Package ‘AICcmodavg’

March 8, 2019

Type          Package
Title         Model Selection and Multimodel Inference Based on (Q)AIC(c)
Version       2.2-1
Date          2019-03-07
Author        Marc J. Mazerolle <marc.mazerolle@sbf.ulaval.ca> and portions of code contributed by Dan Linden.
Maintainer     Marc J. Mazerolle <marc.mazerolle@sbf.ulaval.ca>
Depends       R (>= 3.2.0)
Imports       methods, stats, graphics, lattice, MASS, Matrix, nlme, stats4, survival, unmarked, VGAM, xtable
Suggests      betareg, coxme, fitdistrplus, glmmTMB, lavaan, lme4, maxlike, nnet, ordinal, pscl, R2jags, R2OpenBUGS, R2WinBUGS, jagsUI
Description   Functions to implement model selection and multimodel inference based on Akaike's information criterion (AIC) and the second-order AIC (AICc), as well as their quasi-likelihood counterparts (QAIC, QAICc) from various model object classes. The package implements classic model averaging for a given parameter of interest or predicted values, as well as a shrinkage version of model averaging parameter estimates or effect sizes. The package includes diagnostics and goodness-of-fit statistics for certain model types including those of 'unmarkedFit' classes estimating demographic parameters after accounting for imperfect detection probabilities. Some functions also allow the creation of model selection tables for Bayesian models of the 'bugs', 'rjags', and 'jagsUI' classes. Functions also implement model selection using BIC. Objects following model selection and multimodel inference can be formatted to LaTeX using 'xtable' methods included in the package.

Description: This package includes functions to create model selection tables based on Akaike’s information criterion (AIC) and the second-order AIC (AICc), as well as their quasi-likelihood counterparts (QAIC, QAICc). The package also features functions to conduct classic model averaging (multimodel inference) for a given parameter of interest or predicted values, as well as a shrinkage version of model averaging parameter estimates. Other handy functions enable the computation of relative variable importance, evidence ratios, and confidence sets for the best model.

The present version supports Cox proportional hazards models and conditional logistic regression (coxph and coxme classes), linear models (lm class), generalized linear models (glm, glm.nb, vglm, hurdle, and zeroinfl classes), linear models fit by generalized least squares (gls class), linear mixed models (lme class), generalized linear mixed models (mer, merMod, and glmmTMB classes), multinomial and ordinal logistic regressions (multinom, polr, clm, and clmm classes), robust regression models (rlm class), beta regression models (betareg class), parametric survival models (survreg class), nonlinear models (nls and gnlS classes), nonlinear mixed models (nlme and nlmME classes), univariate models (fitdist and fitdistr classes), and certain types of latent variable models (lavaan class). The package also supports various models of unmarkedFit and maxLikeFit classes estimating demographic parameters after accounting for imperfect detection probabilities. Some functions also allow the creation of model selection tables for Bayesian models of the bugs and rjags classes. Objects following model selection and multimodel inference can be formatted to LaTeX using xtable methods included in the package.

Details

| Package: | AICcmodavg |
| Type: | Package |
| Version: | 2.2-1 |
| Date: | 2019-03-07 |
| License: | GPL (>=2) |
| LazyLoad: | yes |
Many functions of the package require a list of models as the input to conduct model selection and multimodel inference. Thus, you should start by organizing the output of the models in a list (See ‘Examples’ below).

This package contains several useful functions for model selection and multimodel inference for several model classes:

- **AICc** Computes AIC, AICc, and their quasi-likelihood counterparts (QAIC, QAICc).
- **aictab** Constructs model selection tables with number of parameters, AIC, delta AIC, Akaike weights or variants based on AICc, QAIC, and QAICc for a set of candidate models.
- **bictab** Constructs model selection tables with number of parameters, BIC, delta BIC, BIC weights for a set of candidate models.
- **boot.wt** Computes summary statistics from detection histories.
- **confset** Determines the confidence set for the best model based on one of three criteria.
- **DIC** Extracts DIC.
- **dictab** Constructs model selection tables with number of parameters, DIC, delta DIC, DIC weights for a set of candidate models.
- **evidence** Computes the evidence ratio between the highest-ranked model based on the information criteria selected and a lower-ranked model.
- **importance** Computes importance values (w+) for the support of a given parameter among set of candidate models.
- **modavg** Computes model-averaged estimate, unconditional standard error, and unconditional confidence interval of a parameter of interest among a set of candidate models.
- **modavgEffect** Computes model-averaged effect sizes between groups based on the entire candidate model set.
- **modavgShrink** Computes shrinkage version of model-averaged estimate, unconditional standard error, and unconditional confidence interval of a parameter of interest among entire set of candidate models.
- **modavgPred** Computes model-average predictions, unconditional SE’s, and confidence intervals among entire set of candidate models.
- **multComp** Performs multiple comparisons across levels of a factor in a model selection framework.
- **useBIC** Computes BIC or a quasi-likelihood counterparts (QBIC).

For models not yet supported by the functions above, the following can be useful for model selection and multimodel inference conducted from input values supplied by the user:

- **AICcCustom** Computes AIC, AICc, QAIC, and QAICc from user-supplied input values of log-likelihood and number of parameters.
- **aictabCustom** Creates model selection tables based on (Q)AIC(c) from user-supplied input values of log-likelihood and number of parameters.
- **bictabCustom** Creates model selection tables based on (Q)BIC from user-supplied input values of log-likelihood and number of parameters.
- **ictab** Creates model selection tables from user-supplied values of an information criterion.
• modavgCustom Computes model-averaged parameter estimate based on (Q)AIC(c) from user-supplied input values of log-likelihood, number of parameters, parameter estimates, and standard errors.
• modavgIC Computes model-averaged parameter estimate from user-supplied values of information criterion, parameter estimates, and standard errors.
• useBICCustom Computes BIC and QBIC from user-supplied input values of log-likelihoods and number of parameters.

A number of functions for model diagnostics are available:

• c_hat Estimates variance inflation factor for binomial or Poisson GLM’s based on various estimators.
• checkConv Checks the convergence information of the algorithm for the model.
• checkParms Checks the occurrence of parameter estimates with high standard errors in a model.
• countDist Computes summary statistics from distance sampling data.
• countHist Computes summary statistics from count history data.
• covDiag Computes covariance diagnostics for lambda in N-mixture models.
• detHist Computes summary statistics from detection histories.
• extractCN Extracts condition number from models of certain classes.
• mb.gof.test Computes the MacKenzie and Bailey goodness-of-fit test for single season and dynamic occupancy models using the Pearson chi-square statistic.
• Nmix.gof.test Computes goodness-of-fit test for N-mixture models based on the Pearson chi-square statistic.

Other utility functions include:

• anovaOD Computes likelihood-ratio test statistic corrected for overdispersion between two models.
• extractLL Extracts log-likelihood from models of certain classes.
• extractSE Extracts standard errors from models of certain classes and adds the labels.
• extractX Extracts the predictors and associated information on variables from a list of candidate models.
• fam.link.mer Extracts the distribution family and link function from a generalized linear mixed model of classes mer and merMod.
• predictSE Computes predictions and associated standard errors models of certain classes.
• summaryOD Displays summary of model output adjusted for overdispersion.
• xtable Formats various objects resulting from model selection and multimodel inference to LaTeX or HTML tables.

estimate = model.est, se = model.se.est, nobs = 121)
# compute model-averaged estimate and unconditional SE based on BIC
modavgCustom(logL = LL, K = Ks, modnames = Modnames,
estimate = model.est, se = model.se.est, nobs = 121,
useBIC = TRUE)
```

## Not run:

### Example 4: example with user-supplied values of information criterion

#### Model selection based on WAIC

**WAIC values**

```r
waic <- c(105.74, 107.36, 108.24, 100.57)
```

**Number of effective parameters**

```r
effK <- c(7.45, 5.61, 6.14, 6.05)
```

**Create a vector of names to trace back models in set**

```r
Modnames <- c("global model", "interactive model",
"additive model", "invertpred model")
```

**Generate WAIC model selection table**

```r
ictab(ic = waic, K = effK, modnames = Modnames,
sort = TRUE, ic.name = "WAIC")
```

**Model selection table with estimate and SE's from each model**

```r
xtable(modavgIC(ic = waic, K = effK, modnames = Modnames,
estimate = Preds, se = Ses,
ic.name = "WAIC"), print.table = TRUE)
```

## Not run
Description

Functions to compute Akaike's information criterion (AIC), the second-order AIC (AICc), as well as their quasi-likelihood counterparts (QAIC, QAICc).

Usage

AICc(mod, return.K = FALSE, second.ord = TRUE, nob = NULL, ...)

## S3 method for class 'aov'
AICc(mod, return.K = FALSE, second.ord = TRUE, 
     nob = NULL, ...)

## S3 method for class 'betareg'
AICc(mod, return.K = FALSE, second.ord = TRUE, 
     nob = NULL, ...)

## S3 method for class 'clm'
AICc(mod, return.K = FALSE, second.ord = TRUE, 
     nob = NULL, ...)

## S3 method for class 'clmm'
AICc(mod, return.K = FALSE, second.ord = TRUE, 
     nob = NULL, ...)

## S3 method for class 'coxme'
AICc(mod, return.K = FALSE, second.ord = TRUE, 
     nob = NULL, ...)

## S3 method for class 'coxph'
AICc(mod, return.K = FALSE, second.ord = TRUE, 
     nob = NULL, ...)

## S3 method for class 'fitdist'
AICc(mod, return.K = FALSE, second.ord = TRUE, 
     nob = NULL, ...)

## S3 method for class 'fitdistr'
AICc(mod, return.K = FALSE, second.ord = TRUE, 
     nob = NULL, ...)

## S3 method for class 'glm'
AICc(mod, return.K = FALSE, second.ord = TRUE, 
     nob = NULL, c.hat = 1, ...)

Computing AIC, AICc, QAIC, and QAICc
## S3 method for class 'glmmTMB'
AICc(mod, return.K = FALSE, second.ord = TRUE, nobs = NULL, c.hat = 1, ...)

## S3 method for class 'gls'
AICc(mod, return.K = FALSE, second.ord = TRUE, nobs = NULL, ...)

## S3 method for class 'gnls'
AICc(mod, return.K = FALSE, second.ord = TRUE, nobs = NULL, ...)

## S3 method for class 'hurdle'
AICc(mod, return.K = FALSE, second.ord = TRUE, nobs = NULL, ...)

## S3 method for class 'lavaan'
AICc(mod, return.K = FALSE, second.ord = TRUE, nobs = NULL, ...)

## S3 method for class 'lm'
AICc(mod, return.K = FALSE, second.ord = TRUE, nobs = NULL, ...)

## S3 method for class 'lme'
AICc(mod, return.K = FALSE, second.ord = TRUE, nobs = NULL, ...)

## S3 method for class 'lmerkin'
AICc(mod, return.K = FALSE, second.ord = TRUE, nobs = NULL, ...)

## S3 method for class 'maxlikeFit'
AICc(mod, return.K = FALSE, second.ord = TRUE, nobs = NULL, c.hat = 1, ...)

## S3 method for class 'mer'
AICc(mod, return.K = FALSE, second.ord = TRUE, nobs = NULL, ...)

## S3 method for class 'merMod'
AICc(mod, return.K = FALSE, second.ord = TRUE, nobs = NULL, ...)

## S3 method for class 'multinom'
AICc(mod, return.K = FALSE, second.ord = TRUE, nobs = NULL, c.hat = 1, ...)
Arguments

mod an object of class aov, betareg, clm, clmm, clogit, coxme, coxph, fitdist, fitdistr, glm, glmmTMB, gls, gnls, hurdle, lavaan, lm, lme, lme4, maxlikFit, mer, merMod, multinom, negbin, nlme, nls, polr, rlm, survreg, vglm, zeroinfl, and various unmarkedFit classes containing the output of a model.

return.K logical. If FALSE, the function returns the information criterion specified. If TRUE, the function returns K (number of estimated parameters) for a given model.

second.ord logical. If TRUE, the function returns the second-order Akaike information criterion (i.e., AICc).

nobs this argument allows to specify a numeric value other than total sample size to
compute the AICc (i.e., nobs defaults to total number of observations). This is relevant only for mixed models or various models of unmarkedFit classes where sample size is not straightforward. In such cases, one might use total number of observations or number of independent clusters (e.g., sites) as the value of nobs.

c_Nhat value of overdispersion parameter (i.e., variance inflation factor) such as that obtained from c_hat. Note that values of c.hat different from 1 are only appropriate for binomial GLM’s with trials > 1 (i.e., success/trial or cbind(success, failure) syntax), with Poisson GLM’s, single-season occupancy models (MacKenzie et al. 2002), dynamic occupancy models (MacKenzie et al. 2003), or N-mixture models (Royle 2004, Dail and Madsen 2011). If c.hat > 1, AICc will return the quasi-likelihood analogue of the information criteria requested and multiply the variance-covariance matrix of the estimates by this value (i.e., SE’s are multiplied by sqrt(c.hat)). This option is not supported for generalized linear mixed models of the mer or merMod classes.

... additional arguments passed to the function.

Details

AICc computes one of the following four information criteria:

Akaike’s information criterion (AIC, Akaike 1973),

\[-2 \cdot \log \text{-likelihood} + 2 \cdot K,\]

where the log-likelihood is the maximum log-likelihood of the model and K corresponds to the number of estimated parameters.

Second-order or small sample AIC (AICc, Sugiura 1978, Hurvich and Tsai 1991),

\[-2 \cdot \log \text{-likelihood} + 2 \cdot K \cdot \left(\frac{n}{n - K - 1}\right),\]

where n is the sample size of the data set.

Quasi-likelihood AIC (QAIC, Burnham and Anderson 2002),

\[QAIC = \frac{-2 \cdot \log \text{-likelihood}}{c-hat} + 2 \cdot K,\]

where c-hat is the overdispersion parameter specified by the user with the argument c_hat.

Quasi-likelihood AICc (QAICc, Burnham and Anderson 2002),

\[QAICc = \frac{-2 \cdot \log \text{-likelihood}}{c-hat} + 2 \cdot K \cdot \left(\frac{n}{n - K - 1}\right)\]

Note that AIC and AICc values are meaningful to select among gls or lme models fit by maximum likelihood. AIC and AICc based on REML are valid to select among different models that only differ in their random effects (Pinheiro and Bates 2000).

Value

AICc returns the AIC, AICc, QAIC, or QAICc, or the number of estimated parameters, depending on the values of the arguments.
Note

The actual (Q)AIC(c) values are not really interesting in themselves, as they depend directly on the data, parameters estimated, and likelihood function. Furthermore, a single value does not tell much about model fit. Information criteria become relevant when compared to one another for a given data set and set of candidate models.

Examples

```r
# cement data from Burnham and Anderson (2002, p. 101)
data(cement)
## run multiple regression - the global model in Table 3.2
glob.mod <- lm(y ~ x1 + x2 + x3 + x4, data = cement)

## compute AICc with full likelihood
AICc(glob.mod, return.K = FALSE)

## compute AIC with full likelihood
AICC(glob.mod, return.K = FALSE, second.ord = FALSE)
## note that Burnham and Anderson (2002) did not use full likelihood
## in Table 3.2 and that the MLE estimate of the variance was
## rounded to 2 digits after decimal point

## compute AICc for mixed model on Orthodont data set in Pinheiro and
## Bates (2000)
## Not run:
require(nlme)
m1 <- lme(distance ~ age, random = ~1 | Subject, data = Orthodont,
       method= "ML")
AICc(m1, return.K = FALSE)
## End(Not run)
```

### Description

This function computes Akaike’s information criterion (AIC), the second-order AIC (AICc), as well as their quasi-likelihood counterparts (QAIC, QAICc) from user-supplied input instead of extracting the values automatically from a model object. This function is particularly useful for output imported from other software or for model classes that are not currently supported by AICc.

### Usage

