

# Package ‘BayesMallows’

November 25, 2023

**Type** Package

**Title** Bayesian Preference Learning with the Mallows Rank Model

**Version** 1.5.0

**Maintainer** Oystein Sorensen <oystein.sorensen.1985@gmail.com>

**Description** An implementation of the Bayesian version of the Mallows rank model (Vitelli et al., Journal of Machine Learning Research, 2018 <<https://jmlr.org/papers/v18/15-481.html>>; Crispino et al., Annals of Applied Statistics, 2019 <[doi:10.1214/18-AOAS1203](https://doi.org/10.1214/18-AOAS1203)>; Sorensen et al., R Journal, 2020 <[doi:10.32614/RJ-2020-026](https://doi.org/10.32614/RJ-2020-026)>; Stein, PhD Thesis, 2023 <<https://eprints.lancs.ac.uk/id/eprint/195759>>). Both Metropolis-Hastings and sequential Monte Carlo algorithms for estimating the models are available. Cayley, footrule, Hamming, Kendall, Spearman, and Ulam distances are supported in the models. The rank data to be analyzed can be in the form of complete rankings, top-k rankings, partially missing rankings, as well as consistent and inconsistent pairwise preferences. Several functions for plotting and studying the posterior distributions of parameters are provided. The package also provides functions for estimating the partition function (normalizing constant) of the Mallows rank model, both with the importance sampling algorithm of Vitelli et al. and asymptotic approximation with the IPFP algorithm (Mukherjee, Annals of Statistics, 2016 <[doi:10.1214/15-AOS1389](https://doi.org/10.1214/15-AOS1389)>).

assess\_convergence      *Trace Plots from Metropolis-Hastings Algorithm*

**Description**

assess\_convergence provides trace plots for the parameters of the Mallows Rank model, in order to study the convergence of the Metropolis-Hastings algorithm.

**Usage**

```
assess_convergence(
  model_fit,
  parameter = "alpha",
  items = NULL,
  assessors = NULL
)
```

**Arguments**

- model\_fit      A fitted model object of class BayesMallows returned from [compute\\_mallows](#) or an object of class BayesMallowsMixtures returned from [compute\\_mallows\\_mixtures](#).
- parameter      Character string specifying which parameter to plot. Available options are "alpha", "rho", "Rtilde", "cluster\_probs", or "theta".

items	The items to study in the diagnostic plot for rho. Either a vector of item names, corresponding to <code>model_fit\$items</code> or a vector of indices. If NULL, five items are selected randomly. Only used when <code>parameter = "rho"</code> or <code>parameter = "Rtilde"</code> .
assessors	Numeric vector specifying the assessors to study in the diagnostic plot for "Rtilde".

**See Also**

[compute\\_mallows](#), [plot.BayesMallows](#)

Other diagnostics: [label\\_switching](#)

---

assign_cluster	<i>Assign Assessors to Clusters</i>
----------------	-------------------------------------

---

**Description**

Assign assessors to clusters by finding the cluster with highest posterior probability.

**Usage**

```
assign_cluster(
  model_fit,
  burnin = model_fit$burnin,
  soft = TRUE,
  expand = FALSE
)
```

**Arguments**

model_fit	An object of type BayesMallows, returned from <a href="#">compute_mallows</a> .
burnin	A numeric value specifying the number of iterations to discard as burn-in. Defaults to <code>model_fit\$burnin</code> , and must be provided if <code>model_fit\$burnin</code> does not exist. See <a href="#">assess_convergence</a> .
soft	A logical specifying whether to perform soft or hard clustering. If <code>soft=TRUE</code> , all cluster probabilities are returned, whereas if <code>soft=FALSE</code> , only the maximum a posterior (MAP) cluster probability is returned, per assessor. In the case of a tie between two or more cluster assignments, a random cluster is taken as MAP estimate.
expand	A logical specifying whether or not to expand the rowset of each assessor to also include clusters for which the assessor has 0 a posterior assignment probability. Only used when <code>soft = TRUE</code> . Defaults to FALSE.

**Value**

A dataframe. If `soft = FALSE`, it has one row per assessor, and columns `assessor`, `probability` and `map_cluster`. If `soft = TRUE`, it has `n_cluster` rows per assessor, and the additional column `cluster`.

BayesMallows

*BayesMallows: Bayesian Preference Learning with the Mallows Rank Model.*

---

**Description**

The BayesMallows package provides functionality for fully Bayesian analysis of preference or rank data. The package implements the Bayesian Mallows model described in Vitelli et al. (2018), which handles complete rankings, top-k rankings, ranks missing at random, and consistent pairwise preference data, as well as mixtures of rank models. Modeling of pairwise preferences containing inconsistencies, as described in Crispino et al. (2019), is also supported. See also Sørensen et al. (2020) for an overview of the methods and a tutorial.

The documentation and examples for the following functions are likely most useful to get you started:

- For analysis of rank or preference data, see [compute\\_mallows](#).
- For computation of multiple models with varying numbers of mixture components, see [compute\\_mallows\\_mixtures](#).
- For estimation of the partition function (normalizing constant) using either the importance sampling algorithm of Vitelli et al. (2018) or the asymptotic algorithm of Mukherjee (2016), see [estimate\\_partition\\_function](#).
- For sequential Monte Carlo algorithms developed in Stein (2023), see [smc\\_mallows\\_new\\_users](#) and [smc\\_mallows\\_new\\_item\\_rank](#).

---

beach\_preferences      *Beach Preferences*

---

### Description

Example dataset from (Vitelli et al. 2018), Section 6.2.

### Usage

beach\_preferences

### Format

An object of class `data.frame` with 1442 rows and 3 columns.

### References

Vitelli V, Sørensen, Crispino M, Arjas E, Frigessi A (2018). “Probabilistic Preference Learning with the Mallows Rank Model.” *Journal of Machine Learning Research*, **18**(1), 1–49. <https://jmlr.org/papers/v18/15-481.html>.

---

compute\_consensus      *Compute Consensus Ranking*

---

### Description

Compute the consensus ranking using either cumulative probability (CP) or maximum a posteriori (MAP) consensus (Vitelli et al. 2018). For mixture models, the consensus is given for each mixture. Consensus of augmented ranks can also be computed for each assessor, by setting parameter = "Rtilde".

### Usage

```
compute_consensus(model_fit, ...)
```

**Arguments**

model\_fit        A model fit.  
 ...              other arguments passed to methods.

**References**

Vitelli V, Sørensen, Crispino M, Arjas E, Frigessi A (2018). “Probabilistic Preference Learning with the Mallows Rank Model.” *Journal of Machine Learning Research*, **18**(1), 1–49. <https://jmlr.org/papers/v18/15-481.html>.

**Examples**

```
# The example datasets potato_visual and potato_weighing contain complete
# rankings of 20 items, by 12 assessors. We first analyse these using the Mallows
# model:
model_fit <- compute_mallows(potato_visual)

# See the documentation to compute_mallows for how to assess the convergence of the algorithm
# Having chosen burnin = 1000, we compute posterior intervals
model_fit$burnin <- 1000
# We then compute the CP consensus.
compute_consensus(model_fit, type = "CP")
# And we compute the MAP consensus
compute_consensus(model_fit, type = "MAP")

## Not run:
# CLUSTERWISE CONSENSUS
# We can run a mixture of Mallows models, using the n_clusters argument
# We use the sushi example data. See the documentation of compute_mallows for a more elaborate
# example
model_fit <- compute_mallows(sushi_rankings, n_clusters = 5)
# Keeping the burnin at 1000, we can compute the consensus ranking per cluster
model_fit$burnin <- 1000
cp_consensus_df <- compute_consensus(model_fit, type = "CP")
# We can now make a table which shows the ranking in each cluster:
cp_consensus_df$cumprob <- NULL
stats::reshape(cp_consensus_df, direction = "wide", idvar = "ranking",
               timevar = "cluster",
               varying = list(sort(unique(cp_consensus_df$cluster))))

## End(Not run)

## Not run:
# MAP CONSENSUS FOR PAIRWISE PREFERENCE DATA
```

```

# We use the example dataset with beach preferences.
model_fit <- compute_mallows(preferences = beach_preferences)
# We set burnin = 1000
model_fit$burnin <- 1000
# We now compute the MAP consensus
map_consensus_df <- compute_consensus(model_fit, type = "MAP")

## End(Not run)

## Not run:
# CP CONSENSUS FOR AUGMENTED RANKINGS
# We use the example dataset with beach preferences.
model_fit <- compute_mallows(preferences = beach_preferences, save_aug = TRUE,
                             aug_thinning = 2, seed = 123L)
# We set burnin = 1000
model_fit$burnin <- 1000
# We now compute the CP consensus of augmented ranks for assessors 1 and 3
cp_consensus_df <- compute_consensus(model_fit, type = "CP",
                                     parameter = "Rtilde", assessors = c(1L, 3L))
# We can also compute the MAP consensus for assessor 2
map_consensus_df <- compute_consensus(model_fit, type = "MAP",
                                     parameter = "Rtilde", assessors = 2L)

# Caution!
# With very sparse data or with too few iterations, there may be ties in the MAP consensus
# This is illustrated below for the case of only 5 post-burnin iterations. Two MAP rankings are
# equally likely in this case (and for this seed).
model_fit <- compute_mallows(preferences = beach_preferences, nmc = 1005,
                             save_aug = TRUE, aug_thinning = 1, seed = 123L)
model_fit$burnin <- 1000
compute_consensus(model_fit, type = "MAP", parameter = "Rtilde", assessors = 2L)

## End(Not run)

```

---

compute\_consensus.BayesMallows

*Compute Consensus Ranking*

---

## Description

Compute Consensus Ranking

## Usage

```

## S3 method for class 'BayesMallows'
compute_consensus(
  model_fit,
  type = "CP",
  burnin = model_fit$burnin,
  parameter = "rho",

```

```

    assessors = 1L,
    ...
)

```

### Arguments

model_fit	Object of type BayesMallows returned from <a href="#">compute_mallows</a> .
type	Character string specifying which consensus to compute. Either "CP" or "MAP". Defaults to "CP".
burnin	A numeric value specifying the number of iterations to discard as burn-in. Defaults to model_fit\$burnin, and must be provided if model_fit\$burnin does not exist. See <a href="#">assess_convergence</a> .
parameter	Character string defining the parameter for which to compute the consensus. Defaults to "rho". Available options are "rho" and "Rtilde", with the latter giving consensus rankings for augmented ranks.
assessors	When parameter = "rho", this integer vector is used to define the assessors for which to compute the augmented ranking.
...	Other arguments passed on to other methods. Currently not used. Defaults to 1L, which yields augmented rankings for assessor 1.

