DBI-package

Description

DBI defines an interface for communication between R and relational database management systems. All classes in this package are virtual and need to be extended by the various R/DBMS implementations (so-called DBI backends).

Definition

A DBI backend is an R package which imports the DBI and methods packages. For better or worse, the names of many existing backends start with ‘R’, e.g., RSQLite, RMySQL, RSQLServer; it is up to the backend author to adopt this convention or not.

DBI classes and methods

A backend defines three classes, which are subclasses of DBIDriver, DBIConnection, and DBIResult. The backend provides implementation for all methods of these base classes that are defined but not implemented by DBI. All methods defined in DBI are reexported (so that the package can be used without having to attach DBI), and have an ellipsis ... in their formals for extensibility.
Construction of the DBIDriver object

The backend must support creation of an instance of its DBIDriver subclass with a constructor function. By default, its name is the package name without the leading ‘R’ (if it exists), e.g., SQLite for the RSQLite package. However, backend authors may choose a different name. The constructor must be exported, and it must be a function that is callable without arguments. DBI recommends to define a constructor with an empty argument list.

Important generics: dbConnect(), dbGetQuery(), dbReadTable(), dbWriteTable(), dbDisconnect()
Formal specification (currently work in progress and incomplete): vignette("spec",package = "DBI")

Examples
RSQLite::SQLite()

dbAppendTable

Insert rows into a table

Description
The dbAppendTable() method assumes that the table has been created beforehand, e.g., with dbCreateTable(). The default implementation calls sqlAppendTableTemplate() and then dbExecute() with the param argument. Backends compliant to ANSI SQL 99 which use ? as a placeholder for prepared queries don’t need to override it. Backends with a different SQL syntax which use ? as a placeholder for prepared queries can override sqlAppendTable(). Other backends (with different placeholders or with entirely different ways to create tables) need to override the dbAppendTable() method.

Usage
dbAppendTable(conn, name, value, ..., row.names = NULL)
**Arguments**

- `conn`: A `DBIConnection` object, as returned by `dbConnect()`.
- `name`: Name of the table, escaped with `dbQuoteIdentifier()`.
- `value`: A data frame of values. The column names must be consistent with those in the target table in the database.
- `...`: Other arguments used by individual methods.
- `row.names`: Must be `NULL`.

**Details**

The `row.names` argument is not supported by this method. Process the values with `sqlRownamesToColumn()` before calling this method.

**See Also**

Other `DBIConnection` generics: `DBIConnection-class`, `dbCreateTable()`, `dbDataType()`, `dbDisconnect()`, `dbExecute()`, `dbExistsTable()`, `dbGetException()`, `dbGetInfo()`, `dbGetQuery()`, `dbIsReadOnly()`, `dbIsValid()`, `dbListFields()`, `dbListObjects()`, `dbListResults()`, `dbListTables()`, `dbReadTable()`, `dbRemoveTable()`, `dbSendQuery()`, `dbSendStatement()`, `dbWriteTable()`

**Examples**

```r
con <- dbConnect(RSQLite::SQLite(), "::memory:"
dbCreateTable(con, "iris", iris)
dbAppendTable(con, "iris", iris)
dbReadTable(con, "iris")
dbDisconnect(con)
```

---

**dbBind**

*Bind values to a parameterized/prepared statement*

**Description**

For parametrized or prepared statements, the `dbSendQuery()` and `dbSendStatement()` functions can be called with statements that contain placeholders for values. The `dbBind()` function binds these placeholders to actual values, and is intended to be called on the result set before calling `dbFetch()` or `dbGetRowsAffected()`.

**Usage**

`dbBind(res, params, ...)`

**Arguments**

- `res`: An object inheriting from `DBIResult`.
- `params`: A list of bindings, named or unnamed.
- `...`: Other arguments passed on to methods.
Details

DBI supports parametrized (or prepared) queries and statements via the \texttt{dbBind()} generic. Parametrized queries are different from normal queries in that they allow an arbitrary number of placeholders, which are later substituted by actual values. Parametrized queries (and statements) serve two purposes:

- The same query can be executed more than once with different values. The DBMS may cache intermediate information for the query, such as the execution plan, and execute it faster.
- Separation of query syntax and parameters protects against SQL injection.

The placeholder format is currently not specified by DBI; in the future, a uniform placeholder syntax may be supported. Consult the backend documentation for the supported formats. For automated testing, backend authors specify the placeholder syntax with the \texttt{placeholder} pattern tweak. Known examples are:

- \texttt{?} (positional matching in order of appearance) in RMySQL and RSQLite
- \texttt{$1} (positional matching by index) in RPostgres and RSQLite
- \texttt{:name} and \texttt{$name} (named matching) in RSQLite

Value

dbBind() returns the result set, invisibly, for queries issued by \texttt{dbSendQuery()} and also for data manipulation statements issued by \texttt{dbSendStatement()}. Calling \texttt{dbBind()} for a query without parameters raises an error. Binding too many or not enough values, or parameters with wrong names or unequal length, also raises an error. If the placeholders in the query are named, all parameter values must have names (which must not be empty or NA), and vice versa, otherwise an error is raised. The behavior for mixing placeholders of different types (in particular mixing positional and named placeholders) is not specified.

Calling \texttt{dbBind()} on a result set already cleared by \texttt{dbClearResult()} also raises an error.

Specification

DBI clients execute parametrized statements as follows:

1. Call \texttt{dbSendQuery()} or \texttt{dbSendStatement()} with a query or statement that contains placeholders, store the returned DBIResult object in a variable. Mixing placeholders (in particular, named and unnamed ones) is not recommended. It is good practice to register a call to \texttt{dbClearResult()} via \texttt{on.exit()} right after calling \texttt{dbSendQuery()} or \texttt{dbSendStatement()} (see the last enumeration item). Until \texttt{dbBind()} has been called, the returned result set object has the following behavior:
   - \texttt{dbFetch()} raises an error (for \texttt{dbSendQuery()})
   - \texttt{dbGetRowCount()} returns zero (for \texttt{dbSendQuery()})
   - \texttt{dbGetRowsAffected()} returns an integer NA (for \texttt{dbSendStatement()})
   - \texttt{dbIsValid()} returns TRUE
   - \texttt{dbHasCompleted()} returns FALSE
2. Construct a list with parameters that specify actual values for the placeholders. The list must be named or unnamed, depending on the kind of placeholders used. Named values are matched to named parameters, unnamed values are matched by position in the list of parameters. All elements in this list must have the same lengths and contain values supported by the backend; a `data.frame` is internally stored as such a list. The parameter list is passed to a call to `dbBind()` on the `DBIResult` object.

3. Retrieve the data or the number of affected rows from the `DBIResult` object.
   - For queries issued by `dbSendQuery()`, call `dbFetch()`.
   - For statements issued by `dbSendStatements()`, call `dbGetRowsAffected()`. (Execution begins immediately after the `dbBind()` call, the statement is processed entirely before the function returns.)

4. Repeat 2. and 3. as necessary.

5. Close the result set via `dbClearResult()`.

The elements of the `params` argument do not need to be scalars, vectors of arbitrary length (including length 0) are supported. For queries, calling `dbFetch()` binding such parameters returns concatenated results, equivalent to binding and fetching for each set of values and connecting via `rbind()`. For data manipulation statements, `dbGetRowsAffected()` returns the total number of rows affected if binding non-scalar parameters. `dbBind()` also accepts repeated calls on the same result set for both queries and data manipulation statements, even if no results are fetched between calls to `dbBind()`, for both queries and data manipulation statements.

If the placeholders in the query are named, their order in the `params` argument is not important.

At least the following data types are accepted on input (including NA):

- `integer`
- `numeric`
- `logical` for Boolean values
- `character`
- `factor` (bound as character, with warning)
- `Date`
- `POSIXct` timestamps
- `POSIXlt` timestamps
- lists of `raw` for blobs (with `NULL` entries for SQL NULL values)
- objects of type `blob::blob`

**See Also**

Other `DBIResult` generics: `DBIResult-class`, `dbClearResult()`, `dbColumnInfo()`, `dbFetch()`, `dbGetInfo()`, `dbGetRowCount()`, `dbGetRowsAffected()`, `dbGetStatement()`, `dbHasCompleted()`, `dbIsReadOnly()`, `dbIsValid()`, `dbQuoteIdentifier()`, `dbQuoteLiteral()`, `dbQuoteString()`, `dbUnquoteIdentifier()`
Examples

```r
con <- dbConnect(RSQLite::SQLite(), ":memory:")

dbWriteTable(con, "iris", iris)

# Using the same query for different values
iris_result <- dbSendQuery(con, "SELECT * FROM iris WHERE [Petal.Width] > ?")
dbBind(iris_result, list(2.3))
dbFetch(iris_result)
dbBind(iris_result, list(3))
dbFetch(iris_result)
dbClearResult(iris_result)

# Executing the same statement with different values at once
iris_result <- dbSendStatement(con, "DELETE FROM iris WHERE [Species] = $species")
dbBind(iris_result, list(species = c("setosa", "versicolor", "unknown")))
dbGetRowsAffected(iris_result)
dbClearResult(iris_result)

nrow(dbReadTable(con, "iris"))

dbDisconnect(con)
```

---

dbCanConnect  
*Check if a connection to a DBMS can be established*

Description

Like `dbConnect()`, but only checks validity without actually returning a connection object. The default implementation opens a connection and disconnects on success, but individual backends might implement a lighter-weight check.

Usage

```r
dbCanConnect(drv, ...)
```

Arguments

- `drv`  
an object that inherits from DBIDriver, or an existing DBIConnection object (in order to clone an existing connection).

- `...`  
authentication arguments needed by the DBMS instance; these typically include `user`, `password`, `host`, `port`, `dbname`, etc. For details see the appropriate DBIDriver.

Value

A scalar logical. If FALSE, the "reason" attribute indicates a reason for failure.
See Also

Other DBIResult generics: DBIResult-class, dbBind(), dbColumnInfo(), dbFetch(), dbGetInfo(),
dbGetRowCount(), dbGetRowsAffected(), dbGetStatement(), dbHasCompleted(), dbIsReadOnly(),
dbIsValid(), dbQuoteIdentifier(), dbQuoteLiteral(), dbQuoteString(), dbUnquoteIdentifier()
Examples

```r
con <- dbConnect(RSQLite::SQLite(), "::memory:")
rs <- dbSendQuery(con, "SELECT 1")
print(dbFetch(rs))
dbClearResult(rs)
dbDisconnect(con)
```

---

**dbColumnInfo**

Information about result types

**Description**

Produces a data.frame that describes the output of a query. The data.frame should have as many rows as there are output fields in the result set, and each column in the data.frame describes an aspect of the result set field (field name, type, etc.)

**Usage**

```r
dbColumnInfo(res, ...)
```

**Arguments**

- `res` An object inheriting from `DBIResult`.
- `...` Other arguments passed on to methods.

**Value**

`dbColumnInfo()` returns a data frame with at least two columns "name" and "type" (in that order) (and optional columns that start with a dot). The "name" and "type" columns contain the names and types of the R columns of the data frame that is returned from `dbFetch()`. The "type" column is of type `character` and only for information. Do not compute on the "type" column, instead use `dbFetch(res, n = 0)` to create a zero-row data frame initialized with the correct data types.

An attempt to query columns for a closed result set raises an error.

**Specification**

A column named `row.names` is treated like any other column.

The column names are always consistent with the data returned by `dbFetch()`. If the query returns unnamed columns, unique non-empty and non-NA names are assigned. In the case of a duplicate column name, the first occurrence retains the original name, and unique names are assigned for the other occurrences. Column names that correspond to SQL or R keywords are left unchanged.
See Also

Other DBIResult generics: `DBIResult-class`, `dbBind()`, `dbClearResult()`, `dbFetch()`, `dbGetInfo()`, `dbGetRowCount()`, `dbGetRowsAffected()`, `dbGetStatement()`, `dbHasCompleted()`, `dbIsReadOnly()`, `dbIsValid()`, `dbQuoteIdentifier()`, `dbQuoteLiteral()`, `dbQuoteString()`, `dbUnquoteIdentifier()`

Examples

```r
con <- dbConnect(RSQLite::SQLite(), ":memory:"
rs <- dbSendQuery(con, "SELECT 1 AS a, 2 AS b")
dbColumnInfo(rs)
dbFetch(rs)
dbClearResult(rs)
dbDisconnect(con)
```

---

dbConnect

Create a connection to a DBMS

Description

Connect to a DBMS going through the appropriate authentication procedure. Some implementations may allow you to have multiple connections open, so you may invoke this function repeatedly assigning its output to different objects. The authentication mechanism is left unspecified, so check the documentation of individual drivers for details. Use `dbCanConnect()` to check if a connection can be established.

