stored in the srcfile record associated with source references in the parsed code, and retrieved by the getParseData function.

Value

For getParseData:
If parse data is not present, NULL. Otherwise a data frame is returned, containing the following columns:

line1 integer. The line number where the item starts. This is the parsed line number called "parse" in getSrcLocation, which ignores #line directives.
col1 integer. The column number where the item starts. The first character is column 1. This corresponds to "column" in getSrcLocation.
line2 integer. The line number where the item ends.
getParseData

| col2       | integer. The column number where the item ends. |
| id         | integer. An identifier associated with this item. |
| parent     | integer. The id of the parent of this item. |
| token      | character string. The type of the token. |
| terminal   | logical. Whether the token is “terminal”, i.e. a leaf in the parse tree. |
| text       | character string. If includeText is TRUE, the text of all tokens; if it is NA (the default), the text of terminal tokens. If includeText == FALSE, this column is not included. Very long strings (with source of 1000 characters or more) will not be stored; a message giving their length and delimiter will be included instead. |

The rownames of the data frame will be equal to the id values, and the data frame will have a "srcfile" attribute containing the srcfile record which was used. The rows will be ordered by starting position within the source file, with parent items occurring before their children.

For getParseText:
A character vector of the same length as id containing the associated text items. If they are not included in parseData, they will be retrieved from the original file.

Note
There are a number of differences in the results returned by getParseData relative to those in the original parser code:
- Fewer columns are kept.
- The internal token number is not returned.
- col1 starts counting at 1, not 0.
- The id values are not attached to the elements of the parse tree, they are only retained in the table returned by getParseData.
- #line directives are identified, but other comment markup (e.g., roxygen comments) are not.

Parse data by design explore details of the parser implementation, which are subject to change without notice. Applications computing on the parse data may require updates for each R release.

fn <- function(x) {
  x + 1  # A comment, kept as part of the source
}
d <- getParseData(fn)
getS3method

Description
Get a method for an S3 generic, possibly from a namespace or the generic’s registry.

Usage
getS3method(f, class, optional = FALSE, envir = parent.frame())

Arguments
f
a character string giving the name of the generic.
class
a character string giving the name of the class.
optional
logical: should failure to find the generic or a method be allowed?
envir
the environment in which the method and its generic are searched first.

Details
S3 methods may be hidden in namespaces, and will not then be found by get: this function can retrieve such functions, primarily for debugging purposes.

Further, S3 methods can be registered on the generic when a namespace is loaded, and the registered method will be used if none is visible (using namespace scoping rules).

It is possible that which S3 method will be used may depend on where the generic f is called from: getS3method returns the method found if f were called from the same environment.

Value
The function found, or NULL if no function is found and optional = TRUE.

methods, get, getAnywhere

Examples
require(stats)
exists("predict.ppr") # false
getS3method("predict", "ppr")
getWindowsHandle  

Get a Windows Handle

Description
Get the Windows handle of a window or of the \texttt{R} process in MS Windows.

Usage
\begin{verbatim}
getWindowsHandle(which = "Console")
\end{verbatim}

Arguments

\begin{itemize}
\item \texttt{which}: a string (see below), or the number of a graphics device window (which must a windows one).
\end{itemize}

Details

\texttt{getWindowsHandle} gets the Windows handle. Possible choices for \texttt{which} are:

\begin{itemize}
\item "Console"  The console window handle.
\item "Frame"  The MDI frame window handle.
\item "Process"  The process pseudo-handle.
\item A device number  The window handle of a graphics device
\end{itemize}

These values are not normally useful to users, but may be used by developers making addons to \texttt{R}.

\texttt{NULL} is returned for the Frame handle if not running in MDI mode, for the Console handle when running \texttt{Rterm}, for any unrecognized string for \texttt{which}, or for a graphics device with no corresponding window.

Other windows (help browsers, etc.) are not accessible through this function.

Value
An external pointer holding the Windows handle, or \texttt{NULL}.

Note
This is only available on Windows.

See Also
\begin{verbatim}
getIdentification, getWindowsHandles
\end{verbatim}

Examples
\begin{verbatim}
if(.Platform$OS.type == "windows")
print( getWindowsHandle() )
\end{verbatim}
getWindowsHandles  Get handles of Windows in the MS Windows RGui

Description
This function gets the Windows handles of visible top level windows or windows within the R MDI frame (when using the Rgui).

Usage
getWindowsHandles(which = "R", pattern = "", minimized = FALSE)

Arguments
which A vector of strings "R" or "all" (possibly with repetitions). See the Details section.
pattern A vector of patterns that the titles of the windows must match.
minimized A logical vector indicating whether minimized windows should be considered.

Details
This function will search for Windows handles, for passing to external GUIs or to the arrangeWindows function. Each of the arguments may be a vector of values. These will be treated as follows:

• The arguments will all be recycled to the same length.
• The corresponding elements of each argument will be applied in separate searches.
• The final result will be the union of the windows identified in each of the searches.

If an element of which is "R", only windows belonging to the current R process will be returned. In MDI mode, those will be the child windows within the R GUI (Rgui) frame. In SDI mode, all windows belonging to the process will be included.

If the element is "all", then top level windows will be returned.

The elements of pattern will be used to make a subset of windows whose title text matches (according to grep) the pattern.

If minimized = FALSE, minimized windows will be ignored.

Value
A list of external pointers containing the window handles.

Note
This is only available on Windows.

Duncan Murdoch
glob2rx

Change Wildcard or Globbing Pattern into Regular Expression

Description

Change wildcard aka globbing patterns into the corresponding regular expressions (regexp).

Usage

glob2rx(pattern, trim.head = FALSE, trim.tail = TRUE)

Arguments

- **pattern**: character vector
- **trim.head**: logical specifying if leading "^.*" should be trimmed from the result.
- **trim.tail**: logical specifying if trailing ".*$" should be trimmed from the result.

Details

This takes a wildcard as used by most shells and returns an equivalent regular expression. ‘?’ is mapped to ‘.’ (match a single character), ‘*’ to ‘.*’ (match any string, including an empty one), and the pattern is anchored (it must start at the beginning and end at the end). Optionally, the resulting regexp is simplified.

Note that now even ‘(’, ‘[‘ and ‘{‘ can be used in pattern, but glob2rx() may not work correctly with arbitrary characters in pattern.

Value

A character vector of the same length as the input pattern where each wildcard is translated to the corresponding regular expression.

Author(s)

Martin Maechler, Unix/sed based version, 1991; current: 2004

See Also

regexp about regular expression, sub, etc about substitutions using regexps.
**Examples**

```r
call <- stopifnot(glob2rx("abc.*") == "^abc\.",
glob2rx("a?b.*") == "^a.b\.",
glob2rx("a?b.*", trim.tail = FALSE) == "^a.b\..*$",
glob2rx("*.doc") == "^.*\.[.doc]$",
glob2rx("*.doc", trim.head = TRUE) == "\.[.doc$",
glob2rx("*.t*") == "^.*\.[.t",
glob2rx("*.t??") == "^.*\.[.t..$",
glob2rx("*[*) == "^.*\["
```

**Description**

For `globalVariables`, the names supplied are of functions or other objects that should be regarded as defined globally when the check tool is applied to this package. The call to `globalVariables` will be included in the package’s source. Repeated calls in the same package accumulate the names of the global variables.

Typical examples are the fields and methods in reference classes, which appear to be global objects to `codetools`. (This case is handled automatically by `setRefClass()` and friends, using the supplied field and method names.)

For `suppressForeignCheck`, the names supplied are of variables used as `NAME` in foreign function calls which should not be checked by `checkFF(registration = TRUE)`. Without this declaration, expressions other than simple character strings are assumed to evaluate to registered native symbol objects. The type of call (`.Call`, `.External`, etc.) and argument counts will be checked. With this declaration, checks on those names will usually be suppressed. (If the code uses an expression that should only be evaluated at runtime, the message can be suppressed by wrapping it in a `dontCheck` function call, or by saving it to a local variable, and suppressing messages about that variable. See the example below.)

**Usage**

```r
globalVariables(names, package, add = TRUE)
suppressForeignCheck(names, package, add = TRUE)
```

**Arguments**

- `names`  
  The character vector of object names. If omitted, the current list of global variables declared in the package will be returned, unchanged.

- `package`  
  The relevant package, usually the character string name of the package but optionally its corresponding namespace environment.

  When the call to `globalVariables` or `suppressForeignCheck` comes in the package's source file, the argument is normally omitted, as in the example below.

- `add`  
  Should the contents of `names` be added to the current global variables or replace it?
Details

The lists of declared global variables and native symbol objects are stored in a metadata object in the package’s namespace, assuming the `globalVariables` or `suppressForeignCheck` call(s) occur as top-level calls in the package’s source code.

The check command, as implemented in package `tools`, queries the list before checking the R source code in the package for possible problems.

`globalVariables` was introduced in R 2.15.1 and `suppressForeignCheck` was introduced in R 3.1.0 so both should be used conditionally: see the example.

Value

`globalVariables` returns the current list of declared global variables, possibly modified by this call.

`suppressForeignCheck` returns the current list of native symbol objects which are not to be checked.

Note

The global variables list really belongs to a restricted scope (a function or a group of method definitions, for example) rather than the package as a whole. However, implementing finer control would require changes in `check` and/or in `codetools`, so in this version the information is stored at the package level.

Author(s)

John Chambers and Duncan Murdoch

See Also

dontCheck.

Examples

```r
## Not run:
## assume your package has some code that assigns ".obj1" and ".obj2"
## but not in a way that codetools can find.
## In the same source file (to remind you that you did it) add:
if(getRversion() >= "2.15.1") utils::globalVariables(c(".obj1", ".obj2"))

## To suppress messages about a run-time calculated native symbol,
## save it to a local variable.

## At top level, put this:
if(getRversion() >= "3.1.0") utils::suppressForeignCheck("localvariable")

## Within your function, do the call like this:
localvariable <- if (condition) entry1 else entry2
.Call(localvariable, 1, 2, 3)

## HOWEVER, it is much better practice to write code
## that can be checked thoroughly, e.g.
if(condition) .Call(entry1, 1, 2, 3) else .Call(entry2, 1, 2, 3)

## End(Not run)
```
## Hash Tables (Experimental)

### Description
Create and manipulate mutable hash tables.

### Usage
- `hash tab(type = c("identical", "address"), size)`
- `gethash(h, key, nomatch = NULL)`
- `sethash(h, key, value)`
- `remhash(h, key)`
- `numhash(h)`
- `typhash(h)`
- `maphash(h, FUN)`
- `clrhash(h)`
- `is.hashtab(x)`
- `h[[key, nomatch = NULL, ...]]`
- `h[[key, ...]] <- value`
- `print(x, ...)`
- `format(x, ...)`
- `length(x)`
- `str(object, ...)`

### Arguments
- **type**: character string specifying the hash table type.
- **size**: an integer specifying the expected number of entries.
- **h, object**: a hash table.
- **key**: an R object to use as a key.
- **nomatch**: value to return if key does not match.
- **value**: new value to associate with key.
- **FUN**: a function of two arguments, the key and the value, to call for each entry.
- **x**: object to be tested, printed, or formatted.
- **...**: additional arguments.