### See Also

---

```
compute_consensus.SMCMallows
```

*Compute Consensus Ranking*

---

### Description

Compute the consensus ranking using either cumulative probability (CP) or maximum a posteriori (MAP) consensus (Vitelli et al. 2018). For mixture models, the consensus is given for each mixture.

### Usage

```

## S3 method for class 'SMCMallows'
compute_consensus(model_fit, type = "CP", ...)

```

### Arguments

model_fit	An object of class SMCMallows, returned from <a href="#">smc_mallows_new_item_rank</a> or <a href="#">smc_mallows_new_users</a> .
type	Character string specifying which consensus to compute. Either "CP" or "MAP". Defaults to "CP".
...	Other optional arguments passed to methods. Currently not used.

**See Also**

Other posterior quantities: `assign_cluster()`, `compute_consensus.BayesMallows()`, `compute_consensus()`, `compute_posterior_intervals.BayesMallows()`, `compute_posterior_intervals.SMCMallows()`, `compute_posterior_intervals()`, `heat_plot()`, `plot.BayesMallows()`, `plot.SMCMallows()`, `plot_elbow()`, `plot_top_k()`, `predict_top_k()`, `print.BayesMallowsMixtures()`, `print.BayesMallows()`

**Examples**

```
# Basic elements
data <- sushi_rankings[1:100, ]
n_items <- ncol(data)
leap_size <- floor(n_items / 5)
metric <- "footrule"
Time <- 20
N <- 100

# Prepare exact partition function
cardinalities <- prepare_partition_function(metric = metric,
                                           n_items = n_items)$cardinalities

# Performing SMC
smc_test <- smc_mallows_new_users(
  R_obs = data, type = "complete", n_items = n_items,
  metric = metric, leap_size = leap_size,
  N = N, Time = Time,
  cardinalities = cardinalities,
  mcmc_kernel_app = 5,
  num_new_obs = 5,
  alpha_prop_sd = 0.5,
  lambda = 0.15,
  alpha_max = 1e6
)

compute_posterior_intervals(smc_test, parameter = "rho")

compute_consensus(model_fit = smc_test, type = "CP")
compute_consensus(model_fit = smc_test, type = "MAP")

compute_posterior_intervals(smc_test, parameter = "alpha")
```

**Description**

Compute the posterior distributions of the parameters of the Bayesian Mallows Rank Model, given rankings or preferences stated by a set of assessors.

The BayesMallows package uses the following parametrization of the Mallows rank model (Mallows 1957):

$$p(r|\alpha, \rho) = (1/Z_n(\alpha)) \exp -\alpha/nd(r, \rho)$$

where  $r$  is a ranking,  $\alpha$  is a scale parameter,  $\rho$  is the latent consensus ranking,  $Z_n(\alpha)$  is the partition function (normalizing constant), and  $d(r, \rho)$  is a distance function measuring the distance between  $r$  and  $\rho$ . Note that some authors use a Mallows model without division by  $n$  in the exponent; this includes the PerMallows package, whose scale parameter  $\theta$  corresponds to  $\alpha/n$  in the BayesMallows package. We refer to (Vitelli et al. 2018) for further details of the Bayesian Mallows model.

compute\_mallows always returns posterior distributions of the latent consensus ranking  $\rho$  and the scale parameter  $\alpha$ . Several distance measures are supported, and the preferences can take the form of complete or incomplete rankings, as well as pairwise preferences. compute\_mallows can also compute mixtures of Mallows models, for clustering of assessors with similar preferences.

## Usage

```
compute_mallows(
  rankings = NULL,
  preferences = NULL,
  obs_freq = NULL,
  metric = "footrule",
  error_model = NULL,
  n_clusters = 1L,
  clus_thin = 1L,
  nmc = 2000L,
  leap_size = max(1L, floor(n_items/5)),
  swap_leap = 1L,
  rho_init = NULL,
  rho_thinning = 1L,
  alpha_prop_sd = 0.1,
  alpha_init = 1,
  alpha_jump = 1L,
  lambda = 0.001,
  alpha_max = 1e+06,
  psi = 10L,
  include_wcd = (n_clusters > 1),
  save_aug = FALSE,
  aug_thinning = 1L,
  logz_estimate = NULL,
  verbose = FALSE,
  validate_rankings = TRUE,
  na_action = "augment",
  constraints = NULL,
  save_ind_clus = FALSE,
  seed = NULL,
  cl = NULL
)
```

**Arguments**

rankings	A matrix of ranked items, of size <code>n_assessors</code> x <code>n_items</code> . See <a href="#">create_ranking</a> if you have an ordered set of items that need to be converted to rankings. If <code>preferences</code> is provided, <code>rankings</code> is an optional initial value of the rankings, generated by <a href="#">generate_initial_ranking</a> . If <code>rankings</code> has column names, these are assumed to be the names of the items. NA values in <code>rankings</code> are treated as missing data and automatically augmented; to change this behavior, see the <code>na_action</code> argument.
preferences	A dataframe with pairwise comparisons, with 3 columns, named <code>assessor</code> , <code>bottom_item</code> , and <code>top_item</code> , and one row for each stated preference. Given a set of pairwise preferences, generate a transitive closure using <a href="#">generate_transitive_closure</a> . This will give preferences the class "BayesMallowsTC". If preferences is not of class "BayesMallowsTC", <code>compute_mallows</code> will call <a href="#">generate_transitive_closure</a> on preferences before computations are done. In the current version, the pairwise preferences are assumed to be mutually compatible.
obs_freq	A vector of observation frequencies (weights) to apply to each row in <code>rankings</code> . This can speed up computation if a large number of assessors share the same rank pattern. Defaults to NULL, which means that each row of <code>rankings</code> is multiplied by 1. If provided, <code>obs_freq</code> must have the same number of elements as there are rows in <code>rankings</code> , and <code>rankings</code> cannot be NULL. See <a href="#">obs_freq</a> for more information and <a href="#">rank_freq_distr</a> for a convenience function for computing it.
metric	A character string specifying the distance metric to use in the Bayesian Mallows Model. Available options are "footrule", "spearman", "cayley", "hamming", "kendall", and "ulam". The distance given by <code>metric</code> is also used to compute within-cluster distances, when <code>include_wcd = TRUE</code> .
error_model	Character string specifying which model to use for inconsistent rankings. Defaults to NULL, which means that inconsistent rankings are not allowed. At the moment, the only available other option is "bernoulli", which means that the Bernoulli error model is used. See Crispino et al. (2019) for a definition of the Bernoulli model.
n_clusters	Integer specifying the number of clusters, i.e., the number of mixture components to use. Defaults to 1L, which means no clustering is performed. See <a href="#">compute_mallows_mixtures</a> for a convenience function for computing several models with varying numbers of mixtures.
clus_thin	Integer specifying the thinning to be applied to cluster assignments and cluster probabilities. Defaults to 1L.
nmc	Integer specifying the number of iteration of the Metropolis-Hastings algorithm to run. Defaults to 2000L. See <a href="#">assess_convergence</a> for tools to check convergence of the Markov chain.
leap_size	Integer specifying the step size of the leap-and-shift proposal distribution. Defaults <code>floor(n_items / 5)</code> .
swap_leap	Integer specifying the step size of the Swap proposal. Only used when <code>error_model</code> is not NULL.

rho_init	Numeric vector specifying the initial value of the latent consensus ranking $\rho$ . Defaults to NULL, which means that the initial value is set randomly. If rho_init is provided when n_clusters > 1, each mixture component $\rho_c$ gets the same initial value.
rho_thinning	Integer specifying the thinning of rho to be performed in the Metropolis-Hastings algorithm. Defaults to 1L. compute_mallows save every rho_thinningth value of $\rho$ .
alpha_prop_sd	Numeric value specifying the standard deviation of the lognormal proposal distribution used for $\alpha$ in the Metropolis-Hastings algorithm. Defaults to 0.1.
alpha_init	Numeric value specifying the initial value of the scale parameter $\alpha$ . Defaults to 1. When n_clusters > 1, each mixture component $\alpha_c$ gets the same initial value. When chains are run in parallel, by providing an argument c1 = c1, then alpha_init can be a vector of of length length(c1), each element of which becomes an initial value for the given chain.
alpha_jump	Integer specifying how many times to sample $\rho$ between each sampling of $\alpha$ . In other words, how many times to jump over $\alpha$ while sampling $\rho$ , and possibly other parameters like augmented ranks $\tilde{R}$ or cluster assignments $z$ . Setting alpha_jump to a high number can speed up computation time, by reducing the number of times the partition function for the Mallows model needs to be computed. Defaults to 1L.
lambda	Strictly positive numeric value specifying the rate parameter of the truncated exponential prior distribution of $\alpha$ . Defaults to 0.1. When n_cluster > 1, each mixture component $\alpha_c$ has the same prior distribution.
alpha_max	Maximum value of alpha in the truncated exponential prior distribution.
psi	Integer specifying the concentration parameter $\psi$ of the Dirichlet prior distribution used for the cluster probabilities $\tau_1, \tau_2, \dots, \tau_C$ , where $C$ is the value of n_clusters. Defaults to 10L. When n_clusters = 1, this argument is not used.
include_wcd	Logical indicating whether to store the within-cluster distances computed during the Metropolis-Hastings algorithm. Defaults to TRUE if n_clusters > 1 and otherwise FALSE. Setting include_wcd = TRUE is useful when deciding the number of mixture components to include, and is required by <a href="#">plot_elbow</a> .
save_aug	Logical specifying whether or not to save the augmented rankings every aug_thinningth iteration, for the case of missing data or pairwise preferences. Defaults to FALSE. Saving augmented data is useful for predicting the rankings each assessor would give to the items not yet ranked, and is required by <a href="#">plot_top_k</a> .
aug_thinning	Integer specifying the thinning for saving augmented data. Only used when save_aug = TRUE. Defaults to 1L.
logz_estimate	Estimate of the partition function, computed with <a href="#">estimate_partition_function</a> . Be aware that when using an estimated partition function when n_clusters > 1, the partition function should be estimated over the whole range of $\alpha$ values covered by the prior distribution for $\alpha$ with high probability. In the case that a cluster $\alpha_c$ becomes empty during the Metropolis-Hastings algorithm, the posterior of $\alpha_c$ equals its prior. For example, if the rate parameter of the exponential prior equals, say $\lambda = 0.001$ , there is about 37 % (or exactly: $1 - \text{pexp}(1000, 0.001)$ ) prior probability that $\alpha_c > 1000$ . Hence when n_clusters > 1, the estimated partition function should cover this range, or $\lambda$ should be increased.