Usage

```r
dbConnect(drv, ...)
```

Arguments

- `drv` an object that inherits from `DBIDriver`, or an existing `DBIConnection` object (in order to clone an existing connection).
- `...` authentication arguments needed by the DBMS instance; these typically include `user`, `password`, `host`, `port`, `dbname`, etc. For details see the appropriate `DBIDriver`.

Value

`dbConnect()` returns an S4 object that inherits from `DBIConnection`. This object is used to communicate with the database engine.

A `format()` method is defined for the connection object. It returns a string that consists of a single line of text.
Specification

DBI recommends using the following argument names for authentication parameters, with NULL default:

- **user** for the user name (default: current user)
- **password** for the password
- **host** for the host name (default: local connection)
- **port** for the port number (default: local connection)
- **dbname** for the name of the database on the host, or the database file name

The defaults should provide reasonable behavior, in particular a local connection for host = NULL. For some DBMS (e.g., PostgreSQL), this is different to a TCP/IP connection to localhost.

In addition, DBI supports the **bigint** argument that governs how 64-bit integer data is returned. The following values are supported:

- "integer": always return as integer, silently overflow
- "numeric": always return as numeric, silently round
- "character": always return the decimal representation as character
- "integer64": return as a data type that can be coerced using as.integer() (with warning on overflow), as.numeric() and as.character()

See Also

- dbDisconnect() to disconnect from a database.
- Other DBIDriver generics: DBIDriver-class, dbCanConnect(), dbDataType(), dbDriver(), dbGetInfo(), dbIsReadOnly(), dbIsValid(), dbListConnections()
- Other DBIConnector generics: DBIConnector-class, dbDataType(), dbGetConnectArgs(), dbIsReadOnly()

Examples

```r
# SQLite only needs a path to the database. (Here, ":memory:" is a special
# path that creates an in-memory database.) Other database drivers
# will require more details (like user, password, host, port, etc.)
con <- dbConnect(RSQLite::SQLite(), ":memory:"
con

dbListTables(con)

dbDisconnect(con)

# Bad, for subtle reasons:
# This code fails when RSQLite isn't loaded yet,
# because dbConnect() doesn't know yet about RSQLite.
dbListTables(con <- dbConnect(RSQLite::SQLite(), ":memory:"))
```
dbCreateTable

Create a table in the database

Description

The default dbCreateTable() method calls sqlCreateTable() and dbExecute(). Backends compliant to ANSI SQL 99 don’t need to override it. Backends with a different SQL syntax can override sqlCreateTable(), backends with entirely different ways to create tables need to override this method.

Usage

dbCreateTable(conn, name, fields, ..., row.names = NULL, temporary = FALSE)

Arguments

conn A DBIConnection object, as returned by dbConnect().
name Name of the table, escaped with dbQuoteIdentifier().
fields Either a character vector or a data frame.
   A named character vector: Names are column names, values are types.
   Names are escaped with dbQuoteIdentifier(). Field types are unescaped.
   A data frame: field types are generated using dbDataType().
... Other arguments used by individual methods.
row.names Must be NULL.
temporary If TRUE, will generate a temporary table statement.

Details

The row.names argument is not supported by this method. Process the values with sqlRownamesToColumn() before calling this method.

The argument order is different from the sqlCreateTable() method, the latter will be adapted in a later release of DBI.

See Also

Other DBIConnection generics: DBIConnection-class, dbAppendTable(), dbDataType(),
dbDisconnect(), dbExecute(), dbExistsTable(), dbGetException(), dbGetInfo(), dbGetQuery(),
dbIsReadOnly(), dbIsValid(), dbListFields(), dbListObjects(), dbListResults(), dbListTables(),
dbReadTable(), dbRemoveTable(), dbSendQuery(), dbSendStatement(), dbWriteTable()

Examples

con <- dbConnect(RSQLite::SQLite(), "::memory:"
dbCreateTable(con, "iris", iris)
dbReadTable(con, "iris")
dbDisconnect(con)
**dbDataType**

_Determine the SQL data type of an object_

**Description**

Returns an SQL string that describes the SQL data type to be used for an object. The default implementation of this generic determines the SQL type of an R object according to the SQL 92 specification, which may serve as a starting point for driver implementations. DBI also provides an implementation for data.frame which will return a character vector giving the type for each column in the dataframe.

**Usage**

```
dbDataType(dbObj, obj, ...)
```

**Arguments**

- **dbObj** A object inheriting from DBIDriver or DBIConnection
- **obj** An R object whose SQL type we want to determine.
- **...** Other arguments passed on to methods.

**Details**

The data types supported by databases are different than the data types in R, but the mapping between the primitive types is straightforward:

- Any of the many fixed and varying length character types are mapped to character vectors
- Fixed-precision (non-IEEE) numbers are mapped into either numeric or integer vectors.

Notice that many DBMS do not follow IEEE arithmetic, so there are potential problems with under/overflows and loss of precision.

**Value**

`dbDataType()` returns the SQL type that corresponds to the `obj` argument as a non-empty character string. For data frames, a character vector with one element per column is returned. An error is raised for invalid values for the `obj` argument such as a NULL value.

**Specification**

The backend can override the `dbDataType()` generic for its driver class. This generic expects an arbitrary object as second argument. To query the values returned by the default implementation, run `example(dbDataType,package = "DBI")`. If the backend needs to override this generic, it must accept all basic R data types as its second argument, namely logical, integer, numeric, character, dates (see Dates), date-time (see DateTime Classes), and difftime. If the database supports blobs, this method also must accept lists...
of raw vectors, and blob::blob objects. As-is objects (i.e., wrapped by I()) must be supported and return the same results as their unwrapped counterparts. The SQL data type for factor and ordered is the same as for character. The behavior for other object types is not specified.

All data types returned by `dbDataType()` are usable in an SQL statement of the form “CREATE TABLE test (a ...)”.

**See Also**

Other DBIDriver generics: DBIDriver-class, dbCanConnect(), dbConnect(), dbDriver(), dbGetInfo(), dbIsReadOnly(), dbIsValid(), dbListConnections()

Other DBIConnection generics: DBIConnection-class, dbAppendTable(), dbCreateTable(), dbDisconnect(), dbExecute(), dbExistsTable(), dbGetException(), dbGetInfo(), dbGetQuery(), dbIsReadOnly(), dbIsValid(), dbListFields(), dbListObjects(), dbListResults(), dbListTables(), dbReadTable(), dbRemoveTable(), dbSendQuery(), dbSendStatement(), dbWriteTable()

Other DBIConnector generics: DBIConnector-class, dbConnect(), dbGetConnectArgs(), dbIsReadOnly()

**Examples**

dbDataType(ANSI(), 1:5)
dbDataType(ANSI(), 1)
dbDataType(ANSI(), TRUE)
dbDataType(ANSI(), Sys.Date())
dbDataType(ANSI(), Sys.time())
dbDataType(ANSI(), Sys.time() - as.POSIXct(Sys.Date()))
dbDataType(ANSI(), c("x", "abc"))
dbDataType(ANSI(), list(raw(10), raw(20)))
dbDataType(ANSI(), I(3))

dbDataType(ANSI(), iris)

con <- dbConnect(RSQLite::SQLite(), "~memory:~")

dbDataType(con, 1:5)
dbDataType(con, 1)
dbDataType(con, TRUE)
dbDataType(con, Sys.Date())
dbDataType(con, Sys.time())
dbDataType(con, Sys.time() - as.POSIXct(Sys.Date()))
dbDataType(con, c("x", "abc"))
dbDataType(con, list(raw(10), raw(20)))
dbDataType(con, I(3))

ndbDataType(con, iris)

dbDisconnect(con)
**dbDisconnect**

Disconnect (close) a connection

**Description**

This closes the connection, discards all pending work, and frees resources (e.g., memory, sockets).

**Usage**

```
dbDisconnect(conn, ...)```

**Arguments**

- `conn`: A DBIConnection object, as returned by `dbConnect()`.
- `...`: Other parameters passed on to methods.

**Value**

`dbDisconnect()` returns TRUE, invisibly.

**Specification**

A warning is issued on garbage collection when a connection has been released without calling `dbDisconnect()`, but this cannot be tested automatically. A warning is issued immediately when calling `dbDisconnect()` on an already disconnected or invalid connection.

**See Also**

Other DBIConnection generics: `DBIConnection-class, dbAppendTable(), dbCreateTable(), dbDataType(), dbExecute(), dbExistsTable(), dbGetException(), dbGetInfo(), dbGetQuery(), dbIsReadOnly(), dbIsValid(), dbListFields(), dbListObjects(), dbListResults(), dbListTables(), dbReadTable(), dbRemoveTable(), dbSendQuery(), dbSendStatement(), dbWriteTable()`

**Examples**