### Details
Hash tables are a data structure for efficiently associating keys with values. Hash tables are similar to environments, but keys can be arbitrary objects. Like environments, and unlike named lists and most other objects in R, hash tables are mutable, i.e., they are not copied when modified and assignment means just giving a new name to the same object.
New hash tables are created by `hashtab`. Two variants are available: keys can be considered to match if they are `identical()` (type = "identical", the default), or if their addresses in memory are equal (type = "address"). The default "identical" type is almost always the right choice. The size argument provides a hint for setting the initial hash table size. The hash table will grow if necessary, but specifying an expected size can be more efficient.

`gethash` returns the value associated with `key`. If `key` is not present in the table, then the value of `nomatch` is returned.

`sethash` adds a new key/value association or changes the current value for an existing key. `remhash` removes the entry for `key`, if there is one.

`maphash` calls `FUN` for each entry in the hash table with two arguments, the `key` and the `entry` value. The order in which the entries are processed is not predictable. The consequence of `FUN` adding entries to the table or deleting entries from the table is also not predictable, except that removing the entry currently being processed will have the desired effect.

`clrhash` removes all entries from the hash table.

### Value

`hashtab` returns a new hash table of the specified type.

`gethash` returns the value associated with `key`, or `nomatch` if there is no such value.

`sethash` returns `value` invisibly.

`remhash` invisibly returns `TRUE` if an entry for `key` was found and removed, and `FALSE` if no entry was found.

`numhash` returns the current number of entries in the table.

`typhash` returns a character string specifying the type of the hash table, one of "identical" or "address".

`maphash` and `clrhash` return `NULL` invisibly.

### Notes

The interface design is based loosely on hash table support in Common Lisp.

The hash function and equality test used for "identical" hash tables are the same as the ones used internally by `duplicated` and `unique`, with two exceptions:

- Closure environments are not ignored when comparing closures. This corresponds to calling `identical()` with `ignore.environment = FALSE`, which is the default for `identical()`.

- External pointer objects are compared as reference objects, corresponding to calling `identical()` with `extptr.as.ref = TRUE`. This ensures that hash tables with keys containing external pointers behave reasonably when serialized and unserialized.

As an experimental feature, the element operator `[[` can also be used get or set hash table entries, and `length` can be used to obtain the number of entries. It is not yet clear whether this is a good idea.

### Examples

```
## Create a new empty hash table.
h1 <- hashtab()
h1

## Add some key/value pairs.
```
hasName

```r
sethash(h1, NULL, 1)
sethash(h1, .GlobalEnv, 2)
for (i in seq_along(LETTERS)) sethash(h1, LETTERS[i], i)

## Look up values for some keys.
gethash(h1, NULL)
gethash(h1, .GlobalEnv)
gethash(h1, "Q")

## Remove an entry.
(remhash(h1, NULL))
gethash(h1, NULL)
(remhash(h1, "XYZ"))

## Using the element operator.
h1["ABC"]
h1["ABC", nomatch = 77]
h1["ABC"] <- "DEF"
h1["ABC"]

## Integers and real numbers that are equal are considered different
## (not identical) as keys:
identical(3, 3L)
gethash(h1, 3L, "DEF")
gethash(h1, 3L)
gethash(h1, 3)

## Two variables can refer to the same hash table.
h2 <- h1
identical(h1, h2)
## set in one, see in the "other" <=> really one object with 2 names
sethash(h2, NULL, 77)
gethash(h1, NULL)
str(h1)

## An example of using maphash(): get all hashkeys of a hash table:
hashkeys <- function(h) {
  val <- vector("list", numhash(h))
  idx <- 0
  maphash(h, function(k, v) {
    idx <<- idx + 1
    val[idx] <<- list(k)
  })
  val
}

kList <- hashkeys(h1)
str(kList) # the *order* is "arbitrary" & cannot be "known"
```

## hasName

**Check for Name**

**Description**

hasName is a convenient way to test for one or more names in an R object.
Usage

hasName(x, name)

Arguments

x Any object.
name One or more character values to look for.

Details

hasName(x, name) is defined to be equivalent to name %in% names(x), though it will evaluate slightly more quickly. It is intended to replace the common idiom !is.null(x$name). The latter can be unreliable due to partial name matching; see the example below.

Value

A logical vector of the same length as name containing TRUE if the corresponding entry is in names(x).

See Also

%in%, exists

Examples

x <- list(abc = 1, def = 2)
!is.null(x$abc) # correct
!is.null(x$a) # this is the wrong test!
hasName(x, "abc")
hasName(x, "a")

Description

Returns the first or last parts of a vector, matrix, table, data frame or function. Since head() and tail() are generic functions, they may also have been extended to other classes.

Usage

head(x, ...)
## Default S3 method:
head(x, n = 6L, ...)
## S3 method for class 'matrix'
head(x, n = 6L, ...) # is exported as head.matrix()
## NB: The methods for 'data.frame' and 'array' are identical to the 'matrix' one

## S3 method for class 'ftable'
head(x, n = 6L, ...)
## S3 method for class 'function'
head(x, n = 6L, ...)
tail(x, ...)  
## Default S3 method:  
tail(x, n = 6L, keepnums = FALSE, addrownums, ...)  
## S3 method for class 'matrix'  
tail(x, n = 6L, keepnums = TRUE, addrownums, ...) # exported as tail.matrix()  
## NB: The methods for 'data.frame', 'array', and 'table'  
## S3 method for class 'ftable'  
tail(x, n = 6L, keepnums = FALSE, addrownums, ...)  
## S3 method for class 'function'  
tail(x, n = 6L, ...)  

Arguments  

x an object  
n an integer vector of length up to dim(x) (or 1, for non-dimensioned objects). A logical is silently coerced to integer. Values specify the indices to be selected in the corresponding dimension (or along the length) of the object. A positive value of n[i] includes the first/last n[i] indices in that dimension, while a negative value excludes the last/first abs(n[i]), including all remaining indices. NA or non-specified values (when length(n) < length(dim(x))) select all indices in that dimension. Must contain at least one non-missing value.  

keepnums in each dimension, if no names in that dimension are present, create them using the indices included in that dimension. Ignored if dim(x) is NULL or its length 1.  

addrownums deprecated - keepnums should be used instead. Taken as the value of keepnums if it is explicitly set when keepnums is not.  

... arguments to be passed to or from other methods.  

Details  

For vector/array based objects, head() (tail()) returns a subset of the same dimensionality as x, usually of the same class. For historical reasons, by default they select the first (last) 6 indices in the first dimension ("rows") or along the length of a non-dimensioned vector, and the full extent (all indices) in any remaining dimensions. head.matrix() and tail.matrix() are exported.  

The default and array(matrix) methods for head() and tail() are quite general. They will work as is for any class which has a dim() method, a length() method (only required if dim() returns NULL), and a [ method (that accepts the drop argument and can subset in all dimensions in the dimensioned case).  

For functions, the lines of the deparsed function are returned as character strings.  

When x is an array(matrix) of dimensionality two and more, tail() will add dimnames similar to how they would appear in a full printing of x for all dimensions k where n[k] is specified and non-missing and dimnames(x)[[k]] (or dimnames(x) itself) is NULL. Specifically, the form of the added dimnames will vary for different dimensions as follows:  

k=1 (rows): "[n,]" (right justified with whitespace padding)  
k=2 (columns): "[n]" (with no whitespace padding)  
k>2 (higher dims): "n", i.e., the indices as character values
Setting `keepnums = FALSE` suppresses this behaviour.

As `data.frame` subsetting (‘indexing’) keeps attributes, so do the `head()` and `tail()` methods for data frames.

**Value**

An object (usually) like `x` but generally smaller. Hence, for arrays, the result corresponds to `x[., , drop=FALSE]`. For `ftable` objects `x`, a transformed `format(x)`.

**Note**

For array inputs the output of `tail` when `keepnums` is TRUE, any dimnames vectors added for dimensions >2 are the original numeric indices in that dimension as character vectors. This means that, e.g., for 3-dimensional array `arr`, `tail(arr, c(2,2,-1))[ , , 2]` and `tail(arr, c(2,2,-1))[ , , "2"]` may both be valid but have completely different meanings.

**Author(s)**

Patrick Burns, improved and corrected by R-Core. Negative argument added by Vincent Goulet. Multi-dimension support added by Gabriel Becker.

**Examples**

```r
head(letters)
head(letters, n = -6L)

head(freeny.x, n = 10L)
head(freeny.y)

head(iris3)
head(iris3, c(6L, 2L))
head(iris3, c(6L, -1L, 2L))

tail(letters)
tail(letters, n = -6L)

tail(freeny.x)
## the bottom-right "corner":
tail(freeny.x, n = c(4, 2))
tail(freeny.y)

tail(iris3)
tail(iris3, c(6L, 2L))
tail(iris3, c(6L, -1L, 2L))

## iris with dimnames stripped
a3d <- iris3; dimnames(a3d) <- NULL
tail(a3d, c(6, -1, 2)) # keepnums = TRUE is default here!
tail(a3d, c(6, -1, 2), keepnums = FALSE)

## data frame w/ a (non-standard) attribute:
treesS <- structure(trees, foo = "bar")
(n <- nrow(treesS))
stopifnot(exprs = { # attribute is kept
  identical(htS <- head(treesS), treesS[1:6, ])
  identical(attr(htS, "foo"), "bar")
})
```
help

Documentation

Description

help is the primary interface to the help systems.

Usage

help(topic, package = NULL, lib.loc = NULL,
      verbose = getOption("verbose"),
      try.all.packages = getOption("help.try.all.packages"),
      help_type = getOption("help_type"))

Arguments

topic usually a name or character string specifying the topic for which help is sought. A character string (enclosed in explicit single or double quotes) is always taken as naming a topic.

If the value of topic is a length-one character vector the topic is taken to be the value of the only element. Otherwise topic must be a name or a reserved word (if syntactically valid) or character string.

See ‘Details’ for what happens if this is omitted.

package a name or character vector giving the packages to look into for documentation, or NULL. By default, all packages whose namespaces are loaded are used. To avoid a name being deparsed use e.g. (pkg_ref) (see the examples).

lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries. This is not used for HTML help (see ‘Details’).

verbose logical; if TRUE, the file name is reported.
try.all.packages
    logical; see Note.
help_type  character string: the type of help required. Possible values are "text", "html" and "pdf". Case is ignored, and partial matching is allowed.

Details

The following types of help are available:

- Plain text help
- HTML help pages with hyperlinks to other topics, shown in a browser by browseURL.
  (On Unix-alikes, where possible an existing browser window is re-used: the macOS GUI uses its own browser window.)
  If for some reason HTML help is unavailable (see startDynamicHelp), plain text help will be used instead.
- For help only, typeset as PDF – see the section on ‘Offline help’.

On Unix-alikes: The ‘factory-fresh’ default is text help except from the macOS GUI, which uses HTML help displayed in its own browser window.