```r
AICcCustom(logL, K, return.K = FALSE, second.ord = TRUE, nobS = NULL,
c.hat = 1)
```

### Arguments

- `logL`: the value of the model log-likelihood.
- `K`: the number of estimated parameters in the model.
- `return.K`: logical. If `FALSE`, the function returns the information criterion specified. If `TRUE`, the function returns `K` (number of estimated parameters) for a given model.
second. ord logical. If TRUE, the function returns the second-order Akaike information criterion (i.e., AICc).

nobs the sample size required to compute the AICc or QAICc.

c.hat value of overdispersion parameter (i.e., variance inflation factor) such as that obtained from c_hat. Note that values of c.hat different from 1 are only appropriate for binomial GLM’s with trials > 1 (i.e., success/trial or cbind(success, failure) syntax), with Poisson GLM’s, single-season or dynamic occupancy models (MacKenzie et al. 2002, 2003), N-mixture models (Royle 2004, Dail and Madsen 2011), or capture-mark-recapture models (e.g., Lebreton et al. 1992). If c.hat > 1, AICcCustom will return the quasi-likelihood analogue of the information criterion requested.

Details

AICcCustom computes one of the following four information criteria:

Akaike’s information criterion (AIC, Akaike 1973), the second-order or small sample AIC (AICc, Sugiura 1978, Hurvich and Tsai 1991), the quasi-likelihood AIC (QAIC, Burnham and Anderson 2002), and the quasi-likelihood AICc (QAICc, Burnham and Anderson 2002).

Value

AICcCustom returns the AIC, AICc, QAIC, or QAICc, or the number of estimated parameters, depending on the values of the arguments.

Note

The actual (Q)AIC(c) values are not really interesting in themselves, as they depend directly on the data, parameters estimated, and likelihood function. Furthermore, a single value does not tell much about model fit. Information criteria become relevant when compared to one another for a given data set and set of candidate models.

aictab.AICunmarkedFitGMM, or aictab.AICunmarkedFitGPC, depending on the class of the objects.
dictab.bugs has been replaced by dictab.AICbugs.
dictab.jags has been replaced by dictab.AICjags.
modavg.clm has been replaced by modavg.AICSclm.clm.
modavg.clmm has been replaced by modavg.AICSclm.clm.
modavg.coxph has been replaced by modavg.AICCoxph.
modavg.glm has been replaced by modavg.AICglm or modavg.AICglm.1m, depending on the class of the objects.
modavg.gls has been replaced by modavg.AICgls.
modavg.lme has been replaced by modavg.AIClme.
modavg.mer has been replaced by modavg.AICmer.
modavg.merMod has been replaced by modavg.AIClmerMod or modavg.AICglmerMod, depending on the class of the objects.
modavg.mult has been replaced by modavg.AICmultinom.nnet.
modavg.polr has been replaced by modavg.AICpolr.
modavg.rlm has been replaced by modavg.AICrlm.1m.
modavg.unmarked has been replaced by modavg.AICunmarkedFitOccu, modavg.AICunmarkedFitColExt, modavg.AICunmarkedFitOccuRN, modavg.AICunmarkedFitPCount, modavg.AICunmarkedFitPCO, modavg.AICunmarkedFitDS, modavg.AICunmarkedFitGDS, modavg.AICunmarkedFitOccuFP, modavg.AICunmarkedFitMPois, modavg.AICunmarkedFitGMM, or modavg.AICunmarkedFitGPC, depending on the class of the objects.
modavg.effect has been replaced by modavgEffect.
modavg.effect.glm has been replaced by modavgEffect.AICglm.1m or modavgEffect.AIClme, depending on the class of the objects.
modavg.effect.gls has been replaced by modavgEffect.AICgls.
modavg.effect.lme has been replaced by modavgEffect.AIClme.
modavg.effect.mer has been replaced by modavgEffect.AICmer.
modavg.effect.merMod has been replaced by modavgEffect.AIClmerMod or modavgEffect.AIClmerMod, depending on the class of the objects.
modavg.effect.rlm has been replaced by modavgEffect.AICrlm.1m.
modavg.effect.unmarked has been replaced by modavgEffect.AICunmarkedFitOccu, modavgEffect.AICunmarkedFitColExt, modavgEffect.AICunmarkedFitOccuRN, modavgEffect.AICunmarkedFitPCount, modavgEffect.AICunmarkedFitPCO, modavgEffect.AICunmarkedFitDS, modavgEffect.AICunmarkedFitGDS, modavgEffect.AICunmarkedFitOccuFP, modavgEffect.AICunmarkedFitMPois, modavgEffect.AICunmarkedFitGMM, or modavgEffect.AICunmarkedFitGPC, depending on the class of the objects.
modavg.shrink has been replaced by modavgShrink.
modavg.shrink.clm has been replaced by modavgShrink.AICSclm.clm.
modavg.shrink.clmm has been replaced by modavgShrink.AICclmm.
modavg.shrink.coxph has been replaced by modavgShrink.AICCoxph.
modavg.shrink.glm has been replaced by modavgShrink.AICglm.lm or modavgShrink.AICgls.lm, depending on the class of the objects.

modavg.shrink.gls has been replaced by modavgShrink.AICgls.

modavg.shrink.lme has been replaced by modavgShrink.AIClme.

modavg.shrink.mer has been replaced by modavgShrink.AICmer.

modavg.shrink.merMod has been replaced by modavgShrink.AICglmerMod or modavgShrink.AIClmerMod, depending on the class of the objects.

modavg.shrink.mult has been replaced by modavgShrink.AICmultinom.nnet.

modavg.shrink.polr has been replaced by modavgShrink.AICpolr.

modavg.shrink.rlm has been replaced by modavgShrink.AICrlm.lm

modavg.shrink.unmarked has been replaced by modavgShrink.AICunmarkedFitOccu, modavgShrink.AICunmarkedFitOccuRC, modavgShrink.AICunmarkedFitOccuRN, modavgShrink.AICunmarkedFitPCo, modavgShrink.AICunmarkedFitDC, modavgShrink.AICunmarkedFitGDS, modavgShrink.AICunmarkedFitOccuFP, modavgShrink.AICunmarkedFitMPois, modavgShrink.AICunmarkedFitGMM, or modavgShrink.AICunmarkedFitGPC, depending on the class of the objects.

modavgpred has been replaced by modavgPred.

modavgpred.glm has been replaced by modavgPred.AICglm.lm or modavgPred.AIClme, depending on the class of the objects.

modavgpred.gls has been replaced by modavgPred.AICgls.

modavgpred.lme has been replaced by modavgPred.AIClme.

modavgpred.mer has been replaced by modavgPred.AICmer.

modavgpred.merMod has been replaced by modavgPred.AICglmerMod or modavgPred.AIClmerMod, depending on the class of the objects.

modavgpred.rlm has been replaced by modavgPred.AICrlm.lm.

modavgpred.unmarked has been replaced by modavgPred.AICunmarkedFitOccu, modavgPred.AICunmarkedFitOccuRN, modavgPred.AICunmarkedFitPCo, modavgPred.AICunmarkedFitDC, modavgPred.AICunmarkedFitGDS, modavgPred.AICunmarkedFitOccuFP, modavgPred.AICunmarkedFitMPois, modavgPred.AICunmarkedFitGMM, or modavgPred.AICunmarkedFitGPC, depending on the class of the objects.

mult.comp has been replaced by multComp.

predictSE.zip has been replaced by predictSE.

Description

This function creates a model selection table based on one of the following information criteria: AIC, AICc, QAIC, QAICc. The table ranks the models based on the selected information criteria and also provides delta AIC and Akaike weights. aictab selects the appropriate function to create the model selection table based on the object class. The current version works with lists containing objects of aov, betareg, clm, clmm, clogit, coxme, coxph, fitdist, fitdistr, glm, glmmTMB, gls, gnls, hurdle, lavaan, lm, lme, lmekin, maxlikeFit, mer, merMod, multinom, negbin, nlme, nls, polr, rlm, survreg, vglm, and zeroinfl classes as well as various models of unmarkedFit classes but does not yet allow mixing of different classes.

Usage

aictab(cand.set, modnames = NULL, second.ord = TRUE, nobs = NULL,
sort = TRUE, ...)

## S3 method for class 'AICaov.lm'

    second.order = TRUE, nobs = NULL, sort = TRUE, c.hat = 1, ...)
Arguments

**cand.set**
a list storing each of the models in the candidate model set.

**modnames**
a character vector of model names to facilitate the identification of each model in the model selection table. If NULL, the function uses the names in the cand.set list of candidate models (i.e., a named list). If no names appear in the list and no character vector is provided, generic names (e.g., Mod1, Mod2) are supplied in the table in the same order as in the list of candidate models.

**second.ord**
logical. If TRUE, the function returns the second-order Akaike information criterion (i.e., AICc).

**nobs**
this argument allows to specify a numeric value other than total sample size to compute the AICc (i.e., nobs defaults to total number of observations). This is relevant only for mixed models or various models of unmarkedFit classes where sample size is not straightforward. In such cases, one might use total number of observations or number of independent clusters (e.g., sites) as the value of nobs.

**sort**
logical. If TRUE, the model selection table is ranked according to the (Q)AIC(c) values.

**c.hat**
value of overdispersion parameter (i.e., variance inflation factor) such as that obtained from c_hat. Note that values of c.hat different from 1 are only appropriate for binomial GLM’s with trials > 1 (i.e., success/trial or cbind(success, failure) syntax), with Poisson GLM’s, single-season occupancy models (MacKenzie et al. 2002), dynamic occupancy models (MacKenzie et al. 2003), or N-mixture models (Royle 2004, Dail and Madsen 2011). If c.hat > 1, aictab will return the quasi-likelihood analogue of the information criteria requested and multiply the variance-covariance matrix of the estimates by this value (i.e., SE’s are multiplied by sqrt(c.hat)). This option is not supported for generalized linear mixed models of the mer or merMod classes.

... additional arguments passed to the function.

Details

aictab internally creates a new class for the cand.set list of candidate models, according to the contents of the list. The current function is implemented for clogit, coxme, coxph, fitdist, fitdistr, glm, glmmTMB, gls, glnlS, hurdle, lavaan, lm, lme, lme4, maxlikeFit, mer, merMod, multinom, negbin, nlm, nls, polr, rlm, survreg, vglm, and zeroinfl classes as well as various unmarkedFit classes. The function constructs a model selection table based on one of the four information criteria: AIC, AICc, QAIC, and QAICc.

Ten guidelines for model selection:
1) Carefully construct your candidate model set. Each model should represent a specific (interesting) hypothesis to test.
2) Keep your candidate model set short. It is ill-advised to consider as many models as there are data.
3) Check model fit. Use your global model (most complex model) or subglobal models to determine if the assumptions are valid. If none of your models fit the data well, information criteria will only indicate the most parsimonious of the poor models.

4) Avoid data dredging (i.e., looking for patterns after an initial round of analysis).

5) Avoid overfitting models. You should not estimate too many parameters for the number of observations available in the sample.

6) Be careful of missing values. Remember that values that are missing only for certain variables change the data set and sample size, depending on which variable is included in any given model. I suggest to remove missing cases before starting model selection.

7) Use the same response variable for all models of the candidate model set. It is inappropriate to run some models with a transformed response variable and others with the untransformed variable. A workaround is to use a different link function for some models (e.g., identity vs log link).

8) When dealing with models with overdispersion, use the same value of c-hat for all models in the candidate model set. For binomial models with trials > 1 (i.e., success/trial or cbind(success, failure) syntax) or with Poisson GLM’s, you should estimate the c-hat from the most complex model (global model). If c-hat > 1, you should use the same value for each model of the candidate model set (where appropriate) and include it in the count of parameters (K). Similarly, for negative binomial models, you should estimate the dispersion parameter from the global model and use the same value across all models.

9) Burnham and Anderson (2002) recommend to avoid mixing the information-theoretic approach and notions of significance (i.e., P values). It is best to provide estimates and a measure of their precision (standard error, confidence intervals).

10) Determining the ranking of the models is just the first step. Akaike weights sum to 1 for the entire model set and can be interpreted as the weight of evidence in favor of a given model being the best one given the candidate model set considered and the data at hand. Models with large Akaike weights have strong support. Evidence ratios, importance values, and confidence sets for the best model are all measures that assist in interpretation. In cases where the top ranking model has an Akaike weight > 0.9, one can base inference on this single most parsimonious model. When many models rank highly (i.e., delta (Q)AIC(c) < 4), one should model-average effect sizes for the parameters with most support across the entire set of models. Model averaging consists in making inference based on the whole set of candidate models, instead of basing conclusions on a single ‘best’ model. It is an elegant way of making inference based on the information contained in the entire model set.

Value

aictab creates an object of class aictab with the following components:

Modname the name of each model of the candidate model set.

K the number of estimated parameters for each model.

(Q)AIC(c) the information criterion requested for each model (AIC, AICc, QAIC, QAICc).

Delta_(Q)AIC(c) the appropriate delta AIC component depending on the information criteria selected.
the relative likelihood of the model given the data (exp(-0.5*delta[i])). This is not to be confused with the likelihood of the parameters given the data. The relative likelihood can then be normalized across all models to get the model probabilities.

(Q)AIC(c)Wt the Akaike weights, also termed “model probabilities” sensu Burnham and Anderson (2002) and Anderson (2008). These measures indicate the level of support (i.e., weight of evidence) in favor of any given model being the most parsimonious among the candidate model set.

Cum.Wt the cumulative Akaike weights. These are only meaningful if results in table are sorted in decreasing order of Akaike weights (i.e., sort = TRUE).

c.hat if c.hat was specified as an argument, it is included in the table.

LL if c.hat = 1 and parameters estimated by maximum likelihood, the log-likelihood of each model.

Quasi.LL if c.hat > 1, the quasi log-likelihood of each model.

Res.LL if parameters are estimated by restricted maximum-likelihood (REML), the restricted log-likelihood of each model.

Create Model Selection Tables from User-supplied Input Based on (Q)AIC(c)

Description

This function creates a model selection table from model input (log-likelihood, number of estimated parameters) supplied by the user instead of extracting the values automatically from a list of candidate models. The models are ranked based on one of the following information criteria: AIC, AICc, QAIC, QAICc. The table ranks the models based on the selected information criteria and also provides delta AIC and Akaike weights.

Usage

```
aictabCustom(logL, K, modnames = NULL, second.ord = TRUE, nobS = NULL, 
  sort = TRUE, c.hat = 1)
```

Arguments

- `logL`: a vector of log-likelihood values for the models in the candidate model set.
- `K`: a vector containing the number of estimated parameters for each model in the candidate model set.
- `modnames`: a character vector of model names to facilitate the identification of each model in the model selection table. If `NULL`, the function uses the names in the cand.set list of candidate models (i.e., a named list). If no names appear in the list and no character vector is provided, generic names (e.g., `mod1`, `mod2`) are supplied in the table in the same order as in the list of candidate models.
- `second.ord`: logical. If `TRUE`, the function returns the second-order Akaike information criterion (i.e., AICc).
- `nobS`: the sample size required to compute the AICc or QAICc.
- `sort`: logical. If `TRUE`, the model selection table is ranked according to the (Q)AIC(c) values.
- `c.hat`: value of overdispersion parameter (i.e., variance inflation factor) such as that obtained from c.hat. Note that values of c.hat different from 1 are only appropriate for binomial GLM’s with trials > 1 (i.e., success/trial or cbind(success, failure) syntax), with Poisson GLM’s, single-season or dynamic occupancy models (MacKenzie et al. 2002, 2003), N-mixture models (Royle 2004, Dail and Madsen 2011), or capture-mark-recapture models (e.g., Lebreton et al. 1992). If c.hat > 1, aictabCustom will return the quasi-likelihood analogue of the information criterion requested.
aictabCustom

Details

aictabCustom constructs a model selection table based on one of the four information criteria: AIC, AICc, QAIC, and QAICc. This function is most useful when model input is imported into R from other software (e.g., Program MARK, PRESENCE) or for model classes that are not yet supported by aictab.

Value

aictabCustom creates an object of class aictab with the following components:

- **Modname**: the name of each model of the candidate model set.
- **K**: the number of estimated parameters for each model.
- **(Q)AIC(c)**: the information criteria requested for each model (AICc, AICc, QAIC, QAICc).
- **Delta_(Q)AIC(c)**: the appropriate delta AIC component depending on the information criteria selected.
- **ModelLik**: the relative likelihood of the model given the data (exp(-0.5*delta[i])). This is not to be confused with the likelihood of the parameters given the data. The relative likelihood can then be normalized across all models to get the model probabilities.
- **(Q)AIC(c)Wt**: the Akaike weights, also termed "model probabilities" sensu Burnham and Anderson (2002) and Anderson (2008). These measures indicate the level of support (i.e., weight of evidence) in favor of any given model being the most parsimonious among the candidate model set.
- **Cum. Wt**: the cumulative Akaike weights. These are only meaningful if results in table are sorted in decreasing order of Akaike weights (i.e., sort = TRUE).
- **c.hat**: if c.hat was specified as an argument, it is included in the table.
- **LL**: if c.hat = 1 and parameters estimated by maximum likelihood, the log-likelihood of each model.
- **Quasi.LL**: if c.hat > 1, the quasi log-likelihood of each model.

anovaOD(mod.simple, mod.complex, c.hat = 1,
   nobs = NULL, ...)

## S3 method for class 'unmarkedFitMPois'
anovaOD(mod.simple, mod.complex, c.hat = 1,
   nobs = NULL, ...)

## S3 method for class 'unmarkedFitGMM'
anovaOD(mod.simple, mod.complex, c.hat = 1,
   nobs = NULL, ...)

## S3 method for class 'unmarkedFitGPC'
anovaOD(mod.simple, mod.complex, c.hat = 1,
   nobs = NULL, ...)

## S3 method for class 'glmerMod'
anovaOD(mod.simple, mod.complex, c.hat = 1,
   nobs = NULL, ...)

## S3 method for class 'maxlikeFit'
anovaOD(mod.simple, mod.complex, c.hat = 1, 
nobs = NULL, ...)

## S3 method for class 'multinom'
anovaOD(mod.simple, mod.complex, c.hat = 1, 
nobs = NULL, ...)

## S3 method for class 'vglm'
anovaOD(mod.simple, mod.complex, c.hat = 1, 
nobs = NULL, ...)

### Arguments

**mod.simple**
- an object of class `glm`, `glmmTMB`, `maxlikeFit`, `mer`, `merMod`, `multinom`, `vglm`, and various `unmarkedFit` classes containing the output of a model. This model should be a simpler version of `mod.complex` resulting from a deletion of certain terms (i.e., nested model).

**mod.complex**
- an object of the same class as `mod.simple`.

**c.hat**
- value of overdispersion parameter (i.e., variance inflation factor) such as that obtained from `c_hat`, `mb.gof.test`, or `Nmix.gof.test`. Typically, this value should be computed for the most complex model and applied to simpler models.

**nobs**
- the number of observations used in the analysis. If `nobs = NULL`, the total number of rows are used as the sample size to compute the residual degrees of freedom as `nobs - K`, where `K` is the number of estimated parameters. This is relevant only for mixed models or various models of `unmarkedFit` classes where sample size is not straightforward. In such cases, one might use total number of observations or number of independent clusters (e.g., sites) as the value of `nobs`.

... additional arguments passed to the function.

### Details

This function applies a correction for overdispersion on the likelihood-ratio test between a model and its simpler counterpart. The simpler model must be nested within the more complex model, typically as the result of deleting terms. You should supply the `c.hat` value of the most complex of the two models you are comparing.

When $1 < c.hat < 4$, the likelihood-ratio test is computed as:

$$ LR = -2 \frac{(LL.simple - LL.complex)}{(K.complex - K.simple) * c.hat} $$

where $LL.simple$ and $LL.complex$ are the log-likelihoods of the simple and complex models, respectively, and where $K.complex$ and $K.simple$ are the number of estimated parameters in each model. The test statistic is approximately distributed as $F_{K.complex - K.simple, n - K.complex}$, where $n$ is the number of observations (i.e., `nobs`) used in the analysis (Venables and Ripley 2002).

When `nobs = NULL`, the number of observations is based on the number of rows of the data frame used in the analysis. For mixed models or various models of `unmarkedFit`, sample size is less
straightforward, and nobs could be based on the total number of observations or on the number of independent clusters (e.g., sites), among other choices.
When \( \hat{c} = 1 \), the likelihood-ratio test simplifies to:

\[
LR = -2 \times (LL_{\text{simple}} - LL_{\text{complex}})
\]

where in this case the test statistic is distributed as a \( \chi^2_{K_{\text{complex}} - K_{\text{simple}}} \) (McCullagh and Nelder 1989).

The function supports different model types such as Poisson GLM’s and GLMM’s, single-season and dynamic occupancy models (MacKenzie et al. 2002, 2003), and various \( N \)-mixture models (Royle 2004, Dail and Madsen 2011).

Value

`anovaOD` returns an object of class `anovaOD` as a list with the following components:

- `form.simple` a character string of the parameters estimated in `mod.simple`.
- `form.complex` a character string of the parameters estimated in `mod.complex`.
- `c.hat` the \( \hat{c} \) estimate used to adjust the likelihood-ratio test.
- `devMat` a matrix storing as columns the number of parameters estimated (K), the log-likelihood of each model `logLik`, the difference in estimated parameters between the two models (`kdiff`), minus twice the difference in log-likelihoods between the models (`-2LL`), the test statistic, and the associated P-value.

**Flour Beetle Data**

**Description**

This data set illustrates the acute mortality of flour beetles (*Tribolium confusum*) following 5 hour exposure to carbon disulfide gas.

**Usage**

data(beetle)

**Format**

A data frame with 8 rows and 4 variables.

- **dose**: dose of carbon disulfide in mg/L.
- **number_tested**: number of beetles exposed to given dose of carbon disulfide.
- **number_killed**: number of beetles dead after 5 hour exposure to given dose of carbon disulfide.
- **mortality_rate**: proportion of total beetles found dead after 5 hour exposure.

**Details**

Burnham and Anderson (2002, p. 195) use this data set originally from Young and Young (1998) to show model selection for binomial models with different link functions (logit, probit, cloglog).

Create Model Selection Tables Based on BIC

Description

This function creates a model selection table based on the Bayesian information criterion (Schwarz 1978, Burnham and Anderson 2002). The table ranks the models based on the BIC and also provides delta BIC and BIC model weights. The function adjusts for overdispersion in model selection by using the QBIC when \( \hat{c} > 1 \). bictab selects the appropriate function to create the model selection table based on the object class. The current version works with lists containing objects of aov, betareg, clm, clmm, clogit, coxme, coxph, fitdist, fitdistr, glm, glmmTMB, gls, gnls, hurdle, lavaan, lm, lme, lmekin, maxlikeFit, mer, merMod, multinom, nlme, nls, polr, rlm, survreg, vglm, and zeroinf1 classes as well as various models of unmarkedFit classes but does not yet allow mixing of different classes.

Usage

bictab(cand.set, modnames = NULL, nobs = NULL,
       sort = TRUE, ...)

## S3 method for class 'AICaov.lm'
bictab(cand.set, modnames = NULL,

```
Arguments

cand.set
a list storing each of the models in the candidate model set.

modnames
a character vector of model names to facilitate the identification of each model in the model selection table. If NULL, the function uses the names in the cand.set list of candidate models (i.e., a named list). If no names appear in the list and no character vector is provided, generic names (e.g., Mod1, Mod2) are supplied in the table in the same order as in the list of candidate models.

nobs
this argument allows to specify a numeric value other than total sample size to compute the BIC (i.e., nobs defaults to total number of observations). This is relevant only for mixed models or various models of unmarkedFit classes where sample size is not straightforward. In such cases, one might use total number of observations or number of independent clusters (e.g., sites) as the value of nobs.

sort
logical. If TRUE, the model selection table is ranked according to the BIC values.

c.hat
value of overdispersion parameter (i.e., variance inflation factor) such as that obtained from c_hat. Note that values of c.hat different from 1 are only appropriate for binomial GLM’s with trials > 1 (i.e., success/trial or cbind(success, failure) syntax), with Poisson GLM’s, single-season occupancy models (MacKenzie et al. 2002), dynamic occupancy models (MacKenzie et al. 2003), or N-mixture models (Royle 2004, Dail and Madsen 2011). If c.hat > 1, bictab will return the quasi-likelihood analogue of the BIC (QBIC) and multiply the variance-covariance matrix of the estimates by this value (i.e., SE’s are multiplied by sqrt(c.hat)). This option is not supported for generalized linear mixed models of the mer or merMod classes.

... additional arguments passed to the function.

Details

BIC tends to favor simpler models than AIC whenever n > 8 (Schwarz 1978, Link and Barker 2006, Anderson 2008). BIC assigns uniform prior probabilities across all models (i.e., equal 1/R), whereas in AIC and AICc, prior probabilities increase with sample size (Burnham and Anderson 2004, Link and Barker 2010). Some authors argue that BIC requires the true model to be included in the model set, whereas AIC or AICc does not (Burnham and Anderson 2002). However, Link and Barker (2006, 2010) consider both as assuming that a model in the model set approximates truth.

bictab internally creates a new class for the cand.set list of candidate models, according to the contents of the list. The current function is implemented for clogit, coxme, coxph, fitdistr, glm, glmmTMB, gis, gnls, hurdle, lavaan, lm, lme, lme4, maxlikFit, mer, merMod, multinom, nlme, nls, polr, rlm, survreg, vglm, and zeroInfl classes as well as various unmarkedFit classes. The function constructs a model selection table based on BIC.

Value

bictab creates an object of class bictab with the following components:

Modname
the name of each model of the candidate model set.

K
the number of estimated parameters for each model.
(Q)BIC   the Bayesian information criterion for each model.
Delta_(Q)BIC  the delta BIC component.
ModelLik   the relative likelihood of the model given the data (\(\exp(-0.5*\text{delta}[i])\)). This is
            not to be confused with the likelihood of the parameters given the data. The
relative likelihood can then be normalized across all models to get the model
probabilities.
(Q)BICWt   the BIC model weights, also termed "model probabilities" (Burnham and
            Anderson 2002, Link and Barker 2006, Anderson 2008). These measures indicate
the level of support (i.e., weight of evidence) in favor of any given model being
the most parsimonious among the candidate model set.
Cum.Wt   the cumulative BIC weights. These are only meaningful if results in table are
sorted in decreasing order of BIC weights (i.e., \(\text{sort} = \text{TRUE}\)).
c.hat   if c.hat was specified as an argument, it is included in the table.
LL   the log-likelihood of each model.
Res.LL   if parameters are estimated by restricted maximum-likelihood (REML), the
restricted log-likelihood of each model.

```

## End (Not run)

bictabCustom  
Create Model Selection Tables from User-supplied Input Based on (Q)BIC

Description

This function creates a model selection table from model input (log-likelihood, number of estimated parameters) supplied by the user instead of extracting the values automatically from a list of candidate models. The models are ranked based on the BIC (Schwarz 1978) or on a quasi-likelihood analogue (QBIC) corrected for overdispersion. The table ranks the models based on the selected information criteria and also provides delta BIC and BIC weights.

Usage

bictabCustom(logL, K, modnames = NULL, nobs = NULL, sort = TRUE, c.hat = 1)

Arguments

logL  
a vector of log-likelihood values for the models in the candidate model set.

K  
a vector containing the number of estimated parameters for each model in the candidate model set.

modnames  
a character vector of model names to facilitate the identification of each model in the model selection table. If NULL, the function uses the names in the cand.set list of candidate models (i.e., a named list). If no names appear in the list and no character vector is provided, generic names (e.g., Mod1, Mod2) are supplied in the table in the same order as in the list of candidate models.

nobs  
the sample size required to compute the AICc or QAICc.

sort  
logical. If TRUE, the model selection table is ranked according to the (Q)BIC values.

c.hat  
value of overdispersion parameter (i.e., variance inflation factor) such as that obtained from c.hat. Note that values of c.hat different from 1 are only appropriate for binomial GLM’s with trials > 1 (i.e., success/trial or cbind(success, failure) syntax), with Poisson GLM’s, single-season or dynamic occupancy models (MacKenzie et al. 2002, 2003), N-mixture models (Royle 2004, Dail and Madsen 2011), or capture-mark-recapture models (e.g., Lebreton et al. 1992). If c.hat > 1, bictabCustom will return the quasi-likelihood analogue of the information criterion requested.

Details

bictabCustom constructs a model selection table based on BIC or QBIC. This function is most useful when model input is imported into R from other software (e.g., Program MARK, PRESENCE) or for model classes that are not yet supported by bictab.
**Value**

`bictabCustom` creates an object of class `bictab` with the following components:

- **Modname**: the name of each model of the candidate model set.
- **K**: the number of estimated parameters for each model.
- **(Q)BIC**: the information criteria requested for each model (BIC, QBIC).
- **Delta_(Q)BIC**: the appropriate delta BIC component depending on the information criteria selected.
- **ModelLik**: the relative likelihood of the model given the data (exp(-0.5*delta[i])). This is not to be confused with the likelihood of the parameters given the data. The relative likelihood can then be normalized across all models to get the model probabilities.
- **(Q)BICWt**: the BIC weights, also termed "model probabilities" sensu Burnham and Anderson (2002) and Anderson (2008). These measures indicate the level of support (i.e., weight of evidence) in favor of any given model being the most parsimonious among the candidate model set.
- **Cum.Wt**: the cumulative BIC weights. These are only meaningful if results in table are sorted in decreasing order of BIC weights (i.e., sort = TRUE).
- **c.hat**: if c.hat was specified as an argument, it is included in the table.
- **LL**: if c.hat = 1 and parameters estimated by maximum likelihood, the log-likelihood of each model.
- **Quasi.LL**: if c.hat > 1, the quasi log-likelihood of each model.

boot.wt  
Compute Model Selection Relative Frequencies

Description

This function computes the model selection relative frequencies based on the nonparametric bootstrap (Burnham and Anderson 2002). Models are ranked based on the AIC, AICc, QAIC, or QAICc. The function currently supports objects of aov, betareg, clm, glm, hurdle, lm, multinom, polr, rlm, survreg, vglm, and zeroィinf1 classes.

Usage

```r
boot.wt(cand.set, modnames = NULL, second.ord = TRUE, nobs = NULL, sort = TRUE, nsim = 100, ...)
```

```r
## S3 method for class 'AICaov.lm'
boot.wt(cand.set, modnames = NULL, second.ord = TRUE, nobs = NULL, sort = TRUE, nsim = 100, ...)

