Package ‘Boruta’

July 17, 2018

Title Wrapper Algorithm for All Relevant Feature Selection
Version 6.0.0
Depends ranger
Suggests mlbench, rFerns, randomForest, testthat, xgboost
Description An all relevant feature selection wrapper algorithm.
It finds relevant features by comparing original attributes’ importance with importance achievable at random, estimated using their permuted copies (shadows).

attStats

Description

attStats shows a summary of a Boruta run in an attribute-centred way. It produces a data frame containing some importance stats as well as the number of hits that attribute scored and the decision it was given.

Usage

attStats(x)

Arguments

x  
an object of a class Boruta, from which attribute stats should be extracted.

Value

A data frame containing, for each attribute that was originally in information system, mean, median, maximal and minimal importance, number of hits normalised to number of importance source runs performed and the decision copied from finalDecision.

Note

When using a Boruta object generated by a TentativeRoughFix, the resulting data frame will consist a rough-fixed decision.

x has to be made with holdHistory set to TRUE for this code to run.

Examples

```r
## Not run:
library(mlbench); data(Sonar)
# Takes some time, so be patient
Boruta(Class~.,data=Sonar,doTrace=2)->Bor.son
print(Bor.son)
stats<-attStats(Bor.son)
print(stats)
plot(normHits=meanImp,col=stats$decision,data=stats)

## End(Not run)
```
Boruta

Feature selection with the Boruta algorithm

Description

Boruta is an all relevant feature selection wrapper algorithm, capable of working with any classification method that output variable importance measure (VIM); by default, Boruta uses Random Forest. The method performs a top-down search for relevant features by comparing original attributes’ importance with importance achievable at random, estimated using their permuted copies, and progressively eliminating irrelevant features to stabilise that test.

Usage

Boruta(x, ...)

## Default S3 method:
Boruta(x, y, pValue = 0.01, mcAdj = TRUE, maxRuns = 100, doTrace = 0, holdHistory = TRUE, getImp = getImpRfZ, ...)

## S3 method for class 'formula'
Boruta(formula, data = .GlobalEnv, ...)

Arguments

x       data frame of predictors.
...
additional parameters passed to getImp.
y       response vector; factor for classification, numeric vector for regression, Surv object for survival (supports depends on importance adapter capabilities).
pValue confidence level. Default value should be used.
mcAdj if set to TRUE, a multiple comparisons adjustment using the Bonferroni method will be applied. Default value should be used; older (1.x and 2.x) versions of Boruta were effectively using FALSE.
maxRuns maximal number of importance source runs. You may increase it to resolve attributes left Tentative.
doTrace verbosity level. 0 means no tracing, 1 means reporting decision about each attribute as soon as it is justified, 2 means the same as 1, plus reporting each importance source run, 3 means the same as 2, plus reporting of hits assigned to yet undecided attributes.
holdHistory if set to TRUE, the full history of importance is stored and returned as the ImpHistory element of the result. Can be used to decrease a memory footprint of Boruta in case this side data is not used, especially when the number of attributes is huge; yet it disables plotting of such made Boruta objects and the use of the TentativeRoughFix function.
getImp function used to obtain attribute importance. The default is getImpRfZ, which runs random forest from the ranger package and gathers Z-scores of mean decrease accuracy measure. It should return a numeric vector of a size identical to the number of columns of its first argument, containing importance measure of respective attributes. Any order-preserving transformation of this measure will yield the same result. It is assumed that more important attributes get higher importance. +-Inf are accepted, NaNs and NAs are treated as 0s, with a warning.

formula alternatively, formula describing model to be analysed.

data in which to interpret formula.

Details

Boruta iteratively compares importances of attributes with importances of shadow attributes, created by shuffling original ones. Attributes that have significantly worst importance than shadow ones are being consecutively dropped. On the other hand, attributes that are significantly better than shadows are admitted to be Confirmed. Shadows are re-created in each iteration. Algorithm stops when only Confirmed attributes are left, or when it reaches maxRuns importance source runs. If the second scenario occurs, some attributes may be left without a decision. They are claimed Tentative. You may try to extend maxRuns or lower pValue to clarify them, but in some cases their importances do fluctuate too much for Boruta to converge. Instead, you can use TentativeRoughFix function, which will perform other, weaker test to make a final decision, or simply treat them as undecided in further analysis.