On Windows: The default for the type of help is selected when R is installed – the ‘factory-fresh’ default is HTML help.

The rendering of text help will use directional quotes in suitable locales (UTF-8 and single-byte Windows locales): sometimes the fonts used do not support these quotes so this can be turned off by setting options(useFancyQuotes = FALSE).

topic is not optional: if it is omitted R will give

- If a package is specified, (text or, in interactive use only, HTML) information on the package, including hints/links to suitable help topics.
- If lib.loc only is specified, a (text) list of available packages.
- Help on help itself if none of the first three arguments is specified.

Some topics need to be quoted (by backticks) or given as a character string. These include those which cannot syntactically appear on their own such as unary and binary operators, function and control-flow reserved words (including if, else for, in, repeat, while, break and next). The other reserved words can be used as if they were names, for example TRUE, NA and Inf.

If multiple help files matching topic are found, in interactive use a menu is presented for the user to choose one: in batch use the first on the search path is used. (For HTML help the menu will be an HTML page, otherwise a graphical menu if possible if getOption("menu.graphics") is true, the default.)

Note that HTML help does not make use of lib.loc: it will always look first in the loaded packages and then along .libPaths().

Offline help

Typeset documentation is produced by running the LaTeX version of the help page through pdflatex: this will produce a PDF file.

The appearance of the output can be customized through a file ‘Rhelp.cfg’ somewhere in your LaTeX search path: this will be input as a LaTeX style file after Rd.sty. Some environment variables are consulted, notably R_PAPERSIZE (via getOption("papersize")) and R_RD4PDF (see ‘Making manuals’ in the ‘R Installation and Administration’ manual).
If there is a function \texttt{offline\_help\_helper} in the workspace or further down the search path it is used to do the typesetting, otherwise the function of that name in the \texttt{utils} namespace (to which the first paragraph applies). It should accept at least two arguments, the name of the \LaTeX{} file to be typeset and the type (which is nowadays ignored). It accepts a third argument, \texttt{texinputs}, which will give the graphics path when the help document contains figures, and will otherwise not be supplied.

\textbf{Note}

Unless \texttt{lib.loc} is specified explicitly, the loaded packages are searched before those in the specified libraries. This ensures that if a library is loaded from a library not in the known library trees, then the help from the loaded library is used. If \texttt{lib.loc} is specified explicitly, the loaded packages are not searched.

If this search fails and argument \texttt{try.all.packages} is \texttt{TRUE} and neither \texttt{packages} nor \texttt{lib.loc} is specified, then all the packages in the known library trees are searched for help on \texttt{topic} and a list of (any) packages where help may be found is displayed (with hyperlinks for \texttt{help\_type = "html"}). NB: searching all packages can be slow, especially the first time (caching of files by the OS can expedite subsequent searches dramatically).

\textbf{References}

\textbf{See Also}

\texttt{?} for shortcuts to help topics. \texttt{help.search()} or \texttt{??} for finding help pages on a vague topic; \texttt{help.start()} which opens the HTML version of the \texttt{R} help pages; \texttt{library()} for listing available packages and the help objects they contain; \texttt{data()} for listing available data sets; \texttt{methods()}. Use \texttt{prompt()} to get a prototype for writing help pages of your own package.

\textbf{Examples}

\begin{verbatim}
help()
help(help) # the same

help(lapply)

help("for") # or ?"for", but quotes/backticks are needed

try({# requires working TeX installation:
  help(dgamma, help_type = "pdf")
  ## -> nicely formatted pdf -- including math formula -- for help(dgamma):
  system2(getOption("pdfviewer"), "dgamma.pdf", wait = FALSE)
})

help(package = "splines") # get help even when package is not loaded

topi <- "women"
help(topi)

try(help("bs", try.all.packages = FALSE)) # reports not found (an error)
help("bs", try.all.packages = TRUE) # reports can be found
\end{verbatim}
help.request

# in package 'splines'

## For programmatic use:

```
topic <- "family"; pkg_ref <- "stats"
help((topic), (pkg_ref))
```

---

**help.request**  
**Send a Post to R-help**

**Description**

Prompts the user to check they have done all that is expected of them before sending a post to the R-help mailing list, provides a template for the post with session information included and optionally sends the email (on Unix systems).

**Usage**

```
help.request(subject = "",
             address = "r-help@R-project.org",
             file = "R.help.request", ...)
```

**Arguments**

- **subject**: subject of the email. Please do not use single quotes (’) in the subject! Post separate help requests for multiple queries.
- **address**: recipient’s email address.
- **file**: filename to use (if needed) for setting up the email.
- **...**: additional named arguments such as method and ccaddress to pass to `create.post`.

**Details**

This function is not intended to replace the posting guide. Please read the guide before posting to R-help or using this function (see [https://www.r-project.org/posting-guide.html](https://www.r-project.org/posting-guide.html)).

The `help.request` function:

- asks whether the user has consulted relevant resources, stopping and opening the relevant URL if a negative response is given.
- checks whether the current version of R is being used and whether the add-on packages are up-to-date, giving the option of updating where necessary.
- asks whether the user has prepared appropriate (minimal, reproducible, self-contained, commented) example code ready to paste into the post.

Once this checklist has been completed a template post is prepared including current session information, and passed to `create.post`.

**Value**

Nothing useful.
help.search

Author(s)

Heather Turner, based on the then current code and help page of `bug.report()`.

`create.post`.

description

Search the Help System

Description

Allows for searching the help system for documentation matching a given character string in the (file) name, alias, title, concept or keyword entries (or any combination thereof), using either fuzzy matching or regular expression matching. Names and titles of the matched help entries are displayed nicely formatted.

Vignette names, titles and keywords and demo names and titles may also be searched.

Usage

`help.search(pattern, fields = c("alias", "concept", "title"),
apropos, keyword, whatis, ignore.case = TRUE,
package = NULL, lib.loc = NULL,
help.db = getOption("help.db"),
verbose = getOption("verbose"),
rebuild = FALSE, agrep = NULL, use_UTF8 = FALSE,
types = getOption("help.search.types"))`

Arguments

- `pattern`: a character string to be matched in the specified fields. If this is given, the arguments `apropos`, `keyword`, and `whatis` are ignored.
- `fields`: a character vector specifying the fields of the help database to be searched. The entries must be abbreviations of "name", "title", "alias", "concept", and "keyword", corresponding to the help page’s (file) name, its title, the topics and concepts it provides documentation for, and the keywords it can be classified to. See below for details and how vignettes and demos are searched.
- `apropos`: a character string to be matched in the help page topics and title.
- `keyword`: a character string to be matched in the help page ‘keywords’. ‘Keywords’ are really categories: the standard categories are listed in file ‘R.home("doc")/KEYWORDS’ (see also the example) and some package writers have defined their own. If `keyword` is specified, `agrep` defaults to `FALSE`.
- `whatis`: a character string to be matched in the help page topics.
- `ignore.case`: a logical. If `TRUE`, case is ignored during matching; if `FALSE`, pattern matching is case sensitive.
help.search

package a character vector with the names of packages to search through, or NULL in which case all available packages in the library trees specified by lib.loc are searched.

lib.loc a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.

help.db a character string giving the file path to a previously built and saved help database, or NULL.

verbose logical; if TRUE, the search process is traced. Integer values are also accepted, with TRUE being equivalent to 2, and 1 being less verbose. On Windows a progress bar is shown during rebuilding, and on Unix a heartbeat is shown for verbose = 1 and a package-by-package list for verbose >= 2.

rebuild a logical indicating whether the help database should be rebuilt. This will be done automatically if lib.loc or the search path is changed, or if package is used and a value is not found.

agrep if NULL (the default unless keyword is used) and the character string to be matched consists of alphanumeric characters, whitespace or a dash only, approximate (fuzzy) matching via agrep is used unless the string has fewer than 5 characters; otherwise, it is taken to contain a regular expression to be matched via grep. If FALSE, approximate matching is not used. Otherwise, one can give a numeric or a list specifying the maximal distance for the approximate match, see argument max.distance in the documentation for agrep.

use_UTF8 logical: should results be given in UTF-8 encoding? Also changes the meaning of regexps in agrep to be Perl regexps.

types a character vector listing the types of documentation to search. The entries must be abbreviations of "vignette" "help" or "demo". Results will be presented in the order specified.

field a single value of fields to search.

Details

Upon installation of a package, a pre-built help.search index is serialized as ‘hsearch.rds’ in the ‘Meta’ directory (provided the package has any help pages). Vignettes are also indexed in the ‘Meta/vignette.rds’ file. These files are used to create the help search database via hsearch_db.

The arguments apropos and whatis play a role similar to the Unix commands with the same names. Searching with agrep = FALSE will be several times faster than the default (once the database is built). However, approximate searches should be fast enough (around a second with 5000 packages installed).

If possible, the help database is saved in memory for use by subsequent calls in the session.

Note that currently the aliases in the matching help files are not displayed.

As with ?, in ?? the pattern may be prefixed with a package name followed by :: or ::: to limit the search to that package.

For help files, ‘\keyword‘ entries which are not among the standard keywords as listed in file ‘KEYWORDS‘ in the R documentation directory are taken as concepts. For standard keyword entries different from ‘internal’, the corresponding descriptions from file ‘KEYWORDS’ are additionally taken as concepts. All ‘\concept‘ entries used as concepts.

Vignettes are searched as follows. The ”name“ and ”alias“ are both the base of the vignette filename, and the ”concept“ entries are taken from the ‘\VignetteKeyword‘ entries. Vignettes are not classified using the help system ”keyword“ classifications. Demos are handled similarly to vignettes, without the ”concept“ search.
Value

The results are returned in a list object of class "hsearch", which has a print method for nicely formatting the results of the query. This mechanism is experimental, and may change in future versions of R.

In R.app on macOS, this will show up a browser with selectable items. On exiting this browser, the help pages for the selected items will be shown in separate help windows.

The internal format of the class is undocumented and subject to change.

See Also

hsearch_db for more information on the help search database employed, and for utilities to inspect available concepts and keywords.

help; help.start for starting the hypertext (currently HTML) version of R's online documentation, which offers a similar search mechanism.

RSiteSearch to access an on-line search of R resources.

apropos uses regexps and has nice examples.

Examples

help.search("linear models")  # In case you forgot how to fit linear # models
help.search("non-existent topic")

??utils::help # All the topics matching "help" in the utils package

## Documentation with topic/concept/title matching 'print'
## (disabling fuzzy matching to not also match 'point')
help.search("print", agrep = FALSE)
help.search(apropos = "print", agrep = FALSE) # ignores concepts

## Help pages with documented topics starting with 'try':
help.search("try", fields = "alias")
alias??"^try" # the same

## Help pages documenting high-level plots:
help.search(keyword = "hplot")

RShowDoc("KEYWORDS") # show all keywords

help.start  Hypertext Documentation

Description

Start the hypertext (currently HTML) version of R's online documentation.