## S3 method for class 'AICsurvreg'
boot.wt(cand.set, modnames = NULL, second.ord = TRUE, nobs = NULL, sort = TRUE, nsim = 100, ...)
```
Arguments

cand.set

a list storing each of the models in the candidate model set.

modnames

a character vector of model names to facilitate the identification of each model in the model selection table. If NULL, the function uses the names in the cand.set list of candidate models. If no names appear in the list, generic names (e.g., Mod1, Mod2) are supplied in the table in the same order as in the list of candidate models.
Logical. If TRUE, the function returns the second-order Akaike information criterion (i.e., AICc).

This argument allows to specify a numeric value other than total sample size to compute the AICc (i.e., nobs defaults to total number of observations). This is relevant only for certain types of models such as mixed models where sample size is not straightforward. In such cases, one might use total number of observations or number of independent clusters (e.g., sites) as the value of nobs.

Logical. If TRUE, the model selection table is ranked according to the (Q)AIC(c) values.

delta_HqIaicHcI

the appropriate delta AIC component depending on the information criteria selected.

ModelLik

the relative likelihood of the model given the data \( \exp(-0.5*\text{delta}[i]) \). This is not to be confused with the likelihood of the parameters given the data. The relative likelihood can then be normalized across all models to get the model probabilities.

Details

boot.wt is implemented for aov, betareg, glm, hurdle, lm, multinom, polr, rlm, survreg, vglm, and zeroinfl classes. During each bootstrap iteration, the data are resampled with replacement, all the models specified in cand.set are updated with the new data set, and the top-ranked model is saved. When all iterations are completed, the relative frequency of selection is computed for each model appearing in the candidate model set.

Relative frequencies of the models are often similar to Akaike weights, and the latter are often preferred due to their link with a Bayesian perspective (Burnham and Anderson 2002). boot.wt is most useful for teaching purposes of sampling-theory based relative frequencies of model selection. The current implementation is only appropriate with completely randomized designs. For more complex data structures (e.g., blocks or random effects), the bootstrap should be modified accordingly.

Value

boot.wt creates an object of class boot.wt with the following components:

Modname

the names of each model of the candidate model set.

K

the number of estimated parameters for each model.

(Q)AIC(c)

the information criteria requested for each model (AICc, AICc, QAIC, QAICc).

Delta_(Q)AIC(c)

the relative likelihood of the model given the data \( \exp(-0.5*\text{delta}[i]) \). This is not to be confused with the likelihood of the parameters given the data. The relative likelihood can then be normalized across all models to get the model probabilities.
the Akaike weights, also termed “model probabilities” sensu Burnham and Anderson (2002) and Anderson (2008). These measures indicate the level of support (i.e., weight of evidence) in favor of any given model being the most parsimonious among the candidate model set.

the relative frequencies of model selection from the bootstrap.

if c.hat was specified as an argument, it is included in the table.

Modnames <- paste("mod", 1:length(Cand.models), sep = " ")

#generate AICc table with bootstrapped relative
```
## Bullfrog Occupancy and Common Reed Invasion

### Description

This is a data set from Mazerolle et al. (2014) on the occupancy of Bullfrogs (*Lithobates catesbeianus*) in 50 wetlands sampled in 2009 in the area of Montreal, QC.

### Usage

```r
data(bullfrog)
```

### Format

A data frame with 50 observations on the following 23 variables.

- **Location**: a factor with a unique identifier for each wetland.
- **Reed_presence**: a binary variable, either 1 (reed present) or 0 (reed absent).
- **V1**: a binary variable for detection (1) or non detection (0) of bullfrogs during the first survey.
- **V2**: a binary variable for detection (1) or non detection (0) of bullfrogs during the second survey.
V3 a binary variable for detection (1) or non detection (0) of bullfrogs during the third survey.
V4 a binary variable for detection (1) or non detection (0) of bullfrogs during the fourth survey.
V5 a binary variable for detection (1) or non detection (0) of bullfrogs during the fifth survey.
V6 a binary variable for detection (1) or non detection (0) of bullfrogs during the sixth survey.
V7 a binary variable for detection (1) or non detection (0) of bullfrogs during the seventh survey.
Effort1 a numeric variable for the centered number of sampling stations during the first survey.
Effort2 a numeric variable for the centered number of sampling stations during the second survey.
Effort3 a numeric variable for the centered number of sampling stations during the third survey.
Effort4 a numeric variable for the centered number of sampling stations during the fourth survey.
Effort5 a numeric variable for the centered number of sampling stations during the fifth survey.
Effort6 a numeric variable for the centered number of sampling stations during the sixth survey.
Effort7 a numeric variable for the centered number of sampling stations during the seventh survey.
Type1 a binary variable to identify the survey type, either minnow trap (1) or call survey (0) during the first sampling occasion.
Type2 a binary variable to identify the survey type, either minnow trap (1) or call survey (0) during the second sampling occasion.
Type3 a binary variable to identify the survey type, either minnow trap (1) or call survey (0) during the third sampling occasion.
Type4 a binary variable to identify the survey type, either minnow trap (1) or call survey (0) during the fourth sampling occasion.
Type5 a binary variable to identify the survey type, either minnow trap (1) or call survey (0) during the fifth sampling occasion.
Type6 a binary variable to identify the survey type, either minnow trap (1) or call survey (0) during the sixth sampling occasion.
Type7 a binary variable to identify the survey type, either minnow trap (1) or call survey (0) during the seventh sampling occasion.

Details

This data set is used to illustrate single-species single-season occupancy models (MacKenzie et al. 2002) in Mazerolle (2015).

Blood Calcium Concentration in Birds

Description

This data set features calcium concentration in the plasma of birds of both sexes following a hormonal treatment.

Usage
data(calcium)

Format

A data frame with 20 rows and 3 variables.

Calcium  calcium concentration in mg/100 ml in the blood of birds.
Hormone  a factor with two levels indicating whether the bird received a hormonal treatment or not.
Sex      a factor with two levels coding for the sex of birds.

Details

Zar (1984, p. 206) illustrates a two-way ANOVA with interaction with this data set.

Source

Examples
data(calcium)
str(calcium)
Description

This data set illustrates the heat expended (calories) from mixtures of four different ingredients of Portland cement expressed as a percentage by weight.

Usage

data(cement)

Format

A data frame with 13 observations on the following 5 variables.

x1  calcium aluminate.

x2  tricalcium silicate.

x3  tetracalcium alumino ferrite.

x4  dicalcium silicate.

y  calories of heat per gram of cement following 180 days of hardening.

Details

Burnham and Anderson (2002, p. 101) use this data set originally from Woods et al. (1932) to select among a set of multiple regression models.

checkConv(mod, ...)
checkConv

## S3 method for class 'unmarkedFit'
checkConv(mod, ...)

## S3 method for class 'zeroinfl'
checkConv(mod, ...)

**Arguments**

mod       an object containing the output of a model of the classes mentioned above.

...       additional arguments passed to the function.

**Details**

This function checks the element of a model object that contains the convergence information from the optimization function. The function is currently implemented for models of classes \texttt{betareg}, \texttt{clm}, \texttt{clmm}, \texttt{glm}, \texttt{glmmTMB}, \texttt{hurdle}, \texttt{lavaan}, \texttt{maxlikeFit}, \texttt{merMod}, \texttt{multinom}, \texttt{nls}, \texttt{polr}, \texttt{unmarkedFit}, and \texttt{zeroinfl}. The function is particularly useful for functions with several groups of parameters, such as those of the \texttt{unmarked} package (Fiske and Chandler, 2011).

**Value**

checkConv returns a list with the following components:

- converged a logical value indicating whether the algorithm converged or not.
- message  a string containing the message from the optimization function.

---

checkParms  Identify Parameters with Large Standard Errors

**Description**

This function identifies parameter estimates with large standard errors in a model. It is particularly useful for complex models with different parameter types such as those of `unmarkedFit` classes implemented in package `unmarked` (Fiske and Chandler, 2011), as well as other types of regression models.

**Usage**

```r
checkParms(mod, se.max = 25, simplify = TRUE, ...)
```

## S3 method for class 'betareg'
```r
ccheckParms(mod, se.max = 25, ...)
```

## S3 method for class 'clm'
```r
ccheckParms(mod, se.max = 25, ...)
```

## S3 method for class 'clmm'
```r
ccheckParms(mod, se.max = 25, ...)
```

## S3 method for class 'coxme'
```r
ccheckParms(mod, se.max = 25, ...)
```
## S3 method for class 'coxph'
checkParms(mod, se.max = 25, ...)

## S3 method for class 'glm'
checkParms(mod, se.max = 25, ...)

## S3 method for class 'glmmTMB'
checkParms(mod, se.max = 25, ...)

## S3 method for class 'gls'
checkParms(mod, se.max = 25, ...)

## S3 method for class 'gnls'
checkParms(mod, se.max = 25, ...)

## S3 method for class 'hurdle'
checkParms(mod, se.max = 25, ...)

## S3 method for class 'lm'
checkParms(mod, se.max = 25, ...)

## S3 method for class 'lme'
checkParms(mod, se.max = 25, ...)

## S3 method for class 'lmekin'
checkParms(mod, se.max = 25, ...)

## S3 method for class 'maxlikeFit'
checkParms(mod, se.max = 25, ...)

## S3 method for class 'merMod'
checkParms(mod, se.max = 25, ...)

## S3 method for class 'multinom'
checkParms(mod, se.max = 25, ...)

## S3 method for class 'nlme'
checkParms(mod, se.max = 25, ...)

## S3 method for class 'nls'
checkParms(mod, se.max = 25, ...)

## S3 method for class 'polr'
checkParms(mod, se.max = 25, ...)

## S3 method for class 'rlm'
checkParms(mod, se.max = 25, ...)

Arguments

mod
specifies the value beyond which standard errors are deemed high for the model at hand. The function will determine the number of estimates with standard errors that exceed `se.max`.

simplify
this argument is only valid for models of `unmarkedFit` classes which consist of several parameter types for detection probability and demographic parameters (e.g., abundance, occupancy, extinction). If `TRUE`, the function returns a matrix with a single row identifying the parameter type and estimate with the highest standard error. If `FALSE`, the function returns a matrix with as many rows as there are parameter types in the model. In the latter case, the estimate with the highest standard error for each parameter type is presented.

... additional arguments passed to the function.

Details

In some complex models such as certain hierarchical models (Royle and Dorazio 2008, Kéry and Royle 2015), issues in estimating parameters and their standard errors can occur. Large standard errors can be indicative of problems in estimating certain parameters due to sparse data, parameters on the boundary, or model misspecification. The `checkParms` function computes the number of parameter estimates with standard errors larger than `se.max` and identifies the parameter estimate with the largest standard error across all parameter types (`simplify = TRUE`) or for each parameter type (`simplify = FALSE`).

To help identify large standard errors, users can standardize numeric explanatory variables to zero mean and unit variance. The `checkParms` function can also be useful to identify boundary estimates in classic generalized models or their extensions (Venables and Ripley 2002).

Value

`checkParms` returns a list of class `checkParms` with the following components:
checkParms

model.class the class of the model for which diagnostics are requested.
se.max the value of SE used as a threshold in diagnostics. The function reports the number of parameter estimates with SE > se.max.
result a matrix consisting of three columns, namely, the identity of the parameter estimate with the highest SE (variable), its standard error (max.se), and the number of parameter estimates with SE larger than se.max (n.high.se). For classical regression models with a single response variable, the row name is labeled beta. For unmarkedFit models, the matrix either consists of a single row (simplify = TRUE) labeled with the name of the parameter type (e.g., psi, gam, eps, p) where the highest SE occurs, or consists of as many rows as there are parameter types (simplify = FALSE).

confset  

Computing Confidence Set for the Kullback-Leibler Best Model

Description

This function computes the confidence set on the best model given the data and model set. confset implements three different methods proposed by Burnham and Anderson (2002).

Usage

confset(cand.set, modnames = NULL, second.ord = TRUE, nobs = NULL, 
method = "raw", level = 0.95, delta = 6, c.hat = 1)

Arguments

cand.set  
a list storing each of the models in the candidate model set.

modnames  
a character vector of model names to facilitate the identification of each model in the model selection table. If NULL, the function uses the names in the cand.set list of candidate models. If no names appear in the list, generic names (e.g., Mod1, Mod2) are supplied in the table in the same order as in the list of candidate models.

second.ord  
logical. If TRUE, the function returns the second-order Akaike information criterion (i.e., AICc).
This argument allows to specify a numeric value other than total sample size to compute the AICc (i.e., \texttt{nobs} defaults to total number of observations). This is relevant only for mixed models or various models of \texttt{unmarkedfit} classes where sample size is not straightforward. In such cases, one might use total number of observations or number of independent clusters (e.g., sites) as the value of \texttt{nobs}.

\textbf{method}

A character value, either as \texttt{raw}, \texttt{ordinal}, or \texttt{ratio}, indicating the method for determining the confidence set for the best model (see ‘Description’ above for details).

\textbf{level}

The level of confidence (i.e., sum of model probabilities) used to determine the confidence set on the best model when using the \texttt{raw} method. Note that the argument is not used for the other methods of determining the confidence set on the best model.

\textbf{delta}

The delta (Q)AIC(c) value associated with the cutoff point to determine the confidence set for the best model. Note that the argument is only used when \texttt{method} = \texttt{ratio}.

\textbf{cNhat}

Value of overdispersion parameter (i.e., variance inflation factor) such as that obtained from \texttt{cNhat}. Note that values of \texttt{cNhat} different from 1 are only appropriate for binomial GLM’s with trials > 1 (i.e., success/trial or \texttt{cbind(success, failure)} syntax), with Poisson GLM’s, single-season occupancy models (MacKenzie et al. 2002), dynamic occupancy models (MacKenzie et al. 2003), or N-mixture models (Royle 2004, Dail and Madsen 2011). If \texttt{cNhat} > 1, \texttt{confset} will return the quasi-likelihood analogue of the information criteria requested and multiply the variance-covariance matrix of the estimates by this value (i.e., SE’s are multiplied by \texttt{sqrt(cNhat)}). This option is not supported for generalized linear mixed models of the \texttt{mer} or \texttt{merMod} classes.

**Details**

The first and simplest (\texttt{method} = \texttt{‘raw’}), relies on summing the Akaike weights (i.e., model probabilities) of the ranked models until we reach a given cutpoint (e.g., 0.95 for a 95 percent set).

The second method (\texttt{method} = \texttt{‘ordinal’}) suggested is based on the classification of the models on an ordinal scale based on the delta (Q)AIC(c). The models are grouped in different classes based on their weight of support as determined by the delta (Q)AIC(c) values: substantial support (delta (Q)AIC(c) <= 2), some support (2 < delta (Q)AIC(c) <= 7), little support (7 < delta (Q)AIC(c) <= 10), no support (delta (Q)AIC(c) > 10).

The third method (\texttt{method} = \texttt{‘ratio’}) is based on identifying the ratios of model likelihoods (i.e., \texttt{exp(-delta(Q)AIC(c)/2)} ) that exceed a cutpoint, similar to the building of profile likelihood intervals. An evidence ratio of each model relative to the top-ranked model is computed and the ratios exceeding the cutpoint determine which models are included in the confidence set. Note here that small cutoff points are suggested (e.g., 0.125, 0.050). The cutoff point is linked to delta (Q)AIC(c) by the following relationship: \texttt{cutoff} = \texttt{exp(-1 * delta(Q)AIC(c)/2)}.

**Value**

\texttt{confset} returns an object of class \texttt{confset} as a list with the following components, depending on which method is used:
when method = 'raw':

method identifies the method of determining the confidence set on the best model.
level the confidence level used to determine the confidence set on the best model.
table a reduced table with the models included in the confidence set.

when method = 'ordinal':

method identifies the method of determining the confidence set on the best model.
substantial a reduced table with the models included in the confidence set for which delta \( (Q)AIC(c) \leq 2 \).
some a reduced table with the models included in the confidence set for which \( 2 < \delta (Q)AIC(c) \leq 7 \).
little a reduced table with the models included in the confidence set for which \( 7 < \delta (Q)AIC(c) \leq 10 \).
none a reduced table with the models included in the confidence set for which \( \delta (Q)AIC(c) > 10 \).

when method = 'ratio':

method identifies the method of determining the confidence set on the best model.
cutoff the cutoff value for the ratios used to determine the confidence set on the best model.
delta the \( (Q)AIC(c) \) used to compute the cutoff value for ratios to determine the confidence set on the best model.
table a reduced table with the models included in the confidence set.

## S3 method for class 'unmarkedFrameDS'
countDist(object, plot.freq = TRUE,
            plot.distance = TRUE, ...)

## S3 method for class 'unmarkedFitDS'
countDist(object, plot.freq = TRUE,
            plot.distance = TRUE, ...)

## S3 method for class 'unmarkedFrameGDS'
countDist(object, plot.freq = TRUE,
            plot.distance = TRUE, ...)

## S3 method for class 'unmarkedFitGDS'
countDist(object, plot.freq = TRUE,
            plot.distance = TRUE, ...)

### Arguments

- **object**: an object of various `unmarkedFrame` or `unmarkedFit` classes containing distance sampling data.
- **plot.freq**: logical. Specifies if the count data (pooled across seasons and distance classes) should be plotted.
- **plot.distance**: logical. Specifies if the counts in each distance class should be plotted.
- **...**: additional arguments passed to the function.

### Details

This function computes a number of summary statistics in data sets used for the distance sampling models of Royle et al. (2004) and Chandler et al. (2011).

countDist can take data frames of the `unmarkedFrameDS` and `unmarkedFrameGDS` classes as input. For convenience, the function can also extract the raw data from model objects of classes `unmarkedFitDS` and `unmarkedFitGDS`. Note that different model objects using the same data set will have identical values.

### Value

countDist returns a list with the following components:

- **count.table.full**: a table with the frequency of each observed count pooled across distances classes.
- **count.table.seasons**: a list of tables with the frequency of each season-specific count pooled across distance classes.
- **dist.sums.full**: a table with the frequency of counts in each distance class across the entire sampling seasons.
countDist

hist.table.seasons

A list of tables with the frequency of counts in each distance class for each primary period.

out.freqs

A matrix where the rows correspond to each sampling season and where columns consist of the number of sites sampled in season \( t \) (sampled) and the number of sites with at least one detection in season \( t \) (detected). For multiseason data, the matrix includes the number of sites sampled in season \( t - 1 \) with colonizations observed in season \( t \) (colonized), the number of sites sampled in season \( t - 1 \) with extinctions observed in season \( t \) (extinct), the number of sites sampled in season \( t - 1 \) without changes observed in season \( t \) (static), and the number of sites sampled in season \( t \) that were also sampled in season \( t - 1 \) (common).

out.props

A matrix where the rows correspond to each sampling season and where columns consist of the proportion of sites in season \( t \) with at least one detection (naive.occ). For multiseason data, the matrix includes the proportion of sites sampled in season \( t - 1 \) with colonizations observed in season \( t \) (naive.colonization), the proportion of sites sampled in season \( t - 1 \) with extinctions observed in season \( t \) (naive.extinction), and the proportion of sites sampled in season \( t - 1 \) with no changes observed in season \( t \).

n.seasons

The number of seasons (primary periods) in the data set.

n.visits.season

The maximum number of visits per season in the data set.

covDiag | Compute Covariance Diagnostic for Lambda in N-mixture Models

Description

This function extracts the covariance diagnostic of Dennis et al. (2015) for lambda in N-mixture models (Royle 2004) of the unmarkedFitPCount class as well as in data frames of the unmarkedFramePcount class.

Usage

covDiag(object, ...)

## S3 method for class 'unmarkedFitPCount'
covDiag(object, ...)

## S3 method for class 'unmarkedFramePCount'
covDiag(object, ...)

Arguments

object | an object of class unmarkedFitPCount or unmarkedFramePCount.

... | additional arguments passed to the function.

Details

This function extracts the covariance diagnostic developed by Dennis et al. (2015) for lambda in N-mixture models. Values <= 0 suggest sparse data and potential problems during model fitting. covDiag can take data frames of the unmarkedFramePcount class as input. For convenience, the function also takes the repeated count model object as input, extracts the raw data, and computes the covariance diagnostic. Thus, different models on the same data set will have identical values for this covariance diagnostic.
**covDiag**

**Value**

covDiag returns a list with the following components:

- `cov.diag`: the value of the covariance diagnostic.
- `message`: a string indicating whether a warning was issued (i.e., "Warning: lambda is infinite, data too sparse") or not (i.e., `NULL`).

c_hat

Estimate Dispersion for Poisson and Binomial GLM’s and GLMM’s

Description

Functions to compute an estimate of c-hat for binomial or Poisson GLM’s and GLMM’s using different estimators of overdispersion.

Usage

c_hat(mod, method = "pearson", ...)

## S3 method for class 'glm'
c_hat(mod, method = "pearson", ...)

## S3 method for class 'glmmTMB'
c_hat(mod, method = "pearson", ...)

## S3 method for class 'merMod'
c_hat(mod, method = "pearson", ...)

## S3 method for class 'vglm'
c_hat(mod, method = "pearson", ...)

Arguments

mod an object of class glm, glmmTMB, merMod, or vglm for which a c-hat estimate is required.
method this argument defines the estimator used. The default "pearson" uses the Pearson chi-square divided by the residual degrees of freedom. Other methods include "deviance" consisting of the residual deviance divided by the residual degrees of freedom, "farrington" for the estimator suggested by Farrington (1996), and "fletcher" for the estimator suggested by Fletcher (2012).

... additional arguments passed to the function.

Details

Poisson and binomial GLM’s do not have a parameter for the variance and it is usually held fixed to 1 (i.e., mean = variance). However, one must check whether this assumption is appropriate by estimating the overdispersion parameter (c-hat). Though one can obtain an estimate of c-hat by dividing the residual deviance by the residual degrees of freedom (i.e., method = "deviance"), McCullagh and Nelder (1989) and Venables and Ripley (2002) recommend using Pearson’s chi-square divided by the residual degrees of freedom (method = "pearson"). An estimator based on Farrington (1996) is also implemented by the function using the argument method = "farrington". Recent work by Fletcher (2012) suggests that an alternative estimator performs better than the above-mentioned methods in the presence of sparse data and is now implemented with method = "fletcher". For GLMM’s, only the Pearson chi-square estimator of overdispersion is currently implemented.