verbose	Logical specifying whether to print out the progress of the Metropolis-Hastings algorithm. If TRUE, a notification is printed every 1000th iteration. Defaults to FALSE.
validate_rankings	Logical specifying whether the rankings provided (or generated from preferences) should be validated. Defaults to TRUE. Turning off this check will reduce computing time with a large number of items or assessors.
na_action	Character specifying how to deal with NA values in the rankings matrix, if provided. Defaults to "augment", which means that missing values are automatically filled in using the Bayesian data augmentation scheme described in Vitelli et al. (2018). The other options for this argument are "fail", which means that an error message is printed and the algorithm stops if there are NAs in rankings, and "omit" which simply deletes rows with NAs in them.
constraints	Optional constraint set returned from <a href="#">generate_constraints</a> . Defaults to NULL, which means the the constraint set is computed internally. In repeated calls to <code>compute_mallows</code> , with very large datasets, computing the constraint set may be time consuming. In this case it can be beneficial to precompute it and provide it as a separate argument.
save_ind_clus	Whether or not to save the individual cluster probabilities in each step. This results in csv files <code>cluster_probs1.csv</code> , <code>cluster_probs2.csv</code> , ..., being saved in the calling directory. This option may slow down the code considerably, but is necessary for detecting label switching using Stephen's algorithm. See <a href="#">label_switching</a> for more information.
seed	Optional integer to be used as random number seed.
cl	Optional cluster.

**Value**

A list of class `BayesMallows`.

**Examples**

```

# ANALYSIS OF COMPLETE RANKINGS
# The example datasets potato_visual and potato_weighing contain complete
# rankings of 20 items, by 12 assessors. We first analyse these using the Mallows
# model:
model_fit <- compute_mallows(potato_visual)

# We study the trace plot of the parameters
assess_convergence(model_fit, parameter = "alpha")
## Not run: assess_convergence(model_fit, parameter = "rho")

# Based on these plots, we set burnin = 1000.
model_fit$burnin <- 1000
# Next, we use the generic plot function to study the posterior distributions
# of alpha and rho
plot(model_fit, parameter = "alpha")
## Not run: plot(model_fit, parameter = "rho", items = 10:15)

# We can also compute the CP consensus posterior ranking
compute_consensus(model_fit, type = "CP")

# And we can compute the posterior intervals:
# First we compute the interval for alpha
compute_posterior_intervals(model_fit, parameter = "alpha")
# Then we compute the interval for all the items
## Not run: compute_posterior_intervals(model_fit, parameter = "rho")

# ANALYSIS OF PAIRWISE PREFERENCES
## Not run:
# The example dataset beach_preferences contains pairwise
# preferences between beaches stated by 60 assessors. There
# is a total of 15 beaches in the dataset.
# In order to use it, we first generate all the orderings
# implied by the pairwise preferences.
beach_tc <- generate_transitive_closure(beach_preferences)
# We also generate an initial rankings
beach_rankings <- generate_initial_ranking(beach_tc, n_items = 15)
# We then run the Bayesian Mallows rank model
# We save the augmented data for diagnostics purposes.
model_fit <- compute_mallows(rankings = beach_rankings,
                             preferences = beach_tc,
                             save_aug = TRUE,
                             verbose = TRUE)

# We can assess the convergence of the scale parameter
assess_convergence(model_fit)
# We can assess the convergence of latent rankings. Here we
# show beaches 1-5.
assess_convergence(model_fit, parameter = "rho", items = 1:5)
# We can also look at the convergence of the augmented rankings for
# each assessor.
assess_convergence(model_fit, parameter = "Rtilde",
                   items = c(2, 4), assessors = c(1, 2))

```

```

# Notice how, for assessor 1, the lines cross each other, while
# beach 2 consistently has a higher rank value (lower preference) for
# assessor 2. We can see why by looking at the implied orderings in
# beach_tc
subset(beach_tc, assessor %in% c(1, 2) &
       bottom_item %in% c(2, 4) & top_item %in% c(2, 4))
# Assessor 1 has no implied ordering between beach 2 and beach 4,
# while assessor 2 has the implied ordering that beach 4 is preferred
# to beach 2. This is reflected in the trace plots.

## End(Not run)

# CLUSTERING OF ASSESSORS WITH SIMILAR PREFERENCES
## Not run:
# The example dataset sushi_rankings contains 5000 complete
# rankings of 10 types of sushi
# We start with computing a 3-cluster solution
model_fit <- compute_mallows(sushi_rankings, n_clusters = 3,
                            nmc = 10000, verbose = TRUE)
# We then assess convergence of the scale parameter alpha
assess_convergence(model_fit)
# Next, we assess convergence of the cluster probabilities
assess_convergence(model_fit, parameter = "cluster_probs")
# Based on this, we set burnin = 1000
# We now plot the posterior density of the scale parameters alpha in
# each mixture:
model_fit$burnin <- 1000
plot(model_fit, parameter = "alpha")
# We can also compute the posterior density of the cluster probabilities
plot(model_fit, parameter = "cluster_probs")
# We can also plot the posterior cluster assignment. In this case,
# the assessors are sorted according to their maximum a posteriori cluster estimate.
plot(model_fit, parameter = "cluster_assignment")
# We can also assign each assessor to a cluster
cluster_assignments <- assign_cluster(model_fit, soft = FALSE)

## End(Not run)

# DETERMINING THE NUMBER OF CLUSTERS
## Not run:
# Continuing with the sushi data, we can determine the number of cluster
# Let us look at any number of clusters from 1 to 10
# We use the convenience function compute_mallows_mixtures
n_clusters <- seq(from = 1, to = 10)
models <- compute_mallows_mixtures(n_clusters = n_clusters, rankings = sushi_rankings,
                                  nmc = 6000, alpha_jump = 10, include_wcd = TRUE)
# models is a list in which each element is an object of class BayesMallows,
# returned from compute_mallows
# We can create an elbow plot
plot_elbow(models, burnin = 1000)
# We then select the number of cluster at a point where this plot has
# an "elbow", e.g., at 6 clusters.

```

```
## End(Not run)

# SPEEDING UP COMPUTATION WITH OBSERVATION FREQUENCIES
# With a large number of assessors taking on a relatively low number of unique rankings,
# the obs_freq argument allows providing a rankings matrix with the unique set of rankings,
# and the obs_freq vector giving the number of assessors with each ranking.
# This is illustrated here for the potato_visual dataset
#
# assume each row of potato_visual corresponds to between 1 and 5 assessors, as
# given by the obs_freq vector
set.seed(1234)
obs_freq <- sample.int(n = 5, size = nrow(potato_visual), replace = TRUE)
m <- compute_mallows(rankings = potato_visual, obs_freq = obs_freq)

# See the separate help page for more examples, with the following code
help("obs_freq")
```

---

compute\_mallows\_mixtures

*Compute Mixtures of Mallows Models*

---

## Description

Convenience function for computing Mallows models with varying numbers of mixtures. This is useful for deciding the number of mixtures to use in the final model.

## Usage

```
compute_mallows_mixtures(n_clusters, ..., cl = NULL)
```

## Arguments

n_clusters	Integer vector specifying the number of clusters to use.
...	Other named arguments, passed to <a href="#">compute_mallows</a> .
cl	Optional computing cluster used for parallelization, returned from <code>parallel::makeCluster</code> . Defaults to NULL.

## Value

A list of Mallows models of class `BayesMallowsMixtures`, with one element for each number of mixtures that was computed. This object can be studied with [plot\\_elbow](#).

## See Also

---

```
compute_posterior_intervals
```

*Compute Posterior Intervals*

---

### Description

Compute posterior intervals of parameters of interest.

### Usage

```
compute_posterior_intervals(model_fit, ...)
```

### Arguments

model_fit	A model object.
...	other arguments passed to methods.

### Details

This function computes both the Highest Posterior Density Interval (HPDI), which may be discontinuous for bimodal distributions, and the central posterior interval, which is simply defined by the quantiles of the posterior distribution. The HPDI intervals are computed using the HDInterval package (Meredith and Kruschke 2018).

### References

**Description**

Compute posterior intervals

**Usage**

```

## S3 method for class 'BayesMallows'
compute_posterior_intervals(
  model_fit,
  burnin = model_fit$burnin,
  parameter = "alpha",
  level = 0.95,
  decimals = 3L,
  ...
)

```

**Arguments**

model_fit	An object of class BayesMallows returned from <a href="#">compute_mallows</a> .
burnin	A numeric value specifying the number of iterations to discard as burn-in. Defaults to model_fit\$burnin, and must be provided if model_fit\$burnin does not exist. See <a href="#">assess_convergence</a> .
parameter	Character string defining which parameter to compute posterior intervals for. One of "alpha", "rho", or "cluster_probs". Default is "alpha".
level	Decimal number in [0, 1] specifying the confidence level. Defaults to 0.95.
decimals	Integer specifying the number of decimals to include in posterior intervals and the mean and median. Defaults to 3.
...	Other arguments. Currently not used.

 estimate\_partition\_function

*Estimate Partition Function*

---

### Description

Estimate the logarithm of the partition function of the Mallows rank model. Choose between the importance sampling algorithm described in (Vitelli et al. 2018) and the IPFP algorithm for computing an asymptotic approximation described in (Mukherjee 2016).