```
con <- dbConnect(RSQLite::SQLite(), "::memory::")
dbDisconnect(con)
```
\texttt{dbExecute} \hspace{1cm} \textit{Execute an update statement, query number of rows affected, and then close result set}

\section*{Description}

Executes a statement and returns the number of rows affected. \texttt{dbExecute()} comes with a default implementation (which should work with most backends) that calls \texttt{dbSendStatement()}, then \texttt{dbGetRowsAffected()}, ensuring that the result is always freed by \texttt{dbClearResult()}.

\section*{Usage}

\texttt{dbExecute(conn, statement, ...)}

\section*{Arguments}

- \texttt{conn} \hspace{1cm} A \texttt{DBIConnection} object, as returned by \texttt{dbConnect()}.
- \texttt{statement} \hspace{1cm} a character string containing SQL.
- \texttt{...} \hspace{1cm} Other parameters passed on to methods.

\section*{Details}

You can also use \texttt{dbExecute()} to call a stored procedure that performs data manipulation or other actions that do not return a result set. To execute a stored procedure that returns a result set use \texttt{dbGetQuery()} instead.

\section*{Value}

\texttt{dbExecute()} always returns a scalar numeric that specifies the number of rows affected by the statement. An error is raised when issuing a statement over a closed or invalid connection, if the syntax of the statement is invalid, or if the statement is not a non-\texttt{NA} string.

\section*{Implementation notes}

Subclasses should override this method only if they provide some sort of performance optimization.

\section*{Additional arguments}

The following arguments are not part of the \texttt{dbExecute()} generic (to improve compatibility across backends) but are part of the DBI specification:

- \texttt{params} (default: \texttt{NULL})
- \texttt{immediate} (default: \texttt{NULL})

They must be provided as named arguments. See the "Specification" sections for details on their usage.
Specification

The param argument allows passing query parameters, see dbBind() for details.

Specification for the immediate argument

The immediate argument supports distinguishing between "direct" and "prepared" APIs offered by many database drivers. Passing immediate = TRUE leads to immediate execution of the query or statement, via the "direct" API (if supported by the driver). The default NULL means that the backend should choose whatever API makes the most sense for the database, and (if relevant) tries the other API if the first attempt fails. A successful second attempt should result in a message that suggests passing the correct immediate argument. Examples for possible behaviors:

1. DBI backend defaults to immediate = TRUE internally
   (a) A query without parameters is passed: query is executed
   (b) A query with parameters is passed:
      i. params not given: rejected immediately by the database because of a syntax error in the query, the backend tries immediate = FALSE (and gives a message)
      ii. params given: query is executed using immediate = FALSE

2. DBI backend defaults to immediate = FALSE internally
   (a) A query without parameters is passed:
      i. simple query: query is executed
      ii. "special" query (such as setting a config options): fails, the backend tries immediate = TRUE (and gives a message)
   (b) A query with parameters is passed:
      i. params not given: waiting for parameters via dbBind()
      ii. params given: query is executed

See Also

For queries: dbSendQuery() and dbGetQuery().

Other DBIConnection generics: DBIConnection-class, dbAppendTable(), dbCreateTable(), dbDataType(), dbDisconnect(), dbExistsTable(), dbGetException(), dbGetInfo(), dbGetQuery(), dbIsReadOnly(), dbIsValid(), dbListFields(), dblistObjects(), dbListResults(), dbListTables(), dbReadTable(), dbRemoveTable(), dbSendQuery(), dbSendStatement(), dbWriteTable()

Examples

con <- dbConnect(RSQLite::SQLite(), "::memory:"

dbWriteTable(con, "cars", head(cars, 3))
dbReadTable(con, "cars")  # there are 3 rows
dbExecute( 
  con, 
  "INSERT INTO cars (speed, dist) VALUES (1, 1), (2, 2), (3, 3)"
)
dbReadTable(con, "cars")  # there are now 6 rows
# Pass values using the param argument:
dbExecute(
  con,
  "INSERT INTO cars (speed, dist) VALUES (?, ?)",
  params = list(4:7, 5:8)
)
dbReadTable(con, "cars")  # there are now 10 rows

dbDisconnect(con)

---

dbExistsTable  

 Does a table exist?

Description

Returns if a table given by name exists in the database.

Usage

dbExistsTable(conn, name, ...)

Arguments

  conn       A DBIConnection object, as returned by dbConnect().
  name       A character string specifying a DBMS table name.
  ...        Other parameters passed on to methods.

Value

dbExistsTable() returns a logical scalar, TRUE if the table or view specified by the name argument exists, FALSE otherwise.

This includes temporary tables if supported by the database.

An error is raised when calling this method for a closed or invalid connection. An error is also raised if name cannot be processed with dbQuoteIdentifier() or if this results in a non-scalar.

Specification

The name argument is processed as follows, to support databases that allow non-syntactic names for their objects:

- If an unquoted table name as string: dbExistsTable() will do the quoting, perhaps by calling dbQuoteIdentifier(conn,x = name)
- If the result of a call to dbQuoteIdentifier(): no more quoting is done

For all tables listed by dbListTables(), dbExistsTable() returns TRUE.

dbDataType(), dbDisconnect(), dbExecute(), dbGetException(), dbGetInfo(), dbGetQuery(),
dbIsReadOnly(), dbIsValid(), dbListFields(), dblistObjects(), dbListResults(), dbListTables(),
dbReadTable(), dbRemoveTable(), dbSendQuery(), dbSendStatement(), dbWriteTable()

Examples

con <- dbConnect(RSQLite::SQLite(), "::memory:"

dbExistsTable(con, "iris")
dbWriteTable(con, "iris", iris)
dbExistsTable(con, "iris")

dbDisconnect(con)

dbFetch Fetch records from a previously executed query

Description

Fetch the next n elements (rows) from the result set and return them as a data.frame.

Usage

dbFetch(res, n = -1, ...)
fetch(res, n = -1, ...)

Arguments

res An object inheriting from DBIResult, created by dbSendQuery().
n maximum number of records to retrieve per fetch. Use n = -1 or n = Inf to retrieve all pending records. Some implementations may recognize other special values.
... Other arguments passed on to methods.

Details

fetch() is provided for compatibility with older DBI clients - for all new code you are strongly encouraged to use dbFetch(). The default implementation for dbFetch() calls fetch() so that it is compatible with existing code. Modern backends should implement for dbFetch() only.
Value

dbFetch() always returns a `data.frame` with as many rows as records were fetched and as
many columns as fields in the result set, even if the result is a single value or has one or zero
rows. An attempt to fetch from a closed result set raises an error. If the `n` argument is not
an atomic whole number greater or equal to -1 or Inf, an error is raised, but a subsequent
call to `dbFetch()` with proper `n` argument succeeds. Calling `dbFetch()` on a result set from
a data manipulation query created by `dbSendStatement()` can be fetched and return an
empty data frame, with a warning.

Specification

Fetching multi-row queries with one or more columns by default returns the entire result. Multi-row queries can also be fetched progressively by passing a whole number (integer or numeric) as the `n` argument. A value of Inf for the `n` argument is supported and also returns the full result. If more rows than available are fetched, the result is returned in full without warning. If fewer rows than requested are returned, further fetches will return a data frame with zero rows. If zero rows are fetched, the columns of the data frame are still fully typed. Fetching fewer rows than available is permitted, no warning is issued when clearing the result set.

A column named `row.names` is treated like any other column.

The column types of the returned data frame depend on the data returned:

- `integer` (or coercible to an integer) for integer values between \(-2^{31}\) and \(2^{31} - 1\), with NA for SQL NULL values
- `numeric` for numbers with a fractional component, with NA for SQL NULL values
- `logical` for Boolean values (some backends may return an integer); with NA for SQL NULL values
- `character` for text, with NA for SQL NULL values
- lists of `raw` for blobs with NULL entries for SQL NULL values
- coercible using `as.Date()` for dates, with NA for SQL NULL values (also applies to the return value of the SQL function `current_date`)
- coercible using `hms::as_hms()` for times, with NA for SQL NULL values (also applies to the return value of the SQL function `current_time`)
- coercible using `as.POSIXct()` for timestamps, with NA for SQL NULL values (also applies to the return value of the SQL function `current_timestamp`)

If dates and timestamps are supported by the backend, the following R types are used:

- `Date` for dates (also applies to the return value of the SQL function `current_date`)
- `POSIXct` for timestamps (also applies to the return value of the SQL function `current_timestamp`)

R has no built-in type with lossless support for the full range of 64-bit or larger integers. If 64-bit integers are returned from a query, the following rules apply:

- Values are returned in a container with support for the full range of valid 64-bit values
  (such as the `integer64` class of the `bit64` package)
Coercion to numeric always returns a number that is as close as possible to the true value.

Loss of precision when converting to numeric gives a warning.

Conversion to character always returns a lossless decimal representation of the data.

See Also

Close the result set with `dbClearResult()` as soon as you finish retrieving the records you want.

Other DBIResult generics: `DBIResult-class`, `dbBind()`, `dbClearResult()`, `dbColumnInfo()`, `dbGetInfo()`, `dbGetRowCount()`, `dbGetRowsAffected()`, `dbGetStatement()`, `dbHasCompleted()`, `dbIsReadOnly()`, `dbIsValid()`, `dbQuoteIdentifier()`, `dbQuoteLiteral()`, `dbQuoteString()`, `dbUnquoteIdentifier()`

Examples

```r
con <- dbConnect(RSQLite::SQLite(), "::memory:"

dbWriteTable(con, "mtcars", mtcars)

# Fetch all results
rs <- dbSendQuery(con, "SELECT * FROM mtcars WHERE cyl = 4")
dbFetch(rs)
dbClearResult(rs)

# Fetch in chunks
rs <- dbSendQuery(con, "SELECT * FROM mtcars")
while (!dbHasCompleted(rs)) {
  chunk <- dbFetch(rs, 10)
  print(nrow(chunk))
}

dbClearResult(rs)
dbDisconnect(con)
```

---

**Description**

Returns the arguments stored in a `DBIConnector` object for inspection, optionally evaluating them. This function is called by `dbConnect()` and usually does not need to be called directly.

**Usage**

```r
dbGetConnectArgs(drv, eval = TRUE, ...)
```
Arguments

drv A object inheriting from DBIConnector.

eval Set to FALSE to return the functions that generate the argument instead of evaluating them.

... Other arguments passed on to methods. Not otherwise used.

See Also

Other DBIConnector generics: DBIConnector-class, dbConnect(), dbDataType(), dbIsReadOnly()

Examples

cnr <- new("DBIConnector",
   .drv = RSQLite::SQLite(),
   .conn_args = list(dbname = "::memory:", password = function() "supersecret")
)
dbGetConnectArgs(cnr)
dbGetConnectArgs(cnr, eval = FALSE)

---

dbGetInfo Get DBMS metadata

Description

Retrieves information on objects of class DBIDriver, DBIConnection or DBIResult.

Usage

dbGetInfo(dbObj, ...)

Arguments

dbObj An object inheriting from DBIObj ect, i.e. DBIDriver, DBIConnection, or a DBIResult

... Other arguments to methods.

Value

For objects of class DBIDriver, dbGetInfo() returns a named list that contains at least the following components:

- driver.version: the package version of the DBI backend,
- client.version: the version of the DBMS client library.

For objects of class DBIConnection, dbGetInfo() returns a named list that contains at least the following components:

- db.version: version of the database server,
**dbname**: database name,

**username**: username to connect to the database,

**host**: hostname of the database server,

**port**: port on the database server. It must not contain a `password` component. Components that are not applicable should be set to `NA`.

For objects of class `DBIResult`, `dbGetInfo()` returns a named list that contains at least the following components:

- **statement**: the statement used with `dbSendQuery()` or `dbExecute()`, as returned by `dbGetStatement()`,
- **row.count**: the number of rows fetched so far (for queries), as returned by `dbGetRowCount()`,
- **rows.affected**: the number of rows affected (for statements), as returned by `dbGetRowsAffected()`,
- **has.completed**: a logical that indicates if the query or statement has completed, as returned by `dbHasCompleted()`.

**Implementation notes**

The default implementation for `DBIResult` objects constructs such a list from the return values of the corresponding methods, `dbGetStatement()`, `dbGetRowCount()`, `dbGetRowsAffected()`, and `dbHasCompleted()`.

**See Also**

Other `DBIDriver` generics: `DBIDriver-class`, `dbCanConnect()`, `dbConnect()`, `dbDataType()`, `dbDriver()`, `dbIsReadOnly()`, `dbIsValid()`, `dbListConnections()`.

Other `DBIResult` generics: `DBIResult-class`, `dbBind()`, `dbClearResult()`, `dbColumnInfo()`, `dbFetch()`, `dbGetRowCount()`, `dbGetRowsAffected()`, `dbGetStatement()`, `dbHasCompleted()`, `dbIsReadOnly()`, `dbIsValid()`, `dbQuoteIdentifier()`, `dbQuoteLiteral()`, `dbQuoteString()`, `dbUnquoteIdentifier()`.

---

**dbGetQuery**  
*Send query, retrieve results and then clear result set*

**Description**

Returns the result of a query as a data frame. `dbGetQuery()` comes with a default implementation (which should work with most backends) that calls `dbSendQuery()`, then `dbFetch()`, ensuring that the result is always free-d by `dbClearResult()`.

**Usage**

`dbGetQuery(conn, statement, ...)`
Arguments

- **conn**: A DBIConnection object, as returned by `dbConnect()`.
- **statement**: a character string containing SQL.
- ... Other parameters passed on to methods.

Details

This method is for **SELECT** queries only (incl. other SQL statements that return a **SELECT**-alike result, e. g. execution of a stored procedure).

To execute a stored procedure that does not return a result set, use `dbExecute()`.

Some backends may support data manipulation statements through this method for compatibility reasons. However, callers are strongly advised to use `dbExecute()` for data manipulation statements.

Value

`dbGetQuery()` always returns a `data.frame` with as many rows as records were fetched and as many columns as fields in the result set, even if the result is a single value or has one or zero rows. An error is raised when issuing a query over a closed or invalid connection, if the syntax of the query is invalid, or if the query is not a non-NA string. If the `n` argument is not an atomic whole number greater or equal to -1 or Inf, an error is raised, but a subsequent call to `dbGetQuery()` with proper `n` argument succeeds.

Implementation notes

Subclasses should override this method only if they provide some sort of performance optimization.

Additional arguments

The following arguments are not part of the `dbGetQuery()` generic (to improve compatibility across backends) but are part of the DBI specification:

- **n** (default: -1)
- **params** (default: `NULL`)
- **immediate** (default: `NULL`)

They must be provided as named arguments. See the "Specification" and "Value" sections for details on their usage.

Specification

A column named **row.names** is treated like any other column.

The `n` argument specifies the number of rows to be fetched. If omitted, fetching multi-row queries with one or more columns returns the entire result. A value of `Inf` for the `n` argument is supported and also returns the full result. If more rows than available are fetched (by passing a too large value for `n`), the result is returned in full without warning. If zero rows...
are requested, the columns of the data frame are still fully typed. Fetching fewer rows than available is permitted, no warning is issued.

The `param` argument allows passing query parameters, see `dbBind()` for details.

**Specification for the immediate argument**

The `immediate` argument supports distinguishing between "direct" and "prepared" APIs offered by many database drivers. Passing `immediate = TRUE` leads to immediate execution of the query or statement, via the "direct" API (if supported by the driver). The default `NULL` means that the backend should choose whatever API makes the most sense for the database, and (if relevant) tries the other API if the first attempt fails. A successful second attempt should result in a message that suggests passing the correct `immediate` argument. Examples for possible behaviors:

1. DBI backend defaults to `immediate = TRUE` internally
   (a) A query without parameters is passed: query is executed
   (b) A query with parameters is passed:
      i. `params` not given: rejected immediately by the database because of a syntax error in the query, the backend tries `immediate = FALSE` (and gives a message)
      ii. `params` given: query is executed using `immediate = FALSE`

2. DBI backend defaults to `immediate = FALSE` internally
   (a) A query without parameters is passed:
      i. simple query: query is executed
      ii. "special" query (such as setting a config options): fails, the backend tries `immediate = TRUE` (and gives a message)
   (b) A query with parameters is passed:
      i. `params` not given: waiting for parameters via `dbBind()`
      ii. `params` given: query is executed

See Also

For updates: `dbSendStatement()` and `dbExecute()`.

Other DBIConnection generics: `DBIConnection-class, dbAppendTable(), dbCreateTable(), dbDataType(), dbDisconnect(), dbExecute(), dbExistsTable(), dbGetException(), dbGetInfo(), dbIsReadOnly(), dbIsValid(), dbListFields(), dbListObjects(), dbListResults(), dbListTables(), dbReadTable(), dbRemoveTable(), dbSendQuery(), dbSendStatement(), dbWriteTable()`

Examples

```r
con <- dbConnect(RSQLite::SQLite(), "memory:"

dbWriteTable(con, "mtcars", mtcars)
dbGetQuery(con, "SELECT * FROM mtcars")
dbGetQuery(con, "SELECT * FROM mtcars", n = 6)