Note that values of c-hat > 1 indicate overdispersion (variance > mean), but that values much higher than 1 (i.e., > 4) probably indicate lack-of-fit. In cases of moderate overdispersion, one usually multiplies the variance-covariance matrix of the estimates by c-hat. As a result, the SE’s of the estimates are inflated (c-hat is also known as a variance inflation factor).

In model selection, c-hat should be estimated from the global model of the candidate model set and the same value of c-hat applied to the entire model set. Specifically, a global model is the most complex model which can be simplified to obtain all the other (nested) models of the set. When no single global model exists in the set of models considered, such as when sample size does not allow a complex model, one can estimate c-hat from ‘subglobal’ models. Here, ‘subglobal’ models denote models from which only a subset of the models of the candidate set can be derived. In such cases, one can use the smallest value of c-hat for model selection (Burnham and Anderson 2002).

Note that c-hat counts as an additional parameter estimated and should be added to K. All functions in package AICcmodavg automatically add 1 when the c.hat argument > 1 and apply the same value of c-hat for the entire model set. When c.hat > 1, functions compute quasi-likelihood information criteria (either QAICc or QAIC, depending on the value of the second.ord argument) by scaling the log-likelihood of the model by c.hat. The value of c.hat can influence the ranking of the models: as c-hat increases, QAIC or QAICc will favor models with fewer parameters. As an additional check against this potential problem, one can create several model selection tables by incrementing values of c-hat to assess the model selection uncertainty. If ranking changes little up to the c-hat value observed, one can be confident in making inference.

In cases of underdispersion (c-hat < 1), it is recommended to keep the value of c.hat to 1. However, note that values of c-hat « 1 can also indicate lack-of-fit and that an alternative model (and distribution) should be investigated.

Note that c.hat only supports the estimation of c-hat for binomial models with trials > 1 (i.e., success/trial or cbind(success, failure) syntax) or with Poisson GLM’s or GLMM’s.
Value

`c_hat` returns an object of class `c_hat` with the estimated c-hat value and an attribute for the type of estimator used.

## detHist

**Compute Summary Statistics from Detection Histories**

### Description

This function extracts various summary statistics from detection history data of various `unmarkedFrame` and `unmarkedFit` classes.

### Usage

```
detHist(object, ...)  # S3 method for class 'unmarkedFitColExt'
detHist(object, ...)  # S3 method for class 'unmarkedFitOccu'
detHist(object, ...)  # S3 method for class 'unmarkedFitOccuFP'
detHist(object, ...)  # S3 method for class 'unmarkedFitOccuRN'
detHist(object, ...)  # S3 method for class 'unmarkedFitOccuMulti'
detHist(object, ...)  # S3 method for class 'unmarkedFrameOccu'
```
detHist(object, ...)

## S3 method for class 'unmarkedFrameOccuFP'
detHist(object, ...)

## S3 method for class 'unmarkedMultFrame'
detHist(object, ...)

## S3 method for class 'unmarkedFrameOccuMulti'
detHist(object, ...)

### Arguments

- **object**: an object of various unmarkedFrame or unmarkedFit classes containing detection history data.
- **...**: additional arguments passed to the function.

### Details

This function computes a number of summary statistics in data sets used for single-season occupancy models (MacKenzie et al. 2002), dynamic occupancy models (MacKenzie et al. 2003), Royle-Nichols models (Royle and Nichols 2003), false-positive occupancy models (Royle and Link 2006, Miller et al. 2011), and multispecies occupancy models (Rota et al. 2016).

detHist can take data frames of the unmarkedFrameOccu, unmarkedFrameOccuFP, unmarkedMultFrame, and unmarkedFrameOccuMulti classes as input. For convenience, the function can also extract the raw data from model objects of classes unmarkedFitColExt, unmarkedFitOccu, unmarkedFitOccuFP, unmarkedFitOccuRN, and unmarkedFrameOccuMulti. Note that different model objects using the same data set will have identical values.

### Value

For objects of classes unmarkedFitOccu, unmarkedFitOccuRN, unmarkedFitOccuRN, unmarkedFitColExt, unmarkedFrameOccu, unmarkedFrameOccuFP, and unmarkedMultFrame, detHist returns a list with the following components:

- **hist.table.full**: a table with the frequency of each observed detection history.
- **hist.table.seasons**: a list of tables with the frequency of each season-specific detection history.
- **out.freqs**: a matrix where the rows correspond to each sampling season and where columns consist of the number of sites sampled in season \( t \) (sampled) and the number of sites with at least one detection in season \( t \) (detected). For multiseason data, the matrix includes the number of sites sampled in season \( t - 1 \) with colonizations observed in season \( t \) (colonized), the number of sites sampled in season \( t - 1 \) with extinctions observed in season \( t \) (extinct), the number of sites sampled in season \( t - 1 \) without changes observed in season \( t \) (static), and the number of sites sampled in season \( t \) that were also sampled in season \( t - 1 \)
For multispecies data, `out.freqs` presents for each species the number of sites sampled and the number of sites with at least one detection.

`out.props` a matrix where the rows correspond to each sampling season and where columns consist of the proportion of sites in season $t$ with at least one detection (naive.occ). For multiseason data, the matrix includes the proportion of sites sampled in season $t - 1$ with colonizations observed in season $t$ (naive.colonization), the proportion of sites sampled in season $t - 1$ with extinctions observed in season $t$ (naive.extinction), and the proportion of sites sampled in season $t - 1$ with no changes observed in season $t$. For multispecies data, `out.props` presents the proportion of sites with at least one detection for each species.

$n.seasons$ the number of seasons (primary periods) in the data set.

$n.visits.season$ the maximum number of visits per season in the data set.

$n.species$ the number of species in the data set.

For objects of classes `unmarkedFit0ccuMulti` and `unmarkedFrame0ccuMulti`, `detHist` returns a list with the following components:

`hist.table.full` a table with the frequency of each observed detection history. The species are coded with letters and follow the same order of presentation as in the other parts of the output.

`hist.table.species` a list of tables with the frequency of each species-specific detection history. The last element of `hist.table.species` features the number of sites with co-occurrence of the different species (coOcc).

`out.freqs` a matrix where the rows correspond to each species and where columns consist of the number of sites sampled during the season (sampled) and the number of sites with at least one detection (detected).

`out.props` a matrix where the rows correspond to each species and where columns consist of the proportion of sites with at least one detection during the season (naive.occ).

$n.seasons$ the number of seasons (primary periods) in the data set.

$n.visits.season$ the maximum number of visits per season in the data set.

$n.species$ the number of species in the data set.

```
Computing DIC

Description
Functions to extract deviance information criterion (DIC).

Usage
```r
DIC(mod, return.pD = FALSE, ...)
```

## S3 method for class 'bugs'

```r
DIC(mod, return.pD = FALSE, ...)
```

## S3 method for class 'rjags'

```r
DIC(mod, return.pD = FALSE, ...)
```

## S3 method for class 'jagsUI'

```r
DIC(mod, return.pD = FALSE, ...)
```

Arguments
- `mod` an object of class `bugs`, `rjags`, or `jagsUI` containing the output of a model.
- `return.pD` logical. If `FALSE`, the function returns the DIC. If `TRUE`, the function returns the effective number of estimated parameters (pD) for a given model.
- `...` additional arguments passed to the function.

Details
DIC is implemented for `bugs`, `rjags`, and `jagsUI` classes. The function extracts the deviance information criterion (DIC, Spiegelhalter et al. 2002) or the effective number of parameters (pD).

Value
```r
DIC the DIC or pD depending on the values of the arguments.
```

Note
The actual DIC values are not really interesting in themselves, as they depend directly on the data, parameters estimated, and likelihood function. Furthermore, a single value does not tell much about model fit. Information criteria become relevant when compared to Yone another for a given data set and set of candidate models. Model selection with hierarchical models is problematic as the classic DIC is not appropriate for such types of models (Millar 2009).

detach(package:R2jags)

## End(Not run)
```
dictab  Create Model Selection Tables from Bayesian Analyses

Description

This function creates a model selection table based on the deviance information criterion (DIC). The table ranks the models based on the DIC and also provides delta DIC and DIC weights. dictab selects the appropriate function to create the model selection table based on the object class. The current version works with objects of bugs, rjags, jagsUI classes.

Usage

dictab(cand.set, modnames = NULL, sort = TRUE, ...)

## S3 method for class 'AICbugs'
dictab(cand.set, modnames = NULL, sort = TRUE, ...)

## S3 method for class 'AICrjags'
dictab(cand.set, modnames = NULL, sort = TRUE, ...)

## S3 method for class 'AICjagsUI'
dictab(cand.set, modnames = NULL, sort = TRUE, ...)

Arguments

cand.set: a list storing each of the models in the candidate model set.
modnames: a character vector of model names to facilitate the identification of each model in the model selection table. If NULL, the function uses the names in the cand.set list of candidate models. If no names appear in the list, generic names (e.g., Mod1, Mod2) are supplied in the table in the same order as in the list of candidate models.

sort: logical. If TRUE, the model selection table is ranked according to the DIC values.

...: additional arguments passed to the function.

Details

dictab internally creates a new class for the cand.set list of candidate models, according to the contents of the list. The current function is implemented for bugs, jags, jagsUI classes. The function constructs a model selection table based on the DIC (Spiegelhalter et al. 2002). Note that DIC might not be appropriate to select among a set of hierarchical models and that modifications to the information criterion have been proposed (Millar 2009).

Value

dictab creates an object of class dictab with the following components:

Modname: the name of each model of the candidate model set.
pD  the effective number of estimated parameters for each model.
DIC  the deviance information criterion for each model.
Delta_DIC  the delta DIC of each model, measuring the difference in DIC between each
           model and the top-ranked model.
ModelLik  the relative likelihood of the model given the data (exp(-0.5*delta[i])). This is
           not to be confused with the likelihood of the parameters given the data. The
           relative likelihood can then be normalized across all models to get the model
           probabilities.
DICWt  the DIC weights, sensu Burnham and Anderson (2002) and Anderson (2008).
       These measures indicate the level of support (i.e., weight of evidence) in favor
       of any given model being the most parsimonious among the candidate model
       set.
Cum.Wt  the cumulative DIC weights. These are only meaningful if results in table are
       sorted in decreasing order of DIC weights (i.e., sort = TRUE).
Deviance  the deviance of each model.

dry.frog

Frog Dehydration Experiment on Three Substrate Types

Description

This is a data set modified from Mazerolle and Desrochers (2005) on the mass lost by frogs after spending two hours on one of three substrates that are encountered in some landscape types.

Usage

data(dry.frog)

Format

A data frame with 121 observations on the following 16 variables.

Individual  a numeric identifier unique to each individual.
Species     a factor with levels Racla.
Shade       a numeric vector, either 1 (shade) or 0 (no shade).
SVL         the snout-vent length of the individual.
Substrate   the substrate type, a factor with levels PEAT, SOIL, and SPHAGNUM.
Initial_mass the initial mass of individuals.
Mass_lost   the mass lost in g.
evidence

Compute Evidence Ratio Between Two Models

description

This function compares two models of a candidate model set based on their evidence ratio (i.e., ratio of model weights). The default computes the evidence ratio of the model weights between the top-ranked model and the second-ranked model. You must supply a model selection table of class aictab, bictab, boot.wt, dictab, ictab as the first argument.

usage

evidence(aic.table, model.high = "top", model.low = "second.ranked")
Arguments

aic.table  a model selection table of class aictab such as that produced by aictab or of classes bictab, boot.wt, dictab, or ictab. The table may be sorted or not, as the function sorts the table internally.

model.high  the top-ranked model (default), or alternatively, the name of another model as it appears in the model selection table.

model.low  the second-ranked model (default), or alternatively, the name of a lower-ranked model such as it appears in the model selection table.

Details

The default compares the model weights of the top-ranked model to the second-ranked model in the candidate model set. The evidence ratio can be interpreted as the number of times a given model is more parsimonious than a lower-ranked model. If one desires an evidence ratio that does not involve a comparison with the top-ranking model, the label of the required model must be specified in the model.high argument as it appears in the model selection table.

Value

evidence produces an object of class evidence with the following components:

Model.high  the model specified in model.high.

Model.low  the model specified in model.low.

Ev.ratio  the evidence ratio between the two models compared.

extractCN

Description

This function computes the condition number for models of `unmarkedFit` classes as the ratio of the largest eigenvalue of the Hessian matrix to the smallest eigenvalue of the Hessian matrix.

Usage

```r
extractCN(mod, method = "svd", ...)
```

## S3 method for class 'unmarkedFit'

```r
equalCN(mod, method = "svd", ...)
```

Arguments

- `mod` a model of one the `unmarkedFit` classes for which a condition number is requested.
- `method` specifies the method used to extract the singular values or eigenvalues from the Hessian matrix using singular value decomposition (`method = "svd"`) or eigenvalue decomposition (`method = "eigen"`).
- `...` additional arguments passed to the function.

Details

The condition number ($\kappa$) is a measure of the transfer of error to the solution in response to small changes in the input (Cheney and Kincaid 2008). In this implementation, the condition number is computed on the Hessian matrix of models of `unmarkedFit` classes from the `optim` results stored in the model object. The condition number is defined as the ratio of the largest to the smallest non-negative singular values of a given matrix (Cline et al. 1979, Dixon 1983). In the special case of positive semi-definite matrices, the singular values are equal to the eigenvalues (Ruhe 1975).

Large values of the condition number may indicate problems in estimating parameters or their variance (ill-conditioning), possibly due to a model having too many parameters for the given data set. Cheney and Ward (2008) suggest using the $\log_{10}(\kappa)$ of the condition number as a crude estimate of the number of digits of precision lost.
Value

extractCN returns a list of class extractCN with the following components:

- **CN**: the condition number ($\kappa$) of the model.
- **log10**: the log base 10 of the condition number.
- **method**: the method used to extract the singular values or eigenvalues.

**extractLL**  
*Extract Log-Likelihood of Model*

**Description**

This function extracts the log-likelihood from an object of coxme, coxph, lmekin, maxlikeFit, vglm, or various unmarkedFit classes.

**Usage**

```r
extractLL(mod, ...)  
```

```r
# S3 method for class 'coxme'
extractLL(mod, type = "Integrated", ...)
```

```r
# S3 method for class 'coxph'
extractLL(mod, ...)
```

```r
# S3 method for class 'lmekin'
extractLL(mod, ...)
```

```r
# S3 method for class 'maxlikeFit'
extractLL(mod, ...)
```

```r
# S3 method for class 'unmarkedFit'
extractLL(mod, ...)
```

```r
# S3 method for class 'vglm'
extractLL(mod, ...)
```

**Arguments**

- `mod`  
an object of coxme, coxph, lmekin, maxlikeFit, vglm, or unmarkedFit class resulting from the fit of distsamp, gdistsamp, gmultmix, multinomPois, gpcount, occu, occuRN, colext, pcount, or pcountOpen.
- `...`  
additional arguments passed to the function.
- `type`  
a character string indicating whether the integrated partial likelihood ("Integrated") or penalized likelihood ("Penalized") is to be used for a coxme object.

**Details**

This utility function extracts the information from a coxme, coxph, lmekin, maxlikeFit, vglm, or unmarkedFit object resulting from distsamp, gdistsamp, gmultmix, multinomPois, gpcount, occu, occuRN, colext, pcount, or pcountOpen.
Value

These functions return the value of the log-likelihood of the model and associated degrees of freedom.

**extractSE**: Extract SE of Fixed Effects of coxme, glmer, and lme kin Fit

Description

This function extracts the standard errors (SE) of the fixed effects of a mixed model fit with coxme, glmer, lmer, and lme kin and adds the appropriate labels.
extractSE

Usage

extractSE(mod, ...)

## S3 method for class 'coxme'
extractSE(mod, ...)

## S3 method for class 'lmekin'
extractSE(mod, ...)

## S3 method for class 'mer'
extractSE(mod, ...)

## S3 method for class 'merMod'
extractSE(mod, ...)

Arguments

mod an object of coxme, lmekin, mer or merMod class.

... additional arguments passed to the function.

Details

These are extractor functions that use vcov.coxme, vcov.lmekin, vcov.mer, and vcov.merMod. Some of these functions are called by modavg, depending on the class of the objects.

Value

Returns the SE’s of the fixed effects with the appropriate labels for each.

Extract Predictors from Candidate Model List

Description

This function extracts the predictors used in candidate models. The function is currently implemented for glm, glmmTMB, gls, lm, lme, merMod, rlm, survreg object classes that are stored in a list as well as various models of unmarkedFit classes.

Usage

extractX(cand.set, ...)

## S3 method for class 'AICaov.lm'
extractX(cand.set, ...)

## S3 method for class 'AICglm.lm'
extractX(cand.set, ...)

## S3 method for class 'AICglmmTMB'
extractX(cand.set, ...)

## S3 method for class 'AICglm'
extractX(cand.set, ...)

## S3 method for class 'AICglm'
extractX(cand.set, ...)

## S3 method for class 'AICglme'
extractX(cand.set, ...)

## S3 method for class 'AICglmerMod'
extractX(cand.set, ...)

## S3 method for class 'AICglmerMod'
extractX(cand.set, ...)

## S3 method for class 'AICrlm.lm'
extractX(cand.set, ...)

vcov(gml)

##extract SE's of fixed effects - no labels
sqrt(diag(vcov(gml))) #no labels
extractSE(gml) #with labels
detach(package:lme4)
}

## End(Not run)
## S3 method for class 'AICsurvreg'
extractX(cand.set, ...)

## S3 method for class 'AICunmarkedFitOccu'
extractX(cand.set,
  parm.type = NULL, ...)

## S3 method for class 'AICunmarkedFitColExt'
extractX(cand.set,
  parm.type = NULL, ...)

## S3 method for class 'AICunmarkedFitOccuRN'
extractX(cand.set,
  parm.type = NULL, ...)

## S3 method for class 'AICunmarkedFitPCount'
extractX(cand.set,
  parm.type = NULL, ...)

## S3 method for class 'AICunmarkedFitPCO'
extractX(cand.set,
  parm.type = NULL, ...)

## S3 method for class 'AICunmarkedFitDS'
extractX(cand.set,
  parm.type = NULL, ...)

## S3 method for class 'AICunmarkedFitGDS'
extractX(cand.set,
  parm.type = NULL, ...)

## S3 method for class 'AICunmarkedFitOccuFP'
extractX(cand.set,
  parm.type = NULL, ...)

## S3 method for class 'AICunmarkedFitMPois'
extractX(cand.set,
  parm.type = NULL, ...)

## S3 method for class 'AICunmarkedFitGMM'
extractX(cand.set,
  parm.type = NULL, ...)

## S3 method for class 'AICunmarkedFitGPC'
extractX(cand.set,
  parm.type = NULL, ...)

## S3 method for class 'AICunmarkedFitOccuMulti'

`extractX(cand.set, parm.type = NULL, ...)`

### Arguments

- **cand.set**: a list storing each of the models in the candidate model set.
- **parm.type**: this argument specifies the parameter type on which the effect size will be computed and is only relevant for models of `unmarkedFitOccu`, `unmarkedFitColExt`, `unmarkedFitOccuFP`, `unmarkedFitOccuMulti`, `unmarkedFitOccuRN`, `unmarkedFitMPoint`, `unmarkedFitPCount`, `unmarkedFitPCO`, `unmarkedFitDS`, `unmarkedFitGDS`, `unmarkedFitGMM`, and `unmarkedFitGPC` classes. The character strings supported vary with the type of model fitted. For `unmarkedFitOccu` and `unmarkedFitOccuMulti` objects, either `psi` or `detect` can be supplied to indicate whether the parameter is on occupancy or detectability, respectively. For `unmarkedFitColExt`, possible values are `psi`, `gamma`, `epsilon`, and `detect`, for parameters on occupancy in the initial year, colonization, extinction, and detectability, respectively. For `unmarkedFitOccuFP` objects, one can specify `psi`, `detect`, `falsepos`, and `certain`, for occupancy, detectability, probability of assigning false-positives, and probability detections are certain, respectively. For `unmarkedFitOccuRN` objects, either `lambda` or `detect` can be entered for abundance and detectability parameters, respectively. For `unmarkedFitPCount` and `unmarkedFitMPoint` objects, `lambda` or `detect` denote parameters on abundance and detectability, respectively. For `unmarkedFitPCO` objects, one can enter `lambda`, `gamma`, `omega`, `iota`, or `detect`, to specify parameters on abundance, recruitment, apparent survival, immigration, and detectability, respectively. For `unmarkedFitDS` objects, `lambda` and `detect` are supported. For `unmarkedFitGDS`, `lambda`, `phi`, and `detect` denote abundance, availability, and detection probability, respectively. For `unmarkedFitGMM` and `unmarkedFitGPC` objects, `lambda`, `phi`, and `detect` denote abundance, availability, and detectability, respectively.

- **...**: additional arguments passed to the function.

### Details

The candidate models must be stored in a list. The results of `extractX` are useful in preparing a new `data` data frame to use in computing model-averaged predictions with `modavgPred` or differences between groups with `modavgEffect` (Burnham and Anderson 2002, Anderson 2008, Burnham et al. 2011).

### Value

`extractX` returns an object of class `extractX` with the following components:

- **predictors**: a character vector of the names of the predictors included in the model, excluding the intercept term.
- **data**: a data frame or, in the case of `unmarkedFit` objects, a list of data frames (e.g., `obsCovs`, `siteCovs`, `yearlySiteCovs`).

fam.link.mer

Description

This function extracts the distribution family and link function of a generalized linear mixed model fit with glmer or lmer.

Usage

fam.link.mer(mod)

Arguments

mod

an object of mer or merMod class resulting from the fit of glmer or lmer.

Details

This utility function extracts the information from an mer or merMod object resulting from glmer or lmer. The function is called by modavg, modavgEffect, modavgPred, and predictSE.

Value

fam.link.mer returns a list with the following components:

family

the family of the distribution of the model.

link

the link function of the model.

supp.link

a character value indicating whether the link function used is supported by predictSE and modavgPred.

**fat**

*Fat Data and Body Measurements*

**Description**

This data set illustrates the relationship between body measurements and body fat in 252 males aged between 21 and 81 years.

**Usage**

data(fat)

**Format**

A data frame with 252 rows and 26 variables.

