__anova.art__

Aligned Rank Transform Analysis of Variance

Description

Conduct analyses of variance on aligned rank transformed data.

Usage

```r
# S3 method for class 'art'
apova(
  object,
  response = c("art", "aligned"),
  type = c("III", "II", "I", 3, 2, 1),
  factor.contrasts = "contr.sum",
  test = c("F", "Chisq"),
  all.rows = FALSE,
  ...
)
```

```r
# S3 method for class 'anova.art'
print(x, verbose = FALSE, digits = 5, ...)
```

Arguments

- **object** An object of class `art`.
- **response** Which response to run the ANOVA on: the aligned responses ("aligned") or the aligned and ranked responses ("art"). This argument is passed to `artlm`. See 'Details'.
- **type** Type of ANOVAs to conduct. If type is 1 or "I", then conducts Type I ANOVAs using `anova`. Otherwise, conducts Type II or Type III ANOVAs using `Anova`. The default is Type III if the underlying model supports it. Models fit with `Error` terms are fit using `aov`, which only supports Type I ANOVAs.
factor.contrasts
   The name of the contrast-generating function to be applied by default to fixed
   effect factors. See the first element of options("contrasts"). The default is
to use "contr.sum", i.e. sum-to-zero contrasts, which is appropriate for Type
III ANOVAs (also the default). This argument is passed to artlm.

test
   Test statistic to use. Default "F". Note that some models and ANOVA types
   may not support "Chisq".

all.rows
   Show all rows of the resulting ANOVA tables? By default (FALSE), shows only
   the rows that are relevant depending on the type of response.

...  
   Additional arguments passed to Anova or anova by anova.art or to print by
   print.anova.art.

x
   An object of class art.

verbose
   When TRUE, sums of squares and residual sum of squares in addition to de-
grees of freedom are printed in some ANOVA types (e.g. repeated measures
ANOVAs). Default FALSE, for brevity.

digits
   Digits of output in printed table; see print.

Details

This function runs several ANOVAs: one for each fixed effect term in the model object. In each
ANOVA, the independent variables are the same, but the response is aligned by a different fixed
effect term (if response is "aligned") or aligned and ranked by that fixed effect term (if response is
"art"). These models are generated using artlm.

From each model, only the relevant output rows are kept (unless all.rows is TRUE, in which case
all rows are kept).

When response is "art" (the default), only one row is kept from each ANOVA: the row corre-
sponding to fixed effect term the response was aligned and ranked by. These results represent
nonparametric tests of significance for the effect of each term on the original response variable.

When response is "aligned", all rows except the row corresponding to the fixed effect term the
response was aligned by are kept. If the ART procedure is appropriate for this data, these tests
should have all effects "stripped out", and have an F value of ~0. If that is not the case, another
analysis should be considered. This diagnostic is tested by summary.art and a warning generated
if the F values are not all approximately 0.

Value

An object of class "anova", which usually is printed.

Art

Aligned Rank Transform

Description

Apply the aligned rank transform to a factorial model (with optional grouping terms). Usually done in preparation for a nonparametric analyses of variance on models with numeric or ordinal responses, which can be done by following up with `anova.art`.

Usage

```r
art(
  formula,
  data,
  rank.comparison.digits = -floor(log10(.Machine$double.eps^0.5)),
  check.errors.are.factors = TRUE
)
```

Arguments

- `formula`: A factorial formula with optional grouping terms or error terms (but not both). Should be a formula with a single response variable (left-hand side) and one or more terms with all interactions on the right-hand side, e.g. `y ~ x` or `y ~ a+b*c` or `y ~ a + b + b:c`. If you want to run a mixed effects ANOVA on the transformed data using `lmer`, you can include grouping terms, as in `y ~ a*b*c + (1|d)`. If you want to run a repeated measures ANOVA using `aov`, you can include error terms, as in `y ~ a*b*c + Error(d)`. See 'Details'.
- `data`: An optional data frame containing the variables in the model.
- `rank.comparison.digits`: The number of digits to round aligned responses to before ranking (to ensure ties are computed consistently). See the digits argument of `round`. The default value is based on the default tolerance used for fuzzy comparison in `all.equal`.
- `check.errors.are.factors`: Should we check to ensure `Error()` terms are all factors? A common mistake involves coding a categorical variable as numeric and passing it to `Error()`, yielding incorrect results from `aov`. Disabling this check is not recommended unless you know what you are doing; the most common uses of `Error()` (e.g. in repeated measures designs) involve categorical variables (factors).
Details

The aligned rank transform allows a nonparametric analysis of variance to be conducted on factorial models with fixed and random effects (or repeated measures) and numeric or ordinal responses. This is done by first aligning and ranking the fixed effects using this function, then conducting an analysis of variance on linear models built from the transformed data using `anova.art` (see 'Examples'). The model specified using this function must include all interactions of fixed effects.