# Pass values using the param argument:
# (This query runs eight times, once for each different
# parameter. The resulting rows are combined into a single
```
dbGetRowCount

# data frame.
dbGetQuery(
  con,
  "SELECT COUNT(*) FROM mtcars WHERE cyl = ?",
  params = list(1:8)
)

dbDisconnect(con)

dbGetRowCount

The number of rows fetched so far

Description

Returns the total number of rows actually fetched with calls to `dbFetch()` for this result set.

Usage

dbGetRowCount(res, ...)

Arguments

res An object inheriting from `DBIResult`.
...

Other arguments passed on to methods.

Value

dbGetRowCount() returns a scalar number (integer or numeric), the number of rows fetched so far. After calling `dbSendQuery()`, the row count is initially zero. After a call to `dbFetch()` without limit, the row count matches the total number of rows returned. Fetching a limited number of rows increases the number of rows by the number of rows returned, even if fetching past the end of the result set. For queries with an empty result set, zero is returned even after fetching. For data manipulation statements issued with `dbSendStatement()`, zero is returned before and after calling `dbFetch()`. Attempting to get the row count for a result set cleared with `dbClearResult()` gives an error.

See Also

Other `DBIResult` generics: `DBIResult-class`, `dbBind()`, `dbClearResult()`, `dbColumnInfo()`, `dbFetch()`, `dbGetInfo()`, `dbGetRowsAffected()`, `dbGetStatement()`, `dbHasCompleted()`, `dbIsReadOnly()`, `dbIsValid()`, `dbQuoteIdentifier()`, `dbQuoteLiteral()`, `dbQuoteString()`, `dbUnquoteIdentifier()`
Examples

```r
con <- dbConnect(RSQLite::SQLite(), "":memory:")

dbWriteTable(con, "mtcars", mtcars)
rs <- dbSendQuery(con, "SELECT * FROM mtcars")

dbGetRowCount(rs)
ret1 <- dbFetch(rs, 10)
dbGetRowCount(rs)
ret2 <- dbFetch(rs)
dbGetRowCount(rs)
nrow(ret1) + nrow(ret2)

dbClearResult(rs)
dbDisconnect(con)
```

---

**dbGetRowsAffected**  
*The number of rows affected*

Description

This method returns the number of rows that were added, deleted, or updated by a data manipulation statement.

Usage

```r
dbGetRowsAffected(res, ...)
```

Arguments

- `res`  
  An object inheriting from DBIResult.
- `...`  
  Other arguments passed on to methods.

Value

`dbGetRowsAffected()` returns a scalar number (integer or numeric), the number of rows affected by a data manipulation statement issued with `dbSendStatement()`. The value is available directly after the call and does not change after calling `dbFetch()`. For queries issued with `dbSendQuery()`, zero is returned before and after the call to `dbFetch()`. Attempting to get the rows affected for a result set cleared with `dbClearResult()` gives an error.

See Also

Other DBIResult generics: DBIResult-class, `dbBind()`, `dbClearResult()`, `dbColumnInfo()`, `dbFetch()`, `dbGetInfo()`, `dbGetRowCount()`, `dbGetStatement()`, `dbHasCompleted()`, `dbIsReadOnly()`, `dbIsValid()`, `dbQuoteIdentifier()`, `dbQuoteLiteral()`, `dbQuoteString()`, `dbUnquoteIdentifier()`
Examples

```r
con <- dbConnect(RSQLite::SQLite(), "::memory::")

dbWriteTable(con, "mtcars", mtcars)
rs <- dbSendStatement(con, "DELETE FROM mtcars")
dbGetRowsAffected(rs)
nrow(mtcars)

dbClearResult(rs)
dbDisconnect(con)
```

---

**dbGetStatement**

*Get the statement associated with a result set*

### Description

Returns the statement that was passed to `dbSendQuery()` or `dbSendStatement()`.

### Usage

```r
dbGetStatement(res, ...)
```

### Arguments

- `res` An object inheriting from `DBIResult`
- `...` Other arguments passed on to methods.

### Value

`dbGetStatement()` returns a string, the query used in either `dbSendQuery()` or `dbSendStatement()`. Attempting to query the statement for a result set cleared with `dbClearResult()` gives an error.

### See Also

Other `DBIResult` generics: `DBIResult-class`, `dbBind()`, `dbClearResult()`, `dbColumnInfo()`, `dbFetch()`, `dbGetInfo()`, `dbGetRowCount()`, `dbGetRowsAffected()`, `dbHasCompleted()`, `dbIsReadOnly()`, `dbIsValid()`, `dbQuoteIdentifier()`, `dbQuoteLiteral()`, `dbQuoteString()`, `dbUnquoteIdentifier()`

### Examples

```r
con <- dbConnect(RSQLite::SQLite(), "::memory::")

dbWriteTable(con, "mtcars", mtcars)
rs <- dbSendQuery(con, "SELECT * FROM mtcars")
dbGetStatement(rs)

dbClearResult(rs)
dbDisconnect(con)
```
dbHasCompleted Completion status

Description

This method returns if the operation has completed. A SELECT query is completed if all rows have been fetched. A data manipulation statement is always completed.

Usage

dbHasCompleted(res, ...)

Arguments

res An object inheriting from DBIResult.
...
Other arguments passed on to methods.

Value

dbHasCompleted() returns a logical scalar. For a query initiated by dbSendQuery() with non-empty result set, dbHasCompleted() returns FALSE initially and TRUE after calling dbFetch() without limit. For a query initiated by dbSendStatement(), dbHasCompleted() always returns TRUE. Attempting to query completion status for a result set cleared with dbClearResult() gives an error.

Specification

The completion status for a query is only guaranteed to be set to FALSE after attempting to fetch past the end of the entire result. Therefore, for a query with an empty result set, the initial return value is unspecified, but the result value is TRUE after trying to fetch only one row. Similarly, for a query with a result set of length n, the return value is unspecified after fetching n rows, but the result value is TRUE after trying to fetch only one more row.

See Also

Other DBIResult generics: DBIResult-class, dbBind(), dbClearResult(), dbColumnInfo(), dbFetch(), dbGetInfo(), dbGetRowCount(), dbGetRowsAffected(), dbGetStatement(), dbIsReadOnly(), dbIsValid(), dbQuoteIdentifier(), dbQuoteLiteral(), dbQuoteString(), dbUnquoteIdentifier()

Examples

con <- dbConnect(RSQLite::SQLite(), "::memory:"

dWriteTable(con, "mtcars", mtcars)
rs <- dbSendQuery(con, "SELECT * FROM mtcars")

dbHasCompleted(rs)
ret1 <- dbFetch(rs, 10)
dbHasCompleted(rs)
```r
cont <- dbConnect(RSQLite::SQLite(), "memory:"
con

dbDisconnect(con)
```

## Not run:
```r
cont <- dbConnect(RPostgreSQL::PostgreSQL(), "username", "password"
con

dbDisconnect(con)
```

## End(Not run)
DBIConnector-class

**Description**

Wraps objects of the DBIDriver class to include connection options. The purpose of this class is to store both the driver and the connection options. A database connection can be established with a call to `dbConnect()`, passing only that object without additional arguments.

**Details**

To prevent leakage of passwords and other credentials, this class supports delayed evaluation. All arguments can optionally be a function (callable without arguments). In such a case, the function is evaluated transparently when connecting in `dbGetConnectArgs()`.

**See Also**

Other DBI classes: `DBIConnection-class`, `DBIDriver-class`, `DBIObject-class`, `DBIResult-class`
Other DBIConnector generics: `dbConnect()`, `dbDataType()`, `dbGetConnectArgs()`, `dbIsReadOnly()`

**Examples**

```r
# Create a connector:
cnr <- new("DBIConnector",
  .drv = RSQLite::SQLite(),
  .conn_args = list(dbname = "::memory:"))
cnr

# Establish a connection through this connector:
con <- dbConnect(cnr)
con

# Access the database through this connection:
dbGetQuery(con, "SELECT 1 AS a")
```

--

DBIDriver-class

**Description**

Base class for all DBMS drivers (e.g., RSQLite, MySQL, PostgreSQL). The virtual class `DBIDriver` defines the operations for creating connections and defining data type mappings. Actual driver classes, for instance `RPostgres`, `RMariaDB`, etc. implement these operations in a DBMS-specific manner.
**DBIObject-class**

**See Also**

Other DBI classes: **DBIConnection-class**, **DBIConnector-class**, **DBIObject-class**, **DBIResult-class**

Other DBIDriver generics: **dbCanConnect()**, **dbConnect()**, **dbDataType()**, **dbDriver()**, **dbGetInfo()**, **dbIsReadOnly()**, **dbIsValid()**, **dbListConnections()**

---

**Description**

Base class for all other DBI classes (e.g., drivers, connections). This is a virtual Class: No objects may be created from it.

**Details**

More generally, the DBI defines a very small set of classes and generics that allows users and applications access DBMS with a common interface. The virtual classes are **DBIDriver** that individual drivers extend, **DBIConnection** that represent instances of DBMS connections, and **DBIResult** that represent the result of a DBMS statement. These three classes extend the basic class of **DBIObject**, which serves as the root or parent of the class hierarchy.

**Implementation notes**

An implementation MUST provide methods for the following generics:

- **dbGetInfo()**.

It MAY also provide methods for:

- **summary()**. Print a concise description of the object. The default method invokes `dbGetInfo(dbObj)` and prints the name-value pairs one per line. Individual implementations may tailor this appropriately.

**See Also**

Other DBI classes: **DBIConnection-class**, **DBIConnector-class**, **DBIDriver-class**, **DBIResult-class**

**Examples**

```r
drv <- RSQLite::SQLite()
con <- dbConnect(drv)

rs <- dbSendQuery(con, "SELECT 1")
is(drv, "DBIObject")  ## True
is(con, "DBIObject")  ## True
is(rs, "DBIObject")