Usage

help.start(update = FALSE, gui = "irrelevant",
            browser = getOption("browser"), remote = NULL)
Arguments

update logical: should this attempt to update the package index to reflect the currently available packages. (Not attempted if remote is non-NULL.)

gui just for compatibility with S-PLUS.

browser the name of the program to be used as hypertext browser. It should be in the PATH, or a full path specified. Alternatively, it can be an R function which will be called with a URL as its only argument. This option is normally unset on Windows, when the file-association mechanism will be used.

remote A character string giving a valid URL for the 'R_HOME' directory on a remote location.

Details

Unless remote is specified this requires the HTTP server to be available (it will be started if possible: see startDynamicHelp).

One of the links on the index page is the HTML package index, 'R_DOC_DIR/html/packages.html', which can be remade by make.packages.html(). For local operation, the HTTP server will remake a temporary version of this list when the link is first clicked, and each time thereafter check if updating is needed (if .libPaths has changed or any of the directories has been changed). This can be slow, and using update = TRUE will ensure that the packages list is updated before launching the index page.

Argument remote can be used to point to HTML help published by another R installation: it will typically only show packages from the main library of that installation.

See Also

help() for on- and off-line help in other formats.
browseURL for how the help file is displayed.
RSiteSearch to access an on-line search of R resources.

Examples

help.start()

# the 'remote' arg can be tested by
help.start(remote = paste0("file://", R.home()))

hsearch-utils Help Search Utilities

Description

Utilities for searching the help system.
Usage

```r
hsearch_db(package = NULL, lib.loc = NULL,
         types = getOption("help.search.types"),
         verbose = getOption("verbose"),
         rebuild = FALSE, use_UTF8 = FALSE)
```

```r
hsearch_db_concepts(db = hsearch_db())
hsearch_db_keywords(db = hsearch_db())
```

Arguments

- `package` : a character vector with the names of packages to search through, or `NULL` in which case all available packages in the library trees specified by `lib.loc` are searched.
- `lib.loc` : a character vector describing the location of R library trees to search through, or `NULL`. The default value of `NULL` corresponds to all libraries currently known.
- `types` : a character vector listing the types of documentation to search. See `help.search` for details.
- `verbose` : a logical controlling the verbosity of building the help search database. See `help.search` for details.
- `rebuild` : a logical indicating whether the help search database should be rebuilt. See `help.search` for details.
- `use_UTF8` : logical: should results be given in UTF-8 encoding?
- `db` : a help search database as obtained by calls to `hsearch_db()`.

Details

`hsearch_db()` builds and caches the help search database for subsequent use by `help.search`. (In fact, re-builds only when forced (`rebuild = TRUE`) or “necessary”.)

The format of the help search database is still experimental, and may change in future versions. Currently, it consists of four tables: one with base information about all documentation objects found, including their names and titles and unique ids; three more tables contain the individual aliases, concepts and keywords together with the ids of the documentation objects they belong to. Separating out the latter three tables accounts for the fact that a single documentation object may provide several of these entries, and allows for efficient searching.

See the details in `help.search` for how searchable entries are interpreted according to help type.

`hsearch_db_concepts()` and `hsearch_db_keywords()` extract all concepts or keywords, respectively, from a help search database, and return these in a data frame together with their total frequencies and the numbers of packages they are used in, with entries sorted in decreasing total frequency.

Examples

```r
db <- hsearch_db()
# Total numbers of documentation objects, aliases, keywords and concepts (using the current format):
sapply(db, NROW)
# Can also be obtained from print method:
db
# 10 most frequent concepts:
head(hsearch_db_concepts(), 10)
# 10 most frequent keywords:
head(hsearch_db_keywords(), 10)
```
Install Add-on Packages

Description

Utility for installing add-on packages.

Usage

R CMD INSTALL [options] [-l lib] pkgs

Arguments

pkgs  a space-separated list with the path names of the packages to be installed. See ‘Details’.

lib  the path name of the R library tree to install to. Also accepted in the form ‘--library=lib’. Paths including spaces should be quoted, using the conventions for the shell in use.

options  a space-separated list of options through which in particular the process for building the help files can be controlled. Use R CMD INSTALL --help for the full current list of options.

Details

This will stop at the first error, so if you want all the pkgs to be tried, call this via a shell loop.

If used as R CMD INSTALL pkgs without explicitly specifying lib, packages are installed into the library tree rooted at the first directory in the library path which would be used by R run in the current environment.

To install into the library tree lib, use R CMD INSTALL -l lib pkgs. This prepends lib to the library path for duration of the install, so required packages in the installation directory will be found (and used in preference to those in other libraries).

Both lib and the elements of pkgs may be absolute or relative path names of directories. pkgs may also contain names of package archive files: these are then extracted to a temporary directory. These are tarballs containing a single directory, optionally compressed by gzip, bzip2, xz or compress. Finally, binary package archive files (as created by R CMD INSTALL --build) can be supplied.

Tarballs are by default unpackaged by the internal untar function: if needed an external tar command can be specified by the environment variable R_INSTALL_TAR: please ensure that it can handle the type of compression used on the tarball. (This is sometimes needed for tarballs containing invalid or unsupported sections, and can be faster on very large tarballs. Setting R_INSTALL_TAR to ‘tar.exe’ has been needed to overcome permissions issues on some Windows systems.)

The package sources can be cleaned up prior to installation by ‘--preclean’ or after by ‘--clean’: cleaning is essential if the sources are to be used with more than one architecture or platform.

Some package sources contain a ‘configure’ script that can be passed arguments or variables via the option ‘--configure-args’ and ‘--configure-vars’, respectively, if necessary. The latter is useful in particular if libraries or header files needed for the package are in non-system directories. In this case, one can use the configure variables LIBS and CPPFLAGS to specify these locations (and set these via ‘--configure-vars’), see section ‘Configuration variables’ in ‘R Installation and Administration’ for more information. (If these are used more than once on the command line they are concatenated.) The configure mechanism can be bypassed using the option ‘--no-configure’.
If the attempt to install the package fails, leftovers are removed. If the package was already installed, the old version is restored. This happens either if a command encounters an error or if the install is interrupted from the keyboard: after cleaning up the script terminates.

For details of the locking which is done, see the section ‘Locking’ in the help for install.packages.

Option ‘--build’ can be used to tar up the installed package for distribution as a binary package (as used on macOS). This is done by utils::tar unless environment variable R_INSTALL_TAR is set.

By default a package is installed with static HTML help pages if and only if R was: use options ‘--html’ and ‘--no-html’ to override this.

Packages are not by default installed keeping the source formatting (see the keep.source argument to source): this can be enabled by the option ‘--with-keep.source’ or by setting environment variable R_KEEP_PKG_SOURCE to yes.

Specifying the ‘--install-tests’ option copies the contents of the ‘tests’ directory into the package installation. If the R_ALWAYS_INSTALL_TESTS environment variable is set to a true value, the tests will be installed even if ‘--install-tests’ is omitted.

Use R CMD INSTALL --help for concise usage information, including all the available options.

Sub-architectures

An R installation can support more than one sub-architecture: currently this is most commonly used for 32- and 64-bit builds on Windows.

For such installations, the default behaviour is to try to install source packages for all installed sub-architectures unless the package has a configure script or a ‘src/Makefile’ (or ‘src/Makefile.win’ on Windows), when only compiled code for the sub-architecture running R CMD INSTALL is installed.

To install a source package with compiled code only for the sub-architecture used by R CMD INSTALL, use ‘--no-multiarch’. To install just the compiled code for another sub-architecture, use ‘--libs-only’.

There are two ways to install for all available sub-architectures. If the configure script is known to work for both Windows architectures, use flag ‘--force-biarch’ (and packages can specify this via a ‘Biarch: yes’ field in their DESCRIPTION files). Second, a single tarball can be installed with

R CMD INSTALL --merge-multiarch mypkg_version.tar.gz

Staged installation

The default way to install source packages changed in R 3.6.0, so packages are first installed to a temporary location and then (if successful) moved to the destination library directory. Some older packages were written in ways that assume direct installation to the destination library.

Staged installation can currently be overridden by having a line ‘StagedInstall: no’ in the package’s DESCRIPTION file, via flag ‘--no-staged-install’ or by setting environment variable R_INSTALL_STAGED to a false value (e.g. ‘false’ or ‘no’).

Staged installation requires either ‘--pkglock’ or ‘--lock’, one of which is used by default.

Note

The options do not have to precede ‘pkgs’ on the command line, although it will be more legible if they do. All the options are processed before any packages, and where options have conflicting effects the last one will win.
Some parts of the operation of INSTALL depend on the R temporary directory (see `tempdir`, usually under ‘/tmp’) having both write and execution access to the account running R. This is usually the case, but if ‘/tmp’ has been mounted as noexec, environment variable `TMPDIR` may need to be set to a directory from which execution is allowed.

`REMOVE`, `.libPaths` for information on using several library trees; `install.packages` for R-level installation of packages; `update.packages` for automatic update of packages using the Internet or a local repository.

The chapter on ‘Add-on packages’ in ‘R Installation and Administration’ and the chapter on ‘Creating R packages’ in ‘Writing R Extensions’ via `RShowDoc` or in the ‘doc/manual’ subdirectory of the R source tree.

install.packages

Install Packages from Repositories or Local Files

Description

Download and install packages from CRAN-like repositories or from local files.

Usage

```r
install.packages(pkgs, lib, repos = getOption("repos"),
               contriburl = contrib.url(repos, type),
               method, available = NULL, destdir = NULL,
               dependencies = NA, type = getOption("pkgType"),
               configure.args = getOption("configure.args"),
               configure.vars = getOption("configure.vars"),
               clean = FALSE, Ncpus = getOption("Ncpus", 1L),
               verbose = getOption("verbose"),
               libs_only = FALSE, INSTALL_opts, quiet = FALSE,
               keep_outputs = FALSE, ...)
```

Arguments

- `pkgs` character vector of the names of packages whose current versions should be downloaded from the repositories.

If `repos = NULL`, a character vector of file paths, on Windows, file paths of '.zip' files containing binary builds of packages. ('http:///' and 'file:///' URLs are also accepted and the files will be downloaded and installed from local copies.) Source directories or file paths or URLs of archives may be specified with `type = "source"`, but some packages need suitable tools installed (see the 'Details' section).

On Unix-alikes, these file paths can be source directories or archives or binary package archive files (as created by `R CMD build --binary`). ('http:///' and 'file:///' URLs are also accepted and the files will be downloaded and installed from local copies.) On a CRAN build of R for macOS these can be '.tgz' files containing binary package archives. Tilde-expansion will be done on file paths.
If this is missing, a listbox of available packages is presented where possible in an interactive R session.

lib character vector giving the library directories where to install the packages. Recycled as needed. If missing, defaults to the first element of .libPaths().

repos character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as "https://cloud.R-project.org". For more details on supported URL schemes see url.