### Usage

```
estimate_partition_function(
  method = "importance_sampling",
  alpha_vector,
  n_items,
  metric,
  nmc,
  degree,
  n_iterations,
  K,
  cl = NULL,
  seed = NULL
)
```

### Arguments

method	Character string specifying the method to use in order to estimate the logarithm of the partition function. Available options are "importance_sampling" and "asymptotic".
alpha_vector	Numeric vector of $\alpha$ values over which to compute the importance sampling estimate.
n_items	Integer specifying the number of items.
metric	Character string specifying the distance measure to use. Available options are "footrule" and "spearman" when method = "asymptotic" and in addition "cayley", "hamming", "kendall", and "ulam" when method = "importance_sampling".
nmc	Integer specifying the number of Monte Carlo samples to use in the importance sampling. Only used when method = "importance_sampling".
degree	Integer specifying the degree of the polynomial used to estimate $\log(\alpha)$ from the grid of values provided by the importance sampling estimate.
n_iterations	Integer specifying the number of iterations to use in the asymptotic approximation of the partition function. Only used when method = "asymptotic".
K	Integer specifying the parameter $K$ in the asymptotic approximation of the partition function. Only used when method = "asymptotic".

c1	Optional computing cluster used for parallelization, returned from <code>parallel::makeCluster</code> . Defaults to NULL. Only used when <code>method = "importance_sampling"</code> .
seed	Optional random number seed.

### Value

A vector of length `degree` which can be supplied to the `logz_estimate` argument of `compute_mallows`.

  do.call(rbind, lapply(alpha_vector, function(alpha){
    data.frame(
      type = type,
      alpha = alpha,
      logz_estimate = sum(alpha^powers * fit)
    )
  })))
}

estimates <- rbind(
  compute_fit(fit1, type = "Importance Sampling 1e3"),
  compute_fit(fit2, type = "Importance Sampling 1e4"),
  compute_fit(fit3, type = "Asymptotic")
)

# We can now plot the two estimates side-by-side
library(ggplot2)
ggplot(estimates, aes(x = alpha, y = logz_estimate, color = type)) +
  geom_line()

# We see that the two importance sampling estimates, which are unbiased,
# overlap. The asymptotic approximation seems a bit off. It can be worthwhile
# to try different values of n_iterations and K.

# When we are happy, we can provide the coefficient vector in the
# logz_estimate argument to compute_mallows
# Say we choose to use the importance sampling estimate with 1e4 Monte Carlo samples:
model_fit <- compute_mallows(potato_visual, metric = "spearman",
                             logz_estimate = fit2)

## End(Not run)

```

---

expected\_dist

*Expected value of metrics under a Mallows rank model*

---

### Description

Compute the expectation of several metrics under the Mallows rank model.

**Usage**

```
expected_dist(alpha, n_items, metric)
```

**Arguments**

alpha	Non-negative scalar specifying the scale (precision) parameter in the Mallows rank model.
n_items	Integer specifying the number of items.
metric	Character string specifying the distance measure to use. Available options are "kendall", "cayley", "hamming", "ulam" for n_items<=95, "footrule" for n_items<=50 and "spearman" for n_items<=14.

**Value**

A scalar providing the expected value of the metric under the Mallows rank model with distance specified by the metric argument.

**See Also**

Other rank functions: [get\\_mallows\\_loglik\(\)](#), [rank\\_conversion](#), [rank\\_distance\(\)](#), [rank\\_freq\\_distr\(\)](#), [sample\\_mallows\(\)](#)

**Examples**

```
expected_dist(1, 5, metric = "kendall")
expected_dist(2, 6, metric = "cayley")
expected_dist(1.5, 7, metric = "hamming")
expected_dist(5, 30, "ulam")
expected_dist(3.5, 45, "footrule")
expected_dist(4, 10, "spearman")
```

---

generate\_constraints    *Generate Constraint Set from Pairwise Comparisons*

---

**Description**

This function is relevant when [compute\\_mallows](#) is called repeatedly with the same data, e.g., when determining the number of clusters. It precomputes a list of constraints used internally by the MCMC algorithm, which otherwise would be recomputed each time [compute\\_mallows](#) is called.

**Usage**

```
generate_constraints(preferences, n_items, cl = NULL)
```

**Arguments**

preferences	Data frame of preferences. For the case of consistent rankings, preferences should be returned from <a href="#">generate_transitive_closure</a> . For the case of inconsistent preferences, when using an error model as described in Crispino et al. (2019), a dataframe of preferences can be directly provided.
n_items	Integer specifying the number of items.
cl	Optional computing cluster used for parallelization, returned from <code>parallel::makeCluster</code> . Defaults to NULL.

**Value**

A list which is used internally by the MCMC algorithm.

**References**

Other preprocessing: [estimate\\_partition\\_function\(\)](#), [generate\\_initial\\_ranking\(\)](#), [generate\\_transitive\\_closure\\_obs\\_freq](#), [prepare\\_partition\\_function\(\)](#)

**Examples**

```
# Here is an example with the beach preference data.
# First, generate the transitive closure.
beach_tc <- generate_transitive_closure(beach_preferences)

# Next, generate an initial ranking.
beach_init_rank <- generate_initial_ranking(beach_tc)

# Then generate the constrain set used intervally by compute_mallows
constr <- generate_constraints(beach_tc, n_items = 15)

# Provide all these elements to compute_mallows
model_fit <- compute_mallows(rankings = beach_init_rank,
  preferences = beach_tc, constraints = constr)

## Not run:
# The constraints can also be generated in parallel
library(parallel)
cl <- makeCluster(detectCores() - 1)
constr <- generate_constraints(beach_tc, n_items = 15, cl = cl)
stopCluster(cl)

## End(Not run)
```

---

```
generate_initial_ranking
```

*Generate Initial Ranking*

---

### Description

Given a consistent set of pairwise preferences, generate a complete ranking of items which is consistent with the preferences.

### Usage

```
generate_initial_ranking(
  tc,
  n_items = max(tc[, c("bottom_item", "top_item")]),
  cl = NULL,
  shuffle_unranked = FALSE,
  random = FALSE,
  random_limit = 8L
)
```

### Arguments

<code>tc</code>	A dataframe with pairwise comparisons of S3 subclass <code>BayesMallowsTC</code> , returned from <a href="#">generate_transitive_closure</a> .
<code>n_items</code>	The total number of items. If not provided, it is assumed to equal the largest item index found in <code>tc</code> , i.e., <code>max(tc[, c("bottom_item", "top_item")])</code> .
<code>cl</code>	Optional computing cluster used for parallelization, returned from <code>parallel::makeCluster</code> . Defaults to <code>NULL</code> .
<code>shuffle_unranked</code>	Logical specifying whether or not to randomly permuted unranked items in the initial ranking. When <code>shuffle_unranked=TRUE</code> and <code>random=FALSE</code> , all unranked items for each assessor are randomly permuted. Otherwise, the first ordering returned by <code>igraph::topo_sort()</code> is returned.
<code>random</code>	Logical specifying whether or not to use a random initial ranking. Defaults to <code>FALSE</code> . Setting this to <code>TRUE</code> means that all possible orderings consistent with the stated pairwise preferences are generated for each assessor, and one of them is picked at random.
<code>random_limit</code>	Integer specifying the maximum number of items allowed when all possible orderings are computed, i.e., when <code>random=TRUE</code> . Defaults to <code>8L</code> .

### Value

A matrix of rankings which can be given in the `rankings` argument to [compute\\_mallows](#).

**Note**

Setting `random=TRUE` means that all possible orderings of each assessor's preferences are generated, and one of them is picked at random. This can be useful when experiencing convergence issues, e.g., if the MCMC algorithm does not mixed properly. However, finding all possible orderings is a combinatorial problem, which may be computationally very hard. The result may not even be possible to fit in memory, which may cause the R session to crash. When using this option, please try to increase the size of the problem incrementally, by starting with smaller subsets of the complete data. An example is given below.

As detailed in the documentation to [generate\\_transitive\\_closure](#), it is assumed that the items are labeled starting from 1. For example, if a single comparison of the following form is provided, it is assumed that there is a total of 30 items (`n_items=30`), and the initial ranking is a permutation of these 30 items consistent with the preference `29<30`.

assessor	bottom_item	top_item
1	29	30

If in reality there are only two items, they should be relabeled to 1 and 2, as follows:

assessor	bottom_item	top_item
1	1	2

**See Also**

Other preprocessing: [estimate\\_partition\\_function\(\)](#), [generate\\_constraints\(\)](#), [generate\\_transitive\\_closure\(\)](#), [obs\\_freq](#), [prepare\\_partition\\_function\(\)](#)

**Examples**

```
# The example dataset beach_preferences contains pairwise preferences of beach.
# We must first generate the transitive closure
beach_tc <- generate_transitive_closure(beach_preferences)

# Next, we generate an initial ranking
beach_init <- generate_initial_ranking(beach_tc)

# Look at the first few rows:
head(beach_init)

# We can add more informative column names in order
# to get nicer posterior plots:
colnames(beach_init) <- paste("Beach", seq(from = 1, to = ncol(beach_init), by = 1))
head(beach_init)

# By default, the algorithm for generating the initial ranking is deterministic.
# It is possible to randomly permute the unranked items with the argument shuffle_unranked,
# as demonstrated below. This algorithm is computationally efficient, but defaults to FALSE
# for backward compatibility.
```

```

set.seed(2233)
beach_init <- generate_initial_ranking(beach_tc, shuffle_unranked = TRUE)
head(beach_init)

# It is also possible to pick a random sample among all topological sorts.
# This requires first enumerating all possible sorts, and might hence be computationally
# demanding. Here is an example, where we reduce the data considerable to speed up computation.
small_tc <- beach_tc[beach_tc$assessor %in% 1:6 &
                    beach_tc$bottom_item %in% 1:4 & beach_tc$top_item %in% 1:4, ]
set.seed(123)
init_small <- generate_initial_ranking(tc = small_tc, n_items = 4, random = TRUE)
# Look at the initial rankings generated
init_small

# For this small dataset, we can also study the effect of setting shuffle_unranked=TRUE
# in more detail. We consider assessors 1 and 2 only.
# First is the deterministic ordering. This one is equal for each run.
generate_initial_ranking(tc = small_tc[small_tc$assessor %in% c(1, 2), ],
                        n_items = 4, shuffle_unranked = FALSE, random = FALSE)
# Next we shuffle the unranked, setting the seed for reproducibility.
# For assessor 1, item 2 is unranked, and by rerunning the code multiple times,
# we see that element (1, 2) indeed changes ranking randomly.
# For assessor 2, item 3 is unranked, and we can also see that this item changes
# ranking randomly when rerunning the function multiple times.
# The ranked items also change their ranking from one random realization to another,
# but their relative ordering is constant.
set.seed(123)
generate_initial_ranking(tc = small_tc[small_tc$assessor %in% c(1, 2), ],
                        n_items = 4, shuffle_unranked = TRUE, random = FALSE)