**Obs** observation number.
Perc.body.fat.Brozek percent body fat using Brozek’s equation, i.e., 457/Density – 414.2.
Perc.body.fat.Siri percent body fat using Siri’s equation, i.e., 495/Density – 450.
Density density (g/cm^3).
Age age (years).
Weight weight (lbs).
Height height (inches).
Adiposity.index adiposity index computed as Weight/Height^2 (kg/m^2).
Fat.free.weight fat free weight computed as (1 – Brozek’s percent body fat) * Weight (lbs).
Neck.circ neck circumference (cm).
Chest.circ chest circumference (cm).
Abdomen.circ abdomen circumference (cm) measured at the umbilicus and level with the iliac crest.
Hip.circ hip circumference (cm).
Thigh.circ thigh circumference (cm).
Knee.circ knee circumference (cm).
Ankle.circ ankle circumference (cm).
Biceps.circ extended biceps circumference (cm).
Forearm.circ forearm circumference (cm).
Wrist.circ wrist circumference (cm).
inv.Density inverse of density (cm^3/g).

Details

Burnham and Anderson (2002, p. 268) use this data set to show model selection uncertainty in the context of all possible combinations of explanatory variables. The data are originally from Penrose et al. (1985) who used only the first 143 cases of the 252 observations in the data set. Johnson (1996) later used these data as an example of multiple regression. Note that observation number 42 originally had an erroneous height of 29.5 inches and that this value was changed to 69.5 inches.

Burnham and Anderson (2002, p. 274) created six indices based on the original measurements (i.e., z1 – z6). Although Burnham and Anderson (2002) indicate that the fleshiness index (z4) involved the cubic root in the equation, the result table for the full model on p. 276 suggests that the index did not include the cubic root for z4. The latter is the version of z4 used in the data set here.

ictab

Create Model Selection Tables from User-supplied Information Criterion

Description

This function creates a model selection table from information criterion values supplied by the user. The table ranks the models based on the values of the information criterion and also displays delta values and information criterion weights.

Usage

ictab(ic, K, modnames = NULL, sort = TRUE, ic.name = NULL)

Arguments

ic a vector of information criterion values for each model in the candidate model set.
K a vector containing the number of estimated parameters for each model in the candidate model set.
modnames a character vector of model names to identify each model in the model selection table. If NULL, generic names (e.g., Mod1, Mod2) are supplied in the table in the same order as the information criterion values.
sort logical. If TRUE, the model selection table is ranked according to the values of the information criterion.
ic.name a character string denoting the name of the information criterion input by the user. This character string will appear in certain column labels of the model selection table.

Details

ictab constructs a model selection table based on the information criterion values supplied by the user. This function is most useful for information criterion other than AIC, AICc, QAIC, and QAICc (e.g., WAIC: Watanabe 2010) or for classes not supported by aictab or bictab.

Value

ictab creates an object of class ictab with the following components:

Modname the name of each model of the candidate model set.
K the number of estimated parameters for each model.
IC the values of the information criterion input by the user. If a value for ic.name is provided, the table modifies the labels of the table.

Delta.IC the delta information criterion component comparing each model to the top-ranked model.

ModelLik the relative likelihood of the model given the data (exp(-0.5*delta[i])). This is not to be confused with the likelihood of the parameters given the data. The relative likelihood can then be normalized across all models to get the model probabilities.

ICWt the information criterion weights, also termed "model probabilities" sensu Burnham and Anderson (2002) and Anderson (2008). These measures indicate the level of support (i.e., weight of evidence) in favor of any given model being the most parsimonious among the candidate model set.

Cum.Wt the cumulative information criterion weights. These are only meaningful if the results in table are sorted in decreasing order of Akaike weights (i.e., sort = TRUE).

Examples

```R
# create a vector of names to trace back models in set
Modnames <- c("global model", "interactive model", "additive model", "invertpred model")

# WAIC values
waic <- c(105.74, 107.36, 108.24, 100.57)

# number of effective parameters
effK <- c(7.45, 5.61, 6.14, 6.05)

# generate WAIC table
ictab(ic = waic, K = effK, modnames = Modnames, sort = TRUE, ic.name = "WAIC")
```
**importance**

*Compute Importance Values of Variable*

**Description**

This function calculates the relative importance of variables ($w_+$) based on the sum of Akaike weights (model probabilities) of the models that include the variable. Note that this measure of evidence is only appropriate when the variable appears in the same number of models as those that do not include the variable.

**Usage**

importance(cand.set, parm, modnames = NULL,
           second.ord = TRUE, nob = NULL, ...)
```

**Arguments**

- `cand.set` a list storing each of the models in the candidate model set.
- `parm` the parameter of interest for which a measure of relative importance is required.
- `modnames` a character vector of model names to facilitate the identification of each model in the model selection table. If `NULL`, the function uses the names in the `cand.set` list of candidate models. If no names appear in the list, generic names (e.g., `modQ`, `modR`) are supplied in the table in the same order as in the list of candidate models.
- `second.ord` logical. If `TRUE`, the function returns the second-order Akaike information criterion (i.e., AICc).
- `nobs` this argument allows to specify a numeric value other than total sample size to compute the AICc (i.e., `nobs` defaults to total number of observations). This is relevant only for mixed models or various models of `unmarkedFit` classes where sample size is not straightforward. In such cases, one might use total number of observations or number of independent clusters (e.g., sites) as the value of `nobs`.
- `c.hat` value of overdispersion parameter (i.e., variance inflation factor) such as that obtained from `c_hat`. Note that values of `c.hat` different from 1 are only appropriate for binomial GLM’s with trials > 1 (i.e., `success/trial` or `cbind(success, failure)` syntax), with Poisson GLM’s, single-season occupancy models (MacKenzie et al. 2002), dynamic occupancy models (MacKenzie et al. 2003), or N-mixture models (Royle 2004, Dail and Madsen 2011). If `c.hat > 1`, `importance` will return the quasi-likelihood analogue of the information criteria requested and multiply the variance-covariance matrix of the estimates by this value (i.e., SE's are multiplied by `sqrt(c.hat)`). This option is not supported for generalized linear mixed models of the `mer` or `merMod` classes.
this argument specifies the parameter type on which the effect size will be computed and is only relevant for models of unmarkedFitOccu, unmarkedFitColExt, unmarkedFitOccuFP, unmarkedFitOccuRN, unmarkedFitMPois, unmarkedFitGPC, unmarkedFitPCount, unmarkedFitPCO, unmarkedFitDS, unmarkedFitGDS, unmarkedFitGMM, and unmarkedFitOccuMulti classes. The character strings supported vary with the type of model fitted. For unmarkedFitOccu and unmarkedFitOccuMulti objects, either psi or detect can be supplied to indicate whether the parameter is on occupancy or detectability, respectively. For unmarkedFitColExt, possible values are psi, gamma, epsilon, and detect, for parameters on occupancy in the initial year, colonization, extinction, and detectability, respectively. For unmarkedFitOccuFP objects, one can specify psi, detect, or fp, for occupancy, detectability, and probability of assigning false-positives, respectively. For unmarkedFitOccuRN objects, either lambda or detect can be entered for abundance and detectability parameters, respectively. For unmarkedFitPCount and unmarkedFitMPois objects, lambda or detect denote parameters on abundance and detectability, respectively. For unmarkedFitPCO objects, one can enter lambda, gamma, omega, or detect, to specify parameters on abundance, recruitment, apparent survival, and detectability, respectively. For unmarkedFitDS objects, only lambda is supported for the moment. For unmarkedFitGDS objects, lambda and phi denote abundance and availability, respectively. For unmarkedFitGMM and unmarkedFitGPC objects, lambda, phi, and detect denote abundance, availability, and detectability, respectively.

... additional arguments passed to the function.

Value

importance returns an object of class importance consisting of the following components:

parm the parameter for which an importance value is required.
w.plus the sum of Akaike weights for the models that include the parameter of interest.
w.minus the sum of Akaike weights for the models that exclude the parameter of interest.

## Iron Content in Food

### Description

This data set, originally from Adish et al. (1999), describes the iron content of food cooked in different pot types.

### Usage

```r
data(iron)
```
Format

A data frame with 36 rows and 3 variables.

Pot  pot type, one of "aluminium", "clay", or "iron".
Food  food type, one of "legumes", "meat", or "vegetables".
Iron  iron content measured in mg/100 g of food.

Details

Heiberger and Holland (2004, p. 378) use these data as an exercise on two-way ANOVA with interaction.

## S3 method for class 'unmarkedFitOccuRN'
mb.chisq(mod, print.table = TRUE, maxK = 50, ...)

mb.gof.test(mod, nsim = 5, plot.hist = TRUE, report = NULL, 
            parallel = TRUE, ...)

## S3 method for class 'unmarkedFitOccu'
mb.gof.test(mod, nsim = 5, plot.hist = TRUE, 
            report = NULL, parallel = TRUE, ...)

## S3 method for class 'unmarkedFitColExt'
mb.gof.test(mod, nsim = 5, plot.hist = TRUE, 
            report = NULL, parallel = TRUE, 
            plot.seasons = FALSE, ...)

## S3 method for class 'unmarkedFitOccuRN'
mb.gof.test(mod, nsim = 5, plot.hist = TRUE, 
            report = NULL, parallel = TRUE, maxK = 50, ...)
```
Arguments

Mod

the model for which a goodness-of-fit test is required.

Print.table

logical. Specifies if the detailed table of observed and expected values is to be included in the output.

Ns

the number of bootstrapped samples.

Plot.hist

logical. Specifies that a histogram of the bootstrapped test statistic is to be included in the output. For dynamic occupancy models, this produces a histogram of the sum of the season-specific chi-squares for each bootstrap sample.

Report

If NULL, the test statistic for each iteration is not printed in the terminal. Otherwise, an integer indicating the number of values of the test statistic that should be printed on the same line. For example, if report = 3, the values of the test statistic for three iterations are reported on each line.

Parallel

logical. If TRUE, requests that parboot use multiple cores to accelerate computations of the bootstrap.

Plot.seasons

logical. For dynamic occupancy models, specifies that a histogram of the bootstrapped test statistic for each primary period (season) is to be included in the output.

MaxK

the number of support points used as the summation index in the likelihood of the Royle-Nichols model (2003). This should match the value used to estimate the parameters with occur.

... additional arguments passed to the function.

Details

MacKenzie and Bailey (2004) and MacKenzie et al. (2006) suggest using the Pearson chi-square to assess the fit of single season occupancy models (MacKenzie et al. 2002). Given low expected frequencies, the chi-square statistic will deviate from the theoretical distribution and it is recommended to use a parametric bootstrap approach to obtain P-values with the parboot function of the unmarked package. mb.chisq computes the table of observed and expected values based on the detection histories and single season occupancy model used. mb.gof.test calls internally mb.chisq and parboot to generate simulated data sets based on the model and compute the MacKenzie and Bailey test statistic. Missing values are accommodated by creating cohorts for each pattern of missing values.

It is also possible to obtain an estimate of the overdispersion parameter (c-hat) for the model at hand by dividing the observed chi-square statistic by the mean of the statistics obtained from simulation. This test is extended to dynamic occupancy models of MacKenzie et al. (2003) by using the occupancy estimates for each season obtained from the model. These estimates are then used to compute the predicted and observed frequencies separately within each season. The chi-squares are then summed to be used as the test statistic for the dynamic occupancy model.

Note that values of c-hat > 1 indicate overdispersion (variance > mean), but that values much higher than 1 (i.e., > 4) probably indicate lack-of-fit. In cases of moderate overdispersion, one usually multiplies the variance-covariance matrix of the estimates by c-hat. As a result, the SE’s of the estimates are inflated (c-hat is also known as a variance inflation factor).

In model selection, c-hat should be estimated from the global model and the same value of c-hat applied to the entire model set. Specifically, a global model is the most complex model from which
all the other models of the set are simpler versions (nested). When no single global model exists in
the set of models considered, such as when sample size does not allow a complex model, one can
estimate c-hat from 'subglobal' models. Here, ‘subglobal’ models denote models from which only
a subset of the models of the candidate set can be derived. In such cases, one can use the smallest
value of c-hat for model selection (Burnham and Anderson 2002).

Note that c-hat counts as an additional parameter estimated and should be added to K. All functions
in package AICcmodavg automatically add 1 when the c.hat argument > 1 and apply the same value
of c-hat for the entire model set. When c-hat > 1, functions compute quasi-likelihood information
criteria (either QAICc or QAIC, depending on the value of the second.ord argument) by scaling the
log-likelihood of the model by c-hat. The value of c-hat can influence the ranking of the models: as
c-hat increases, QAIC or QAICc will favor models with fewer parameters. As an additional check
against this potential problem, one can generate several model selection tables by incrementing
values of c-hat to assess the model selection uncertainty. If ranking changes little up to the c-hat
value observed, one can be confident in making inference.

In cases of underdispersion (c-hat < 1), it is recommended to keep the value of c-hat to 1. However,
note that values of c-hat « 1 can also indicate lack-of-fit and that an alternative model should be
investigated.

Value

mb.chisq returns the following components for single-season and Royle-Nichols occupancy mod-
els:

chisq.table the table of observed and expected values for each detection history and its chi-
square component (if print.table = TRUE). Note that the table only
shows the observed detection histories. Unobserved detection histories are not
shown, but are included in the computation of the test statistic.

chi.square the Pearson chi-square statistic. This test statistic should be compared against a
bootstrap distribution instead of the theoretical chi-square distribution because
low expected frequencies invalidate the chi-square assumption.

model.type the model type, either single.season, royle-nichols, or dynamic.

mb.chisq returns the following additional components for dynamic occupancy models:

tables a list containing the season-specific chi-square tables (if print.table = TRUE).

all.chisq an element containing the season-specific chi-squares.

n.seasons the number of primary periods (seasons).

mb.gof.test returns the following components for single-season and Royle-Nichols occupancy
models:

chisq.table the table of observed and expected values for each detection history and its chi-
square component.

chi.square the Pearson chi-square statistic.

t.star the bootstrapped chi-square test statistics (i.e., obtained for each of the simulated
data sets).
p.value  the P-value assessed from the parametric bootstrap, computed as the proportion of the simulated test statistics greater than or equal to the observed test statistic.

c.hat.est  the estimate of the overdispersion parameter, c-hat, computed as the observed test statistic divided by the mean of the simulated test statistics.

nsim  the number of bootstrap samples. The recommended number of samples varies with the data set, but should be on the order of 1000 or 5000, and in cases with a large number of visits, even 10 000 samples, namely to reduce the effect of unusually small values of the test statistics.

mb.gof.test returns the following additional components for dynamic occupancy models:

chisq.table  a list including the table of observed and expected values for each detection history and its chi-square component for each primary period (season).

chi.square  the chi-square test statistic, as the sum of the chi-squares across the primary periods.

p.value  a list of the P-values for each of the primary periods, computed separately as the proportion of the simulated test statistics greater than or equal to the observed test statistic.

p.global  the P-value of the chi-square test statistic for the dynamic occupancy model. This P-value is computed as the proportion of the simulated sums of chi-squares greater than or equal to the observed sum of chi-squares across the primary periods.

min.trap

Anuran Larvae Counts in Minnow Traps Across Pond Type

Description

This data set consists of counts of anuran larvae as a function of pond type, pond perimeter, and presence of water scorpions (Ranatra sp.).

Usage

data(min.trap)

Format

A data frame with 24 observations on the following 6 variables.

- **type**: pond type, denotes the location of ponds in either bog or upland environment
- **num_anura**: number of anuran larvae in minnow traps
- **effort**: number of trap nights (i.e., number of traps x days of trapping) in each pond
- **perimeter**: pond perimeter in meters
- **num_ranatra**: number of water scorpions trapped in minnow traps
- **log.Perimeter**: natural log of perimeter

Details

Mazerolle (2006) uses this data set to illustrate model selection for Poisson regression with low overdispersion.

Source

Examples

data(min.trap)

```r
## maybe str(min.trap) ; plot(min.trap) ...
```
Description

This function model-averages the estimate of a parameter of interest among a set of candidate models, computes the unconditional standard error and unconditional confidence intervals as described in Buckland et al. (1997) and Burnham and Anderson (2002). This model-averaged estimate is also referred to as a natural average of the estimate by Burnham and Anderson (2002, p. 152).

Arguments

- **cand.set**: a list storing each of the models in the candidate model set.
- **parm**: the parameter of interest, enclosed between quotes, for which a model-averaged estimate is required. For a categorical variable, the label of the estimate must be included as it appears in the output (see 'Details' below).
- **modnames**: a character vector of model names to facilitate the identification of each model in the model selection table. If NULL, the function uses the names in the cand.set list of candidate models. If no names appear in the list, generic names (e.g., `modQ`, `modR`) are supplied in the table in the same order as in the list of candidate models.
- **second.ord**: logical. If TRUE, the function returns the second-order Akaike information criterion (i.e., AICc).
- **nobs**: this argument allows to specify a numeric value other than total sample size to compute the AICc (i.e., nobs defaults to total number of observations). This is relevant only for mixed models or various models of unmarkedFit classes where sample size is not straightforward. In such cases, one might use total number of observations or number of independent clusters (e.g., sites) as the value of nobs.
- **uncond.se**: either, "old", or "revised", specifying the equation used to compute the unconditional standard error of a model-averaged estimate. With uncond.se = "old",...
computations are based on equation 4.9 of Burnham and Anderson (2002), which was the former way to compute unconditional standard errors. With `uncond.se = "revised"`, equation 6.12 of Burnham and Anderson (2002) is used. Anderson (2008, p. 111) recommends use of the revised version for the computation of unconditional standard errors and it is now the default. Note that versions of package AICcmodavg < 1.04 used the old method to compute unconditional standard errors.

`conf.level` the confidence level \(1 - \alpha\) requested for the computation of unconditional confidence intervals.

`exclude` this argument excludes models based on the terms specified for the computation of a model-averaged estimate of `parm`. The `exclude` argument is set to NULL by default and does not exclude any models other than those without the `parm`. When `parm` is a main effect but is also involved in interactions/polynomial terms in some models, one should specify the interaction/polynomial terms as a list to exclude models with these terms from the computation of model-averaged estimate of the main effect (e.g., `exclude = list("sex:mass", "mass2")`). See 'Details' and 'Examples' below.

`warn` logical. If TRUE, `modavg` performs a check and issues a warning when the value in `parm` occurs more than once in any given model. This is a check for potential interaction/polynomial terms in the model when such terms are constructed with the usual operators (e.g., I() for polynomial terms, : for interaction terms).

`c.hat` value of overdispersion parameter (i.e., variance inflation factor) such as that obtained from `c.hat`. Note that values of c.hat different from 1 are only appropriate for binomial GLM’s with trials > 1 (i.e., success/trial or cbind(success, failure) syntax), with Poisson GLM’s, single-season occupancy models (MacKenzie et al. 2002), dynamic occupancy models (MacKenzie et al. 2003), or N-mixture models (Royle 2004, Dail and Madsen 2011). If c.hat > 1, `modavg` will return the quasi-likelihood analogue of the information criteria requested and multiply the variance-covariance matrix of the estimates by this value (i.e., SE’s are multiplied by \(\sqrt{c.hat}\)). This option is not supported for generalized linear mixed models of the `mer` or `merMod` classes.

`gamdisp` if gamma GLM is used, the dispersion parameter should be specified here to apply the same value to each model.

`parm.type` this argument specifies the parameter type on which the effect size will be computed and is only relevant for models of `unmarkedFitOccu`, `unmarkedFitColExt`, `unmarkedFitOccuFP`, `unmarkedFitOccuRN`, `unmarkedFitMPPois`, `unmarkedFitPCount`, `unmarkedFitPCO`, `unmarkedFitDS`, `unmarkedFitGDS`, `unmarkedFitGMM`, `unmarkedFitGPC`, and `unmarkedFitOccuMulti` classes. The character strings supported vary with the type of model fitted. For `unmarkedFitOccu` and `unmarkedFitOccuMulti` objects, either `psi` or `detect` can be supplied to indicate whether the parameter is on occupancy or detectability, respectively. For `unmarkedFitColExt`, possible values are `psi`, `gamma`, `epsilon`, and `detect`, for parameters on occupancy in the initial year, colonization, extinction, and detectability, respectively. For `unmarkedFitOccuFP` objects, one can specify `psi`, `detect`, `falsepos`, and `certain`, for occupancy, detectability, probability of assigning false-positives, and probability detections are certain, respectively. For `unmarkedFitOccuRN` objects, either `lambda` or `detect` can be entered for abundance and detectability
parameters, respectively. For unmarkedFitPC objects and unmarkedFitPM objects, lambda or detect denote parameters on abundance and detectability, respectively. For unmarkedFitPC objects, one can enter lambda, gamma, omega, iota, or detect, to specify parameters on abundance, recruitment, apparent survival, immigration, and detectability, respectively. For unmarkedFitDS objects, lambda and detect are supported. For unmarkedFitDS objects, lambda, phi, and detect denote abundance, availability, and detectability, respectively. For unmarkedFitGMM and unmarkedFitGPC objects, lambda, phi, and detect denote abundance, availability, and detectability, respectively.

... additional arguments passed to the function.

Details

The parameter for which a model-averaged estimate is requested must be specified with the parm argument and must be identical to its label in the model output (e.g., from summary). For factors, one must specify the name of the variable and the level of interest. modavg includes checks to find variations of interaction terms specified in the parm and exclude arguments. However, to avoid problems, one should specify interaction terms consistently for all models: e.g., either a:b or b:a for all models, but not a mixture of both.

You must exercise caution when some models include interaction or polynomial terms, because main effect terms do not have the same interpretation when they also appear in an interaction/polynomial term in the same model. In such cases, one should exclude models containing interaction terms where the main effect is involved with the exclude argument of modavg. Note that modavg checks for potential cases of multiple instances of a variable appearing more than once in a given model (presumably in an interaction) and issues a warning. To correctly compute the model-averaged estimate of a main effect involved in interaction/polynomial terms, specify the interaction terms(s) that should not appear in the same model with the exclude argument. This will effectively exclude models from the computation of the model-averaged estimate.

When warn = TRUE, modavg looks for matches among the labels of the estimates with identical. It then compares the results to partial matches with regexpr, and issues a warning whenever they are different. As a result, modavg may issue a warning when some variables or levels of categorical variables have nested names (e.g., treat, treat0: L, TL). When this warning is only due to the presence of similarly named variables in the models (and NOT due to interaction terms), you can suppress this warning by setting warn = FALSE.

The model-averaging estimator implemented in modavg is known to be biased away from 0 when there is substantial model selection uncertainty (Cade 2015). In such instances, it is recommended to use the model-averaging shrinkage estimator (i.e., modavgShrink) for inference on beta estimates or to focus on model-averaged effect sizes (modavgEffect) and model-averaged predictions (modavgPred).

modavg is implemented for a list containing objects of aov, betareg, clm, clmm, clogit, coxme, coxph, glm, glmmTMB, gls, hurdle, lm, lme, lme4, lmer, lmerMod, lmerMod, multinom, polr, rlm, survreg, vglm, zeroinfl classes as well as various models of unmarkedFit classes.