Can be NULL to install from local files, directories or URLs: this will be inferred by extension from pkgs if of length one.

contriburl URL(s) of the contrib sections of the repositories. Use this argument if your repository mirror is incomplete, e.g., because you mirrored only the 'contrib' section, or only have binary packages. Overrides argument repos. Incompatible with type = "both".

method download method, see download.file. Unused if a non-NULL available is supplied.

available a matrix as returned by available.packages listing packages available at the repositories, or NULL when the function makes an internal call to available.packages. Incompatible with type = "both".

destdir directory where downloaded packages are stored. If it is NULL (the default) a subdirectory downloaded_packages of the session temporary directory will be used (and the files will be deleted at the end of the session).

dependencies logical indicating whether to also install uninstalled packages which these packages depend on/link to/import/suggest (and so on recursively). Not used if repos = NULL. Can also be a character vector, a subset of c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances").

Only supported if lib is of length one (or missing), so it is unambiguous where to install the dependent packages. If this is not the case it is ignored, with a warning.

The default, NA, means c("Depends", "Imports", "LinkingTo").

TRUE means to use c("Depends", "Imports", "LinkingTo", "Suggests") for pkgs and c("Depends", "Imports", "LinkingTo") for added dependencies: this installs all the packages needed to run pkgs, their examples, tests and vignettes (if the package author specified them correctly).

In all of these, "LinkingTo" is omitted for binary packages.

type character, indicating the type of package to download and install. Will be "source" except on Windows and some macOS builds: see the section on 'Binary packages' for those.

configure.args (Used only for source installs.) A character vector or a named list. If a character vector with no names is supplied, the elements are concatenated into a single string (separated by a space) and used as the value for the '--configure-args' flag in the call to R CMD INSTALL. If the character vector has names these are assumed to identify values for '--configure-args' for individual packages. This allows one to specify settings for an entire collection of packages which will be used if any of those packages are to be installed. (These settings can therefore be re-used and act as default settings.)

A named list can be used also to the same effect, and that allows multi-element character strings for each package which are concatenated to a single string to be used as the value for '--configure-args'.

configure.vars (Used only for source installs.) Analogous to configure.args for flag `--configure-vars`, which is used to set environment variables for the configure run.

clean a logical value indicating whether to add the `--clean` flag to the call to R CMD INSTALL. This is sometimes used to perform additional operations at the end of the package installation in addition to removing intermediate files.

Ncpus the number of parallel processes to use for a parallel install of more than one source package. Values greater than one are supported if the make command specified by Sys.getenv("MAKE", "make") accepts argument `--k -j <Ncpus>`.

verbose a logical indicating if some “progress report” should be given.

libs_only a logical value: should the `--libs-only` option be used to install only additional sub-architectures for source installs? (See also INSTALL_opts.) This can also be used on Windows to install just the DLL(s) from a binary package, e.g. to add 64-bit DLLs to a 32-bit install.

INSTALL_opts an optional character vector of additional option(s) to be passed to R CMD INSTALL for a source package install. E.g., c("--html", "--no-multiarch", "--no-test-load"). Can also be a named list of character vectors to be used as additional options, with names the respective package names.

quiet logical: if true, reduce the amount of output. This is not passed to available.packages() in case that is called, on purpose.

keep_outputs a logical: if true, keep the outputs from installing source packages in the current working directory, with the names of the output files the package names with ‘.out’ appended (overwriting existing files, possibly from previous installation attempts). Alternatively, a character string giving the directory in which to save the outputs. Ignored when installing from local files.

... further arguments to be passed to download.file, available.packages, or to the functions for binary installs on macOS and Windows (which accept an argument "lock": see the section on ‘Locking’).

Details

This is the main function to install packages. It takes a vector of names and a destination library, downloads the packages from the repositories and installs them. (If the library is omitted it defaults to the first directory in .libPaths(), with a message if there is more than one.) If lib is omitted or is of length one and is not a (group) writable directory, in interactive use the code offers to create a personal library tree (the first element of Sys.getenv("R_LIBS_USER")) and install there.

Detection of a writable directory is problematic on Windows: see the ‘Note’ section.

For installs from a repository an attempt is made to install the packages in an order that respects their dependencies. This does assume that all the entries in lib are on the default library path for installs (set by environment variable R_LIBS).

You are advised to run update.packages before install.packages to ensure that any already installed dependencies have their latest versions.

Value

Invisible NULL.
Binary packages

This section applies only to platforms where binary packages are available: Windows and CRAN builds for macOS.

R packages are primarily distributed as source packages, but binary packages (a packaging up of the installed package) are also supported, and the type most commonly used on Windows and by the CRAN builds for macOS. This function can install either type, either by downloading a file from a repository or from a local file.

Possible values of type are (currently) "source", "mac.binary", and "win.binary": the appropriate binary type where supported can also be selected as "binary".

For a binary install from a repository, the function checks for the availability of a source package on the same repository, and reports if the source package has a later version, or is available but no binary version is. This check can be suppressed by using

```r
options(install.packages.check.source = "no")
```

and should be if there is a partial repository containing only binary files.

An alternative (and the current default) is "both" which means 'use binary if available and current, otherwise try source'. The action if there are source packages which are preferred but may contain code which needs to be compiled is controlled by `getOption("install.packages.compile.from.source")`. type = "both" will be silently changed to "binary" if either contriburl or available is specified.

Using packages with type = "source" always works provided the package contains no C/C++/Fortran code that needs compilation. Otherwise,

on Windows, you will need to have installed the Rtools collection as described in the 'R for Windows FAQ' and you must have the PATH environment variable set up as required by Rtools.

For a 32/64-bit installation of R on Windows, a small minority of packages with compiled code need either INSTALL_opts = "--force-biarch" or INSTALL_opts = "--merge-multiarch" for a source installation. (It is safe to always set the latter when installing from a repository or tarballs, although it will be a little slower.)

When installing a package on Windows, `install.packages` will abort the install if it detects that the package is already installed and is currently in use. In some circumstances (e.g., multiple instances of R running at the same time and sharing a library) it will not detect a problem, but the installation may fail as Windows locks files in use.

On Unix-alikes, when the package contains C/C++/Fortran code that needs compilation, suitable compilers and related tools need to be installed. On macOS you need to have installed the 'Command-line tools for Xcode' (see the 'R Installation and Administration' manual) and if needed by the package a Fortran compiler, and have them in your path.

Locking

There are various options for locking: these differ between source and binary installs.

By default for a source install, the library directory is 'locked' by creating a directory `00LOCK` within it. This has two purposes: it prevents any other process installing into that library concurrently, and is used to store any previous version of the package to restore on error. A finer-grained locking is provided by the option `--pkglock` which creates a separate lock for each package: this allows enough freedom for parallel installation. Per-package locking is the default when installing a single package, and for multiple packages when `Ncpus > 1L`. Finally locking (and restoration on error) can be suppressed by `--no-lock`.
install.packages

For a macOS binary install, no locking is done by default. Setting argument lock to TRUE (it defaults to the value of `getOption("install.lock", FALSE)`) will use per-directory locking as described for source installs. For Windows binary install, per-directory locking is used by default (lock defaults to the value of `getOption("install.lock", TRUE)`). If the value is "pkglock" per-package locking will be used.

If package locking is used on Windows with `libs_only = TRUE` and the installation fails, the package will be restored to its previous state.

Note that it is possible for the package installation to fail so badly that the lock directory is not removed: this inhibits any further installs to the library directory (or for `--pkglock`, of the package) until the lock directory is removed manually.

Parallel installs

Parallel installs are attempted if `pkgs` has length greater than one and `Ncpus > 1`. It makes use of a parallel make, so the make specified (default make) when `R` was built must be capable of supporting `make -j N`: GNU make, `dmake` and `pmake` do, but Solaris make and older FreeBSD make do not: if necessary environment variable `MAKE` can be set for the current session to select a suitable make.

`install.packages` needs to be able to compute all the dependencies of `pkgs` from `available`, including if one element of `pkgs` depends indirectly on another. This means that if for example you are installing CRAN packages which depend on Bioconductor packages which in turn depend on CRAN packages, `available` needs to cover both CRAN and Bioconductor packages.

Timeouts

A limit on the elapsed time for each call to `R CMD INSTALL` (so for source installs) can be set via environment variable `_R_INSTALL_PACKAGES_ELAPSED_TIMEOUT_` in seconds (or in minutes or hours with optional suffix 'm' or 'h', suffix 's' being allowed for the default seconds) with 0 meaning no limit.

For non-parallel installs this is implemented via the `timeout` argument of `system2`: for parallel installs via the OS’s `timeout` command. (The one tested is from GNU `coreutils`, commonly available on Linux but not other Unix-alikes. If no such command is available the timeout request is ignored, with a warning. On Windows, one needs to specify a suitable timeout command via environment variable `R_TIMEOUT`, because `c:/Windows/system32/timeout.exe` is not.) For parallel installs a ‘Error 124’ message from `make` indicates that timeout occurred.

Timeouts during installation might leave lock directories behind and not restore previous versions.

Version requirements on source installs

If you are not running an up-to-date version of `R` you may see a message like

```
package ‘RODBC’ is not available (for R version 3.5.3)
```

One possibility is that the package is not available in any of the selected repositories; another is that is available but only for current or recent versions of `R`. For CRAN packages take a look at the package’s CRAN page (e.g., https://cran.r-project.org/package=RODBC). If that indicates in the ‘Depends’ field a dependence on a later version of `R` you will need to look in the ‘Old sources’ section and select the URL of a version of comparable age to your `R`. Then you can supply that URL as the first argument of `install.packages()`: you may need to first manually install its dependencies.

For other repositories, using `available.packages(filters = "OS_type")[pkgname, ]` will show if the package is available for any `R` version (for your OS).
Note

On Unix-alikes: Some binary distributions of \texttt{R} have \texttt{INSTALL} in a separate bundle, e.g.
an \texttt{R-devel} RPM. \texttt{install.packages} will give an error if called with \texttt{type} = "source" on such
a system.

Some binary Linux distributions of \texttt{R} can be installed on a machine without the tools needed
to install packages: a possible remedy is to do a complete install of \texttt{R} which should bring in
all those tools as dependencies.

On Windows: \texttt{install.packages} tries to detect if you have write permission on the library di-
rectories specified, but Windows reports unreliably. If there is only one library directory (the
default), \texttt{R} tries to find out by creating a test directory, but even this need not be the whole
story: you may have permission to write in a library directory but lack permission to write
binary files (such as '*.dll' files) there. See the ‘\texttt{R} for Windows FAQ’ for workarounds.

Examples

\begin{verbatim}
## Not run:
## A Linux example for Fedora's layout of udunits2 headers.
install.packages(c("ncdf4", "RNetCDF"),
    configure.args = c(RNetCDF = "--with-netcdf-include=/usr/include/udunits2"))
## End(Not run)
\end{verbatim}

\section*{Description}

Find (or retrieve) details of all packages installed in the specified libraries.

\section*{Usage}

\begin{verbatim}
install.packages(lib.loc = NULL, priority = NULL,
    noCache = FALSE, fields = NULL,
    subarch = .Platform$arch, ...)
\end{verbatim}
Arguments

lib.loc  character vector describing the location of R library trees to search through, or NULL for all known trees (see .libPaths).

priority  character vector or NULL (default). If non-null, used to select packages; "high" is equivalent to c("base", "recommended"). To select all packages without an assigned priority use priority = NA_character_.

noCache  Do not use cached information, nor cache it.

fields  a character vector giving the fields to extract from each package’s ‘DESCRIPTION’ file in addition to the default ones, or NULL (default). Unavailable fields result in NA values.

subarch  character string or NULL. If non-null and non-empty, used to select packages which are installed for that sub-architecture.