## Not run:
# We now give beach_init and beach_tc to compute_mallows. We tell compute_mallows
# to save the augmented data, in order to study the convergence.
model_fit <- compute_mallows(rankings = beach_init,
                             preferences = beach_tc,
                             nmc = 2000,
                             save_aug = TRUE)

# We can study the acceptance rate of the augmented rankings
assess_convergence(model_fit, parameter = "Rtilde")

# We can also study the posterior distribution of the consensus rank of each beach
model_fit$burnin <- 500
plot(model_fit, parameter = "rho", items = 1:15)

## End(Not run)

## Not run:
# The computations can also be done in parallel
library(parallel)
cl <- makeCluster(detectCores() - 1)
beach_tc <- generate_transitive_closure(beach_preferences, cl = cl)

```

```

beach_init <- generate_initial_ranking(beach_tc, cl = cl)
stopCluster(cl)

## End(Not run)

```

---

```

generate_transitive_closure
      Generate Transitive Closure

```

---

### Description

Generate the transitive closure for a set of consistent pairwise comparisons. The result can be given in the preferences argument to [compute\\_mallows](#).

### Usage

```
generate_transitive_closure(df, cl = NULL)
```

### Arguments

**df** A data frame with one row per pairwise comparison, and columns `assessor`, `top_item`, and `bottom_item`. Each column contains the following:

- `assessor` is a numeric vector containing the assessor index, or a character vector containing the (unique) name of the assessor.
- `bottom_item` is a numeric vector containing the index of the item that was disfavored in each pairwise comparison.
- `top_item` is a numeric vector containing the index of the item that was preferred in each pairwise comparison.

So if we have two assessors and five items, and assessor 1 prefers item 1 to item 2 and item 1 to item 5, while assessor 2 prefers item 3 to item 5, we have the following df:

<b>assessor</b>	<b>bottom_item</b>	<b>top_item</b>
1	2	1
1	5	1
2	5	3

**cl** Optional computing cluster used for parallelization, returned from `parallel::makeCluster`. Defaults to `NULL`.

### Value

A dataframe with the same columns as `df`, but with its set of rows expanded to include all pairwise preferences implied by the ones stated in `df`. The returned object has S3 subclass `BayesMallowsTC`, to indicate that this is the transitive closure.

**See Also**

[generate\\_initial\\_ranking](#)

Other preprocessing: [estimate\\_partition\\_function\(\)](#), [generate\\_constraints\(\)](#), [generate\\_initial\\_ranking\(\)](#), [obs\\_freq](#), [prepare\\_partition\\_function\(\)](#)

**Examples**

```
# Let us first consider a simple case with two assessors, where assessor 1
# prefers item 1 to item 2, and item 1 to item 5, while assessor 2 prefers
# item 3 to item 5. We then have the following dataframe of pairwise
# comparisons:
pair_comp <- data.frame(
  assessor = c(1, 1, 2),
  bottom_item = c(2, 5, 5),
  top_item = c(1, 1, 3))
# We then generate the transitive closure of these preferences:
(pair_comp_tc <- generate_transitive_closure(pair_comp))
# In this case, no additional relations we implied by the ones
# stated in pair_comp, so pair_comp_tc has exactly the same rows
# as pair_comp.

# Now assume that assessor 1 also preferred item 5 to item 3, and
# that assessor 2 preferred item 4 to item 3.
pair_comp <- data.frame(
  assessor = c(1, 1, 1, 2, 2),
  bottom_item = c(2, 5, 3, 5, 3),
  top_item = c(1, 1, 5, 3, 4))

# We generate the transitive closure again:
(pair_comp_tc <- generate_transitive_closure(pair_comp))
# We now have one implied relation for each assessor.
# For assessor 1, it is implied that 1 is preferred to 3.
# For assessor 2, it is implied that 4 is preferred to 5.

## Not run:
# If assessor 1 in addition preferred item 3 to item 1,
# the preferences would not be consistent. This is not yet supported by compute_mallows,
# so it causes an error message. It will be supported in a future release of the package.
# First, we add the inconsistent row to pair_comp
pair_comp <- rbind(
  pair_comp,
  data.frame(assessor = 1, bottom_item = 1, top_item = 3))

# This causes an error message and prints out the problematic rankings:
(pair_comp_tc <- generate_transitive_closure(pair_comp))

## End(Not run)

## Not run:
# The computations can also be done in parallel
library(parallel)
```

```

cl <- makeCluster(detectCores() - 1)
beach_tc <- generate_transitive_closure(beach_preferences, cl = cl)
stopCluster(cl)

## End(Not run)

```

---

get\_mallows\_loglik      *Likelihood and log-likelihood evaluation for a Mallows mixture model*

---

### Description

Compute either the likelihood or the log-likelihood value of the Mallows mixture model parameters for a dataset of complete rankings.

### Usage

```

get_mallows_loglik(
  rho,
  alpha,
  weights,
  metric,
  rankings,
  obs_freq = NULL,
  log = TRUE
)

```

### Arguments

rho	A matrix of size $n\_clusters \times n\_items$ whose rows are permutations of the first $n\_items$ integers corresponding to the modal rankings of the Mallows mixture components.
alpha	A vector of $n\_clusters$ non-negative scalar specifying the scale (precision) parameters of the Mallows mixture components.
weights	A vector of $n\_clusters$ non-negative scalars specifying the mixture weights.
metric	Character string specifying the distance measure to use. Available options are "kendall", "cayley", "hamming", "ulam" for $n\_items \leq 95$ , "footrule" for $n\_items \leq 50$ and "spearman" for $n\_items \leq 14$ .
rankings	A matrix with observed rankings in each row.
obs_freq	A vector of observation frequencies (weights) to apply to each row in rankings. This can speed up computation if a large number of assessors share the same rank pattern. Defaults to NULL, which means that each row of rankings is multiplied by 1. If provided, obs_freq must have the same number of elements as there are rows in rankings, and rankings cannot be NULL.
log	A logical; if TRUE, the log-likelihood value is returned, otherwise its exponential. Default is TRUE.

**Value**

The likelihood or the log-likelihood value corresponding to one or more observed complete rankings under the Mallows mixture rank model with distance specified by the `metric` argument.

**See Also**

Other rank functions: [expected\\_dist\(\)](#), [rank\\_conversion](#), [rank\\_distance\(\)](#), [rank\\_freq\\_distr\(\)](#), [sample\\_mallows\(\)](#)

**Examples**

```
# Simulate a sample from a Mallows model with the Kendall distance

n_items <- 5
mydata <- sample_mallows(
  n_samples = 100,
  rho0 = 1:n_items,
  alpha0 = 10,
  metric = "kendall")

# Compute the likelihood and log-likelihood values under the true model...
get_mallows_loglik(
  rho = rbind(1:n_items, 1:n_items),
  alpha = c(10, 10),
  weights = c(0.5, 0.5),
  metric = "kendall",
  rankings = mydata,
  log = FALSE
)

get_mallows_loglik(
  rho = rbind(1:n_items, 1:n_items),
  alpha = c(10, 10),
  weights = c(0.5, 0.5),
  metric = "kendall",
  rankings = mydata,
  log = TRUE
)

# or equivalently, by using the frequency distribution
freq_distr <- rank_freq_distr(mydata)
get_mallows_loglik(
  rho = rbind(1:n_items, 1:n_items),
  alpha = c(10, 10),
  weights = c(0.5, 0.5),
  metric = "kendall",
  rankings = freq_distr[, 1:n_items],
  obs_freq = freq_distr[, n_items + 1],
  log = FALSE
)

get_mallows_loglik(
```

```

rho = rbind(1:n_items, 1:n_items),
alpha = c(10, 10),
weights = c(0.5, 0.5),
metric = "kendall",
rankings = freq_distr[, 1:n_items],
obs_freq = freq_distr[, n_items + 1],
log = TRUE
)

```

---

heat\_plot

*Heat plot of posterior probabilities*

---

### Description

Generates a heat plot with items in their consensus ordering along the horizontal axis and ranking along the vertical axis. The color denotes posterior probability.

### Usage

```
heat_plot(model_fit, burnin = model_fit$burnin, ...)
```

### Arguments

model_fit	An object of type <code>BayesMallows</code> , returned from <a href="#">compute_mallows</a> .
burnin	A numeric value specifying the number of iterations to discard as burn-in. Defaults to <code>x\$burnin</code> , and must be provided if <code>x\$burnin</code> does not exist. See <a href="#">assess_convergence</a> .
...	Additional arguments passed on to other methods. In particular, <code>type = "CP"</code> or <code>type = "MAP"</code> can be passed on to <a href="#">compute_consensus</a> to determine the order of items along the horizontal axis.

### Value

A `ggplot` object.

### See Also

Other posterior quantities: [assign\\_cluster\(\)](#), [compute\\_consensus.BayesMallows\(\)](#), [compute\\_consensus.SCMallows](#), [compute\\_consensus\(\)](#), [compute\\_posterior\\_intervals.BayesMallows\(\)](#), [compute\\_posterior\\_intervals.SCMallows](#), [compute\\_posterior\\_intervals\(\)](#), [plot.BayesMallows\(\)](#), [plot.SCMallows\(\)](#), [plot\\_elbow\(\)](#), [plot\\_top\\_k\(\)](#), [predict\\_top\\_k\(\)](#), [print.BayesMallowsMixtures\(\)](#), [print.BayesMallows\(\)](#)

**Examples**

```
# Setting the number of Monte Carlo samples very low for the example to run fast.
# A real application should run much longer, and have a large burnin.
model_fit <- compute_mallows(potato_visual, nmc = 500, seed = 1)
model_fit$burnin <- 100

heat_plot(model_fit)

# Items are ordered along the horizontal axis according to the ordering
# returned by compute_consensus, whose default argument is type="CP".