dbClearResult(rs)
dbDisconnect(con)
```
Description

This virtual class describes the result and state of execution of a DBMS statement (any statement, query or non-query). The result set keeps track of whether the statement produces output how many rows were affected by the operation, how many rows have been fetched (if statement is a query), whether there are more rows to fetch, etc.

Implementation notes

Individual drivers are free to allow single or multiple active results per connection.

The default show method displays a summary of the query using other DBI generics.

See Also

Other DBI classes: DBIConnection-class, DBIConnector-class, DBIDriver-class, DBIObject-class

Other DBIResult generics: dbBind(), dbClearResult(), dbColumnInfo(), dbFetch(), dbGetInfo(), dbGetRowCount(), dbGetRowsAffected(), dbGetStatement(), dbHasCompleted(), dbIsReadOnly(), dbIsValid(), dbQuoteIdentifier(), dbQuoteLiteral(), dbQuoteString(), dbUnquoteIdentifier()

---

**dbIsReadOnly**

*Is this DBMS object read only?*

Description

This generic tests whether a database object is read only.

Usage

dbIsReadOnly(dbObj, ...)

Arguments

- **dbObj**: An object inheriting from DBIOobject, i.e. DBIDriver, DBIConnection, or a DBIResult
- **...**: Other arguments to methods.
See Also

Other DBIDriver generics: DBIDriver-class, dbCanConnect(), dbConnect(), dbDataType(), dbDriver(), dbGetInfo(), dbIsValid(), dblistConnections()

Other DBIConnection generics: DBIConnection-class, dbAppendTable(), dbCreateTable(), dbDataType(), dbDisconnect(), dbExecute(), dbExistsTable(), dbGetException(), dbGetInfo(), dbGetQuery(), dbIsValid(), dbListFields(), dbListObjects(), dbListResults(), dbListTables(), dbReadTable(), dbRemoveTable(), dbSendQuery(), dbSendStatement(), dbWriteTable()

Other DBIResult generics: DBIResult-class, dbBind(), dbClearResult(), dbColumnInfo(), dbFetch(), dbGetInfo(), dbGetRowCount(), dbGetRowsAffected(), dbGetStatement(), dbHasCompleted(), dbIsValid(), dbQuoteIdentifier(), dbQuoteLiteral(), dbQuoteString(), dbUnquoteIdentifier()

Other DBIConnector generics: DBIConnector-class, dbConnect(), dbDataType(), dbGetConnectArgs()

Examples

dbIsReadOnly(ANSI())

---

dbIsValid Is this DBMS object still valid?

Description

This generic tests whether a database object is still valid (i.e. it hasn’t been disconnected or cleared).

Usage

dbIsValid(dbObj, ...)

Arguments

dbObj An object inheriting from DBIObject, i.e. DBIDriver, DBIConnection, or a DBIResult

... Other arguments to methods.

Value

dbIsValid() returns a logical scalar, TRUE if the object specified by dbObj is valid, FALSE otherwise. A DBIConnection object is initially valid, and becomes invalid after disconnecting with dbDisconnect(). For an invalid connection object (e.g., for some drivers if the object is saved to a file and then restored), the method also returns FALSE. A DBIResult object is valid after a call to dbSendQuery(), and stays valid even after all rows have been fetched; only clearing it with dbClearResult() invalidates it. A DBIResult object is also valid after a call to dbSendStatement(), and stays valid after querying the number of rows affected; only clearing it with dbClearResult() invalidates it. If the connection to the database system is dropped (e.g., due to connectivity problems, server failure, etc.), dbIsValid() should return FALSE. This is not tested automatically.
See Also

Other DBIDriver generics: DBIDriver-class, dbCanConnect(), dbConnect(), dbDataType(), dbDriver(), dbGetInfo(), dbIsReadOnly(), dbListConnections()

Other DBIConnection generics: DBIConnection-class, dbAppendTable(), dbCreateTable(), dbDataType(), dbDisconnect(), dbExecute(), dbExistsTable(), dbGetException(), dbGetInfo(), dbGetQuery(), dbIsReadOnly(), dbListFields(), dbListObjects(), dbListResults(), dbListTables(), dbReadTable(), dbRemoveTable(), dbSendQuery(), dbSendStatement(), dbWriteTable()

Other DBIResult generics: DBIResult-class, dbBind(), dbClearResult(), dbColumnInfo(), dbFetch(), dbGetInfo(), dbGetRowCount(), dbGetRowsAffected(), dbGetStatement(), dbHasCompleted(), dbIsReadOnly(), dbQuoteIdentifier(), dbQuoteLiteral(), dbQuoteString(), dbUnquoteIdentifier()

Examples

dbIsValid(RSQLite::SQLite())

con <- dbConnect(RSQLite::SQLite(), "::memory:"

dbIsValid(con)

rs <- dbSendQuery(con, "SELECT 1")

dbIsValid(rs)

dbClearResult(rs)

dbIsValid(rs)

dbDisconnect(con)

dbIsValid(con)

dbListFields

**List field names of a remote table**

Description

List field names of a remote table

Usage

dbListFields(conn, name, ...)

Arguments

conn A DBIConnection object, as returned by dbConnect().
name a character string with the name of the remote table.
... Other parameters passed on to methods.
Value

`dbListFields()` returns a character vector that enumerates all fields in the table in the correct order. This also works for temporary tables if supported by the database. The returned names are suitable for quoting with `dbQuoteIdentifier()`. If the table does not exist, an error is raised. Invalid types for the `name` argument (e.g., character of length not equal to one, or numeric) lead to an error. An error is also raised when calling this method for a closed or invalid connection.

Specification

The `name` argument can be

- a string
- the return value of `dbQuoteIdentifier()`
- a value from the `table` column from the return value of `dbListObjects()` where `is_prefix` is `FALSE`

A column named `row.names` is treated like any other column.

See Also

`dbColumnInfo()` to get the type of the fields.

Other DBIConnection generics: `DBIConnection-class`, `dbAppendTable()`, `dbCreateTable()`, `dbDataType()`, `dbDisconnect()`, `dbExecute()`, `dbExistsTable()`, `dbGetException()`, `dbGetInfo()`, `dbGetQuery()`, `dbIsReadOnly()`, `dbIsValid()`, `dbListObjects()`, `dbListResults()`, `dbListTables()`, `dbReadTable()`, `dbRemoveTable()`, `dbSendQuery()`, `dbSendStatement()`, `dbWriteTable()`

Examples

```r
con <- dbConnect(RSQLite::SQLite(), "::memory:"

dbWriteTable(con, "mtcars", mtcars)
dbListFields(con, "mtcars")

dbDisconnect(con)
```

---

**dbListObjects**

*List remote objects*

Description

Returns the names of remote objects accessible through this connection as a data frame. This should include temporary objects, but not all database backends (in particular `RMariaDB` and `RMySQL`) support this. Compared to `dbListTables()`, this method also enumerates tables and views in schemas, and returns fully qualified identifiers to access these objects. This allows exploration of all database objects available to the current user, including those that can only be accessed by giving the full namespace.
Usage

dbListObjects(conn, prefix = NULL, ...)

Arguments

conn
A DBIConnection object, as returned by dbConnect().

prefix
A fully qualified path in the database’s namespace, or NULL. This argument will be processed with dbUnquoteIdentifier(). If given the method will return all objects accessible through this prefix.

...
Other parameters passed on to methods.

Value

dbListObjects() returns a data frame with columns table and is_prefix (in that order), optionally with other columns with a dot (.) prefix. The table column is of type list. Each object in this list is suitable for use as argument in dbQuoteIdentifier(). The is_prefix column is a logical. This data frame contains one row for each object (schema, table and view) accessible from the prefix (if passed) or from the global namespace (if prefix is omitted). Tables added with dbWriteTable() are part of the data frame. As soon a table is removed from the database, it is also removed from the data frame of database objects.

The same applies to temporary objects if supported by the database.

The returned names are suitable for quoting with dbQuoteIdentifier(). An error is raised when calling this method for a closed or invalid connection.

Specification

The table object can be quoted with dbQuoteIdentifier(). The result of quoting can be passed to dbUnquoteIdentifier(). The unquoted results are equal to the original table object. (For backends it may be convenient to use the Id class, but this is not required.)

The prefix column indicates if the table value refers to a table or a prefix. For a call with the default prefix = NULL, the table values that have is_prefix == FALSE correspond to the tables returned from dbListTables(),

Values in table column that have is_prefix == TRUE can be passed as the prefix argument to another call to dbListObjects(). For the data frame returned from a dbListObject() call with the prefix argument set, all table values where is_prefix is FALSE can be used in a call to dbExistsTable() which returns TRUE.

Examples

```r
con <- dbConnect(RSQLite::SQLite(), "':memory:'")

dbListObjects(con)
dbWriteTable(con, "mtcars", mtcars)
dbListObjects(con)

dbDisconnect(con)
```

---

### dbListTables

**List remote tables**

**Description**

Returns the unquoted names of remote tables accessible through this connection. This should include views and temporary objects, but not all database backends (in particular `RMariaDB` and `RMySQL`) support this.

**Usage**

```r
dbListTables(conn, ...)
```

**Arguments**

- **conn**: A `DBIConnection` object, as returned by `dbConnect()`.
- **...**: Other parameters passed on to methods.

**Value**

`dbListTables()` returns a character vector that enumerates all tables and views in the database. Tables added with `dbWriteTable()` are part of the list. As soon a table is removed from the database, it is also removed from the list of database tables.

The same applies to temporary tables if supported by the database.

The returned names are suitable for quoting with `dbQuoteIdentifier()`. An error is raised when calling this method for a closed or invalid connection.

**See Also**

Other `DBIConnection` generics: `DBIConnection-class, dbAppendTable(), dbCreateTable(), dbDataType(), dbDisconnect(), dbExecute(), dbExistsTable(), dbGetException(), dbGetInfo(), dbGetQuery(), dbIsReadOnly(), dbIsValid(), dbListFields(), dbListObjects(), dbListResults(), dbReadTable(), dbRemoveTable(), dbSendQuery(), dbSendStatement(), dbWriteTable()`
Examples

```r
c <- dbConnect(RSQLite::SQLite(), ":memory:"

dbListTables(c)
dbWriteTable(c, "mtcars", mtcars)
dbListTables(c)
dbDisconnect(c)
```

### dbQuoteIdentifier

#### Quote identifiers

**Description**

Call this method to generate a string that is suitable for use in a query as a column or table name, to make sure that you generate valid SQL and protect against SQL injection attacks. The inverse operation is `dbUnquoteIdentifier()`.

**Usage**

```r
dbQuoteIdentifier(conn, x, ...)
```

**Arguments**

- `conn`: A `DBICconnection` object, as returned by `dbConnect()`.
- `x`: A character vector, SQL or `Id` object to quote as identifier.
- `...`: Other arguments passed on to methods.

**Value**

`dbQuoteIdentifier()` returns an object that can be coerced to `character`, of the same length as the input. For an empty character vector this function returns a length-0 object. The names of the input argument are preserved in the output. When passing the returned object again to `dbQuoteIdentifier()` as `x` argument, it is returned unchanged. Passing objects of class `SQL` should also return them unchanged. (For backends it may be most convenient to return `SQL` objects to achieve this behavior, but this is not required.)

An error is raised if the input contains `NA`, but not for an empty string.

**Specification**

Calling `dbGetQuery()` for a query of the format `SELECT 1 AS ...` returns a data frame with the identifier, unquoted, as column name. Quoted identifiers can be used as table and column names in SQL queries, in particular in queries like `SELECT 1 AS ...` and `SELECT * FROM (SELECT 1) ....` The method must use a quoting mechanism that is unambiguously different from the quoting mechanism used for strings, so that a query like `SELECT ... FROM (SELECT 1 AS ...) throws an error if the column names do not match.
The method can quote column names that contain special characters such as a space, a dot, a comma, or quotes used to mark strings or identifiers, if the database supports this. In any case, checking the validity of the identifier should be performed only when executing a query, and not by `dbQuoteIdentifier()`.

**See Also**

Other DBIResult generics: `DBIResult-class`, `dbBind()`, `dbClearResult()`, `dbColumnInfo()`, `dbFetch()`, `dbGetInfo()`, `dbGetRowCount()`, `dbGetRowsAffected()`, `dbGetStatement()`, `dbHasCompleted()`, `dbIsReadOnly()`, `dbIsValid()`, `dbQuoteLiteral()`, `dbQuoteString()`, `dbUnquoteIdentifier()`

**Examples**

```r
# Quoting ensures that arbitrary input is safe for use in a query
name <- "Robert's"; DROP TABLE Students;--
dbQuoteIdentifier(ANSI(), name)

# SQL vectors are always passed through as is
var_name <- SQL("select")
var_name

dbQuoteIdentifier(ANSI(), var_name)