...  allows unused arguments to be passed down from other functions.

Details

installed.packages scans the ‘DESCRIPTION’ files of each package found along lib.loc and returns a matrix of package names, library paths and version numbers.

The information found is cached (by library) for the R session and specified fields argument, and updated only if the top-level library directory has been altered, for example by installing or removing a package. If the cached information becomes confused, it can be avoided by specifying noCache = TRUE.

Value

A matrix with one row per package, row names the package names and column names (currently) "Package", "LibPath", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "OS_type", "License" and "Built" (the R version the package was built under). Additional columns can be specified using the fields argument.

Note

This needs to read several files per installed package, which will be slow on Windows and on some network-mounted file systems.

It will be slow when thousands of packages are installed, so do not use it to find out if a named package is installed (use find.package or system.file) nor to find out if a package is usable (call requireNamespace or require and check the return value) nor to find details of a small number of packages (use packageDescription).

See Also

update.packages, install.packages, INSTALL, REMOVE.

Examples

## confine search to .Library for speed
str(ip <- installed.packages(.Library, priority = "high"))
ip[, c(1,3:5)]
plic <- installed.packages(.Library, priority = "high", fields = "License")
## what licenses are there:
table( plic[, "License"] )
## Recommended setup (by many pros):
## Keep packages that come with R (priority="high") and all others separate!
## Consequently, .Library, R's "system" library, shouldn't have any
## non-"high"-priority packages :
pSys <- installed.packages(.Library, priority = NA_character_)
length(pSys) == 0 # TRUE under such a setup

isS3method

Is 'method' the Name of an S3 Method?

Description

Checks if method is the name of a valid / registered S3 method. Alternatively, when f and class are specified, it is checked if f is the name of an S3 generic function and paste(f, class, sep=".") is a valid S3 method.

Usage

isS3method(method, f, class, envir = parent.frame())

Arguments

method a character string, typically of the form "fn.class". If omitted, f and class have to be specified instead.
f optional character string, typically specifying an S3 generic function. Used, when method is not specified.
class optional character string, typically specifying an S3 class name. Used, when method is not specified.
envir the environment in which the method and its generic are searched first, as in getS3method().

Value

logical TRUE or FALSE

See Also

methods, getS3method.

Examples

isS3method("t") # FALSE - it is an S3 generic
isS3method("t.default") # TRUE
isS3method("t.ts") # TRUE
isS3method("t.test") # FALSE
isS3method("t.data.frame") # TRUE
isS3method("t.lm") # FALSE - not existing
isS3method("t.foo.bar") # FALSE - not existing

## S3 methods with "4 parts" in their name:
ff <- c("as.list", "as.matrix", "is.na", "row.names", "row.names<-")
for(m in ff) if(isS3method(m)) stop("wrongly declared an S3 method: ", m)
(m4 <- paste(ff, "data.frame", sep="."))
for(m in m4) if(!isS3method(m)) stop("not an S3 method: ", m)

isS3stdGeneric    Check if a Function Acts as an S3 Generic

Description
Determine whether f acts as a standard S3-style generic function.

Usage
isS3stdGeneric(f)

Arguments
f     a function object

Details
A closure is considered a standard S3 generic if the first expression in its body calls UseMethod. Functions which perform operations before calling UseMethod will not be considered “standard” S3 generics.

If f is currently being traced, i.e., inheriting from class “traceable”, the definition of the original untraced version of the function is used instead.

Value
If f is an S3 generic, a logical containing TRUE with the name of the S3 generic (the string passed to UseMethod). Otherwise, FALSE (unnamed).

R CMD LINK [options] linkcmd

Arguments
linkcmd a list of commands to link together suitable object files (include library objects) to create the executable program.

options further options to control the linking, or for obtaining information about usage and version.
Details

The linker front-end is useful in particular when linking against the R shared or static library: see the examples.

The actual linking command is constructed by the version of libtool installed at ‘R_HOME/bin’. `R CMD LINK --help` gives usage information.

Note

Some binary distributions of R have LINK in a separate bundle, e.g. an R-devel RPM.

This is not available on Windows.

See Also

`COMPILE`.

Examples

```r
## Not run: ## examples of front-ends linked against R.
## First a C program
CC=`R CMD config CC`
R CMD LINK $CC -o foo foo.o `R CMD config --ldflags`

## if Fortran code has been compiled into ForFoo.o
FLIBS=`R CMD config FLIBS`
R CMD LINK $CC -o foo foo.o ForFoo.o `R CMD config --ldflags` $FLIBS

## And for a C++ front-end
CXX=`R CMD config CXX`
R CMD COMPILE foo.cc
R CMD LINK $CXX -o foo foo.o `R CMD config --ldflags`

## End(Not run)
```

localeToCharset

Select a Suitable Encoding Name from a Locale Name

Description

This functions aims to find a suitable coding for the locale named, by default the current locale, and if it is a UTF-8 locale a suitable single-byte encoding.

Usage

`localeToCharset(locale = Sys.getlocale("LC_CTYPE"))`

Arguments

`locale` character string naming a locale.
Details

The operation differs by OS.

On Windows, a locale is specified like "English_United_Kingdom.1252". The final component gives the codepage, and this defines the encoding.

On Unix-alikes: Locale names are normally like es_MX.iso88591. If final component indicates an encoding and it is not utf8 we just need to look up the equivalent encoding name. Otherwise, the language (here es) is used to choose a primary or fallback encoding.

In the C locale the answer will be "ASCII".

Value

A character vector naming an encoding and possibly a fallback single-encoding, NA if unknown.

Note

The encoding names are those used by libiconv, and ought also to work with glibc but maybe not with commercial Unixen.

See Also

Sys.getlocale, iconv.

Examples

localeToCharset()
Arguments

pos  integer indicating search path position, or -1 for the current environment.
name  optional name indicating search path position, see ls.
envir  environment to use, see ls.
all.names  logical indicating if names which begin with a . are omitted; see ls.
pattern  a regular expression passed to ls. Only names matching pattern are considered.
max.level  maximal level of nesting which is applied for displaying nested structures, e.g., a list containing sub lists. Default 1: Display only the first nested level.
give.attr  logical; if TRUE (default), show attributes as sub structures.
mode  character specifying the mode of objects to consider. Passed to exists and get.
x  an object of class "ls_str".
...  further arguments to pass. lsf.str passes them to ls.str which passes them on to ls. The (non-exported) print method print.ls_str passes them to str.
digits  the number of significant digits to use for printing.

Value

ls.str and lsf.str return an object of class "ls_str", basically the character vector of matching names (functions only for lsf.str), similarly to ls, with a print() method that calls str() on each object.

Author(s)

Martin Maechler

See Also

str, summary, args.

Examples

require(stats)

lsf.str()  # how do the functions look like which I am using?
ls.str(mode = "list")  # what are the structured objects I have defined?

## create a few objects
example(glm, echo = FALSE)
ll <- as.list(LETTERS)
print(ls.str(), max.level = 0)# don't show details

## which base functions have "file" in their name?
lsf.str(pos = length(search())), pattern = "file")

## demonstrating that ls.str() works inside functions
## ["browser/debug mode"]: tt <- function(x, y = 1) { aa <- 7; r <- x + y; ls.str() }
(nms <- sapply(strsplit(capture.output(tt(2))," *: *"), `[`, 1))
stopifnot(nms == c("aa", "r","x","y"))
Description

Show the name and email address of the maintainer of an installed package.

Usage

maintainer(pkg)

Arguments

pkg a character string, the name of an installed package.

Details

Accesses the package description to return the name and email address of the maintainer.

Questions about contributed packages should often be addressed to the package maintainer; questions about base packages should usually be addressed to the R-help or R-devel mailing lists. Bug reports should be submitted using the bug.report function.

Value

A character string giving the name and email address of the maintainer of the package, or NA_character_ if no such package is installed.

Author(s)

David Scott <d.scott@auckland.ac.nz> from code on R-help originally due to Charlie Sharpsteen <source@sharpsteen.net>; multiple corrections by R-core.

References

packageDescription, bug.report

Examples

maintainer("MASS")
Description

Re-create the HTML list of packages.

Usage

```r
make.packages.html(lib.loc = .libPaths(), temp = FALSE,
                   verbose = TRUE, docdir = R.home("doc"))
```

Arguments

- `lib.loc`: character vector. List of libraries to be included.
- `temp`: logical: should the package indices be created in a temporary location for use by the HTTP server?
- `verbose`: logical. If true, print out a message.
- `docdir`: If `temp` is false, directory in whose `html` directory the `packages.html` file is to be created/updated.

Details

This creates the `packages.html` file, either a temporary copy for use by `help.start`, or the copy in `R.home("doc")/html` (for which you will need write permission).

It can be very slow, as all the package `DESCRIPTION` files in all the library trees are read.

For `temp = TRUE` there is some caching of information, so the file will only be re-created if `lib.loc` or any of the directories it lists have been changed.

Value

Invisible logical, with `FALSE` indicating a failure to create the file, probably due to lack of suitable permissions.

See Also

`help.start`

Examples

```r
## Not run:
make.packages.html()
# this can be slow for large numbers of installed packages.

## End(Not run)
```
make.socket  Create a Socket Connection

Description

With server = FALSE attempts to open a client socket to the specified port and host. With server = TRUE the R process listens on the specified port for a connection and then returns a server socket. It is a good idea to use on.exit to ensure that a socket is closed, as you only get 64 of them.

Usage

make.socket(host = "localhost", port, fail = TRUE, server = FALSE)

Arguments

- host: name of remote host
- port: port to connect to/listen on
- fail: failure to connect is an error?
- server: a server socket?

Value

An object of class "socket", a list with components:

- socket: socket number. This is for internal use. On a Unix-alike it is a file descriptor.
- port: port number of the connection.
- host: name of remote computer.

Warning

I don’t know if the connecting host name returned when server = TRUE can be trusted. I suspect not.

Author(s)

Thomas Lumley

References

Adapted from Luke Tierney’s code for XLISP-Stat, in turn based on code from Robbins and Robbins “Practical UNIX Programming”.

See Also

close.socket, read.socket.

Compiling in support for sockets was optional prior to R 3.3.0: see capabilities("sockets") to see if it is available.
Examples

daytime <- function(host = "localhost"){  
a <- make.socket(host, 13)  
on.exit(close.socket(a))  
   read.socket(a)  
}  
## Official time (UTC) from US Naval Observatory
## Not run: daytime("tick.usno.navy.mil")

---

**menu**

*Menu Interaction Function*

**Description**

`menu` presents the user with a menu of choices labelled from 1 to the number of choices. To exit without choosing an item one can select ‘0’.

**Usage**

```r
menu(choices, graphics = FALSE, title = NULL)
```

**Arguments**

- `choices` a character vector of choices
- `graphics` a logical indicating whether a graphics menu should be used if available.
- `title` a character string to be used as the title of the menu. `NULL` is also accepted.