heat_plot(model_fit, type = "MAP")
```

---

label\_switching

*Checking for Label Switching in the Mallows Mixture Model*

---

**Description**

Label switching may sometimes be a problem when running mixture models. The algorithm by Stephens (Stephens 2000), implemented in the `label_switching` package (Papastamoulis 2016), allows assessment of label switching after MCMC. At the moment, this is the only available option in the `BayesMallows` package. The Stephens algorithm requires the individual cluster probabilities of each assessor to be saved in each iteration of the MCMC algorithm. As this potentially requires much memory, the current implementation of `compute_mallows` saves these cluster probabilities to a csv file in each iteration. The example below shows how to perform such a check for label switching in practice.

Beware that this functionality is under development. Later releases might let the user determine the directory and filenames of the csv files.

**Examples**

```
## Not run:
# This example shows how to assess if label switching happens in BayesMallows

library(BayesMallows)
```

```

# We start by creating a directory in which csv files with individual
# cluster probabilities should be saved in each step of the MCMC algorithm
dir.create("./test_label_switch")
# Next, we go into this directory
setwd("./test_label_switch/")
# For comparison, we run compute_mallows with and without saving the cluster
# probabilities The purpose of this is to assess the time it takes to save
# the cluster probabilities
system.time(m <- compute_mallows(rankings = sushi_rankings,
                                n_clusters = 6, nmc = 2000,
                                save_ind_clus = FALSE, verbose = TRUE))
# With this options, compute_mallows will save cluster_probs2.csv,
# cluster_probs3.csv, ..., cluster_probs[nmc].csv.
system.time(m <- compute_mallows(rankings = sushi_rankings, n_clusters = 6,
                                nmc = 2000,
                                save_ind_clus = TRUE, verbose = TRUE))

# Next, we check convergence of alpha
assess_convergence(m)

# We set the burnin to 1000
burnin <- 1000

# Find all files that were saved. Note that the first file saved is cluster_probs2.csv
cluster_files <- list.files(pattern = "cluster\\_probs[[:digit:]]+\\.csv")

# Check the size of the files that were saved.
paste(sum(do.call(file.size, list(cluster_files))) * 1e-6, "MB")

# Find the iteration each file corresponds to, by extracting its number
iteration_number <- as.integer(
  gsub("(^[a-zA-Z\\_\\.]*)([0-9]+)([a-zA-Z\\_\\.]+$)", "\\2",
    cluster_files, perl = TRUE))
# Remove all files before burnin
file.remove(cluster_files[iteration_number <= burnin])
# Update the vector of files, after the deletion
cluster_files <- list.files(pattern = "cluster\\_probs[[:digit:]]+\\.csv")
# Create 3d array, with dimensions (iterations, assessors, clusters)
prob_array <- array(dim = c(length(cluster_files), m$n_assessors, m$n_clusters))
# Read each file, adding to the right element of the array
for(i in seq_along(cluster_files)){
  prob_array[i, , ] <- as.matrix(
    read.csv(cluster_files[[i]], header = FALSE))
}

# Create an integer array of latent allocations, as this is required by label.switching
z <- subset(m$cluster_assignment, iteration > burnin)
z$value <- as.integer(gsub("Cluster ", "", z$value))
z <- stats::reshape(z, direction = "wide", idvar = "iteration", timevar = "assessor")
z$iteration <- NULL
z <- as.matrix(z)

```

```

# Now apply Stephen's algorithm
library(label.switching)
ls <- label.switching("STEPHENS", z = z, K = m$n_clusters, p = prob_array)

# Check the proportion of cluster assignments that were switched
mean(apply(ls$permutations$STEPHENS, 1, function(x) !all.equal(x, seq(1, m$n_clusters))))

# Remove the rest of the csv files
file.remove(cluster_files)
# Move up one directory
setwd("../")
# Remove the directory in which the csv files were saved
file.remove("./test_label_switch/")

## End(Not run)

```

---

obs\_freq

*Observation frequencies in the Bayesian Mallows model*

---

### Description

When more than one assessor have given the exact same rankings or preferences, considerable speed-up can be obtained by providing only the unique set of rankings/preferences to [compute\\_mallows](#), and instead providing the number of assessors in the `obs_freq` argument. This topic is illustrated here. See also the function [rank\\_freq\\_distr](#) for how to easily compute the observation frequencies.

### See Also

Other preprocessing: [estimate\\_partition\\_function\(\)](#), [generate\\_constraints\(\)](#), [generate\\_initial\\_ranking\(\)](#), [generate\\_transitive\\_closure\(\)](#), [prepare\\_partition\\_function\(\)](#)

### Examples

```

# The first example uses full rankings in the potato_visual dataset, but we assume
# that each row in the data corresponds to between 100 and 500 assessors.
set.seed(1234)
# We start by generating random observation frequencies
obs_freq <- sample(x = seq(from = 100L, to = 500L, by = 1L),
                  size = nrow(potato_visual), replace = TRUE)
# We also create a set of repeated indices, used to extend the matrix rows
repeated_indices <- unlist(Map(function(x, y) rep(x, each = y),
                              seq_len(nrow(potato_visual)), obs_freq))
# The potato_repeated matrix consists of all rows repeated corresponding to
# the number of assessors in the obs_freq vector. This is how a large dataset
# would look like without using the obs_freq argument
potato_repeated <- potato_visual[repeated_indices, ]

# We now first compute the Mallows model using obs_freq
# This takes about 0.2 seconds

```

```

system.time({

# As demonstrated here, using a obs_freq argument to exploit patterns in data

```

```
# where multiple assessors have given identical rankings or preferences, may
# lead to considerable speedup.

## End(Not run)
```

---

plot.BayesMallows      *Plot Posterior Distributions*

---

## Description

Plot posterior distributions of the parameters of the Mallows Rank model.

## Usage

```
## S3 method for class 'BayesMallows'
plot(x, burnin = x$burnin, parameter = "alpha", items = NULL, ...)
```

## Arguments

x	An object of type BayesMallows, returned from <a href="#">compute_mallows</a> .
burnin	A numeric value specifying the number of iterations to discard as burn-in. Defaults to x\$burnin, and must be provided if x\$burnin does not exist. See <a href="#">assess_convergence</a> .
parameter	Character string defining the parameter to plot. Available options are "alpha", "rho", "cluster_probs", "cluster_assignment", and "theta".
items	The items to study in the diagnostic plot for rho. Either a vector of item names, corresponding to x\$items or a vector of indices. If NULL, five items are selected randomly. Only used when parameter = "rho".
...	Other arguments passed to plot (not used).

## See Also

Other posterior quantities: [assign\\_cluster\(\)](#), [compute\\_consensus.BayesMallows\(\)](#), [compute\\_consensus.SCMallows](#), [compute\\_consensus\(\)](#), [compute\\_posterior\\_intervals.BayesMallows\(\)](#), [compute\\_posterior\\_intervals.SCMallows](#), [compute\\_posterior\\_intervals\(\)](#), [heat\\_plot\(\)](#), [plot.SCMallows\(\)](#), [plot\\_elbow\(\)](#), [plot\\_top\\_k\(\)](#), [predict\\_top\\_k\(\)](#), [print.BayesMallowsMixtures\(\)](#), [print.BayesMallows\(\)](#)

## Examples

```
# The example datasets potato_visual and potato_weighing contain complete
# rankings of 20 items, by 12 assessors. We first analyse these using the Mallows
# model:
model_fit <- compute_mallows(potato_visual)

# See the documentation to compute_mallows for how to assess the convergence
# of the algorithm
```

```

# We set the burnin = 1000
model_fit$burnin <- 1000
# By default, the scale parameter "alpha" is plotted
plot(model_fit)
## Not run:
# We can also plot the latent rankings "rho"
plot(model_fit, parameter = "rho")
# By default, a random subset of 5 items are plotted
# Specify which items to plot in the items argument.
plot(model_fit, parameter = "rho",
      items = c(2, 4, 6, 9, 10, 20))
# When the ranking matrix has column names, we can also
# specify these in the items argument.
# In this case, we have the following names:
colnames(potato_visual)
# We can therefore get the same plot with the following call:
plot(model_fit, parameter = "rho",
      items = c("P2", "P4", "P6", "P9", "P10", "P20"))

## End(Not run)

## Not run:
# Plots of mixture parameters:
# We can run a mixture of Mallows models, using the n_clusters argument
# We use the sushi example data. See the documentation of compute_mallows for a more elaborate
# example
model_fit <- compute_mallows(sushi_rankings, n_clusters = 5)
model_fit$burnin <- 1000
# We can then plot the posterior distributions of the cluster probabilities
plot(model_fit, parameter = "cluster_probs")
# We can also get a cluster assignment plot, showing the assessors along the horizontal
# axis and the clusters along the vertical axis. The color show the probability
# of belonging to each clusters. The assessors are sorted along the horizontal
# axis according to their maximum a posterior cluster assignment. This plot
# illustrates the posterior uncertainty in cluster assignments.
plot(model_fit, parameter = "cluster_assignment")
# See also ?assign_cluster for a function which returns the cluster assignment
# back in a dataframe.