# This mechanism is used to prevent double escaping
dbQuoteIdentifier(ANSI(), dbQuoteIdentifier(ANSI(), name))
```

---

**dbQuoteLiteral**

*Quote literal values*

**Description**

Call these methods to generate a string that is suitable for use in a query as a literal value of the correct type, to make sure that you generate valid SQL and protect against SQL injection attacks.

**Usage**

`dbQuoteLiteral(conn, x, ...)`

**Arguments**

- **conn** A `DBIConnection` object, as returned by `dbConnect()`.
- **x** A vector to quote as string.
- **...** Other arguments passed on to methods.
**Value**

`dbQuoteLiteral()` returns an object that can be coerced to `character`, of the same length as the input. For an empty character vector this function returns a length-0 object.

When passing the returned object again to `dbQuoteLiteral()` as `x` argument, it is returned unchanged. Passing objects of class `SQL` should also return them unchanged. (For backends it may be most convenient to return `SQL` objects to achieve this behavior, but this is not required.)

**Specification**

The returned expression can be used in a SELECT ... query, and the value of `dbGetQuery(paste0("SELECT ", dbQuoteLiteral(x)))[[1]]` must be equal to `x` for any scalar integer, numeric, string, and logical. If `x` is NA, the result must merely satisfy `is.na()`. The literals "NA" or "NULL" are not treated specially.

NA should be translated to an unquoted SQL NULL, so that the query SELECT * FROM (SELECT 1) a WHERE ... IS NULL returns one row.

Passing a list for the `x` argument raises an error.

**See Also**

Other DBIResult generics: `DBIResult-class`, `dbBind()`, `dbClearResult()`, `dbColumnInfo()`, `dbFetch()`, `dbGetInfo()`, `dbGetRowCount()`, `dbGetRowsAffected()`, `dbGetStatement()`, `dbHasCompleted()`, `dbIsReadOnly()`, `dbIsValid()`, `dbQuoteIdentifier()`, `dbQuoteString()`, `dbUnquoteIdentifier()`

**Examples**

# Quoting ensures that arbitrary input is safe for use in a query
name <- "Robert"); DROP TABLE Students;--"
`dbQuoteLiteral(ANSI(), name)`

# NAs become NULL
`dbQuoteLiteral(ANSI(), c(1:3, NA))`

# Logicals become integers by default
`dbQuoteLiteral(ANSI(), c(TRUE, FALSE, NA))`

# Raw vectors become hex strings by default
`dbQuoteLiteral(ANSI(), list(as.raw(1:3), NULL))`

# SQL vectors are always passed through as is
`var_name <- SQL("select")
`var_name`
`dbQuoteLiteral(ANSI(), var_name)`

# This mechanism is used to prevent double escaping
`dbQuoteLiteral(ANSI(), dbQuoteLiteral(ANSI(), name))`
**dbQuoteString**

*Quote literal strings*

**Description**

Call this method to generate a string that is suitable for use in a query as a string literal, to make sure that you generate valid SQL and protect against SQL injection attacks.

**Usage**

\[\text{dbQuoteString}(\text{conn}, \text{x}, \ldots)\]

**Arguments**

- **conn**: A DBIConnection object, as returned by `dbConnect()`.
- **x**: A character vector to quote as string.
- **...**: Other arguments passed on to methods.

**Value**

`dbQuoteString()` returns an object that can be coerced to character, of the same length as the input. For an empty character vector this function returns a length-0 object.

When passing the returned object again to `dbQuoteString()` as `x` argument, it is returned unchanged. Passing objects of class SQL should also return them unchanged. (For backends it may be most convenient to return SQL objects to achieve this behavior, but this is not required.)

**Specification**

The returned expression can be used in a SELECT ... query, and for any scalar character `x` the value of `dbGetQuery(paste0("SELECT ", dbQuoteString(x))[[1]])` must be identical to `x`, even if `x` contains spaces, tabs, quotes (single or double), backticks, or newlines (in any combination) or is itself the result of a `dbQuoteString()` call coerced back to character (even repeatedly). If `x` is `NA`, the result must merely satisfy `is.na()`. The strings "NA" or "NULL" are not treated specially.

`NA` should be translated to an unquoted SQL NULL, so that the query `SELECT * FROM (SELECT 1) a WHERE ... IS NULL` returns one row.

Passing a numeric, integer, logical, or raw vector, or a list for the `x` argument raises an error.

**See Also**

Other DBIResult generics: `DBIResult-class`, `dbBind()`, `dbClearResult()`, `dbColumnInfo()`, `dbFetch()`, `dbGetInfo()`, `dbGetRowCount()`, `dbGetRowsAffected()`, `dbGetStatement()`, `dbHasCompleted()`, `dbIsReadOnly()`, `dbIsValid()`, `dbQuoteIdentifier()`, `dbQuoteLiteral()`, `dbUnquoteIdentifier()`
Examples

# Quoting ensures that arbitrary input is safe for use in a query
name <- "Robert"); DROP TABLE Students;--"
dbQuoteString(ANSI(), name)

# NAs become NULL
dbQuoteString(ANSI(), c("x", NA))

# SQL vectors are always passed through as is
var_name <- SQL("select")
var_name
dbQuoteString(ANSI(), var_name)

# This mechanism is used to prevent double escaping
dbQuoteString(ANSI(), dbQuoteString(ANSI(), name))

dbReadTable

Copy data frames from database tables

Description

Reads a database table to a data frame, optionally converting a column to row names and converting the column names to valid R identifiers.

Usage

dbReadTable(conn, name, ...)

Arguments

conn A DBIConnection object, as returned by \texttt{dbConnect()}.
name A character string specifying the unquoted DBMS table name, or the result of a call to \texttt{dbQuoteIdentifier()}.
...
Other parameters passed on to methods.

Value

\texttt{dbReadTable()} returns a data frame that contains the complete data from the remote table, effectively the result of calling \texttt{dbGetQuery()} with \texttt{SELECT * FROM [name];}. An error is raised if the table does not exist. An empty table is returned as a data frame with zero rows.

The presence of \texttt{rownames} depends on the \texttt{row.names} argument, see \texttt{sqlColumnToRownames()} for details:

- If FALSE or NULL, the returned data frame doesn’t have row names.
- If TRUE, a column named "row_names" is converted to row names, an error is raised if no such column exists.
If NA, a column named "row_names" is converted to row names if it exists, otherwise no translation occurs.

If a string, this specifies the name of the column in the remote table that contains the row names, an error is raised if no such column exists.

The default is `row.names = FALSE`.

If the database supports identifiers with special characters, the columns in the returned data frame are converted to valid R identifiers if the `check.names` argument is TRUE. If `check.names = FALSE`, the returned table has non-syntactic column names without quotes.

An error is raised when calling this method for a closed or invalid connection. An error is raised if `name` cannot be processed with `dbQuoteIdentifier()` or if this results in a non-scalar. Unsupported values for `row.names` and `check.names` (non-scalars, unsupported data types, NA for `check.names`) also raise an error.

Additional arguments

The following arguments are not part of the `dbReadTable()` generic (to improve compatibility across backends) but are part of the DBI specification:

- `row.names` (default: FALSE)
- `check.names`

They must be provided as named arguments. See the "Value" section for details on their usage.

Specification

The `name` argument is processed as follows, to support databases that allow non-syntactic names for their objects:

- If an unquoted table name as string: `dbReadTable()` will do the quoting, perhaps by calling `dbQuoteIdentifier(conn,x = name)`
- If the result of a call to `dbQuoteIdentifier()`: no more quoting is done

See Also

Other DBIConnection generics: `DBIConnection-class`, `dbAppendTable()`, `dbCreateTable()`, `dbDataType()`, `dbDisconnect()`, `dbExecute()`, `dbExistsTable()`, `dbGetException()`, `dbGetInfo()`, `dbGetQuery()`, `dbIsReadOnly()`, `dbIsValid()`, `dbListFields()`, `dbListObjects()`, `dbListResults()`, `dbListTables()`, `dbRemoveTable()`, `dbSendQuery()`, `dbSendStatement()`, `dbWriteTable()`

Examples

```r
con <- dbConnect(RSQLite::SQLite(), ":memory:")

dbWriteTable(con, "mtcars", mtcars[1:10, ])
dbReadTable(con, "mtcars")

dbDisconnect(con)
```
dbRemoveTable

Remove a table from the database

Description

Remove a remote table (e.g., created by \texttt{dbWriteTable()}) from the database.

Usage

\texttt{dbRemoveTable(conn, name, \ldots)}

Arguments

\begin{itemize}
  \item \texttt{conn} \hspace{1cm} A \texttt{DBIConnection} object, as returned by \texttt{dbConnect()}.
  \item \texttt{name} \hspace{1cm} A character string specifying a DBMS table name.
  \item \ldots \hspace{1cm} Other parameters passed on to methods.
\end{itemize}

Value

\texttt{dbRemoveTable()} returns \texttt{TRUE}, invisibly. If the table does not exist, an error is raised. An attempt to remove a view with this function may result in an error.

An error is raised when calling this method for a closed or invalid connection. An error is also raised if \texttt{name} cannot be processed with \texttt{dbQuoteIdentifier()} or if this results in a non-scalar.

Additional arguments

The following arguments are not part of the \texttt{dbRemoveTable()} generic (to improve compatibility across backends) but are part of the DBI specification:

\begin{itemize}
  \item \texttt{temporary} (default: \texttt{FALSE})
  \item \texttt{fail_if_missing} (default: \texttt{TRUE})
\end{itemize}

These arguments must be provided as named arguments.

If \texttt{temporary} is \texttt{TRUE}, the call to \texttt{dbRemoveTable()} will consider only temporary tables. Not all backends support this argument. In particular, permanent tables of the same name are left untouched.

If \texttt{fail_if_missing} is \texttt{FALSE}, the call to \texttt{dbRemoveTable()} succeeds if the table does not exist.

Specification

A table removed by \texttt{dbRemoveTable()} doesn’t appear in the list of tables returned by \texttt{dbListTables()}, and \texttt{dbExistsTable()} returns \texttt{FALSE}. The removal propagates immediately to other connections to the same database. This function can also be used to remove a temporary table.

The \texttt{name} argument is processed as follows, to support databases that allow non-syntactic names for their objects:
• If an unquoted table name as string: `dbRemoveTable()` will do the quoting, perhaps by calling `dbQuoteIdentifier(conn,x = name)`

• If the result of a call to `dbQuoteIdentifier()`: no more quoting is done

See Also

Other DBIConnection generics: `DBIConnection-class, dbAppendTable(), dbCreateTable(), dbDataType(), dbDisconnect(), dbExecute(), dbExistsTable(), dbGetException(), dbGetInfo(), dbGetQuery(), dbIsReadOnly(), dbIsValid(), dbListFields(), dbListObjects(), dbListResults(), dbListTables(), dbReadTable(), dbSendQuery(), dbSendStatement(), dbWriteTable()`

Examples

```r
con <- dbConnect(RSQLite::SQLite(), "::memory:")
dbExistsTable(con, "iris")
dbWriteTable(con, "iris", iris)
dbExistsTable(con, "iris")
dbRemoveTable(con, "iris")
dbExistsTable(con, "iris")
dbDisconnect(con)
```

---

**dbSendQuery**

Execute a query on a given database connection

---

**Description**

The `dbSendQuery()` method only submits and synchronously executes the SQL query to the database engine. It does *not* extract any records — for that you need to use the `dbFetch()` method, and then you must call `dbClearResult()` when you finish fetching the records you need. For interactive use, you should almost always prefer `dbGetQuery()`.

**Usage**

```r
dbSendQuery(conn, statement, ...)
```

**Arguments**

- `conn` A `DBIConnection` object, as returned by `dbConnect()`.
- `statement` a character string containing SQL.
- `...` Other parameters passed on to methods.
Details
This method is for SELECT queries only. Some backends may support data manipulation queries through this method for compatibility reasons. However, callers are strongly encouraged to use \texttt{dbSendStatement()} for data manipulation statements.

The query is submitted to the database server and the DBMS executes it, possibly generating vast amounts of data. Where these data live is driver-specific: some drivers may choose to leave the output on the server and transfer them piecemeal to R, others may transfer all the data to the client – but not necessarily to the memory that R manages. See individual drivers’ \texttt{dbSendQuery()} documentation for details.

Value
\texttt{dbSendQuery()} returns an S4 object that inherits from \texttt{DBIResult}. The result set can be used with \texttt{dbFetch()} to extract records. Once you have finished using a result, make sure to clear it with \texttt{dbClearResult()}. An error is raised when issuing a query over a closed or invalid connection, or if the query is not a non-NA string. An error is also raised if the syntax of the query is invalid and all query parameters are given (by passing the \texttt{params} argument) or the \texttt{immediate} argument is set to \texttt{TRUE}.

Additional arguments
The following arguments are not part of the \texttt{dbSendQuery()} generic (to improve compatibility across backends) but are part of the DBI specification:

\begin{itemize}
  \item \texttt{params} (default: \texttt{NULL})
  \item \texttt{immediate} (default: \texttt{NULL})
\end{itemize}

They must be provided as named arguments. See the "Specification" sections for details on their usage.

Specification
No warnings occur under normal conditions. When done, the DBIResult object must be cleared with a call to \texttt{dbClearResult()}. Failure to clear the result set leads to a warning when the connection is closed.

If the backend supports only one open result set per connection, issuing a second query invalidates an already open result set and raises a warning. The newly opened result set is valid and must be cleared with \texttt{dbClearResult()}.

The \texttt{param} argument allows passing query parameters, see \texttt{dbBind()} for details.

Specification for the immediate argument
The \texttt{immediate} argument supports distinguishing between "direct" and "prepared" APIs offered by many database drivers. Passing \texttt{immediate = TRUE} leads to immediate execution of the query or statement, via the "direct" API (if supported by the driver). The default \texttt{NULL} means that the backend should choose whatever API makes the most sense for the database, and (if relevant) tries the other API if the first attempt fails. A successful second attempt should result in a message that suggests passing the correct \texttt{immediate} argument. Examples for possible behaviors:
1. DBI backend defaults to `immediate = TRUE` internally
   (a) A query without parameters is passed: query is executed
   (b) A query with parameters is passed:
      i. `params` not given: rejected immediately by the database because of a syntax error in the query, the backend tries `immediate = FALSE` (and gives a message)
      ii. `params` given: query is executed using `immediate = FALSE`

2. DBI backend defaults to `immediate = FALSE` internally
   (a) A query without parameters is passed:
      i. simple query: query is executed
      ii. "special" query (such as setting a config options): fails, the backend tries `immediate = TRUE` (and gives a message)
   (b) A query with parameters is passed:
      i. `params` not given: waiting for parameters via `dbBind()`
      ii. `params` given: query is executed

See Also

For updates: `dbSendStatement()` and `dbExecute()`.

Other DBIConnection generics: `DBIConnection-class`, `dbAppendTable()`, `dbCreateTable()`, `dbDataType()`, `dbDisConnect()`, `dbExecute()`, `dbExistsTable()`, `dbGetException()`, `dbGetInfo()`, `dbGetQuery()`, `dbIsReadOnly()`, `dbIsValid()`, `dbListFields()`, `dbListObjects()`, `dbListResults()`, `dbListTables()`, `dbReadTable()`, `dbRemoveTable()`, `dbSendStatement()`, `dbWriteTable()`

Examples

```r
con <- dbConnect(RSQLite::SQLite(), "::memory:"

dbWriteTable(con, "mtcars", mtcars)
rs <- dbSendQuery(con, "SELECT * FROM mtcars WHERE cyl = 4")
dbFetch(rs)
dbClearResult(rs)