The formula should contain a single response variable (left-hand side) that can be numeric, an ordered factor, or logical. The right-hand side of the formula should contain one or more fixed effect factors, zero or more grouping terms, and zero or more error terms. Error terms and grouping terms cannot be used simultaneously. All possible interactions of the fixed effect terms must be included. For example, y ~ x and y ~ a*b*c and y ~ a + b + b:c are legal, but y ~ a + b is not, as it omits the interaction a:b. Grouping terms are specified as in `lmer`, e.g. y ~ a*b*c + (1|d) includes the random intercept term (1|d). Error terms are specified as in `aov`, e.g. y ~ a*b*c + Error(d). Grouping terms and error terms are not involved in the transformation, but are included in the model when ANOVAs are conducted, see `anova.art`.

For details on the transformation itself, see Wobbrock et al. (2011) or the ARTool website: [http://depts.washington.edu/aimgroup/proj/art/](http://depts.washington.edu/aimgroup/proj/art/).

Value

An object of class "art":

- **call**: The call used to generate the transformed data.
- **formula**: The formula used to generate the transformed data.
- **cell.means**: A data frame of cell means for each fixed term and interaction on the right-hand side of formula.
- **estimated.effects**: A data frame of estimated effects for each fixed term and interaction on the right-hand side of formula.
- **residuals**: A vector of residuals (response - cell mean of highest-order interaction).
- **aligned**: A data frame of aligned responses for each fixed term and interaction on the right-hand side of formula.
- **aligned.ranks**: A data frame of aligned and ranked responses for each fixed term and interaction on the right-hand side of formula.
- **data**: The input data frame.
- **n.grouping.terms**: The number of grouping variables in the input formula.

For a complete description of cell means, estimated effects, aligned ranks, etc., in the above output, see Wobbrock et al. (2011).

summary.art, anova.art, artlm.

Examples

## Not run:
data(Higgins1990Table5, package="ARTool")

## perform aligned rank transform
m <- art(DryMatter ~ Moisture*Fertilizer + (1|Tray), data=Higgins1990Table5)

## see summary data to ensure aligned rank transform is appropriate for this data
summary(m)

## looks good (aligned effects sum to 0 and F values on aligned responses
## not of interest are all ~0)

## we can always look at the anova of aligned data if we want more detail
## to assess the appropriateness of ART. F values in this anova should all
## be approx 0.
anova(m, response="aligned")

## then we can run an anova on the ART responses (equivalent to anova(m, response="art"))
anova(m)

## if we want post-hoc tests, artlm(m, term) returns the linear model for the
## given term
## which we can then examine using our preferred method (emmeans, glht, etc)
## e.g., pairwise contrasts on Moisture:
library(emmeans)
emmeans(artlm(m, "Moisture"), pairwise ~ Moisture)

## pairwise contrasts on Fertilizer:
emmeans(artlm(m, "Fertilizer"), pairwise ~ Fertilizer)

## N.B. The above types of contrasts ARE NOT valid for interactions.
## Instead, use testInteractions from the phia package. For example:
library(phia)
testInteractions(artlm(m, "Moisture:Fertilizer"), pairwise=c("Moisture", "Fertilizer"))

## For a more in-depth explanation and example, see this vignette:
vignette("art-contrasts")
## End (Not run)

### Per-Term Linear Model from Aligned Rank Transformed Data

**Description**

Build a linear model for ART data with response aligned or aligned and ranked by the specified term from the model.

**Usage**

```r
artlm(
m, 
term, 
response = c("art", "aligned"), 
factor.contrasts = "contr.sum", 
...
)
```

**Arguments**

- `m` An object of class `art`.
- `term` An object of type "character" indicating the effect term in the transformed data in `m` to use as the aligned or art response.
- `response` Which response to use: the aligned response ("aligned") or the aligned and ranked ("art") response.
- `factor.contrasts` The name of the contrast-generating function to be applied by default to fixed effect factors. Sets the the first element of `options("contrasts")` for the duration of this function. The default is to use "contr.sum", i.e. sum-to-zero contrasts, which is appropriate for Type III ANOVAs (the default ANOVA type for `anova.art`).
- `...` Additional arguments passed to `lm` or `lmer`.