Value

An object of class boruta, which is a list with the following components:

finalDecision a factor of three value: Confirmed, Rejected or Tentative, containing final result of feature selection.

ImpHistory a data frame of importances of attributes gathered in each importance source run. Beside predictors’ importances, it contains maximal, mean and minimal importance of shadow attributes in each run. Rejected attributes get -Inf importance. Set to NULL if holdHistory was given FALSE.

timeTaken time taken by the computation.

impSource string describing the source of importance, equal to a comment attribute of the getImp argument.

call the original call of the Boruta function.

References

Examples

set.seed(777)
#Add some nonsense attributes to iris dataset by shuffling original attributes
iris.extended<-data.frame(iris,apply(iris[,-5],2,sample))
getConfirmedFormula

Export Boruta result as a formula

Description

Functions which convert the Boruta selection into a formula, so that it could be passed further to other functions.
getImpExtra

Usage

getConfirmedFormula(x)

getNonRejectedFormula(x)

Arguments

x an object of a class Boruta, made using a formula interface.

Value

Formula, corresponding to the Boruta results. getConfirmedFormula returns only Confirmed attributes, getNonRejectedFormula also adds Tentative ones.

Note

This operation is possible only when Boruta selection was invoked using a formula interface.

getImpExtra ranger Extra-trees importance adapters

Description

Those function is intended to be given to a getImp argument of Boruta function to be called by the Boruta algorithm as an importance source. getImpExtraZ generates default, normalized permutation importance, getImpExtraRaw raw permutation importance, finally getImpExtraGini generates Gini impurity importance.

Usage

getImpExtraZ(x, y, ntree = 500, num.trees = ntree, ...)

getImpExtraGini(x, y, ntree = 500, num.trees = ntree, ...)

getImpExtraRaw(x, y, ntree = 500, num.trees = ntree, ...)

Arguments

x data frame of predictors including shadows.

y response vector.

ntree Number of trees in the forest; copied into ranger’s native num.trees, put to retain transparent compatibility with randomForest.

num.trees Number of trees in the forest, as according to ranger’s nomenclature. If not given, set to ntree value. If both are given, num.trees takes precedence.

... parameters passed to the underlying ranger call; they are relayed from ... of Boruta. Note that these function work just by setting splitrule to "extratrees".
### getImpFerns

**Random Ferns importance**

**Description**

This function is intended to be given to a `getImp` argument of `Boruta` function to be called by the Boruta algorithm as an importance source.

**Usage**

```r
getImpFerns(x, y, ...)```

**Arguments**

- `x`: data frame of predictors including shadows.
- `y`: response vector.
- `...`: parameters passed to the underlying `rFerns` call; they are relayed from `...` of `Boruta`.

**Note**

Random Ferns importance calculation should be much faster than using Random Forest; however, one must first optimize the value of the `depth` parameter and it is quite likely that the number of ferns in the ensemble required for the importance to converge will be higher than the number of trees in case of Random Forest.

### getImpLegacyRf

**randomForest importance adapters**

**Description**

Those function is intended to be given to a `getImp` argument of `Boruta` function to be called by the Boruta algorithm as an importance source. `getImpLegacyRfZ` generates default, normalized permutation importance, `getImpLegacyRfRaw` raw permutation importance, finally `getImpLegacyRfGini` generates Gini index importance, all using `randomForest` as a Random Forest algorithm implementation.

**Usage**

```r
getImpLegacyRfZ(x, y, ...)
getImpLegacyRfRaw(x, y, ...)
getImpLegacyRfGini(x, y, ...)```
getImpRf

Arguments

x  data frame of predictors including shadows.
y  response vector.
...  parameters passed to the underlying randomForest call; they are relayed from ...
...  of Boruta.

Note

The getImpLegacyRfZ function was a default importance source in Boruta versions prior to 5.0; since then ranger Random Forest implementation is used instead of randomForest, for speed, memory conservation and an ability to utilise multithreading. Both importance sources should generally lead to the same results, yet there are differences.