# Pass one set of values with the param argument:
rs <- dbSendQuery(con, "SELECT * FROM mtcars WHERE cyl = ?",
    params = list(4L))
dbFetch(rs)
dbClearResult(rs)

# Pass multiple sets of values with `dbBind()`:
rs <- dbSendQuery(con, "SELECT * FROM mtcars WHERE cyl = ?")
dbBind(rs, list(6L))
dbFetch(rs)
dbBind(rs, list(8L))
dbFetch(rs)
dbClearResult(rs)

dbDisconnect(con)
```
**dbSendStatement**

---

**dbSendStatement**

*Execute a data manipulation statement on a given database connection*

---

**Description**

The `dbSendStatement()` method only submits and synchronously executes the SQL data manipulation statement (e.g., `UPDATE`, `DELETE`, `INSERT INTO`, `DROP TABLE`, ...) to the database engine. To query the number of affected rows, call `dbGetRowsAffected()` on the returned result object. You must also call `dbClearResult()` after that. For interactive use, you should almost always prefer `dbExecute()`.

**Usage**

```r
dbSendStatement(conn, statement, ...)
```

**Arguments**

- **conn**: A `DBIConnection` object, as returned by `dbConnect()`.
- **statement**: A character string containing SQL.
- **...**: Other parameters passed on to methods.

**Details**

`dbSendStatement()` comes with a default implementation that simply forwards to `dbSendQuery()`, to support backends that only implement the latter.

**Value**

`dbSendStatement()` returns an S4 object that inherits from `DBIResult`. The result set can be used with `dbGetRowsAffected()` to determine the number of rows affected by the query. Once you have finished using a result, make sure to clear it with `dbClearResult()`. An error is raised when issuing a statement over a closed or invalid connection, or if the statement is not a non-NA string. An error is also raised if the syntax of the query is invalid and all query parameters are given (by passing the `params` argument) or the `immediate` argument is set to `TRUE`.

**Additional arguments**

The following arguments are not part of the `dbSendStatement()` generic (to improve compatibility across backends) but are part of the DBI specification:

- **params** (default: `NULL`)
- **immediate** (default: `NULL`)

They must be provided as named arguments. See the "Specification" sections for details on their usage.
Specification

No warnings occur under normal conditions. When done, the DBIResult object must be cleared with a call to `dbClearResult()`. Failure to clear the result set leads to a warning when the connection is closed. If the backend supports only one open result set per connection, issuing a second query invalidates an already open result set and raises a warning. The newly opened result set is valid and must be cleared with `dbClearResult()`.

The `param` argument allows passing query parameters, see `dbBind()` for details.

Specification for the `immediate` argument

The `immediate` argument supports distinguishing between "direct" and "prepared" APIs offered by many database drivers. Passing `immediate = TRUE` leads to immediate execution of the query or statement, via the "direct" API (if supported by the driver). The default `NULL` means that the backend should choose whatever API makes the most sense for the database, and (if relevant) tries the other API if the first attempt fails. A successful second attempt should result in a message that suggests passing the correct `immediate` argument. Examples for possible behaviors:

1. DBI backend defaults to `immediate = TRUE` internally
   (a) A query without parameters is passed: query is executed
   (b) A query with parameters is passed:
      i. `params` not given: rejected immediately by the database because of a syntax error in the query, the backend tries `immediate = FALSE` (and gives a message)
      ii. `params` given: query is executed using `immediate = FALSE`

2. DBI backend defaults to `immediate = FALSE` internally
   (a) A query without parameters is passed:
      i. simple query: query is executed
      ii. "special" query (such as setting a config options): fails, the backend tries `immediate = TRUE` (and gives a message)
   (b) A query with parameters is passed:
      i. `params` not given: waiting for parameters via `dbBind()`
      ii. `params` given: query is executed

See Also

For queries: `dbSendQuery()` and `dbGetQuery()`.
Other DBIConnection generics: `DBIConnection-class`, `dbAppendTable()`, `dbCreateTable()`, `dbDataType()`, `dbDisconnect()`, `dbExecute()`, `dbExistsTable()`, `dbGetException()`, `dbGetInfo()`, `dbGetQuery()`, `dbIsReadOnly()`, `dbIsValid()`, `dbListFields()`, `dbListObjects()`, `dbListResults()`, `dbListTables()`, `dbReadTable()`, `dbRemoveTable()`, `dbSendQuery()`, `dbWriteTable()`

Examples

```r
con <- dbConnect(RSQLite::SQLite(), "::memory:"

dbWriteTable(con, "cars", head(cars, 3))
```
rs <- dbSendStatement(
  con,
  "INSERT INTO cars (speed, dist) VALUES (1, 1), (2, 2), (3, 3)"
)
dbHasCompleted(rs)
dbGetRowsAffected(rs)
dbClearResult(rs)
dbReadTable(con, "cars")  # there are now 6 rows

# Pass one set of values directly using the param argument:
rs <- dbSendStatement(
  con,
  "INSERT INTO cars (speed, dist) VALUES (?, ?)",
  params = list(4L, 5L)
)
dbClearResult(rs)

# Pass multiple sets of values using dbBind():
rs <- dbSendStatement(
  con,
  "INSERT INTO cars (speed, dist) VALUES (?, ?)"
)
dbBind(rs, list(5:6, 6:7))
dbBind(rs, list(7L, 8L))
dbClearResult(rs)
dbReadTable(con, "cars") # there are now 10 rows

dbDisconnect(con)

---

dbUnquoteIdentifier  Unquote identifiers

Description
Call this method to convert a SQL object created by dbQuoteIdentifier() back to a list of Id objects.

Usage
dbUnquoteIdentifier(conn, x, ...)

Arguments
conn A DBIConnection object, as returned by dbConnect().
x An SQL or Id object.
... Other arguments passed on to methods.
dbUnquoteIdentifier

Value

dbUnquoteIdentifier() returns a list of objects of the same length as the input. For an empty character vector this function returns a length-0 object. The names of the input argument are preserved in the output. When passing the first element of a returned object again to dbUnquoteIdentifier() as x argument, it is returned unchanged (but wrapped in a list). Passing objects of class Id should also return them unchanged (but wrapped in a list). (For backends it may be most convenient to return Id objects to achieve this behavior, but this is not required.)

An error is raised if plain character vectors are passed as the x argument.

Specification

For any character vector of length one, quoting (with dbQuoteIdentifier()) then unquoting then quoting the first element is identical to just quoting. This is also true for strings that contain special characters such as a space, a dot, a comma, or quotes used to mark strings or identifiers, if the database supports this.

Unquoting simple strings (consisting of only letters) wrapped with SQL() and then quoting via dbQuoteIdentifier() gives the same result as just quoting the string. Similarly, unquoting expressions of the form SQL("schema.table") and then quoting gives the same result as quoting the identifier constructed by Id(schema = "schema", table = "table").

See Also

Other DBIResult generics: DBIResult-class, dbBind(), dbClearResult(), dbColumnInfo(), dbFetch(), dbGetInfo(), dbGetRowCount(), dbGetRowsAffected(), dbGetStatement(), dbHasCompleted(), dbIsReadOnly(), dbIsValid(), dbQuoteIdentifier(), dbQuoteLiteral(), dbQuoteString()

Examples

# Unquoting allows to understand the structure of a # possibly complex quoted identifier
dbUnquoteIdentifier(
  ANSI(),
  SQL(c("Catalog"."Schema"."Table", "Schema"."Table", "UnqualifiedTable")))
)

# The returned object is always a list,
# also for Id objects
dbUnquoteIdentifier(
  ANSI(),
  Id(catalog = "Catalog", schema = "Schema", table = "Table"))
)

# Quoting is the inverse operation to unquoting the elements # of the returned list
dbQuoteIdentifier(
  ANSI(),
  dbUnquoteIdentifier(ANSI(), SQL("UnqualifiedTable"))[1])
)
dbWithTransaction  

Self-contained SQL transactions

Description

Given that transactions are implemented, this function allows you to pass in code that is run in a transaction. The default method of dbWithTransaction() calls dbBegin() before executing the code, and dbCommit() after successful completion, or dbRollback() in case of an error. The advantage is that you don’t have to remember to do dbBegin() and dbCommit() or dbRollback() – that is all taken care of. The special function dbBreak() allows an early exit with rollback, it can be called only inside dbWithTransaction().

Usage

dbWithTransaction(conn, code, ...)

dbBreak()

Arguments

conn       A DBIConnection object, as returned by dbConnect().

code      An arbitrary block of R code.

...    Other parameters passed on to methods.

Details

DBI implements dbWithTransaction(), backends should need to override this generic only if they implement specialized handling.

Value

dbWithTransaction() returns the value of the executed code. Failure to initiate the transaction (e.g., if the connection is closed or invalid of if dbBegin() has been called already) gives an error.

Specification

dbWithTransaction() initiates a transaction with dbBegin(), executes the code given in the code argument, and commits the transaction with dbCommit(). If the code raises an error, the transaction is instead aborted with dbRollback(), and the error is propagated. If the code calls dbBreak(), execution of the code stops and the transaction is silently aborted. All side effects caused by the code (such as the creation of new variables) propagate to the calling environment.
**dbWriteTable**

*Copy data frames to database tables*

**Description**

Writes, overwrites or appends a data frame to a database table, optionally converting row names to a column and specifying SQL data types for fields. New code should prefer `dbCreateTable()` and `dbAppendTable()`.
Usage

dbWriteTable(conn, name, value, ...)

Arguments

- **conn**: A DBIConnection object, as returned by `dbConnect()`.
- **name**: A character string specifying the unquoted DBMS table name, or the result of a call to `dbQuoteIdentifier()`.
- **value**: a data.frame (or coercible to data.frame).
- **...**: Other parameters passed on to methods.

Value

dbWriteTable() returns TRUE, invisibly. If the table exists, and both `append` and `overwrite` arguments are unset, or `append = TRUE` and the data frame with the new data has different column names, an error is raised; the remote table remains unchanged.

An error is raised when calling this method for a closed or invalid connection. An error is also raised if `name` cannot be processed with `dbQuoteIdentifier()` or if this results in a non-scalar. Invalid values for the additional arguments `row.names`, `overwrite`, `append`, `field.types`, and `temporary` (non-scalars, unsupported data types, NA, incompatible values, duplicate or missing names, incompatible columns) also raise an error.

Additional arguments

The following arguments are not part of the `dbWriteTable()` generic (to improve compatibility across backends) but are part of the DBI specification:

- `row.names` (default: FALSE)
- `overwrite` (default: FALSE)
- `append` (default: FALSE)
- `field.types` (default: NULL)
- `temporary` (default: FALSE)

They must be provided as named arguments. See the "Specification" and "Value" sections for details on their usage.

Specification

The `name` argument is processed as follows, to support databases that allow non-syntactic names for their objects:

- If an unquoted table name as string: `dbWriteTable()` will do the quoting, perhaps by calling `dbQuoteIdentifier(conn, x = name)`
- If the result of a call to `dbQuoteIdentifier()`: no more quoting is done
If the `overwrite` argument is TRUE, an existing table of the same name will be overwritten. This argument doesn’t change behavior if the table does not exist yet.

If the `append` argument is TRUE, the rows in an existing table are preserved, and the new data are appended. If the table doesn’t exist yet, it is created.

If the `temporary` argument is TRUE, the table is not available in a second connection and is gone after reconnecting. Not all backends support this argument. A regular, non-temporary table is visible in a second connection and after reconnecting to the database.

SQL keywords can be used freely in table names, column names, and data. Quotes, commas, and spaces can also be used in the data, and, if the database supports non-syntactic identifiers, also for table names and column names.

The following data types must be supported at least, and be read identically with `dbReadTable()`:

- integer
- numeric (the behavior for `Inf` and `NaN` is not specified)
- logical
- `NA` as NULL
- 64-bit values (using "bigint" as field type); the result can be
  - converted to a numeric, which may lose precision,
  - converted a character vector, which gives the full decimal representation
  - written to another table and read again unchanged
- character (in both UTF-8 and native encodings), supporting empty strings before and after a non-empty string
- factor (returned as character)
- list of raw (if supported by the database)
- objects of type `blob::blob` (if supported by the database)
- date (if supported by the database; returned as `Date`)
- time (if supported by the database; returned as objects that inherit from `difftime`)
- timestamp (if supported by the database; returned as `POSIXct` respecting the time zone but not necessarily preserving the input time zone)

Mixing column types in the same table is supported.

The `field.types` argument must be a named character vector with at most one entry for each column. It indicates the SQL data type to be used for a new column. If a column is missed from `field.types`, the type is inferred from the input data with `dbDataType()`.

The interpretation of `rownames` depends on the `row.names` argument, see `sqlRownamesToColumn()` for details:

- If `FALSE` or `NULL`, row names are ignored.
- If `TRUE`, row names are converted to a column named "row_names", even if the input data frame only has natural row names from 1 to `nrow(...).
- If `NA`, a column named "row_names" is created if the data has custom row names, no extra column is created in the case of natural row names.
- If a string, this specifies the name of the column in the remote table that contains the row names, even if the input data frame only has natural row names.

The default is `row.names = FALSE`. 

See Also

Other DBIConnection generics: DBIConnection-class, dbAppendTable(), dbCreateTable(),
dbNameType(), dBDisconnect(), dBExecute(), dBExistsTable(), dBGetException(), dBGetInfo(),
DBGetQuery(), dBIsReadOnly(), dBIsValid(), dBListFields(), dBListObjects(), dBListResults(),
DBListTables(), dBReadTable(), dBRemoveTable(), dBSendQuery(), dBSendStatement()

Examples

con <- dBConnect(RSQLite::SQLite(), ":memory:"

dbWriteTable(con, "mtcars", mtcars[1:5, ])
    dBReadTable(con, "mtcars"

dbWriteTable(con, "mtcars", mtcars[6:10, ], append = TRUE)
    dBReadTable(con, "mtcars"

dbWriteTable(con, "mtcars", mtcars[1:10, ], overwrite = TRUE)
    dBReadTable(con, "mtcars"

# No row names
    dBWriteTable(con, "mtcars", mtcars[1:10, ], overwrite = TRUE, row.names = FALSE)
    dBReadTable(con, "mtcars"

Id-class

Refer to a table nested in a hierarchy (e.g. within a schema)

Description

Objects of class Id have a single slot name, which is a named character vector. The
dbQuoteIdentifier() method converts Id objects to strings. Support for Id objects de-
pends on the database backend. They can be used in the following methods as name argu-
ment:

- dbCreateTable()
- dbAppendTable()
- dBReadTable()
- dBWriteTable()
- dBExistsTable()
- dBRemoveTable() Objects of this class are also returned from dBListObjects.

Usage

Id(...)
Arguments

Components of the hierarchy, e.g. schema, table, or cluster, catalog, schema, table. For more on these concepts, see https://stackoverflow.com/questions/7022755/

Examples

Id(schema = "dbo", table = "Customer")
dbQuoteIdentifier(ANSI(), Id(schema = "nycflights13", table = "flights"))
Id(cluster = "mycluster", catalog = "mycatalog", schema = "myschema", table = "mytable")

rownames Convert row names back and forth between columns

Description

These functions provide a reasonably automatic way of preserving the row names of data frame during back-and-forth translation to an SQL table. By default, row names will be converted to an explicit column called "row_names", and any query returning a column called "row_names" will have those automatically set as row names. These methods are mostly useful for backend implementers.

Usage

sqlRownamesToColumn(df, row.names = NA)
sqlColumnToRownames(df, row.names = NA)

Arguments

df A data frame
row.names Either TRUE, FALSE, NA or a string.
If TRUE, always translate row names to a column called "row_names".
If FALSE, never translate row names. If NA, translate rownames only if they’re a character vector.
A string is equivalent to TRUE, but allows you to override the default name.
For backward compatibility, NULL is equivalent to FALSE.

Examples

# If have row names
sqlRownamesToColumn(head(mtcars))
sqlRownamesToColumn(head(mtcars), FALSE)
sqlRownamesToColumn(head(mtcars), "ROWNAMES")

# If don't have
sqlRownamesToColumn(head(iris))
sqlRownamesToColumn(head(iris), TRUE)
sqlRownamesToColumn(head(iris), "ROWNAMES")

---

**Description**

This set of classes and generics make it possible to flexibly deal with SQL escaping needs. By default, any user supplied input to a query should be escaped using either `dbQuoteIdentifier()` or `dbQuoteString()` depending on whether it refers to a table or variable name, or is a literal string. These functions may return an object of the SQL class, which tells DBI functions that a character string does not need to be escaped anymore, to prevent double escaping. The SQL class has associated the SQL() constructor function.

**Usage**