**Details**

This function is used primarily for post-hoc tests. To run an ANOVA, it does not need to be called directly; instead, use `anova.art`, which calls this function as needed.

**Value**

An object of class `lm` if `formula(m)` does not contain grouping or error terms, an object of class `merMod` (i.e. a model fit by `lmer`) if it contains grouping terms, or an object of class `aovlist` (i.e. a model fit by `aov`) if it contains error terms.

## Higgins1990Table1 Synthetic 3x3 Factorial Randomized Experiment

### Description

Synthetic data from a balanced 3x3 factorial experiment with main effects, no interaction, and independent and identically distributed (i.i.d.) Normal errors.

### Format

A data frame with 36 observations on the following 4 variables.

- **Subject** a factor with levels "s1" .. "s36"
- **Row** a factor with levels "r1" .. "r3"
- **Column** a factor with levels "c1" .. "c3"
- **Response** a numeric vector

### Source

### See Also

art, anova.art.

### Examples

```r
data(Higgins1990Table1)

# run aligned-rank transform and ANOVA on the data
# Note: because there is only one observation per Subject
# in this dataset, we do not need to include Subject as
# a grouping term in this formula. Indeed, if we did,
# lmer would complain when we attempt the ANOVA.
m <- art(Response ~ Row*Column, data=Higgins1990Table1)
anova(m)
```
**Description**

This dataset comes from a split-plot experiment examining Trays of 4 peat pots each. Moisture was varied between Trays (i.e. it was the whole-plot treatment) and Fertilizer was varied within Trays (i.e. it was the sub-plot treatment). The outcome measure was DryMatter.

**Format**

A data frame with 48 observations on the following 4 variables.

- **Tray** a factor with levels "t1" .. "t12"
- **Moisture** a factor with levels "m1" .. "m4"
- **Fertilizer** a factor with levels "f1" .. "f4"
- **DryMatter** a numeric vector

**Details**

This dataset, originally from Milliken & Johnson (1984), is reproduced here from Higgins et al. (1990).

**Source**

**References**

**See Also**

See art for a more complete example. See also anova.art.

**Examples**

```r
data(Higgins1990Table5)

# run aligned-rank transform and ANOVA on the data
m <- art(DryMatter ~ Moisture*Fertilizer + (1|Tray), data=Higgins1990Table5)
anova(m)
```
**HigginsABC**  
*Synthetic 2x2x2 Mixed Design Experiment*

**Description**

Synthetic data from an experiment with two between-Subjects factors (A and B) having two levels each and one within-Subjects factor (C) with two levels.

**Format**

A data frame with 16 observations on the following 5 variables.

- **Subject** a factor with levels "s1" .. "s8"
- **A** a factor with levels "a1" "a2"
- **B** a factor with levels "b1" "b2"
- **C** a factor with levels "c1" "c2"
- **Y** a numeric vector

**Source**

**See Also**

- `art`, `anova.art`

**Examples**

```r
## Not run:
data(HigginsABC, HigginsABC.art, package="ARTool")

## run aligned-rank transform and ANOVA on the data
m <- art(Y ~ A*B*C + Error(Subject), data=HigginsABC)
anova(m)

## End(Not run)
```
InteractionTestData

Synthetic Data Used in the Contrast Test Vignette

Description

See (vignette("art-contrasts")) for a description of this data.

See Also

art, anova.art.

Examples

## Not run:
## see this vignette
evignette("art-contrasts")
## End(Not run)

summary.art

Aligned Rank Transform Summary

Description

Summary and diagnostics for aligned rank transformed data

Usage

## S3 method for class 'art'
summary(object, ...)

Arguments

object An object of class art.
...

Potentially further arguments passed from other methods.

Details

This function gives diagnostic output to help evaluate whether the ART procedure is appropriate for an analysis. It tests that column sums of aligned responses are ~0 and that F values of ANOVAs on aligned responses not of interest are ~0. For more details on these diagnostics see Wobbrock et al. (2011).

Value

An object of class "summary.art", which usually is printed.