Most notably, ranger by default treats factor attributes as ordered (and works very slow if instructed otherwise with respect.unordered.factors=TRUE); on the other hand it lifts 32 levels limit specific to randomForest. To this end, Boruta decision for factor attributes may be different.

Random Forest methods has two main parameters, number of attributes tried at each split and the number of trees in the forest; first one is called mtry in both implementations, but the second ntree in randomForest and num.trees in ranger. To this end, to maintain compatibility, getImpRf* functions still accept ntree parameter relaying it into num.trees. Still, both parameters take the same defaults in both implementations (square root of the number all attributes and 500 respectively).

Moreover, ranger brings some addition capabilities to Boruta, like analysis of survival problems or sticky variables which are always considered on splits.

Finally, the results for the same PRNG seed will be different.

Examples

set.seed(777)
#Add some nonsense attributes to iris dataset by shuffling original attributes
iris.extended<-data.frame(iris,apply(iris[, -5], 2, sample))
names(iris.extended)[6:9]<-paste("Nonsense",1:4,sep="")
#Run Boruta on this data
Boruta(Species~.,getImp=getImpLegacyRfZ,
data=iris.extended,doTrace=2)->Boruta.iris.extended
#Nonsense attributes should be rejected
print(Boruta.iris.extended)

getImpRf  ranger Random Forest importance adapters

Description

Those function is intended to be given to a getImp argument of Boruta function to be called by the Boruta algorithm as an importance source. getImpRfZ generates default, normalized permutation importance, getImpRfRaw raw permutation importance, finally getImpRfGini generates Gini index importance.
getImpXgboost

Usage

getImpRfZ(x, y, ntree = 500, num.trees = ntree, ...)

getImpRfGini(x, y, ntree = 500, num.trees = ntree, ...)

getImpRfRaw(x, y, ntree = 500, num.trees = ntree, ...)

Arguments

x  
data frame of predictors including shadows.

y  
response vector.

ntree  
Number of trees in the forest; copied into ranger’s native num.trees, put to retain transparent compatibility with randomForest.

num.trees  
Number of trees in the forest, as according to ranger’s nomenclature. If not given, set to ntree value. If both are given, num.trees takes precedence.

...  
parameters passed to the underlying ranger call; they are relayed from ... of Boruta.

Note

Prior to Boruta 5.0, getImpLegacyRfZ function was a default importance source in Boruta; see getImpLegacyRf for more details.

getImpXgboost  
Xgboost importance

Description

This function is intended to be given to a getImp argument of Boruta function to be called by the Boruta algorithm as an importance source.

Usage

getImpXgboost(x, y, nrounds = 5, verbose = 0, ...)

Arguments

x  
data frame of predictors including shadows.

y  
response vector.

nrounds  
Number of rounds; passed to the underlying xgboost call.

verbose  
Verbosity level of xgboost; either 0 (silent) or 1 (progress reports). Passed to the underlying xgboost call.

...  
other parameters passed to the underlying xgboost call. Similarly as nrounds and verbose, they are relayed from ... of Boruta. For convenience, this function sets nrounds to 5 and verbose to 0, but this can be overridden.
Note

Only dense matrix interface is supported; all predictions given to Boruta call have to be numeric (not integer). Categorical features should be split into indicator attributes. This functionality is inspired by the Python package BoostARoota by Chase DeHan. I have some doubts whether boosting importance can be used for all relevant selection without hitting substantial false negative rates; please consider this functionality experimental.

得到SelectedAttributes  Extract names of the selected attributes

Description

gSelectedAttributes returns a vector of names of attributes selected during a Boruta run.

Usage

gSelectedAttributes(x, withTentative = FALSE)

Arguments

x an object of a class Boruta, from which relevant attributes names should be extracted.

withTentative if set to TRUE, Tentative attributes will be also returned.

Value

A character vector with names of the relevant attributes.

Examples

## Not run:
data(iris)
#Takes some time, so be patient
Boruta(Species~.,data=iris,doTrace=2)->Bor.iris
print(Bor.iris)
print(gSelectedAttributes(Bor.iris))

## End(Not run)
plot.Boruta

Plot Boruta object

Description

Default plot method for Boruta objects, showing boxplots of attribute importances over run.