Value

modavg creates an object of class modavg with the following components:
Parameter the parameter for which a model-averaged estimate was obtained.
Mod.avg.table the reduced model selection table based on models including the parameter of interest.
Mod.avg.beta the model-averaged estimate based on all models including the parameter of interest (see 'Details' above regarding the exclusion of models where parameter of interest is involved in an interaction).
Uncond.SE the unconditional standard error for the model-averaged estimate (as opposed to the conditional SE based on a single model).
Conf.level the confidence level used to compute the confidence interval.
Lower.CL the lower confidence limit.
Upper.CL the upper confidence limit.

Description

reverse.parm and reverse.exclude reverse the order of variables in an interaction term.
formatCands creates new classes for lists containing candidate models.
formulaShort prints a succinct formula from an unmarkedFit object.

Usage

reverse.parm(parm)
reverse.exclude(exclude)
formatCands(cand.set)
formulaShort(mod, unmarked.type = NULL)

Arguments

parm a parameter to be model-averaged, enclosed between quotes, as it appears in the output of some models.
exclude a list of interaction or polynomial terms appearing in some models, as they would appear in the call to the model function (i.e., A*B, A:B). Models containing elements from the list will be excluded to obtain a model-averaged estimate.
cand.set a list storing each of the models in the candidate model set.
mod an object storing the result of an unmarkedFit.
unmarked.type a character string specifying the type of parameter in an unmarkedFit for which a formula is requested. This argument uses the character string for each parameter group as defined by unmarked.

Details

These utility functions are used internally by aictab, modavg, and other related functions.
reverse.parm and reverse.exclude enable the user to specify differently interaction terms (e.g., A:*B, B:A) across models for model averaging. These functions have been added to avoid problems when users are not consistent in the specification of interaction terms across models.
formatCands creates new classes for the list of candidate models based on the contents of the list. These new classes are used for method dispatch.
formulaShort is used by anovaO0D.

Value

reverse.parm returns all possible combinations of an interaction term to identify models that include the parm of interest and find the corresponding estimate and standard error in the model object.
reverse.exclude returns a list of all possible combinations of exclude to identify models that should be excluded when computing a model-averaged estimate.
formatCands adds a new class to the list of candidate models based on the classes of the models.
formulaShort creates a character string for the formula related to a given parameter type from an unmarkedFit object.

## End(Not run)
**modavgCustom**

*Compute Model-averaged Parameter Estimate from User-supplied Input Based on (Q)AIC(c)*

**Description**

This function model-averages the estimate of a parameter of interest among a set of candidate models, and computes the unconditional standard error and unconditional confidence intervals as described in Buckland et al. (1997) and Burnham and Anderson (2002).

**Usage**

```r
modavgCustom(logL, K, modnames = NULL, estimate, se, second.ord = TRUE,
             nobls = NULL, uncond.se = "revised", conf.level = 0.95,
             c.hat = 1, useBIC = FALSE)
```

**Arguments**

- `logL`: a vector of log-likelihood values for the models in the candidate model set.
- `K`: a vector containing the number of estimated parameters for each model in the candidate model set.
- `modnames`: a character vector of model names to facilitate the identification of each model in the model selection table. If `NULL`, the function uses the names in the cand.set list of candidate models. If no names appear in the list, generic names (e.g., `modQ`, `modR`) are supplied in the table in the same order as in the list of candidate models.
- `estimate`: a vector of estimates for each of the models in the candidate model set. Estimates can be either beta estimates for a parameter of interest or a single prediction from each model.
- `se`: a vector of standard errors for each of the estimates appearing in the `estimate` vector.
- `second.ord`: logical. If `TRUE`, the function returns the second-order Akaike information criterion (i.e., AICc). This argument is ignored if `useBIC = TRUE`.
- `nobs`: the sample size required to compute the AICc, QAICc, BIC, or QBIC.
- `uncond.se`: either, "old", or "revised", specifying the equation used to compute the unconditional standard error of a model-averaged estimate. With `uncond.se = "old"`, computations are based on equation 4.9 of Burnham and Anderson (2002), which was the former way to compute unconditional standard errors. With `uncond.se = "revised"`, equation 6.12 of Burnham and Anderson (2002) is used. Anderson (2008, p. 111) recommends use of the revised version for the computation of unconditional standard errors and it is now the default.
- `conf.level`: the confidence level \((1 - \alpha)\) requested for the computation of unconditional confidence intervals.
value of overdispersion parameter (i.e., variance inflation factor) such as that obtained from \(c_{\text{hat}}\). Note that values of \(c_{\text{hat}}\) different from 1 are only appropriate for binomial GLM’s with trials > 1 (i.e., success/trial or cbind(success, failure) syntax), with Poisson GLM’s, single-season and dynamic occupancy models (MacKenzie et al. 2002, 2003), \(N\)-mixture models (Royle 2004, Dail and Madsen 2011), or capture-mark-recapture models (e.g., Lebreton et al. 1992). If \(c_{\text{hat}} > 1\), modavgCustom will return the quasi-likelihood analogue of the information criteria requested and multiply the variance-covariance matrix of the estimates by this value (i.e., SE’s are multiplied by \(\sqrt{c_{\text{hat}}}\)).

logical. If TRUE, the function returns the Bayesian information criterion (BIC) when \(c_{\text{hat}} = 1\) or the quasi-likelihood BIC (QBIC) when \(c_{\text{hat}} > 1\).

modavgCustom computes a model-averaged estimate from the vector of parameter estimates specified in estimate. Estimates and their associated standard errors must be specified in the same order as the log-likelihood, number of estimated parameters, and model names. Estimates provided may be for a parameter of interest (i.e., beta estimates) or predictions from each model. This function is most useful when model input is imported into R from other software (e.g., Program MARK, PRESENCE) or for model classes that are not yet supported by the other model averaging functions such as modavg or modavgPred.

modavgCustom creates an object of class modavgCustom with the following components:

- Mod.avg.table: the model selection table
- Mod.avg.est: the model-averaged estimate
- Uncond.SE: the unconditional standard error for the model-averaged estimate
- Conf.level: the confidence level used to compute the confidence interval
- Lower.CL: the lower confidence limit

modavgEffect

Compute Model-averaged Effect Sizes (Multimodel Inference on Group Differences)

Description

This function model-averages the effect size between two groups defined by a categorical variable based on the entire model set and computes the unconditional standard error and unconditional confidence intervals as described in Buckland et al. (1997) and Burnham and Anderson (2002). This can be particularly useful when dealing with data from an experiment (e.g., ANOVA) and when the focus is to determine the effect of a given factor. This is an information-theoretic alternative to multiple comparisons (e.g., Burnham et al. 2011).

Usage

modavgEffect(cand.set, modnames = NULL, newdata, second.ord = TRUE,
modavgEffect

    nobs = NULL, uncond.se = "revised", conf.level = 0.95, ...

## S3 method for class 'AICaov.lm'
modavgEffect(cand.set, modnames = NULL, newdata,
    second.ord = TRUE, nobs = NULL, uncond.se = "revised",
    conf.level = 0.95, ...

## S3 method for class 'AICglm.lm'
modavgEffect(cand.set, modnames = NULL, newdata,
    second.ord = TRUE, nobs = NULL, uncond.se = "revised",
    conf.level = 0.95, type = "response", c.hat = 1, gamdisp = NULL, ...

## S3 method for class 'AICgls'
modavgEffect(cand.set, modnames = NULL, newdata,
    second.ord = TRUE, nobs = NULL, uncond.se = "revised",
    conf.level = 0.95, ...

## S3 method for class 'AIClm'
modavgEffect(cand.set, modnames = NULL, newdata,
    second.ord = TRUE, nobs = NULL, uncond.se = "revised",
    conf.level = 0.95, ...

## S3 method for class 'AIClme'
modavgEffect(cand.set, modnames = NULL, newdata,
    second.ord = TRUE, nobs = NULL, uncond.se = "revised",
    conf.level = 0.95, ...

## S3 method for class 'AICmer'
modavgEffect(cand.set, modnames = NULL, newdata,
    second.ord = TRUE, nobs = NULL, uncond.se = "revised",
    conf.level = 0.95, type = "response", ...

## S3 method for class 'AICglmerMod'
modavgEffect(cand.set, modnames = NULL, newdata, second.ord = TRUE, nobs = NULL, uncond.se = "revised",
    conf.level = 0.95, type = "response", ...

## S3 method for class 'AIClmerMod'
modavgEffect(cand.set, modnames = NULL, newdata, second.ord = TRUE, nobs = NULL, uncond.se = "revised",
    conf.level = 0.95, ...

## S3 method for class 'AICnegbin.glm.lm'
modavgEffect(cand.set, modnames = NULL, newdata, second.ord = TRUE, nobs = NULL, uncond.se = "revised",
    conf.level = 0.95, type = "response", ...)
## S3 method for class 'AICrlm.lm'
`modavgEffect(cand.set, modnames = NULL, newdata, second.order = TRUE, nobs = NULL, uncond.se = "revised", conf.level = 0.95, ...)`

## S3 method for class 'AICsurvreg'
`modavgEffect(cand.set, modnames = NULL, newdata, second.order = TRUE, nobs = NULL, uncond.se = "revised", conf.level = 0.95, type = "response", ...)`

## S3 method for class 'AICunmarkedFitOccu'
`modavgEffect(cand.set, modnames = NULL, newdata, second.order = TRUE, nobs = NULL, uncond.se = "revised", conf.level = 0.95, type = "response", c.hat = 1, parm.type = NULL, ...)`

## S3 method for class 'AICunmarkedFitColExt'
`modavgEffect(cand.set, modnames = NULL, newdata, second.order = TRUE, nobs = NULL, uncond.se = "revised", conf.level = 0.95, type = "response", c.hat = 1, parm.type = NULL, ...)`

## S3 method for class 'AICunmarkedFitOccuRN'
`modavgEffect(cand.set, modnames = NULL, newdata, second.order = TRUE, nobs = NULL, uncond.se = "revised", conf.level = 0.95, type = "response", c.hat = 1, parm.type = NULL, ...)`

## S3 method for class 'AICunmarkedFitPCount'
`modavgEffect(cand.set, modnames = NULL, newdata, second.order = TRUE, nobs = NULL, uncond.se = "revised", conf.level = 0.95, type = "response", c.hat = 1, parm.type = NULL, ...)`

## S3 method for class 'AICunmarkedFitPCO'
`modavgEffect(cand.set, modnames = NULL, newdata, second.order = TRUE, nobs = NULL, uncond.se = "revised", conf.level = 0.95, type = "response", c.hat = 1, parm.type = NULL, ...)`

## S3 method for class 'AICunmarkedFitDS'
`modavgEffect(cand.set, modnames = NULL, newdata, second.order = TRUE, nobs = NULL, uncond.se = "revised", conf.level = 0.95, type = "response", c.hat = 1, parm.type = NULL, ...)`

## S3 method for class 'AICunmarkedFitGDS'
modavgEffect(cand.set, modnames = NULL, 
    newdata, second.ord = TRUE, nobs = NULL, uncond.se = "revised", 
    conf.level = 0.95, type = "response", c.hat = 1, 
    parm.type = NULL, ...)

### S3 method for class 'AICunmarkedFitOccuFP'

    "revised", conf.level = 0.95, type = "response", 
    c.hat = 1, parm.type = NULL, ...)

### S3 method for class 'AICunmarkedFitGPC'
modavgEffect(cand.set, modnames = 
    NULL, newdata, second.ord = TRUE, nobs = NULL, uncond.se = 
    "revised", conf.level = 0.95, type = "response", 
    c.hat = 1, parm.type = NULL, ...)

**Arguments**

- **cand.set**
  - a list storing each of the models in the candidate model set.

- **modnames**
  - a character vector of model names to facilitate the identification of each model in the model selection table. If NULL, the function uses the names in the cand.set list of candidate models. If no names appear in the list, generic names (e.g., modQ, modR) are supplied in the table in the same order as in the list of candidate models.

- **newdata**
  - a data frame with two rows and where the columns correspond to the explanatory variables specified in the candidate models. Note that this data set must have the same structure as that of the original data frame for which we want to make predictions, specifically, the same variable type and names that appear in the original data set. Each row of the data set defines one of the two groups compared. The first row in newdata defines the first group, whereas the second row defines the second group. The effect size is computed as the prediction in the first row minus the prediction in the second row (first row - second row). Only the column relating to the grouping variable can change value and all others must be held constant for the comparison (see 'Details').
| second.ord | logical. If TRUE, the function returns the second-order Akaike information criterion (i.e., AICc). |
| nobs | this argument allows the specification of a numeric value other than total sample size to compute the AICc (i.e., nobs defaults to total number of observations). This is relevant only for mixed models or various models of unmarkedfit classes where sample size is not straightforward. In such cases, one might use total number of observations or number of independent clusters (e.g., sites) as the value of nobs. |
| uncond.se | either, "old", or "revised", specifying the equation used to compute the unconditional standard error of a model-averaged estimate. With uncond.se = "old", computations are based on equation 4.9 of Burnham and Anderson (2002), which was the former way to compute unconditional standard errors. With uncond.se = "revised", equation 6.12 of Burnham and Anderson (2002) is used. Anderson (2008, p. 111) recommends use of the revised version for the computation of unconditional standard errors and it is now the default. Note that versions of package AICcmodavg < 1.04 used the old method to compute unconditional standard errors. |
| conf.level | the confidence level \((1 - \alpha)\) requested for the computation of unconditional confidence intervals. To obtain confidence intervals corrected for multiple comparisons between pairs of treatments, it is possible to adjust the \(\alpha\) level according to various strategies such as the Bonferroni correction (Dunn 1961). |
| type | the scale of prediction requested, one of "response" or "link" (only relevant for glm, mer, and unmarkedFit classes). Note that the value "terms" is not defined for modavgEffect). |
| c.hat | value of overdispersion parameter (i.e., variance inflation factor) such as that obtained from c_hat. Note that values of c.hat different from 1 are only appropriate for binomial GLM’s with trials > 1 (i.e., success/trial or cbind(success, failure) syntax), with Poisson GLM’s, single-season and dynamic occupancy models (MacKenzie et al. 2002, 2003), or N-mixture models (Royle 2004, Dail and Madsen 2011). If c.hat > 1, modavgEffect will return the quasi-likelihood analogue of the information criteria requested and multiply the variance-covariance matrix of the estimates by this value (i.e., SE’s are multiplied by \(\sqrt{c.hat}\)). This option is not supported for generalized linear mixed models of the mer class. |
| gamdisp | if gamma GLM is used, the dispersion parameter should be specified here to apply the same value to each model. |
| parm.type | this argument specifies the parameter type on which the effect size will be computed and is only relevant for models of unmarkedFitOccu, unmarkedFitColExt, unmarkedFitOccuFP, unmarkedFitOccuRN, unmarkedFitMoi, unmarkedFitPC, unmarkedFitGC, unmarkedFitDS, unmarkedFitGMD, and unmarkedFitGPC classes. The character strings supported vary with the type of model fitted. For unmarkedFitOccu objects, either psi or detect can be supplied to indicate whether the parameter is on occupancy or detectability, respectively. For unmarkedFitColExt, possible values are psi, gamma, epsilon, and detect, for parameters on occupancy in the initial year, colonization, extinction, and detectability, respectively. For unmarkedFitOccuFP objects, one can specify psi, detect, falsepos, or certain, for occupancy, detectability, probability |
of assigning false-positives, and probability detections are certain, respectively. For unmarkedFitOccuRN objects, either lambda or detect can be entered for abundance and detectability parameters, respectively. For unmarkedFitPCount and unmarkedFitMPois objects, lambda or detect denote parameters on abundance and detectability, respectively. For unmarkedFitPCO objects, one can enter lambda, gamma, omega, iota, or detect, to specify parameters on abundance, recruitment, apparent survival, immigration, and detectability, respectively. For unmarkedFitDS objects, lambda and detect are supported. For unmarkedFitGDS, lambda, phi, and detect denote abundance, availability, and detectability, respectively. For unmarkedFitGMM and unmarkedFitGPC objects, lambda, phi, and detect denote abundance, availability, and detectability, respectively.

Details

The strategy used here to compute effect sizes is to work from the newdata object to create two predictions from a given model and compute the differences and standard errors between both values. This step is executed for each model in the candidate model set, to obtain a model-averaged estimate of the effect size and unconditional standard error. As a result, the newdata argument is restricted to two rows, each for a given prediction. To specify each group, the values entered in the column for each explanatory variable can be identical, except for the grouping variable. In such a case, the function will identify the variable and the assign group names based on the values of the variable. If more than a single variable has different values in its respective column, the function will print generic names in the output to identify the two groups. A sensible choice of value for the explanatory variables to be held constant is the average of the variable.

Model-averaging effect sizes is most useful in true experiments (e.g., ANOVA-type designs), where one wants to obtain the best estimate of effect size given the support of each candidate model. This can be considered as a information-theoretic analog of traditional multiple comparisons, except that the information contained in the entire model set is used instead of being restricted to a single model. See 'Examples' below for applications.

modavgEffect calls the appropriate method depending on the class of objects in the list. The current classes supported include aov, glm, gls, lm, lme, mer, glmerMod, lmerMod, rlm, survreg, as well as unmarkedFitOccu, unmarkedFitColExt, unmarkedFitOccuFP, unmarkedFitOccuRN, unmarkedFitPCount, unmarkedFitPCO, unmarkedFitDS, unmarkedFitGDS, unmarkedFitMPois, unmarkedFitGMM, and unmarkedFitGPC classes.

Value

The result is an object of class modavgEffect with the following components:

- **Group.variable**: the grouping variable defining the two groups compared.
- **Group1**: the first group considered in the comparison.
- **Group2**: the second group considered in the comparison.
- **Type**: the scale on which the model-averaged effect size was computed (e.g., response or link).
- **Mod.avg.table**: the full model selection table including the entire set of candidate models.
Mod. avg. eff  the model-averaged effect size based on the entire candidate model set.
Uncond. SE  the unconditional standard error for the model-averaged effect size.
Conf. level  the confidence level used to compute the confidence interval.
Lower. CL   the lower confidence limit.
Upper. CL   the upper confidence limit.

modavgIC

**Compute Model-averaged Parameter Estimate from User-supplied Information Criterion**

**Description**

This function model-averages the estimate of a parameter of interest among a set of candidate models, and computes the unconditional standard error and unconditional confidence intervals as described in Buckland et al. (1997) and Burnham and Anderson (2002). Computations are based on the values of the information criterion supplied manually by the user.

**Usage**

```r
modavgIC(ic, K, modnames = NULL, estimate, se, uncond.se = "revised", conf.level = 0.95, ic.name = NULL)
```

**Arguments**

- `ic`: a vector of information criterion values for each model in the candidate model set.
- `K`: a vector containing the number of estimated parameters for each model in the candidate model set.
- `modnames`: a character vector of model names to identify each model in the model selection table. If NULL, generic names (e.g., `Mod1`, `Mod2`) are supplied in the table in the same order as the information criterion values.
- `estimate`: a vector of estimates for each of the models in the candidate model set. Estimates can be either beta estimates for a parameter of interest or a single prediction from each model.
- `se`: a vector of standard errors for each of the estimates appearing in the `estimate` vector.
- `uncond.se`: either, "old", or "revised", specifying the equation used to compute the unconditional standard error of a model-averaged estimate. With `uncond.se = "old"`, computations are based on equation 4.9 of Burnham and Anderson (2002), which was the former way to compute unconditional standard errors. With `uncond.se = "revised"`, equation 6.12 of Burnham and Anderson (2002) is used. Anderson (2008, p. 111) recommends use of the revised version for the computation of unconditional standard errors and it is now the default.
- `conf.level`: the confidence level \((1 - \alpha)\) requested for the computation of unconditional confidence intervals.
- `ic.name`: a character string denoting the name of the information criterion input by the user. This character string will appear in certain column labels of the model selection table.
modavgIC

Details

modavgIC computes a model-averaged estimate from the vector of parameter estimates specified in `estimate`. Estimates and their associated standard errors must be specified in the same order as the values of the information criterion, the number of estimated parameters, and the model names. Estimates provided may be for a parameter of interest (i.e., beta estimates) or predictions from each model. This function is most useful for information criterion other than AIC, AICc, QAIC, and QAICc (e.g., WAIC: Watanabe 2010) or for classes not supported by `modavg`, `modavgCustom`, or `modavgPred`.

Value

modavgIC creates an object of class `modavgIC` with the following components:

- `modNavgNtable`: the model selection table.
- `modNavgNest`: the model-averaged estimate.
- `uncondNse`: the unconditional standard error for the model-averaged estimate.
- `confNlevel`: the confidence level used to compute the confidence interval.
- `lowerNcl`: the lower confidence limit.
- `upperNcl`: the upper confidence limit.

Compute Model-averaged Predictions

Description

This function computes the model-averaged predictions, unconditional standard errors, and confidence intervals based on the entire candidate model set. The function is currently implemented for glm, gls, lm, lme, mer, merMod, negbin, rlm, survreg object classes that are stored in a list as well as various models of unmarkedFit classes.

Usage

modavgPred(cand.set, modnames = NULL, newdata, second.order = TRUE, 
          nobs = NULL, uncond.se = "revised", conf.level = 0.95, ...)

## S3 method for class 'AICaov.lm'
modavgPred(cand.set, modnames = NULL, newdata, 
          second.order = TRUE, nobs = NULL, uncond.se = "revised", 
          conf.level = 0.95, ...)

## S3 method for class 'AICglm.lm'
modavgPred(cand.set, modnames = NULL, newdata, 
          second.order = TRUE, nobs = NULL, uncond.se = "revised",

Arguments

cand.set a list storing each of the models in the candidate model set.

modnames a character vector of model names to facilitate the identification of each model in the model selection table. If NULL, the function uses the names in the cand.set list of candidate models. If no names appear in the list, generic names (e.g., Mod1, Mod2) are supplied in the table in the same order as in the list of candidate models.

newdata a data frame with the same structure as that of the original data frame for which we want to make predictions.

second.ord logical. If TRUE, the function returns the second-order Akaike information criterion (i.e., AICc).

nobs this argument allows to specify a numeric value other than total sample size to compute the AICc (i.e., nobs defaults to total number of observations). This is relevant only for mixed models or various models of unmarkedFit classes where sample size is not straightforward. In such cases, one might use total number of observations or number of independent clusters (e.g., sites) as the value of nobs.

uncond.se either, old, or revised, specifying the equation used to compute the unconditional standard error of a model-averaged estimate. With uncond.se = "old", computations are based on equation 4.9 of Burnham and Anderson (2002), which was the former way to compute unconditional standard errors. With uncond.se = "revised", equation 6.12 of Burnham and Anderson (2002) is used. Anderson (2008, p. 111) recommends use of the revised version for the computation of unconditional standard errors and it is now the default. Note that versions of package AICcmodavg < 1.04 used the old method to compute unconditional standard errors.

conf.level the confidence level \((1 - \alpha)\) requested for the computation of unconditional confidence intervals.

type the scale of prediction requested, one of response or link. The latter is only relevant for glm, mer, and unmarkedFit classes. Note that the value terms is not defined for modavgPred.

c.hat value of overdispersion parameter (i.e., variance inflation factor) such as that obtained from c.hat. Note that values of c.hat different from 1 are only appropriate for binomial GLM’s with trials > 1 (i.e., success/trial or cbind(success, fail-
modavgPred

The candidate models must be stored in a list. Note that a data frame from which to make predictions must be supplied with the newdata argument and that all variables appearing in the model set must appear in this data frame. Variables must be of the same type as in the original analysis (e.g., factor, numeric).