**Details**

If `graphics = TRUE` and a windowing system is available (Windows, macOS or X11 *via* Tcl/Tk) a listbox widget is used, otherwise a text menu. It is an error to use `menu` in a non-interactive session.

Ten or fewer items will be displayed in a single column, more in multiple columns if possible within the current display width.

No title is displayed if `title` is `NULL` or "".

**Value**

The number corresponding to the selected item, or 0 if no choice was made.

**References**

**See Also**

`select.list`, which is used to implement the graphical menu, and allows multiple selections.
Methods

Examples

```r
## Not run:
switch(menu(c(“List letters”, “List LETTERS”)) + 1,
cat(“Nothing done\n”), letters, LETTERS)
## End(Not run)
```

Description

List all available methods for a S3 and S4 generic function, or all methods for an S3 or S4 class.

Usage

```r
methods(generic.function, class, all.names = FALSE, dropPath = FALSE)
.S3methods(generic.function, class, envir = parent.frame(),
all.names = FALSE, dropPath = FALSE)
```

Arguments

- `generic.function`: a generic function, or a character string naming a generic function.
- `class`: a symbol or character string naming a class: only used if `generic.function` is not supplied.
- `envir`: the environment in which to look for the definition of the generic function, when the generic function is passed as a character string.
- `all.names`: a logical indicating if all object names are returned. When FALSE as by default, names beginning with a ‘.’ are omitted.
- `dropPath`: a logical indicating if the `search()` path, apart from `.GlobalEnv` and `package:base` (i.e., `baseenv()`), should be skipped when searching for method definitions. The default FALSE is back compatible and typically desired for `print()`ing, with or without asterisk; dropPath=TRUE has been hard coded in R 4.3.0 and is faster for non-small `search()` paths.
- `x`: typically the result of `methods(..)`, an R object of S3 class `"MethodsFunction"`, see ‘Value’ below.
- `byclass`: an optional logical allowing to override the "byclass" attribute determining how the result is printed, see ‘Details’.
- `...`: potentially further arguments passed to and from methods; unused currently.
Details

methods() finds S3 and S4 methods associated with either the generic.function or class argument. Methods found are those provided by all loaded namespaces via registration, see UseMethod; normally, this includes all packages on the current search() path. .S3methods() finds only S3 methods, .S4methods() finds only S4 methods.

When invoked with the generic.function argument, the "byclass" attribute (see Details) is FALSE, and the print method by default displays the signatures (full names) of S3 and S4 methods. S3 methods are printed by pasting the generic function and class together, separated by a ".", as generic.class. The S3 method name is followed by an asterisk * if the method definition is not exported from the package namespace in which the method is defined. S4 method signatures are printed as generic,class-method; S4 allows for multiple dispatch, so there may be several classes in the signature generic,A,B-method.

When invoked with the class argument, "byclass" is TRUE, and the print method by default displays the names of the generic functions associated with the class, generic.

The source code for all functions is available. For S3 functions exported from the namespace, enter the method at the command line as generic.class. For S3 functions not exported from the namespace, see getAnywhere or getS3method. For S4 methods, seegetMethod.

Help is available for each method, in addition to each generic. For interactive help, use the documentation shortcut ? with the name of the generic and tab completion, ?"generic<tab>" to select the method for which help is desired.

The S3 functions listed are those which are named like methods and may not actually be methods (known exceptions are discarded in the code).

Value

An object of class "MethodsFunction", a character vector of method names with "byclass" and "info" attributes. The "byclass" attribute is a logical indicating if the results were obtained with argument class defined. The "info" attribute is a data frame with columns:

generic character vector of the names of the generic.
visible logical(), is the method "visible" to the user? When true, it typically is exported from the namespace of the package in which it is defined, and the package is attach()ed to the search() path.
isS4 logical(), true when the method is an S4 method.
from a factor, the location or package name where the method was found.

Note

The original methods function was written by Martin Maechler.

mirrorAdmin

Managing Repository Mirrors

Description

Functions helping to maintain CRAN, some of them may also be useful for administrators of other repository networks.

Usage

```
mirror2html(mirrors = NULL, file = "mirrors.html",
           head = "mirrors-head.html", foot = "mirrors-foot.html")
checkCRAN(method)
```

Arguments

- **mirrors**: A data frame, by default the CRAN list of mirrors is used.
- **file**: A connection or a character string.
- **head**: Name of optional header file.
- **foot**: Name of optional footer file.
- **method**: Download method, see `download.file`. 

modifyList

Description

Modifies a possibly nested list recursively by changing a subset of elements at each level to match a second list.

Usage

modifyList(x, val, keep.null = FALSE)

Arguments

x A named list, possibly empty.
val A named list with components to replace corresponding components in x or add new components.
keep.null If TRUE, NULL elements in val become NULL elements in x. Otherwise, the corresponding element, if present, is deleted from x.

Value

A modified version of x, with the modifications determined as follows (here, list elements are identified by their names). Elements in val which are missing from x are added to x. For elements that are common to both but are not both lists themselves, the component in x is replaced (or possibly deleted, depending on the value of keep.null) by the one in val. For common elements that are in both lists, x[[name]] is replaced by modifyList(x[[name]], val[[name]]).

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

Examples

foo <- list(a = 1, b = list(c = "a", d = FALSE))
bar <- modifyList(foo, list(e = 2, b = list(d = TRUE)))
str(foo)
str(bar)
## Build and Query R or Package News Information

**Description**

Build and query the news data base for R or add-on packages.

### Usage

```r
news(query, package = "R", lib.loc = NULL, format = NULL,
     reader = NULL, db = NULL)
```

```r
## S3 method for class 'news_db'
print(x, doBrowse = interactive(),
     browser = getOption("browser"), ...)
```

### Arguments

- **query**  
an optional expression for selecting news entries.
- **package**  
a character string giving the name of an installed add-on package, or "R" or "R-3" or "R-2".
- **lib.loc**  
a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.
- **format**  
Not yet used.
- **reader**  
Not yet used.
- **db, x**  
a news db obtained from `news()`.
- **doBrowse**  
logical specifying that the news should be opened in the browser (by `browseURL`, accessible as via `help.start`) instead of printed to the console.
- **browser**  
the browser to be used, see `browseURL`.
- **...**  
potentially further arguments passed to `print()`.

### Details

If package is "R" (default), a news db is built with the news since the 4.0.0 release of R, corresponding to the `NEWS` file in the R.home("doc") directory. "R-3" or "R-2" give the news for R 3.x.y or R 2.x.y respectively. Otherwise, if the given add-on package can be found in the given libraries, it is attempted to read its news in structured form from files `inst/NEWS.Rd`, `NEWS.md` (since R version 3.6.0, needs packages `commonmark` and `xml2` to be available), `NEWS` or `inst/NEWS` (in that order). See section `NEWS Formats` for the file specifications.

Using query, one can select news entries from the db. If missing or NULL, the complete db is returned. Otherwise, query should be an expression involving (a subset of) the variables Version, Category, Date and Text, and when evaluated within the db returning a logical vector with length the number of entries in the db. The entries for which evaluation gave TRUE are selected. When evaluating, Version and Date are coerced to `numeric_version` and `Date` objects, respectively, so that the comparison operators for these classes can be employed.
Value

A data frame inheriting from class "news_db", with character variables Version, Category, Date, Text and HTML, where the last two each contain the entry texts read (in plain-text and HTML format, respectively), and the other variables may be NA if they were missing or could not be determined. The data frame has attributes "package" (and "subset" if the query lead to proper subsetting).

NEWS Formats

`inst/NEWS.Rd`: File `inst/NEWS.Rd` should be an Rd `\itemize` lists, grouped according to version using `\section` elements. Section titles start with a suitable prefix followed by a space and the version number, and optionally end with a (parenthesized) ISO 8601 (%Y-%m-%d, see `strptime`) format date (optionally including a note), for example:

```r
\section{Changes in version 2.0 (2020-02-02, <note>)}\
\itemize{\textbullet\item ....}
```

The entries can be further grouped according to categories using `\subsection` elements named as the categories. The `NEWS.Rd` file is assumed to be UTF-8-encoded (but an included `\encoding` specification takes precedence).

`NEWS.md`: File `NEWS.md` should contain the news in Markdown (following the CommonMark ([https://commonmark.org/](https://commonmark.org/)) specification), with the primary heading level giving the version number after a prefix followed by a space, and optionally followed by a space and a parenthesized ISO 8601 format date. Where available, secondary headings are taken to indicate categories. To accommodate for common practice, news entries are only split down to the category level.

`NEWS`: The plain text `NEWS` files in add-on packages use a variety of different formats; the default news reader should be capable to extract individual news entries from a majority of packages from the standard repositories, which use (slight variations of) the following format:

- Entries are grouped according to version, with version header "Changes in version" at the beginning of a line, followed by a version number, optionally followed by an ISO 8601 format date, possibly parenthesized.
- Entries may be grouped according to category, with a category header (different from a version header) starting at the beginning of a line.
- Entries are written as itemize-type lists, using one of ‘o’, ‘*’, ‘-’ or ‘+’ as item tag. Entries must be indented, and ideally use a common indentation for the item texts.

Package tools provides an (internal) utility function news2Rd to convert plain text `NEWS` files to Rd. For `NEWS` files in a format which can successfully be handled by the default reader, package maintainers can use tools:::news2Rd(dir, "NEWS.Rd"), possibly with additional argument `codify = TRUE`, with `dir` a character string specifying the path to a package's root directory. Upon success, the `NEWS.Rd` file can further be improved and then be moved to the `inst` subdirectory of the package source directory.

Examples

```r
## Build a db of all R news entries.

db <- news()
```
## Bug fixes with PR number in 4.0.0.

```r
db4 <- news(Version == "4.0.0" & grepl("^BUG", Category) & grepl("PR#", Text),
            db = db)
nrow(db4)
```

## print db4 to show in an HTML browser.

```r
## News from a date range (’Matrix’ is there in a regular R installation):
if(length(iM <- find.package("Matrix", quiet = TRUE)) && nzchar(iM)) {
  dM <- news(package="Matrix")
  stopifnot(identical(dM, news(db=dM)))
  dM2014 <- news("2014-01-01" <= Date & Date <= "2014-12-31", db = dM)
  stopifnot(paste0("1.1-", 2:4) %in% dM2014[,"Version"])
}
```

## Which categories have been in use? % R-core maybe should standardize a bit more

```r
sort(table(db[, "Category"]), decreasing = TRUE)
```

## Entries with version >= 4.0.0

```r
table(news(Version >= "4.0.0", db = db)$Version)
```

## do the same for R 3.x.y, more slowly

```r
db3 <- news(package = "R-3")
```

```r
sort(table(db3[, "Category"]), decreasing = TRUE)
```

## Entries with version >= 3.6.0

```r
table(news(Version >= "3.6.0", db = db3)$Version)
```

---

### nsl

Look up the IP Address by Hostname (on Unix-alikes)

#### Description

Interface to the system `gethostbyname`, currently available only on unix-alikes, i.e., not on Windows.