## End(Not run)

```

---

plot.SMCMallows

*Plot SMC Posterior Distributions*

---

### Description

Plot posterior distributions of SMC-Mallow parameters.

**Usage**

```
## S3 method for class 'SMCMallows'
plot(
  x,
  nmc = nrow(x$rho_samples[, 1, ]),
  burnin = 0,
  parameter = "alpha",
  time = ncol(x$rho_samples[, 1, ]),
  C = 1,
  colnames = NULL,
  items = NULL,
  ...
)
```

**Arguments**

<code>x</code>	An object of type SMC-Mallows, returned for example from <a href="#">smc_mallows_new_users</a> .
<code>nmc</code>	Number of Monte Carlo samples
<code>burnin</code>	A numeric value specifying the number of iterations to discard as burn-in. Defaults to <code>model_fit\$burnin</code> , and must be provided if <code>model_fit\$burnin</code> does not exist. See <a href="#">assess_convergence</a> .
<code>parameter</code>	Character string defining the parameter to plot. Available options are "alpha" and "rho".
<code>time</code>	Integer determining the update slice to plot
<code>C</code>	Number of cluster
<code>colnames</code>	A vector of item names. If NULL, generic names are generated for the items in the ranking.
<code>items</code>	Either a vector of item names, or a vector of indices. If NULL, five items are selected randomly.
<code>...</code>	Other arguments passed to <a href="#">plot</a> (not used).

**Value**

A plot of the posterior distributions

**Author(s)**

Waldir Leoncio

**See Also**

## Examples

```

set.seed(994)

n_items <- dim(sushi_rankings)[2]
metric <- "footrule"

# Estimate the logarithm of the partition function of the Mallows rank model
logz_estimate <- estimate_partition_function(
  method = "importance_sampling",
  alpha_vector = seq(from = 0, to = 15, by = 0.5), n_items = n_items,
  metric = metric, nmc = 1e2, degree = 10
)

# Perform the resample-move SMC algorithm
smc_test <- smc_mallows_new_users(
  R_obs = sushi_rankings[1:100, ], type = "complete", n_items = n_items,
  metric = metric, leap_size = floor(n_items / 5), N = 100, Time = 10,
  logz_estimate = logz_estimate, mcmc_kernel_app = 5, num_new_obs = 5,
  alpha_prop_sd = 0.5, lambda = 0.15, alpha_max = 1e3
)

# Plot rho
plot(smc_test, colnames = colnames(sushi_rankings), parameter = "rho")

# Plot alpha
plot(smc_test, parameter = "alpha")

```

---

plot\_elbow

*Plot Within-Cluster Sum of Distances*

---

## Description

Plot the within-cluster sum of distances from the corresponding cluster consensus for different number of clusters. This function is useful for selecting the number of mixture.

## Usage

```
plot_elbow(..., burnin = NULL)
```

## Arguments

...	One or more objects returned from <code>compute_mallows</code> , separated by comma, or a list of such objects. Typically, each object has been run with a different number of mixtures, as specified in the <code>n_clusters</code> argument to <code>compute_mallows</code> .
burnin	The number of iterations to discard as burnin. Either a vector of numbers, one for each model, or a single number which is taken to be the burnin for all models. If each model provided has a <code>burnin</code> element, then this is taken as the default.

**Value**

A boxplot with the number of clusters on the horizontal axis and the with-cluster sum of distances on the vertical axis.

**See Also**

plot\_top\_k

*Plot Top-k Rankings with Pairwise Preferences*

---

### Description

Plot the posterior probability, per item, of being ranked among the top- $k$  for each assessor. This plot is useful when the data take the form of pairwise preferences.

### Usage

```

plot_top_k(
  model_fit,
  burnin = model_fit$burnin,
  k = 3,
  rel_widths = c(model_fit$n_clusters, 10)
)

```

### Arguments

model_fit	An object of type BayesMallows, returned from <a href="#">compute_mallows</a> .
burnin	A numeric value specifying the number of iterations to discard as burn-in. Defaults to model_fit\$burnin, and must be provided if model_fit\$burnin does not exist. See <a href="#">assess_convergence</a> .
k	Integer specifying the $k$ in top- $k$ .
rel_widths	The relative widths of the plots of rho per cluster and the plot of assessors, respectively. This argument is passed on to <a href="#">plot_grid</a> .

**See Also**[predict\\_top\\_k](#)

---

**Description**

`create_ranking` takes a vector or matrix of ordered items `orderings` and returns a corresponding vector or matrix of ranked items. `create_ordering` takes a vector or matrix of rankings `rankings` and returns a corresponding vector or matrix of ordered items.

**Usage**

```
create_ranking(orderings)
```

```
create_ordering(rankings)
```

**Arguments**

`orderings` A vector or matrix of ordered items. If a matrix, it should be of size  $N$  times  $n$ , where  $N$  is the number of samples and  $n$  is the number of items.

`rankings` A vector or matrix of ranked items. If a matrix, it should be  $N$  times  $n$ , where  $N$  is the number of samples and  $n$  is the number of items.

**Value**

A vector or matrix of rankings. Missing `orderings` coded as `NA` are propagated into corresponding missing ranks and vice versa.

**Functions**

- `create_ranking()`: Convert from ordering to ranking.
- `create_ordering()`: Convert from ranking to ordering.

**See Also**

Other rank functions: [expected\\_dist\(\)](#), [get\\_mallows\\_loglik\(\)](#), [rank\\_distance\(\)](#), [rank\\_freq\\_distr\(\)](#), [sample\\_mallows\(\)](#)

**Examples**

```

# A vector of ordered items.
orderings <- c(5, 1, 2, 4, 3)
# Get ranks
rankings <- create_ranking(orderings)
# rankings is c(2, 3, 5, 4, 1)
# Finally we convert it backed to an ordering.
orderings_2 <- create_ordering(rankings)
# Confirm that we get back what we had
all.equal(orderings, orderings_2)

# Next, we have a matrix with N = 19 samples
# and n = 4 items
set.seed(21)
N <- 10
n <- 4
orderings <- t(replicate(N, sample.int(n)))
# Convert the ordering to ranking
rankings <- create_ranking(orderings)
# Now we try to convert it back to an ordering.
orderings_2 <- create_ordering(rankings)
# Confirm that we get back what we had
all.equal(orderings, orderings_2)

```

rank\_distance

*Distance between a set of rankings and a given rank sequence***Description**

Compute the distance between a matrix of rankings and a rank sequence.

**Usage**

```
rank_distance(rankings, rho, metric, obs_freq = 1)
```

**Arguments**

rankings	A matrix of size $N \times n_{items}$ of rankings in each row. Alternatively, if $N$ equals 1, rankings can be a vector.
rho	A ranking sequence.
metric	Character string specifying the distance measure to use. Available options are "kendall", "cayley", "hamming", "ulam", "footrule" and "spearman".
obs_freq	Vector of observation frequencies of length $N$ , or of length 1, which means that all ranks are given the same weight. Defaults to 1.

**Details**

The implementation of Cayley distance is based on a C++ translation of Rankcluster::distCayley (Grimonprez and Jacques 2016).

**Value**

A vector of distances according to the given metric.

**References**

Grimonprez Q, Jacques J (2016). *Rankcluster: Model-Based Clustering for Multivariate Partial Ranking Data*. R package version 0.94, <https://CRAN.R-project.org/package=Rankcluster>.

Other rank functions: [expected\\_dist\(\)](#), [get\\_mallows\\_loglik\(\)](#), [rank\\_conversion](#), [rank\\_freq\\_distr\(\)](#), [sample\\_mallows\(\)](#)

**Examples**

```
# Distance between two vectors of rankings:
rank_distance(1:5, 5:1, metric = "kendall")
rank_distance(c(2, 4, 3, 6, 1, 7, 5), c(3, 5, 4, 7, 6, 2, 1), metric = "cayley")
rank_distance(c(4, 2, 3, 1), c(3, 4, 1, 2), metric = "hamming")
rank_distance(c(1, 3, 5, 7, 9, 8, 6, 4, 2), c(1, 2, 3, 4, 9, 8, 7, 6, 5), "ulam")
rank_distance(c(8, 7, 1, 2, 6, 5, 3, 4), c(1, 2, 8, 7, 3, 4, 6, 5), "footrule")
rank_distance(c(1, 6, 2, 5, 3, 4), c(4, 3, 5, 2, 6, 1), "spearman")

# Difference between a metric and a vector
# We set the burn-in and thinning too low for the example to run fast
data0 <- sample_mallows(rho0 = 1:10, alpha = 20, n_samples = 1000,
                       burnin = 10, thinning = 1)

rank_distance(rankings = data0, rho = 1:10, metric = "kendall")
```

---

rank_freq_distr	<i>Frequency distribution of the ranking sequences</i>
-----------------	--

---

**Description**

Construct the frequency distribution of the distinct ranking sequences from the dataset of the individual rankings. This can be of interest in itself, but also used to speed up computation by providing the `obs_freq` argument to [compute\\_mallows](#).

**Usage**

```
rank_freq_distr(rankings)
```

**Arguments**

`rankings` A matrix with the individual rankings in each row.

**Value**

Numeric matrix with the distinct rankings in each row and the corresponding frequencies indicated in the last (n\_items+1)-th column.

**See Also**

Other rank functions: [expected\\_dist\(\)](#), [get\\_mallows\\_loglik\(\)](#), [rank\\_conversion](#), [rank\\_distance\(\)](#), [sample\\_mallows\(\)](#)

**Examples**

```
# Create example data. We set the burn-in and thinning very low
# for the sampling to go fast
data0 <- sample_mallows(rho0 = 1:5, alpha = 10, n_samples = 1000,
                       burnin = 10, thinning = 1)
# Find the frequency distribution
rank_freq_distr(rankings = data0)
```

---

sample_dataset	<i>A synthetic 3D matrix generated using the sample_mallows function</i>
----------------	--

---

**Description**

A synthetic 3D matrix (n\_users, n\_items, Time) generated using the sample\_mallows function. These are test datasets used to run the SMC-Mallows framework for the cases where we know all of the users in our system and their original ranking information are partial rankings. However at some point in time, we observe extra information about an existing user in the form of a rank for an item that was previously not known (NA). These datasets are very contrived as the first time step (sample\_dataset[, , 1]) we observed the top  $m / 2$  items from each user, where  $m$  is the number of items in a ranking. Then, as we increase the time, we observe the next top ranked item from one user at a time, then the next top ranked item, and so on until we have a complete dataset at sample\_dataset[, , Time].

**Usage**

```
sample_dataset
```

**Format**

An object of class array of dimension 10 x 6 x 31.

**References**

<https://github.com/anjastein/SMC-Mallows/tree/main/data>

---

sample_mallows	<i>Random Samples from the Mallows Rank Model</i>
----------------	---

---

### Description

Generate random samples from the Mallows Rank Model (Mallows 1957) with consensus ranking  $\rho$  and scale parameter  $\alpha$ . The samples are obtained by running the Metropolis-Hastings algorithm described in Appendix C of Vitelli et al. (2018).

### Usage