One can compute unconditional confidence intervals around the predictions from the elements returned by modavgPred. The classic computation based on asymptotic normality of the estimator is appropriate to estimate confidence intervals on the linear predictor (i.e., link scale). For predictions of some types of response variables such as counts or binary variables, the normal approximation may be inappropriate. In such cases, it is often better to compute the confidence intervals on the linear predictor scale and then back-transform the limits to the scale of the response variable. These are the confidence intervals returned by modavgPred. Burnham et al. (1987), Burnham and Anderson (2002, p. 164), and Williams et al. (2002) suggest alternative methods of computing confidence intervals.

(2002) suggest alternative methods of computing confidence intervals.
intervals for small degrees of freedom with profile likelihood intervals or bootstrapping, but these approaches are not yet implemented in modavgPred.

Value

modavgPred returns an object of class modavgPred with the following components:

- **type**: the scale of predicted values (response or link) for glm, mer, merMod, or unmarkedFit classes.
- **mod.avg.pred**: the model-averaged prediction over the entire candidate model set.
- **uncond.se**: the unconditional standard error of each model-averaged prediction.
- **conf.level**: the confidence level used to compute the confidence interval.
- **lower.CL**: the lower confidence limit.
- **upper.CL**: the upper confidence limit.
- **matrix.output**: a matrix with rows consisting of the model-averaged predictions, the unconditional standard errors, and the confidence limits.

### modavgShrink

**Compute Model-averaged Parameter Estimate with Shrinkage (Multimodel Inference)**

### Description

This function computes an alternative version of model-averaging parameter estimates that consists in shrinking estimates toward 0 to reduce model selection bias as in Burnham and Anderson (2002, p. 152), Anderson (2008, pp. 130-132) and Lukacs et al. (2010). Specifically, models without the parameter of interest have an estimate and variance of 0. `modavgShrink` also returns unconditional standard errors and unconditional confidence intervals as described in Buckland et al. (1997) and Burnham and Anderson (2002).

### Usage

```r
modavgShrink(cand.set, parm, modnames = NULL, second.ord = TRUE,
              nobs = NULL, uncond.se = "revised", conf.level = 0.95,
              ...
)
```

)
Arguments

cand.set a list storing each of the models in the candidate model set.
parm the parameter of interest, enclosed between quotes, for which a model-averaged
estimate is required. For a categorical variable, the label of the estimate must be
included as it appears in the output (see 'Details' below).
modnames a character vector of model names to facilitate the identification of each model
in the model selection table. If NULL, the function uses the names in the cand.set
list of candidate models. If no names appear in the list, generic names (e.g., `Mod1`, `Mod2`) are supplied in the table in the same order as in the list of candidate models.

**second.ord** logical. If TRUE, the function returns the second-order Akaike information criterion (i.e., AICc).

**nobs** this argument allows to specify a numeric value other than total sample size to compute the AICc (i.e., nobs defaults to total number of observations). This is relevant only for mixed models or various models of unmarkedFit classes where sample size is not straightforward. In such cases, one might use total number of observations or number of independent clusters (e.g., sites) as the value of nobs.

**uncond.se** either, "old", or "revised", specifying the equation used to compute the unconditional standard error of a model-averaged estimate. With uncond.se = "old", computations are based on equation 4.9 of Burnham and Anderson (2002), which was the former way to compute unconditional standard errors. With uncond.se = "revised", equation 6.12 of Burnham and Anderson (2002) is used. Anderson (2008, p. 111) recommends use of the revised version for the computation of unconditional standard errors and it is now the default. Note that versions of package AICcmodavg < 1.04 used the old method to compute unconditional standard errors.

**conf.level** the confidence level ($1 - \alpha$) requested for the computation of unconditional confidence intervals.

**c.hat** value of overdispersion parameter (i.e., variance inflation factor) such as that obtained from c.hat. Note that values of c.hat different from 1 are only appropriate for binomial GLM’s with trials > 1 (i.e., success/trial or cbind(success, failure) syntax), with Poisson GLM’s, single-season occupancy models (MacKenzie et al. 2002), dynamic occupancy models (MacKenzie et al. 2003), or N-mixture models (Royle 2004, Dail and Madsen 2011). If c.hat > 1, modavgShrink will return the quasi-likelihood analogue of the information criteria requested and multiply the variance-covariance matrix of the estimates by this value (i.e., SE’s are multiplied by $\sqrt{c.hat}$). This option is not supported for generalized linear mixed models of the mer or merMod classes.

**gamdisp** if gamma GLM is used, the dispersion parameter should be specified here to apply the same value to each model.

**parm.type** this argument specifies the parameter type on which the effect size will be computed and is only relevant for models of unmarkedFitOccu, unmarkedFitColExt, unmarkedFitOccuFP, unmarkedFitOccuRN, unmarkedFitMPois, unmarkedFitPCount, unmarkedFitPC0, unmarkedFitDS, unmarkedFitGDS, unmarkedFitGMM, unmarkedFitGPC, and unmarkedFitOccuMulti classes. The character strings supported vary with the type of model fitted. For unmarkedFitOccu and unmarkedFitOccuMulti objects, either psi or detect can be supplied to indicate whether the parameter is on occupancy or detectability, respectively. For unmarkedFitColExt, possible values are psi, gamma, epsilon, and detect, for parameters on occupancy in the initial year, colonization, extinction, and detectability, respectively. For unmarkedFitOccuFP objects, one can specify psi, detect, falsepos, and certain, for occupancy, detectability, probability of assigning false-positives, and probability detections are certain, respectively. For unmarkedFitOccuRN
objects, either lambda or detect can be entered for abundance and detectability parameters, respectively. For unmarkedFitPCount and unmarkedFitMPois objects, lambda or detect denote parameters on abundance and detectability, respectively. For unmarkedFitPCO objects, one can enter lambda, gamma, omega, iota, or detect, to specify parameters on abundance, recruitment, apparent survival, immigration, and detectability, respectively. For unmarkedFitDS objects, lambda and detect are supported. For unmarkedFitGDS, lambda, phi, and detect denote abundance, availability, and detectability, respectively. For unmarkedFitGMM and unmarkedFitGPC objects, lambda, phi, and detect denote abundance, availability, and detectability, respectively.

... additional arguments passed to the function.

Details

The parameter for which a model-averaged estimate is requested must be specified with the parm argument and must be identical to its label in the model output (e.g., from summary). For factors, one must specify the name of the variable and the level of interest. The shrinkage version of model averaging is only appropriate for cases where each parameter is given an equal weighting in the model (i.e., each parameter must appear the same number of times in the models) and has the same interpretation across all models. As a result, models with interaction terms or polynomial terms are not supported by modavgShrink.

modavgShrink is implemented for a list containing objects of aov, betareg, clm, clmm, clogit, coxme, coxph, glm, glmmTMB, gls, hurdle, lm, lme, lme4, maxlikeFit, mer, glmerMod, lmerMod, multinom, polr, rlm, survreg, vglm, zeroinfl classes as well as various models of unmarkedFit classes.

Value

modavgShrink creates an object of class modavgShrink with the following components:

Parameter the parameter for which a model-averaged estimate with shrinkage was obtained.
Mod.avg.table the model selection table based on models including the parameter of interest.
Mod.avg.beta the model-averaged estimate based on all models.
Uncond.SE the unconditional standard error for the model-averaged estimate (as opposed to the conditional SE based on a single model).
Conf.level the confidence level used to compute the confidence interval.
Lower.CL the lower confidence limit.
Upper.CL the upper confidence limit.

        parm.type = "lambda")
detach(package: unmarked)

## End(Not run)
Description

This function is an alternative to traditional multiple comparison tests in designed experiments. It creates a model selection table based on different grouping patterns of a factor and computes model-averaged predictions for each of the factor levels. The current version works with objects of aov, glm, gls, lm, lme, mer, merMod, negbin, and rlm, survreg classes.

Usage

```r
multComp(mod, factor.id, letter.labels = TRUE, second.ord = TRUE,
nobs = NULL, sort = TRUE, newdata = NULL, uncond.se = "revised",
conf.level = 0.95, correction = "none", ...)

## S3 method for class 'aov'
multComp(mod, factor.id, letter.labels = TRUE,
    second.ord = TRUE, nobs = NULL, sort = TRUE, newdata = NULL,
    uncond.se = "revised", conf.level = 0.95, correction = "none",
    ...
)

## S3 method for class 'lm'
multComp(mod, factor.id, letter.labels = TRUE,
    second.ord = TRUE, nobs = NULL, sort = TRUE, newdata = NULL,
    uncond.se = "revised", conf.level = 0.95, correction = "none",
    ...
)

## S3 method for class 'gls'
multComp(mod, factor.id, letter.labels = TRUE,
    second.ord = TRUE, nobs = NULL, sort = TRUE, newdata = NULL,
    uncond.se = "revised", conf.level = 0.95, correction = "none",
    ...
)

## S3 method for class 'glm'
multComp(mod, factor.id, letter.labels = TRUE,
    second.ord = TRUE, nobs = NULL, sort = TRUE, newdata = NULL,
    uncond.se = "revised", conf.level = 0.95, correction = "none",
    type = "response", c.hat = 1, gamdisp = NULL, ...)

## S3 method for class 'lme'
multComp(mod, factor.id, letter.labels = TRUE,
    second.ord = TRUE, nobs = NULL, sort = TRUE, newdata = NULL,
    uncond.se = "revised", conf.level = 0.95, correction = "none",
    ...
)

## S3 method for class 'negbin'
multComp(mod, factor.id, letter.labels = TRUE,
    second.ord = TRUE, nobs = NULL, sort = TRUE, newdata = NULL,
    uncond.se = "revised", conf.level = 0.95, correction = "none",
    type = "response", ...)
```
Arguments

mod
a model of one of the above-mentioned classes that includes at least one factor as an explanatory variable.

factor.id
the factor of interest, on which the groupings (multiple comparisons) are based. The user must supply the name of the categorical variable between quotes as it appears in the model formula.

letter.labels
logical. If TRUE, letters are used as labels to denote the grouping structure. If FALSE, numbers are used as group labels.

second.ord
logical. If TRUE, the function returns the second-order Akaike information criterion (i.e., AICc), otherwise returns Akaike's Information Criterion (AIC).

nobs
this argument allows to specify a numeric value other than total sample size to compute the AICc (i.e., nobs defaults to total number of observations). This is relevant only for certain types of models such as mixed models where sample size is not straightforward. In such cases, one might use total number of observations or number of independent clusters (e.g., sites) as the value of nobs.

sort
logical. If TRUE, the model selection table is ranked according to the (Q)AIC(c) values.

newdata
a data frame with the same structure as that of the original data frame for which we want to make predictions. This data frame should hold all variables constant other than the factor.id variable. All levels of the factor.id variables should be included in the newdata data frame to get model-averaged predictions for each level. If NULL, model-averaged predictions are computed for each level of
the `factor.id` variable while the values of the other explanatory variables are taken from the first row of the original data set.

`uncond.se` either, "old", or "revised", specifying the equation used to compute the unconditional standard error of a model-averaged estimate. With `uncond.se = "old"`, computations are based on equation 4.9 of Burnham and Anderson (2002), which was the former way to compute unconditional standard errors. With `uncond.se = "revised"`, equation 6.12 of Burnham and Anderson (2002) is used. Anderson (2008, p. 111) recommends use of the revised version for the computation of unconditional standard errors and it is now the default. Note that versions of package AICmodavg < 1.04 used the old method to compute unconditional standard errors.

`conf.level` the confidence level \((1 - \alpha)\) requested for the computation of unconditional confidence intervals around predicted values for each level of `factor.id`.

`correction` the type of correction applied to obtain confidence intervals for simultaneous inference (i.e., corrected for multiple comparisons). Current corrections include "none" for uncorrected unconditional confidence intervals, "bonferroni" for Bonferroni-adjusted confidence intervals (Dunn 1961), and "sidak" for Sidak-adjusted confidence intervals (Sidak 1967).

`type` the scale of prediction requested, one of "response" or "link". The latter is only relevant for `glm` and `mer` classes. Note that the value "terms" is not defined for `multComp`.

`c.hat` value of overdispersion parameter (i.e., variance inflation factor) such as that obtained from `c_hat`. Note that values of `c.hat` different from 1 are only appropriate for binomial GLM's with trials > 1 (i.e., success/trial or `cbind(success, failure)` syntax) or with Poisson GLM's. If `c.hat > 1`, `multComp` will return the quasi-likelihood analogue of the information criterion requested. This option is not supported for generalized linear mixed models of the `mer` class.

`gamdisp` the value of the gamma dispersion parameter in a gamma GLM.

... additional arguments passed to the function.

Details

A number of pairwise comparison tests are available for traditional experimental designs, some controlling for the experiment-wise error and others for comparison-wise errors (Day and Quinn 1991). With the advent of information-theoretic approaches, there has been a need for methods analogous to multiple comparison tests in a model selection framework. Dayton (1998) and Burnham et al. (2011) suggested using different parameterizations or grouping patterns of a factor to perform multiple comparisons with model selection. As such, it is possible to assess the support in favor of certain grouping patterns based on a factor.

For example, a factor with three levels has four possible grouping patterns: abc (all groups are different), abb (the first group differs from the other two), aab (the first two groups differ from the third), and aaa (all groups are equal). `multComp` implements such an approach by pooling groups of the factor variable in a model and updating the model, for each grouping pattern possible. The models are ranked according to one of four information criteria (AIC, AICc, QAIC, and QAICc), and the labels in the table correspond to the grouping pattern. Note that the factor levels are sorted according to their means for the response variable before being assigned to a group. The function
also returns model-averaged predictions and unconditional standard errors for each level of the `factor.id` variable based on the support in favor of each model (i.e., grouping pattern).

The number of grouping patterns increases substantially with the number of factor levels, as $2^k - 1$, where $k$ is the number of factor levels. `multComp` supports factors with a maximum of 6 levels. Also note that `multComp` does not handle models where the `factor.id` variable is involved in an interaction. In such cases, one should create the interaction variable manually before fitting the model (see Examples).

`multComp` currently implements three methods of computing confidence intervals. The default unconditional confidence intervals do not account for multiple comparisons (`correction = "none"`).

With a large number $m$ of potential pairwise comparisons among levels of `factor.id`, there is an increased risk of type I error. For $m$ pairwise comparisons and a given $\alpha$ level, `correction = "bonferroni"` computes the unconditional confidence intervals based on $\alpha_{corr} = \frac{\alpha}{m}$ (Dunn 1961). When `correction = "sidak"`, `multComp` reports Sidak-adjusted confidence intervals, i.e., $\alpha_{corr} = 1 - (1 - \alpha)^{\frac{1}{m}}$.

**Value**

`multComp` creates a list of class `multComp` with the following components:

- `factor.id` the factor for which grouping patterns are investigated.
- `models` a list with the output of each model representing a different grouping pattern for the factor of interest.
- `model.names` a vector of model names denoting the grouping pattern for each level of the factor.
- `model.table` the model selection table for the models corresponding to each grouping pattern for the factor of interest.
- `ordered.levels` the levels of the factor ordered according to the mean of the response variable. The grouping patterns (and model names) in the model selection table are based on the same order.
- `model.avg.est` a matrix with the model-averaged prediction, unconditional standard error, and confidence intervals for each level of the factor.
- `conf.level` the confidence level used for the confidence intervals.
- `correction` the type of correction applied to the confidence intervals to account for potential pairwise comparisons.

## Returns an error because 'Hormone' factor is
## involved in an interaction

## Create interaction variable
calcium$inter <- interaction(calcium$Hormone, calcium$Sex)
```
## Newt Capture-mark-recapture Data

**Description**

This is a capture-mark-recapture data set on adult male and female Red-spotted Newts (*Notophthalmus viridescens*) recorded by Gill (1985). A total of 1079 unique individuals were captured in
pitfall traps at a breeding site (White Oak Flat pond, Virginia) between 1975 and 1983.

Usage
data(newt)

Format
A data frame with 78 observations on the following 11 variables.

- T1975 a binary variable, either 1 (captured) or 0 (not captured) during the 1975 breeding season.
- T1976 a binary variable, either 1 (captured) or 0 (not captured) during the 1976 breeding season.
- T1977 a binary variable, either 1 (captured) or 0 (not captured) during the 1977 breeding season.
- T1978 a binary variable, either 1 (captured) or 0 (not captured) during the 1978 breeding season.
- T1979 a binary variable, either 1 (captured) or 0 (not captured) during the 1979 breeding season.
- T1980 a binary variable, either 1 (captured) or 0 (not captured) during the 1980 breeding season.
- T1981 a binary variable, either 1 (captured) or 0 (not captured) during the 1981 breeding season.
- T1982 a binary variable, either 1 (captured) or 0 (not captured) during the 1982 breeding season.
- T1983 a binary variable, either 1 (captured) or 0 (not captured) during the 1983 breeding season.
- Males a numeric variable indicating the total number of males with a given capture history.
- Females a numeric variable indicating the total number of females with a given capture history.

Details
A single cohort of individuals was followed throughout the study, as all individuals were marked in 1975 and no new individuals were added during the subsequent years. This data set is used to illustrate classic Cormack-Jolly-Seber and related models (Cormack 1964, Jolly 1965, Seber 1965, Lebreton et al. 1992, Mazerolle 2015).

Nmix.gof.test  Compute Chi-square Goodness-of-fit Test for N-mixture Models

Description

These functions compute a goodness-of-fit test for N-mixture models based on Pearson's chi-square.

Usage

### methods for 'unmarkedFitPCount', 'unmarkedFitPCO',
### 'unmarkedFitDS', 'unmarkedFitGDS', 'unmarkedFitGMM',
### 'unmarkedFitGPC', and 'unmarkedFitMPois' classes
Nmix.chisq(mod, ...)

Nmix.gof.test(mod, nsim = 5, plot.hist = TRUE, report = NULL, parallel = TRUE, ...)

Arguments

- **mod**
  - the N-mixture model of 'unmarkedFitPCount', 'unmarkedFitPCO', 'unmarkedFitDS', 'unmarkedFitGDS', 'unmarkedFitGMM', 'unmarkedFitGPC', or 'unmarkedFitMPois' classes for which a goodness-of-fit test is required.

- **nsim**
  - the number of bootstrapped samples.
plot.hist logical. Specifies that a histogram of the bootstrapped test statistic is to be included in the output.

report If NULL, the test statistic for each iteration is not printed in the terminal. Otherwise, an integer indicating the number of values of the test statistic that should be printed on the same line. For example, if report = 3, the values of the test statistic for three iterations are reported on each line.

parallel logical. If TRUE, requests that parboot use multiple cores to accelerate computations of the bootstrap.

Details

The Pearson chi-square can be used to assess the fit of N-mixture models. Instead of relying on the theoretical distribution of the chi-square, a parametric bootstrap approach is implemented to obtain P-values with the parboot function of the unmarked package. nmix.chisq computes the observed chi-square statistic based on the observed and expected counts from the model. nmix.gof.test calls internally nmix.chisq and parboot to generate simulated data sets based on the model and compute the chi-square test statistic.

It is also possible to obtain an estimate of the overdispersion parameter (c-hat) for the model at hand by dividing the observed chi-square statistic by the mean of the statistics obtained from simulation (MacKenzie and Bailey 2004, McKenny et al. 2006). This method of estimating c-hat is similar to the one implemented for capture-mark-recapture models in program MARK (White and Burnham 1999).

Note that values of c-hat > 1 indicate overdispersion (variance > mean). Values much higher than 1 (i.e., > 4) probably indicate lack-of-fit. In cases of moderate overdispersion, one can multiply the variance-covariance matrix of the estimates by c-hat. As a result, the SE’s of the estimates are inflated (c-hat is also known as a variance inflation factor).

In model selection, c-hat should be estimated from the global model and the same value of c-hat applied to the entire model set. Specifically, a global model is the most complex model which can be simplified to yield all the other (nested) models of the set. When no single global model exists in the set of models considered, such as when sample size does not allow a complex model, one can estimate c-hat from ‘subglobal’ models. Here, ‘subglobal’ models denote models from which only a subset of the models of the candidate set can be derived. In such cases, one can use the smallest value of c-hat for model selection (Burnham and Anderson 2002).

Note that c-hat counts as an additional parameter estimated and should be added to K. All functions in package AICcmodavg automatically add 1 when the c.hat argument > 1 and apply the same value of c-hat for the entire model set. When c.hat > 1, functions compute quasi-likelihood information criteria (either QAICc or QAIC, depending on the value of the second, ord argument) by scaling the log-likelihood of the model by c-hat. The value of c-hat can influence the ranking of the models: as c-hat increases, QAIC or QAICc will favor models with fewer parameters. As an additional check against this potential problem, one can generate several model selection tables by incrementing values of c-hat to assess the model selection uncertainty. If ranking changes only slightly up to the c-hat value observed, one can be confident in making inference.

In cases of underdispersion (c-hat < 1), it is recommended to keep the value of c-hat to 1. However, note that values of c-hat « 1 can also indicate lack-of-fit and that an alternative model should be investigated.
Value
Nmix.chisq returns two value:

chi.square the Pearson chi-square statistic.
model.type the class of the fitted model.

Nmix.gof.test returns the following components:

model.type the class of the fitted model.
chi.square the Pearson chi-square statistic.
t.star the bootstrapped chi-square test statistics (i.e., obtained for each of the simulated data sets).
p.value the $P$-value assessed from the parametric bootstrap, computed as the proportion of the simulated test statistics greater than or equal to the observed test statistic.
c.hat.est the estimate of the overdispersion parameter, c-hat, computed as the observed test statistic divided by the mean of the simulated test statistics.
nsim the number of bootstrap samples. The recommended number of samples varies with the data set, but should be on the order of 1000 or 5000, and in cases with a large number of visits, even 10 000 samples, namely to reduce the effect of unusually small values of the test statistics.

pine Strength of Pine Wood Based on the Density Adjusted for Resin Content

Description

This data set consists of the strength of pine wood as a function of density or density adjusted for resin content.

Usage

data(pine)

Format

A data frame with 42 observations on the following 3 variables.

y  pine wood strength.
x  pine wood density.
z  pine wood density adjusted for resin content.

**predictSE**

Computing Predicted Values and Standard Errors

Description

Function to compute predicted values based on linear predictor and associated standard errors from various fitted models.

Usage

```
predictSE(mod, newdata, se.fit = TRUE, print.matrix = FALSE, ...)
```

## S3 method for class 'gls'
```
predictSE(mod, newdata, se.fit = TRUE, print.matrix = FALSE, ...)
```

## S3 method for class 'lme'
```
predictSE(mod, newdata, se.fit = TRUE, print.matrix = FALSE, level = 0, ...)
```

## S3 method for class 'mer'
```
predictSE(mod, newdata, se.fit = TRUE, print.matrix = FALSE, level = 0, type = "response", ...)
```

## S3 method for class 'merMod'
```
predictSE(mod, newdata, se.fit = TRUE, print.matrix = FALSE, level = 0, type = "response", ...)
```

## S3 method for class 'unmarkedFitPCOUNT'
```
predictSE(mod, newdata, se.fit = TRUE,
    print.matrix = FALSE, type = "response", c.hat = 1, parm.type ="response", ...)
"lambda", ...)