Usage

```r
## S3 method for class 'Boruta'
plot(x, colCode = c("green", "yellow", "red", "blue"),
     sort = TRUE, whichShadow = c(TRUE, TRUE, TRUE), col = NULL,
     xlab = "Attributes", ylab = "Importance", ...)
```

Arguments

- `x`: an object of a class Boruta.
- `colCode`: a vector containing colour codes for attribute decisions, respectively Confirmed, Tentative, Rejected and shadow.
- `sort`: controls whether boxplots should be ordered, or left in original order.
- `whichShadow`: a logical vector controlling which shadows should be drawn; switches respectively max shadow, mean shadow and min shadow.
- `xlab`: X axis label that will be passed to boxplot.
- `ylab`: Y axis label that will be passed to boxplot.
- `...`: additional graphical parameter that will be passed to boxplot.

Value

Invisible copy of `x`.

Note

If `col` is given and `sort` is TRUE, the `col` will be permuted, so that its order corresponds to attribute order in `ImpHistory`.

This function will throw an error when `x` lacks importance history, i.e., was made with `holdHistory` set to FALSE.

Examples

```r
## Not run:
library(mlbench); data(HouseVotes84)
na.omit(HouseVotes84) -> hvo
# Takes some time, so be patient
Boruta(Class~., data=hvo, doTrace=2) -> Bor.hvo
print(Bor.hvo)
```
```
plot(Bor.hvo)
## End(Not run)
```

### plotImpHistory

**Plot Boruta object as importance history**

**Description**

Alternative plot method for Boruta objects, showing matplot of attribute importances over run.

**Usage**

```r
plotImpHistory(x, colCode = c("green", "yellow", "red", "blue"), col = NULL,
               type = "l", lty = 1, pch = 0, xlab = "Classifier run",
               ylab = "Importance", ...
```

**Arguments**

- `x` an object of a class Boruta.
- `colCode` a vector containing colour codes for attribute decisions, respectively Confirmed, Tentative, Rejected and shadow.
- `col` standard col attribute, passed to `matplot`. If given, suppresses effects of `colCode`.
- `type` Plot type that will be passed to `matplot`.
- `lty` Line type that will be passed to `matplot`.
- `pch` Point mark type that will be passed to `matplot`.
- `xlab` X axis label that will be passed to `matplot`.
- `ylab` Y axis label that will be passed to `matplot`.
- `...` additional graphical parameter that will be passed to `matplot`.

**Value**

Invisible copy of `x`.

**Note**

This function will throw an error when `x` lacks importance history, i.e., was made with `holdHistory` set to `FALSE`.
print.Boruta

Examples

```r
## Not run:
library(mlbench); data(Sonar)
# Takes some time, so be patient
Boruta(Class~., data=Sonar, doTrace=2) -> Bor.son
print(Bor.son)
plotImpHistory(Bor.son)

## End(Not run)
```

print.Boruta

Print Boruta object

Description

Print method for the Boruta objects.

Usage

```r
## S3 method for class 'Boruta'
print(x, ...)
```

Arguments

- `x`: an object of a class `Boruta`.
- `...`: additional arguments passed to `print`.

Value

Invisible copy of `x`.

TentativeRoughFix

Rough fix of Tentative attributes

Description

In some circumstances (too short Boruta run, unfortunate mixing of shadow attributes, tricky dataset...), Boruta can leave some attributes Tentative. TentativeRoughFix performs a simplified, weaker test for judging such attributes.

Usage

```r
TentativeRoughFix(x, averageOver = Inf)
```
Arguments

- \( x \) an object of a class Boruta.
- averageOver Either number of last importance source runs to average over or Inf for averaging over the whole Boruta run.

Details

Function claims as Confirmed those attributes that have median importance higher than the median importance of maximal shadow attribute, and the rest as Rejected. Depending of the user choice, medians for the test are count over last round, all rounds or \( N \) last importance source runs.

Value

A Boruta class object with modified finalDecision element. Such object has few additional elements:
- originalDecision Original finalDecision.
- averageOver Copy of averageOver parameter.

Note

This function should be used only when strict decision is highly desired, because this test is much weaker than Boruta and can lower the confidence of the final result.

\( x \) has to be made with holdHistory set to TRUE for this code to run.