```
sample_mallows(
  rho0,
  alpha0,
  n_samples,
  leap_size = max(1L, floor(n_items/5)),
  metric = "footrule",
  diagnostic = FALSE,
  burnin = ifelse(diagnostic, 0, 1000),
  thinning = ifelse(diagnostic, 1, 1000),
  items_to_plot = NULL,
  max_lag = 1000L
)
```

### Arguments

<code>rho0</code>	Vector specifying the latent consensus ranking in the Mallows rank model.
<code>alpha0</code>	Scalar specifying the scale parameter in the Mallows rank model.
<code>n_samples</code>	Integer specifying the number of random samples to generate. When <code>diagnostic = TRUE</code> , this number must be larger than 1.
<code>leap_size</code>	Integer specifying the step size of the leap-and-shift proposal distribution.
<code>metric</code>	Character string specifying the distance measure to use. Available options are "footrule" (default), "spearman", "cayley", "hamming", "kendall", and "ulam". See also the <code>rmm</code> function in the <code>PerMallows</code> package (Irurozki et al. 2016) for sampling from the Mallows model with Cayley, Hamming, Kendall, and Ulam distances.
<code>diagnostic</code>	Logical specifying whether to output convergence diagnostics. If <code>TRUE</code> , a diagnostic plot is printed, together with the returned samples.
<code>burnin</code>	Integer specifying the number of iterations to discard as burn-in. Defaults to 1000 when <code>diagnostic = FALSE</code> , else to 0.
<code>thinning</code>	Integer specifying the number of MCMC iterations to perform between each time a random rank vector is sampled. Defaults to 1000 when <code>diagnostic = FALSE</code> , else to 1.
<code>items_to_plot</code>	Integer vector used if <code>diagnostic = TRUE</code> , in order to specify the items to plot in the diagnostic output. If not provided, 5 items are picked at random.

`max_lag` Integer specifying the maximum lag to use in the computation of autocorrelation. Defaults to 1000L. This argument is passed to `stats::acf`. Only used when `diagnostic = TRUE`.

## See Also

Other rank functions: [expected\\_dist\(\)](#), [get\\_mallows\\_loglik\(\)](#), [rank\\_conversion](#), [rank\\_distance\(\)](#), [rank\\_freq\\_distr\(\)](#)

## Examples

```
# Sample 100 random rankings from a Mallows distribution with footrule distance
set.seed(1)
# Number of items
n_items <- 15
# Set the consensus ranking
rho0 <- seq(from = 1, to = n_items, by = 1)
# Set the scale
alpha0 <- 10
# Number of samples
n_samples <- 100
# We first do a diagnostic run, to find the thinning and burnin to use
# We set n_samples to 1000, in order to run 1000 diagnostic iterations.
test <- sample_mallows(rho0 = rho0, alpha0 = alpha0, diagnostic = TRUE,
                      n_samples = 1000, burnin = 1, thinning = 1)
# When items_to_plot is not set, 5 items are picked at random. We can change this.
# We can also reduce the number of lags computed in the autocorrelation plots
test <- sample_mallows(rho0 = rho0, alpha0 = alpha0, diagnostic = TRUE,
                      n_samples = 1000, burnin = 1, thinning = 1,
                      items_to_plot = c(1:3, 10, 15), max_lag = 500)
# From the autocorrelation plot, it looks like we should use
# a thinning of at least 200. We set thinning = 1000 to be safe,
# since the algorithm in any case is fast. The Markov Chain
# seems to mix quickly, but we set the burnin to 1000 to be safe.
# We now run sample_mallows again, to get the 100 samples we want:
samples <- sample_mallows(rho0 = rho0, alpha0 = alpha0, n_samples = 100,
                        burnin = 1000, thinning = 1000)
# The samples matrix now contains 100 rows with rankings of 15 items.
# A good diagnostic, in order to confirm that burnin and thinning are set high
# enough, is to run compute_mallows on the samples
model_fit <- compute_mallows(samples, nmc = 10000)
```

```
# The highest posterior density interval covers alpha0 = 10.
compute_posterior_intervals(model_fit, burnin = 2000, parameter = "alpha")
```

---

```
smc_mallows_new_item_rank
      SMC-Mallows new item rank
```

---

## Description

Function to perform resample-move SMC algorithm where we receive a new item ranks from an existing user at each time step. Each correction and augmentation is done by filling in the missing item ranks using pseudolikelihood augmentation.

## Usage

```
smc_mallows_new_item_rank(
  n_items,
  R_obs,
  N,
  Time,
  logz_estimate,
  cardinalities,
  mcmc_kernel_app,
  aug_rankings_init = NULL,
  rho_samples_init = NULL,
  alpha_samples_init = 0L,
  alpha = 0,
  alpha_prop_sd = 0.5,
  lambda = 0.1,
  alpha_max = 1e+06,
  aug_method = "random",
  verbose = FALSE,
  alpha_fixed = FALSE,
  metric = "footrule",
  leap_size = 1L
)
```

## Arguments

<code>n_items</code>	Integer is the number of items in a ranking
<code>R_obs</code>	3D matrix of size <code>n_assessors</code> by <code>n_items</code> by <code>Time</code> containing a set of observed rankings of <code>Time</code> time steps
<code>N</code>	Integer specifying the number of particles
<code>Time</code>	Integer specifying the number of time steps in the SMC algorithm
<code>logz_estimate</code>	Estimate of the partition function, computed with <a href="#">estimate_partition_function</a> .

<code>cardinalities</code>	Cardinalities for exact computation of partition function, returned from <a href="#">prepare_partition_function</a> .
<code>mcmc_kernel_app</code>	Integer value for the number of applications we apply the MCMC move kernel
<code>aug_rankings_init</code>	Initial values for augmented rankings.
<code>rho_samples_init</code>	Initial values for rho samples.
<code>alpha_samples_init</code>	Initial values for alpha samples.
<code>alpha</code>	numeric value of the scale parameter.
<code>alpha_prop_sd</code>	Numeric value of the standard deviation of the prior distribution for alpha
<code>lambda</code>	Strictly positive numeric value specifying the rate parameter of the truncated exponential prior distribution of alpha.
<code>alpha_max</code>	Maximum value of alpha in the truncated exponential prior distribution.
<code>aug_method</code>	A character string specifying the approach for filling in the missing data, options are "pseudolikelihood" or "random"
<code>verbose</code>	Logical specifying whether to print out the progress of the SMC-Mallows algorithm. Defaults to FALSE.
<code>alpha_fixed</code>	Logical indicating whether to sample alpha or not.
<code>metric</code>	A character string specifying the distance metric to use in the Bayesian Mallows Model. Available options are "footrule", "spearman", "cayley", "hamming", "kendall", and "ulam".
<code>leap_size</code>	<code>leap_size</code> Integer specifying the step size of the leap-and-shift proposal distribution

**Value**

a 3d matrix containing: the samples of: rho, alpha and the augmented rankings, and the effective sample size at each iteration of the SMC algorithm.

**See Also**

Other modeling: [compute\\_mallows\\_mixtures\(\)](#), [compute\\_mallows\(\)](#), [smc\\_mallows\\_new\\_users\(\)](#)

---

`smc_mallows_new_users` *SMC-Mallows New Users*

---

**Description**

Function to perform resample-move SMC algorithm where we receive new users with complete rankings at each time step. See Chapter 4 of (Stein 2023)

**Usage**

```
smc_mallows_new_users(
  R_obs,
  type,
  n_items,
  N,
  Time,
  mcmc_kernel_app,
  num_new_obs,
  alpha_prop_sd = 0.5,
  lambda = 0.1,
  alpha_max = 1e+06,
  alpha = 0,
  aug_method = "random",
  logz_estimate = NULL,
  cardinalities = NULL,
  verbose = FALSE,
  metric = "footnote",
  leap_size = 1L
)
```

**Arguments**

R_obs	Matrix containing the full set of observed rankings of size n_assessors by n_items
type	One of "complete", "partial", or "partial_alpha_fixed".
n_items	Integer is the number of items in a ranking
N	Integer specifying the number of particles
Time	Integer specifying the number of time steps in the SMC algorithm
mcmc_kernel_app	Integer value for the number of applications we apply the MCMC move kernel
num_new_obs	Integer value for the number of new observations (complete rankings) for each time step
alpha_prop_sd	Numeric value specifying the standard deviation of the lognormal proposal distribution used for $\alpha$ in the Metropolis-Hastings algorithm. Defaults to 0.1.
lambda	Strictly positive numeric value specifying the rate parameter of the truncated exponential prior distribution of $\alpha$ . Defaults to 0.1. When <code>n_cluster &gt; 1</code> , each mixture component $\alpha_c$ has the same prior distribution.
alpha_max	Maximum value of alpha in the truncated exponential prior distribution.
alpha	A numeric value of the scale parameter which is known and fixed.
aug_method	A character string specifying the approach for filling in the missing data, options are "pseudolikelihood" or "random".
logz_estimate	Estimate of the partition function, computed with <a href="#">estimate_partition_function</a> .
cardinalities	Cardinalities for exact evaluation of partition function, returned from <a href="#">prepare_partition_function</a> .
verbose	Logical specifying whether to print out the progress of the SMC-Mallows algorithm. Defaults to FALSE.

metric	A character string specifying the distance metric to use in the Bayesian Mallows Model. Available options are "footrule", "spearman", "cayley", "hamming", "kendall", and "ulam".
leap_size	leap_size Integer specifying the step size of the leap-and-shift proposal distribution

**Value**

a set of particles each containing a value of rho and alpha

**See Also**

Other modeling: `compute_mallows_mixtures()`, `compute_mallows()`, `smc_mallows_new_item_rank()`

**Examples**

```
# Generate basic elements
data <- sushi_rankings[1:100, ]
n_items <- ncol(sushi_rankings)
metric <- "footrule"
num_new_obs <- 10

# Prepare exact partition function
cardinalities <- prepare_partition_function(metric = metric,
                                           n_items = n_items)$cardinalities

# Calculating rho and alpha samples
samples <- smc_mallows_new_users(
  R_obs = data, type = "complete", n_items = n_items, metric = metric,
  leap_size = floor(n_items / 5), N = 100, Time = nrow(data) / num_new_obs,
  mcmc_kernel_app = 5, cardinalities = cardinalities,
  alpha_prop_sd = 0.1, lambda = 0.001, alpha_max = 1e6,
  num_new_obs = num_new_obs, verbose = TRUE
)

# Studying the structure of the output
str(samples)
```

---

sushi\_rankings

*Sushi Rankings*

---

**Description**

Complete rankings of 10 types of sushi from 5000 assessors (Kamishima 2003).

**Usage**

```
sushi_rankings
```

**Format**

An object of class `matrix` (inherits from `array`) with 5000 rows and 10 columns.

**References**