#### Usage

```r
nsl(hostname)
```

#### Arguments

- `hostname`: the name of the host.

#### Details

This was included as a test of internet connectivity, to fail if the node running R is not connected. It will also return NULL if BSD networking is not supported, including the header file ‘arpa/inet.h’.

This function is not available on Windows.

#### Value

The IP address, as a character string, or NULL if the call fails.
object.size

Examples

if(.Platform$OS.type == "unix") # includes Mac
  print( nsl("www.r-project.org") )

object.size

Report the Space Allocated for an Object

Description

Provides an estimate of the memory that is being used to store an R object.

Usage

object.size(x)

## S3 method for class 'object_size'
format(x, units = "b", standard = "auto", digits = 1L, ...)  
## S3 method for class 'object_size'
print(x, quote = FALSE, units = "b", standard = "auto",  
digits = 1L, ...)

Arguments

x an R object.

quote logical, indicating whether or not the result should be printed with surrounding quotes.

units the units to be used in formatting and printing the size. Allowed values for the different standards are

standard = "legacy": "b", "KB", "MB", "GB", "TB", "PB", "KB", "MB", "GB", "TB" and "PB".

For all standards, units = "auto" is also allowed. If standard = "auto", any of the "legacy" and IEC units are allowed. See ‘Formatting and printing object sizes’ for details.

standard the byte-size unit standard to be used. A character string, possibly abbreviated from "legacy", "IEC", "SI" and "auto". See ‘Formatting and printing object sizes’ for details.

digits the number of digits after the decimal point, passed to round.

... arguments to be passed to or from other methods.
Details

Exactly which parts of the memory allocation should be attributed to which object is not clear-cut. This function merely provides a rough indication: it should be reasonably accurate for atomic vectors, but does not detect if elements of a list are shared, for example. (Sharing amongst elements of a character vector is taken into account, but not that between character vectors in a single object.) The calculation is of the size of the object, and excludes the space needed to store its name in the symbol table.

Associated space (e.g., the environment of a function and what the pointer in a EXTPTRSX points to) is not included in the calculation.

Object sizes are larger on 64-bit builds than 32-bit ones, but will very likely be the same on different platforms with the same word length and pointer size.

Sizes of objects using a compact internal representation may be over-estimated.

Value

An object of class "object_size" with a length-one double value, an estimate of the memory allocation attributable to the object in bytes.

Formatting and printing object sizes

Object sizes can be formatted using byte-size units from R's legacy standard, the IEC standard, or the SI standard. As illustrated by below tables, the legacy and IEC standards use binary units (multiples of 1024), whereas the SI standard uses decimal units (multiples of 1000).

For methods format and print, argument standard specifies which standard to use and argument units specifies which byte-size unit to use. units = "auto" chooses the largest units in which the result is one or more (before rounding). Byte sizes are rounded to digits decimal places. standard = "auto" chooses the standard based on units, if possible, otherwise, the legacy standard is used.

Summary of R's legacy and IEC units:

<table>
<thead>
<tr>
<th>object size</th>
<th>legacy</th>
<th>IEC</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1 bytes</td>
<td>1 B</td>
</tr>
<tr>
<td>1024</td>
<td>1 Kb</td>
<td>1 KiB</td>
</tr>
<tr>
<td>1024^2</td>
<td>1 Mb</td>
<td>1 MiB</td>
</tr>
<tr>
<td>1024^3</td>
<td>1 Gb</td>
<td>1 GiB</td>
</tr>
<tr>
<td>1024^4</td>
<td>1 Tb</td>
<td>1 TiB</td>
</tr>
<tr>
<td>1024^5</td>
<td>1 Pb</td>
<td>1 PiB</td>
</tr>
<tr>
<td>1024^6</td>
<td></td>
<td>1 EiB</td>
</tr>
<tr>
<td>1024^7</td>
<td></td>
<td>1 ZiB</td>
</tr>
<tr>
<td>1024^8</td>
<td></td>
<td>1 YiB</td>
</tr>
</tbody>
</table>

Summary of SI units:

<table>
<thead>
<tr>
<th>object size</th>
<th>SI</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1 B</td>
</tr>
<tr>
<td>1000</td>
<td>1 kB</td>

<tr>
<td>1000^2</td>
<td>1 MB</td>
</tr>
<tr>
<td>1000^3</td>
<td>1 GB</td>
</tr>
<tr>
<td>1000^4</td>
<td>1 TB</td>
</tr>
<tr>
<td>1000^5</td>
<td>1 PB</td>
</tr>
</tbody>
</table>
package.skeleton

Description

package.skeleton automates some of the setup for a new source package. It creates directories, saves functions, data, and R code files to appropriate places, and creates skeleton help files and a ‘Read-and-delete-me’ file describing further steps in packaging.
Usage

```r
default_args <- list(name = "anRpackage",
                      list = NULL,
                      environment = .GlobalEnv,
                      path = ".",
                      force = FALSE,
                      code_files = character(),
                      encoding = "unknown")
default_args
```

Arguments

- **name**: character string: the package name and directory name for your package. Must be a valid package name.
- **list**: character vector naming the R objects to put in the package. Usually, at most one of `list`, `environment`, or `code_files` will be supplied. See `Details`.
- **environment**: an environment where objects are looked for. See ‘Details’.
- **path**: path to put the package directory in.
- **force**: If `FALSE` will not overwrite an existing directory.
- **code_files**: a character vector with the paths to R code files to build the package around. See ‘Details’.
- **encoding**: optionally a character string with an encoding for an optional ‘Encoding:’ line in ‘DESCRIPTION’ when non-ASCII characters will be used; typically one of “latin1”, “latin2”, or “UTF-8”; see the WRE manual.

Details

The arguments `list`, `environment`, and `code_files` provide alternative ways to initialize the package. If `code_files` is supplied, the files so named will be sourced to form the environment, then used to generate the package skeleton. Otherwise `list` defaults to the objects in `environment` (including those whose names start with `.`, but can be supplied to select a subset of the objects in that environment.

Stubs of help files are generated for functions, data objects, and S4 classes and methods, using the `prompt`, `promptClass`, and `promptMethods` functions. If an object from another package is intended to be imported and re-exported without changes, the `promptImport` function should be used after `package.skeleton` to generate a simple help file linking to the original one.

The package sources are placed in subdirectory `name` of `path`. If `code_files` is supplied, these files are copied; otherwise, objects will be dumped into individual source files. The file names in `code_files` should have suffix `".R"` and be in the current working directory.

The filenames created for source and documentation try to be valid for all OSes known to run R. Invalid characters are replaced by `"_"`, invalid names are preceded by `"zz"`, names are converted to lower case (to avoid case collisions on case-insensitive file systems) and finally the converted names are made unique by `make.unique(sep = "_")`. This can be done for code and help files but not data files (which are looked for by name). Also, the code and help files should have names starting with an ASCII letter or digit, and this is checked and if necessary z prepended.

Functions with names starting with a dot are placed in file ‘R/name-interna.l.R’.

When you are done, delete the ‘Read-and-delete-me’ file, as it should not be distributed.

Value

Used for its side-effects.
packageDescription

References

Read the ‘Writing R Extensions’ manual for more details.

Once you have created a source package you need to install it: see the ‘R Installation and Administration’ manual, INSTALL and install.packages.

See Also

prompt, promptClass, and promptMethods.

package_native_routine_registration_skeleton for helping in preparing packages with compiled code.

Examples

require(stats)
## two functions and two "data sets":
f <- function(x, y) x+y
g <- function(x, y) x-y
d <- data.frame(a = 1, b = 2)
e <- rnorm(1000)

package.skeleton(list = c("f","g","d","e"), name = "mypkg")
drop

If TRUE and the length of fields is 1, then a single character string with the value of the respective field is returned instead of an object of class "packageDescription".

encoding

If there is an Encoding field, to what encoding should re-encoding be attempted? If NA, no re-encoding. The other values are as used by iconv, so the default "" indicates the encoding of the current locale.

date.fields

character vector of field tags to be tried. The first for which as.Date(.) is not NA will be returned. (Partly experimental, see Note.)

tryFormats

date formats to try, see as.Date.character().

desc

optionally, a named list with components named from date.fields; where the default is fine, a complete packageDescription() maybe specified as well.

built

for asDateBuilt(), a character string as from packageDescription(*, fields="Built").

Details

A package will not be ‘found’ unless it has a ‘DESCRIPTION’ file which contains a valid Version field. Different warnings are given when no package directory is found and when there is a suitable directory but no valid ‘DESCRIPTION’ file.

An attached environment named to look like a package (e.g., package:utils2) will be ignored.

packageVersion() is a convenience shortcut, allowing things like if (packageVersion("MASS") < "7.3") { do.things }

For packageDate(), if desc is valid, both pkg and lib.loc are not made use of.

Value

If a ‘DESCRIPTION’ file for the given package is found and can successfully be read, packageDescription returns an object of class "packageDescription", which is a named list with the values of the (given) fields as elements and the tags as names, unless drop = TRUE.

If parsing the ‘DESCRIPTION’ file was not successful, it returns a named list of NAs with the field tags as names if fields is not null, and NA otherwise.

packageVersion() returns a (length-one) object of class "package_version".

packageDate() will return a "Date" object from as.Date() or NA.

asDateBuilt(built) returns a "Date" object or signals an error if built is invalid.

Note

The default behavior of packageDate(), notably for date.fields, is somewhat experimental and may change.

read.dcf

Examples

packageDescription("stats")
packageDescription("stats", fields = c("Package", "Version"))

packageDescription("stats", fields = "Version")
packageName

Description

Many environments are associated with a package; this function attempts to determine that package.

Usage

packageName(env = parent.frame())

Arguments

env The environment whose name we seek.

Details

Environment env would be associated with a package if `topenv(env)` is the namespace environment for that package. Thus when env is the environment associated with functions inside a package, or local functions defined within them, `packageName` will normally return the package name.

Not all environments are associated with a package: for example, the global environment, or the evaluation frames of functions defined there. `packageName` will return NULL in these cases.

Value

A length one character vector containing the name of the package, or NULL if there is no name.

See Also

`getPackageName` is a more elaborate function that can construct a name if none is found.

Examples

packageName()
packageName(environment(mean))
packageStatus  Package Management Tools

Description

Summarize information about installed packages and packages available at various repositories, and automatically upgrade outdated packages.

Usage

packageStatus(lib.loc = NULL, repositories = NULL, method,
             type = getOption("pkgType"), ...)

## S3 method for class 'packageStatus'
summary(object, ...)

## S3 method for class 'packageStatus'
update(object, lib.loc = levels(object$inst$LibPath),
        repositories = levels(object$avail$Repository), ...)

## S3 method for class 'packageStatus'
upgrade(object, ask = TRUE, ...)

Arguments

lib.loc  a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.

repositories  a character vector of URLs describing the location of R package repositories on the Internet or on the local machine. These should be full paths to the appropriate 'contrib' sections of the repositories. The default (NULL) derives URLs from option "repos" and type.

method  download method, see download.file.

type  type of package distribution: see install.packages.