## S3 method for class 'unmarkedFitPCO'
predictSE(mod, newdata, se.fit = TRUE,
       print.matrix = FALSE, type = "response", c.hat = 1,
       parm.type = "lambda", ...)

### Arguments

- **mod**: an object of class `gls`, `lme`, `mer`, `merMod`, `unmarkedFitPCount`, or `unmarkedFitPCO` containing the output of a model.
- **newdata**: a data frame with the same structure as that of the original data frame for which we want to make predictions.
- **se.fit**: logical. If `TRUE`, compute standard errors on predictions.
- **print.matrix**: logical. If `TRUE`, the output is returned as a matrix, with predicted values and standard errors in columns. If `FALSE`, the output is returned as a list.
- **level**: the level for which predicted values and standard errors are to be computed. The current version of the function only supports predictions for the populations excluding random effects (i.e., `level = 0`).
- **type**: specifies the type of prediction requested. This argument can take the value `response` or `link`, for predictions on the scale of the response variable or on the scale of the linear predictor, respectively.
- **c.hat**: value of overdispersion parameter (i.e., variance inflation factor) such as that obtained from `Nmix.gof.test`. If `c.hat > 1`, `predictSE` will multiply the variance-covariance matrix of the predictions by this value (i.e., SE's are multiplied by `sqrt(c.hat)`). High values of `c.hat` (e.g., `c.hat > 4`) may indicate that model structure is inappropriate.
- **parm.type**: the parameter for which predictions are made based on the `N`-mixture model of class `unmarkedFitPCount` or `unmarkedFitPCO` classes.
- ... additional arguments passed to the function.

### Details

`predictSE` computes predicted values and associated standard errors. Standard errors are approximated using the delta method (Oehlert 1992). Predictions and standard errors for objects of `gls` class and mixed models of `lme`, `mer`, `merMod` classes exclude the correlation or variance structure of the model.

`predictSE` computes predicted values on abundance and standard errors based on the estimates from an `unmarkedFitPCount` or `unmarkedFitPCO` object. Currently, only predictions on abundance (i.e., `parm.type = "lambda"`) with the zero-inflated Poisson distribution is supported. For other parameters or distributions for models of `unmarkedFit` classes, use `predict` from the `unmarked` package.

### Value

`predictSE` returns requested values either as a matrix (`print.matrix = TRUE`) or list (`print.matrix = FALSE`) with components:
fit the predicted values.

se.fit the standard errors of the predicted values (if se.fit = TRUE).

Note

For standard errors with better properties, especially for small samples, one can opt for simulations (see Gelman and Hill 2007), or nonparametric bootstrap (Efron and Tibshirani 1998).

salamander  Salamander Capture-mark-recapture Data

Description

This is a capture-mark-recapture data set on male and female Spotted Salamanders (Ambystoma maculatum) recorded by Husting (1965). A total of 1244 unique individuals were captured in pitfall traps at a breeding site between 1959 and 1963.

Usage

data(salamander)

Format

A data frame with 36 observations on the following 7 variables.

- **T1959** a binary variable, either 1 (captured) or 0 (not captured) during the 1959 breeding season.
- **T1960** a binary variable, either 1 (captured) or 0 (not captured) during the 1960 breeding season.
- **T1961** a binary variable, either 1 (captured) or 0 (not captured) during the 1961 breeding season.
- **T1962** a binary variable, either 1 (captured) or 0 (not captured) during the 1962 breeding season.
- **T1963** a binary variable, either 1 (captured) or 0 (not captured) during the 1963 breeding season.
- **Males** a numeric variable indicating the total number of males with a given capture history. Negative values indicate losses on capture (animals not released on last capture).
- **Females** a numeric variable indicating the total number of females with a given capture history. Negative values indicate losses on capture (animals not released on last capture).
Details

This data set is used to illustrate classic Cormack-Jolly-Seber and related models (Cormack 1964, Jolly 1965, Seber 1965, Lebreton et al. 1992).

Display Model Summary Corrected for Overdispersion

**Description**

This function displays the estimates of a model with standard errors corrected for overdispersion for a variety of model classes. The output includes either confidence intervals based on the normal approximation or Wald hypothesis tests corrected for overdispersion.

**Usage**

```
summaryOD(mod, c.hat = 1, conf.level = 0.95,
          out.type = "confint", ...)
```

## S3 method for class 'glm'
```
summaryOD(mod, c.hat = 1, conf.level = 0.95,
          out.type = "confint", ...)
```

## S3 method for class 'unmarkedFitOccu'
```
summaryOD(mod, c.hat = 1, conf.level = 0.95,
          out.type = "confint", ...)
```

## S3 method for class 'unmarkedFitColExt'
```
summaryOD(mod, c.hat = 1, conf.level = 0.95,
          out.type = "confint", ...)
```

## S3 method for class 'unmarkedFitOccuRN'
```
summaryOD(mod, c.hat = 1, conf.level = 0.95,
          out.type = "confint", ...)
```

## S3 method for class 'unmarkedFitPCO'
```
summaryOD(mod, c.hat = 1, conf.level = 0.95,
          out.type = "confint", ...)
```

## S3 method for class 'unmarkedFitDS'
```
summaryOD(mod, c.hat = 1, conf.level = 0.95,
          out.type = "confint", ...)
```

## S3 method for class 'unmarkedFitGDS'
```
summaryOD(mod, c.hat = 1, conf.level = 0.95,
          out.type = "confint", ...)
```

## S3 method for class 'unmarkedFitOccuFP'
```
Arguments

mod an object of class glm, glmmTMB, maxlikeFit, mer, merMod, multinom, vglm, and various unmarkedFit classes containing the output of a model.
c.hat value of overdispersion parameter (i.e., variance inflation factor) such as that obtained from c_hat, mb.gof.test, or Nmix.gof.test.
conf.level the confidence level \((1 - \alpha)\) requested for the computation of confidence intervals.
out.type the type of summary requested for each parameter estimate. If out.type = "confint", computes confidence intervals corrected for overdispersion, whereas out.type = "nhst" conducts null-hypothesis statistical testing corrected for overdispersion.
... additional arguments passed to the function.

Details

Overdispersion occurs when the variance in the data exceeds that expected from a theoretical distribution such as the Poisson or binomial (McCullagh and Nelder 1989, Burnham and Anderson
When the model is correct, small values of c-hat (1 < c-hat < 4) can reflect minor deviations from model assumptions (Burnham and Anderson 2002). In such cases, it is possible to adjust standard errors of parameter estimates by multiplying with \(\sqrt{\text{c-hat}}\) (McCullagh and Nelder 1989). This is the correction applied by `summaryOD`.

Depending on the type of summary requested, i.e., `out.type = "confint"` or `out.type = "nhst"`, `summaryOD` will return either confidence intervals based on the normal approximation or Wald tests for each parameter estimate (Agresti 1990).

For binomial distributions, note that values of \(\text{c-hat} > 1\) are only appropriate with trials > 1 (i.e., `success/trial` or `cbind(success, failure)` syntax). The function supports different model types such as Poisson GLM's and GLMM's, single-season occupancy models (MacKenzie et al. 2002), dynamic occupancy models (MacKenzie et al. 2003), or N-mixture models (Royle 2004, Dail and Madsen 2011).

**Value**

`summaryOD` returns an object of class `summaryOD` as a list with the following components:

- `out.type` the type of output requested by the user.
- `c.hat` the c.hat estimate used to adjust standard errors.
- `conf.level` the confidence level used to compute confidence intervals around the estimates.
- `outMat` the output of the model corrected for overdispersion organized in a matrix.

tortoise

Gopher Tortoise Distance Sampling Data

Description

This simulated data set by Mazerolle (2015) is based on the biological parameters for the Gopher Tortoise (*Gopherus polyphemus*) reported by Smith et al. (2009). A half-normal distribution with a scale of 10 and without an adjustment factor was used to simulate the distance data for a study area of 120 km$^2$. An effort of 500 m in 300 line transects was deployed. A density of 72 individuals per km$^2$ was used in the simulation using the approach outlined in Buckland et al. (2001).

Usage

data(tortoise)

Format

A data frame with 410 observations on the following 5 variables.

Region.Label a numeric identifier for the study area.

Area a numeric variable for the surface area of the study area in square meters.

Sample.Label a numeric identifier for each line transect relating each observation to its corresponding transect.

Effort Effort in meters expended in each line transect.

distance a numeric variable for the perpendicular distances in meters relative to the transect line for each of the individuals detected during the survey. Note that transects without detections have a value of NA for this variable.

Details

This data set is used to illustrate classic distance sampling (Buckland et al. 2001, Mazerolle 2015).

Source

Examples

1, ...) 

## S3 method for class 'vglm'
useBIC(mod, return.K = FALSE, nobs = NULL, c.hat = 1, 
...

## S3 method for class 'zeroinfl'
useBIC(mod, return.K = FALSE, nobs = NULL, ...) 

Arguments

mod an object of class aov, betareg, clm, clmm, clogit, coxme, coxph, fitdist, fitdistr, glm, glmmTMB, gls, gls, hurdle, lavaan, lm, lme, lme4, maxlikefit, mer, merMod, multinom, nlme, nls, polr, rlm, survreg, vglm, zeroinefl, and various unmarkedFit classes containing the output of a model.

return.K logical. If FALSE, the function returns the information criterion specified. If TRUE, the function returns K (number of estimated parameters) for a given model.

nobs this argument allows to specify a numeric value other than total sample size to compute the BIC (i.e., nobs defaults to total number of observations). This is relevant only for mixed models or various models of unmarkedFit classes where sample size is not straightforward. In such cases, one might use total number of observations or number of independent clusters (e.g., sites) as the value of nobs.

c.hat value of overdispersion parameter (i.e., variance inflation factor) such as that obtained from c.hat. Note that values of c.hat different from 1 are only appropriate for binomial GLM’s with trials > 1 (i.e., success/trial or cbind(success, failure) syntax), with Poisson GLM’s, single-season occupancy models (MacKenzie et al. 2002), dynamic occupancy models (MacKenzie et al. 2003), or N-mixture models (Royle 2004, Dail and Madsen 2011). If c.hat > 1, useBIC will return the quasi-likelihood analogue of the information criteria requested and multiply the variance-covariance matrix of the estimates by this value (i.e., SE’s are multiplied by sqrt(c.hat)). This option is not supported for generalized linear mixed models of the mer or merMod classes.

... additional arguments passed to the function.

Details

useBIC computes the Bayesian information criterion (BIC, Schwarz 1978):

\[
BIC = -2 \log \text{likelihood} + K \log n,
\]

where the log-likelihood is the maximum log-likelihood of the model, K corresponds to the number of estimated parameters, and n corresponds to the sample size of the data set.

In the presence of overdispersion, a quasi-likelihood analogue of the BIC (QBIC) will be computed, as

\[
QBIC = \frac{-2 \log \text{likelihood}}{c - \hat{c}} + K \log n,
\]
where \( c-hat \) is the overdispersion parameter specified by the user with the argument \( c.hat \). Note that BIC or QBIC values are meaningful to select among \( gls \) or \( lme \) models fit by maximum likelihood. BIC or QBIC based on REML are valid to select among different models that only differ in their random effects (Pinheiro and Bates 2000).

**Value**

\( \text{useBIC} \) returns the BIC or the number of estimated parameters, depending on the values of the arguments.

**Note**

The actual (Q)BIC values are not really interesting in themselves, as they depend directly on the data, parameters estimated, and likelihood function. Furthermore, a single value does not tell much about model fit. Information criteria become relevant when compared to one another for a given data set and set of candidate models.

**Author(s)**

Marc J. Mazerolle

**References**

**See Also**

\( \text{AICc,bictab,bictabCustom,useBICCustom} \)
Examples

```r
# cement data from Burnham and Anderson (2002, p. 101)
data(cement)

# run multiple regression - the global model in Table 3.2
glob.mod <- lm(y ~ x1 + x2 + x3 + x4, data = cement)

# compute BIC with full likelihood
useBIC(glob.mod, return.K = FALSE)

# compute BIC for mixed model on Orthodont data set in Pinheiro and Bates (2000)
## Not run:
require(nlme)
m1 <- lme(distance ~ age, random = ~1 | Subject, data = Orthodont, method = "ML")
useBIC(m1, return.K = FALSE)

## End(Not run)
```

useBICCustom  

Custom Computation of BIC and QBIC from User-supplied Input

Description

This function computes the Bayesian information criterion (BIC) or a quasi-likelihood counterpart (QBIC) from user-supplied input instead of extracting the values automatically from a model object. This function is particularly useful for output imported from other software or for model classes that are not currently supported by useBIC.

Usage

```r
useBICCustom(logL, K, return.K = FALSE, nobs = NULL, c.hat = 1)
```

Arguments

- `logL`  
  the value of the model log-likelihood.
- `K`  
  the number of estimated parameters in the model.
- `return.K`  
  logical. If FALSE, the function returns the information criterion specified. If TRUE, the function returns K (number of estimated parameters) for a given model.
- `nobs`  
  the sample size required to compute the BIC or QBIC.
- `c.hat`  
  value of overdispersion parameter (i.e., variance inflation factor) such as that obtained from `c_hat`. Note that values of `c.hat` different from 1 are only appropriate for binomial GLM’s with trials > 1 (i.e., success/trial or cbind(success, failure) syntax), with Poisson GLM’s, single-season or dynamic occupancy models (MacKenzie et al. 2002, 2003), N-mixture models (Royle 2004, Dail and Madsen 2011), or capture-mark-recapture models (e.g., Lebreton et al. 1992). If `c.hat > 1`, useBICCustom will return the quasi-likelihood analogue of the information criterion requested.
useBICCustom computes one of the following two information criteria:

the Bayesian information criterion (BIC, Schwarz 1978) or the quasi-likelihood BIC (QBIC).

Value

useBICCustom returns the BIC or QBIC depending on the values of the c.hat argument.

Note

The actual (Q)BIC values are not really interesting in themselves, as they depend directly on the data, parameters estimated, and likelihood function. Furthermore, a single value does not tell much about model fit. Information criteria become relevant when compared to one another for a given data set and set of candidate models.

### xtable

#### Format Objects to LaTeX or HTML

**Description**

Functions to format various objects following model selection and multimodel inference to LaTeX or HTML tables. These functions extend the methods from the xtable package (Dahl 2014).

**Usage**

```r
## S3 method for class 'aictab'
xtable(x, caption = NULL, label = NULL, align = NULL,
       digits = NULL, display = NULL, nice.names = TRUE,
       include.AICc = TRUE, include.LL = TRUE, include.Cum.Wt = FALSE,
       ...)

## S3 method for class 'anovaOD'
xtable(x, caption = NULL, label = NULL, align = NULL,
       digits = NULL, display = NULL,
       nice.names = TRUE, ...)

## S3 method for class 'bictab'
xtable(x, caption = NULL, label = NULL, align = NULL,
       digits = NULL, display = NULL, nice.names = TRUE,
       include.BIC = TRUE, include.LL = TRUE, include.Cum.Wt = FALSE,
       ...)

## S3 method for class 'boot.wt'
xtable(x, caption = NULL, label = NULL, align = NULL,
       digits = NULL, display = NULL, nice.names = TRUE,
```
include.AICc = TRUE, include.AICcWt = FALSE, ...)

## S3 method for class 'countDist'
\texttt{xtable(x, caption = NULL, label = NULL, align = NULL, digits = NULL, display = NULL, nice.names = TRUE, table.countDist = "distance", ...)}

## S3 method for class 'checkParms'
\texttt{xtable(x, caption = NULL, label = NULL, align = NULL, digits = NULL, display = NULL, nice.names = TRUE, include.variable = TRUE, include.max.se = TRUE, include.n.high.se = TRUE, ...)}

## S3 method for class 'countHist'
\texttt{xtable(x, caption = NULL, label = NULL, align = NULL, digits = NULL, display = NULL, nice.names = TRUE, table.countHist = "count", ...)}

## S3 method for class 'detHist'
\texttt{xtable(x, caption = NULL, label = NULL, align = NULL, digits = NULL, display = NULL, nice.names = TRUE, table.detHist = "freq", ...)}

## S3 method for class 'dictab'
\texttt{xtable(x, caption = NULL, label = NULL, align = NULL, digits = NULL, display = NULL, nice.names = TRUE, include.DIC = TRUE, include.Cum.Wt = FALSE, ...)}

## S3 method for class 'ictab'
\texttt{xtable(x, caption = NULL, label = NULL, align = NULL, digits = NULL, display = NULL, nice.names = TRUE, include.IC = TRUE, include.Cum.Wt = FALSE, ...)}

## S3 method for class 'mb.chisq'
\texttt{xtable(x, caption = NULL, label = NULL, align = NULL, digits = NULL, display = NULL, nice.names = TRUE, include.detection.histories = TRUE, ...)}

## S3 method for class 'modavg'
\texttt{xtable(x, caption = NULL, label = NULL, align = NULL, digits = NULL, display = NULL, nice.names = TRUE, print.table = FALSE, ...)}

## S3 method for class 'modavgCustom'
\texttt{xtable(x, caption = NULL, label = NULL, align = NULL, digits = NULL, display = NULL, nice.names = TRUE, print.table = FALSE, ...)}
Arguments

- **x**: An object of class `aictab`, `anovaOD`, `bictab`, `boot.wt`, `checkParms`, `countDist`, `countHist`, `detHist`, `dictab`, `ictab`, `mb.chisq`, `modavg`, `modavgEffect`, `modavgCustom`, `modavgIC`, `modavgPred`, `modavgShrink`, `multComp`, or `summaryOD`.

- **caption**: A character vector of length 1 or 2 storing the caption or title of the table. If the vector is of length 2, the second item is the short caption used when LaTeX generates a list of tables. The default value is `NULL` and suppresses the caption.

- **label**: A character vector storing the LaTeX label or HTML anchor. The default value is `NULL` and suppresses the label.

- **align**: A character vector of length equal to the number of columns of the table specifying the alignment of the elements. Note that the rownames are considered as an additional column and require an alignment value.

- **digits**: A numeric vector of length one or equal to the number of columns in the table (including the rownames) specifying the number of digits to display in each column.
display  a character vector of length equal to the number of columns (including the row-
names) specifying the format of each column. For example, use s for strings, f for numbers in the regular format, or d for integers. See formatC for additional possible values.
nice.names logical. If TRUE, column labels are modified to improve their appearance in the
table. If FALSE, simpler labels are used, or the ones supplied directly by the user
in the object storing the output.
include.AICc logical. If TRUE, the column containing the information criterion (AIC, AICc,
QAIC, or QAICc) of each model is printed in the table. If FALSE, the column is
suppressed.
include.BIC logical. If TRUE, the column containing the information criterion (BIC or QBIC)
of each model is printed in the table. If FALSE, the column is suppressed.
include.DIC logical. If TRUE, the column containing the deviance information criterion (DIC)
of each model is printed in the table. If FALSE, the column is suppressed.
include.IC logical. If TRUE, the column containing the information criterion of each model
is printed in the table. If FALSE, the column is suppressed.
include.LL logical. If TRUE, the column containing the log-likelihood of each model is
printed in the table. If FALSE, the column is suppressed.
include.Cum.Wt logical. If TRUE, the column containing the cumulative Akaike weights is printed
in the table. If FALSE, the column is suppressed.
include.AICc.Wt logical. If TRUE, the column containing the Akaike weight of each model is
printed in the table. If FALSE, the column is suppressed.
include.detection.histories logical. If TRUE, the column containing detection histories is printed in the table.
If FALSE, the column is suppressed.
include.variable logical. If TRUE, the column containing the variable name is printed in the table.
If FALSE, the column is suppressed.
include.max.se logical. If TRUE, the column containing the maximum SE in the model is printed
in the table. If FALSE, the column is suppressed.
include.n.high.se logical. If TRUE, the column containing the number of SE’s greater than the
threshold specified by the user is printed in the table. If FALSE, the column is
suppressed.
print.table logical. If TRUE, the model selection table is printed and other sections of the
output are suppressed (e.g., model-averaged estimates). If FALSE, the model
selection table is suppressed and only the other portion of the output is printed
in the table.
table.detHist character string specifying, either "freq", "prop", or "hist". If table.type = "freq",
the function returns a table of frequencies of sites sampled, of sites with at least
one detection, and for data with multiple primary periods, the frequencies of
sites with observed extinctions and colonizations. If table.type = "prop",
the table returns the proportion of sites with at least one detection, and for data
with multiple periods, the proportion of sites with observed extinctions and col-
onizations. If table.type = "hist", the function returns the frequencies of
each observed detection history.
table.countDist
character string specifying, either "distance", "count", "freq", or "prop". If table.type = "distance", the function returns a table of counts summarized for each distance class. If table.type = "count", the function returns the table of frequencies of counts observed across sites. If table.type = "freq", the function returns a table of frequencies of sites sampled, of sites with at least one detection, and for data with multiple primary periods, the frequencies of sites with observed extinctions and colonizations. If table.type = "prop", the function returns the proportion of sites with at least one detection, and for data with multiple periods, the proportion of sites with observed extinctions and colonizations.

table.countHist
character string specifying, either "count", "freq", "prop", or "hist". If table.type = "count", the function returns the table of frequencies of counts observed across sites. If table.type = "freq", the function returns a table of frequencies of sites sampled, of sites with at least one detection, and for data with multiple primary periods, the frequencies of sites with observed extinctions and colonizations. If table.type = "prop", the table returns the proportion of sites with at least one detection, and for data with multiple periods, the proportion of sites with observed extinctions and colonizations. If table.type = "hist", the function returns the frequencies of each observed count history.

... additional arguments passed to the function.

Details
xtable creates an object of the xtable class inheriting from the data.frame class. This object can then be used with print.xtable for added flexibility such as suppressing row names, modifying caption placement, and format tables in LaTeX or HTML format.