```r
SQL(x, ..., names = NULL)
```

**Arguments**

- `x` A character vector to label as being escaped SQL.
- `...` Other arguments passed on to methods. Not otherwise used.
- `names` Names for the returned object, must have the same length as `x`.

**Value**

An object of class SQL.

**Implementation notes**

DBI provides default generics for SQL-92 compatible quoting. If the database uses a different convention, you will need to provide your own methods. Note that because of the way that S4 dispatch finds methods and because SQL inherits from character, if you implement (e.g.) a method for `dbQuoteString(MyConnection,character)`, you will also need to implement `dbQuoteString(MyConnection,SQL)` - this should simply return `x` unchanged.

**Examples**

```r
dbQuoteIdentifier(ANSI(), "SELECT")
dbQuoteString(ANSI(), "SELECT")

# SQL vectors are always passed through as is
var_name <- SQL("SELECT")
var_name

dbQuoteIdentifier(ANSI(), var_name)
dbQuoteString(ANSI(), var_name)
```
sqlAppendTable

# This mechanism is used to prevent double escaping
dbQuoteString(ANSI(), dbQuoteString(ANSI(), "SELECT"))

sqlAppendTable

Compose query to insert rows into a table

Description

sqlAppendTable() generates a single SQL string that inserts a data frame into an existing table. sqlAppendTableTemplate() generates a template suitable for use with \texttt{dbBind()}. The default methods are ANSI SQL 99 compliant. These methods are mostly useful for backend implementers.

Usage

\begin{verbatim}
sqlAppendTable(con, table, values, row.names = NA, ...)

sqlAppendTableTemplate(
  con,
  table,
  values,
  row.names = NA,
  prefix = "?",
  ...,
  pattern = ""
)
\end{verbatim}

Arguments

- \textbf{con} A database connection.
- \textbf{table} Name of the table. Escaped with \texttt{dbQuoteIdentifier()}.
- \textbf{values} A data frame. Factors will be converted to character vectors. Character vectors will be escaped with \texttt{dbQuoteString()}.
- \textbf{row.names} Either TRUE, FALSE, NA or a string. If TRUE, always translate row names to a column called "row.names". If FALSE, never translate row names. If NA, translate rownames only if they’re a character vector.
- \textbf{...} Other arguments used by individual methods.
- \textbf{prefix} Parameter prefix to use for placeholders.
- \textbf{pattern} Parameter pattern to use for placeholders:
  - ":" no pattern
  - "1": position
  - anything else: field name
sqlCreateTable

Details

The `row.names` argument must be passed explicitly in order to avoid a compatibility warning. The default will be changed in a later release.

Examples

```r
sqlAppendTable(ANSI(), "iris", head(iris))
sqlAppendTable(ANSI(), "mtcars", head(mtcars))
sqlAppendTable(ANSI(), "mtcars", head(mtcars), row.names = FALSE)
sqlAppendTableTemplate(ANSI(), "iris", iris)
sqlAppendTableTemplate(ANSI(), "mtcars", mtcars)
sqlAppendTableTemplate(ANSI(), "mtcars", mtcars, row.names = FALSE)
```

sqlCreateTable  Compose query to create a simple table

Description

Exposes an interface to simple CREATE TABLE commands. The default method is ANSI SQL 99 compliant. This method is mostly useful for backend implementers.

Usage

```r
sqlCreateTable(con, table, fields, row.names = NA, temporary = FALSE, ...)
```

Arguments

- `con` A database connection.
- `table` Name of the table. Escaped with `dbQuoteIdentifier()`.
- `fields` Either a character vector or a data frame.
  A named character vector: Names are column names, values are types. Names are escaped with `dbQuoteIdentifier()`. Field types are unescaped.
  A data frame: field types are generated using `dbDataType()`.
- `row.names` Either TRUE, FALSE, NA or a string.
  If TRUE, always translate row names to a column called "row_names".
  If FALSE, never translate row names. If NA, translate rownames only if they're a character vector.
  A string is equivalent to TRUE, but allows you to override the default name.
  For backward compatibility, NULL is equivalent to FALSE.
- `temporary` If TRUE, will generate a temporary table statement.
- `...` Other arguments used by individual methods.
sqlData  63

Details

The `row.names` argument must be passed explicitly in order to avoid a compatibility warning. The default will be changed in a later release.

Examples

```r
sqlCreateTable(ANSI(), "my-table", c(a = "integer", b = "text"))
sqlCreateTable(ANSI(), "my-table", iris)

# By default, character row names are converted to a row_names column
sqlCreateTable(ANSI(), "mtcars", mtcars[, 1:5])
sqlCreateTable(ANSI(), "mtcars", mtcars[, 1:5], row.names = FALSE)
```

Description

This is a generic method that coerces R objects into vectors suitable for upload to the database. The output will vary a little from method to method depending on whether the main upload device is through a single SQL string or multiple parameterized queries. This method is mostly useful for backend implementers.

Usage

```r
sqlData(con, value, row.names = NA, ...)
```

Arguments

- `con`  
  A database connection.
- `value`  
  A data frame.
- `row.names`  
  Either TRUE, FALSE, NA or a string.
  - If TRUE, always translate row names to a column called "row_names".
  - If FALSE, never translate row names. If NA, translate rownames only if they’re a character vector.
  - A string is equivalent to TRUE, but allows you to override the default name.
  - For backward compatibility, NULL is equivalent to FALSE.
- `...`  
  Other arguments used by individual methods.

Details

The default method:

- Converts factors to characters
- Quotes all strings
- Converts all columns to strings
- Replaces NA with NULL
Examples
con <- dbConnect(RSQLite::SQLite(), "::memory:"

sqlData(con, head(iris))
sqlData(con, head(mtcars))
dbDisconnect(con)

Description
Accepts a query string with placeholders for values, and returns a string with the values embedded. The function is careful to quote all of its inputs with dbQuoteLiteral() to protect against SQL injection attacks.

Placeholders can be specified with one of two syntaxes:

- `?`: each occurrence of a standalone ? is replaced with a value
- `?name1, ?name2, ...`: values are given as named arguments or a named list, the names are used to match the values

Mixing ? and ?name syntaxes is an error. The number and names of values supplied must correspond to the placeholders used in the query.

Usage
sqlInterpolate(conn, sql, ..., .dots = list())

Arguments

conn A DBIConnection object, as returned by dbConnect().
sql A SQL string containing variables to interpolate. Variables must start with a question mark and can be any valid R identifier, i.e. it must start with a letter or ., and be followed by a letter, digit, . or _.
..., .dots Values (for ...) or a list (for .dots) to interpolate into a string. Names are required if sql uses the ?name syntax for placeholders. All values will be first escaped with dbQuoteLiteral() prior to interpolation to protect against SQL injection attacks. Arguments created by SQL() or dbQuoteIdentifier() remain unchanged.

Value
The sql query with the values from ... and .dots safely embedded.
Backend authors

If you are implementing an SQL backend with non-ANSI quoting rules, you’ll need to implement a method for `sqlParseVariables()`. Failure to do so does not expose you to SQL injection attacks, but will (rarely) result in errors matching supplied and interpolated variables.

Examples

```r
sql <- "SELECT * FROM X WHERE name = ?name"
sqlInterpolate(ANSI(), sql, name = "Hadley")

# This is safe because the single quote has been double escaped
sqlInterpolate(ANSI(), sql, name = "H'\'quotesingle.Var\'\'\'; DROP TABLE--;")

# Using paste0() could lead to dangerous SQL with carefully crafted inputs
# (SQL injection)
name <- "H'\''; DROP TABLE--;"
paste0("SELECT * FROM X WHERE name = '\', name, '\'")

# Use SQL() or dbQuoteIdentifier() to avoid escaping
sql2 <- "SELECT * FROM ?table WHERE name in ?names"
sqlInterpolate(ANSI(), sql2,
    table = dbQuoteIdentifier(ANSI(), "X"),
    names = SQL("('a', 'b')")
)

# Don’t use SQL() to escape identifiers to avoid SQL injection
sqlInterpolate(ANSI(), sql2,
    table = SQL("X; DELETE FROM X; SELECT * FROM X"),
    names = SQL("('a', 'b')")
)

# Use dbGetQuery() or dbExecute() to process these queries:
if (requireNamespace("RSQLite", quietly = TRUE)) {
    con <- dbConnect(RSQLite::SQLite())
    sql <- "SELECT ?value AS value"
    query <- sqlInterpolate(con, sql, value = 3)
    print(dbGetQuery(con, query))
    dbDisconnect(con)
}
```

transactions

Begin/commit/rollback SQL transactions

Description

A transaction encapsulates several SQL statements in an atomic unit. It is initiated with `dbBegin()` and either made persistent with `dbCommit()` or undone with `dbRollback()`. In any case, the DBMS guarantees that either all or none of the statements have a permanent effect. This helps ensuring consistency of write operations to multiple tables.
Usage

dbBegin(conn, ...)

dbCommit(conn, ...)

dbRollback(conn, ...)

Arguments

conn A DBIConnection object, as returned by dbConnect().

... Other parameters passed on to methods.

Details

Not all database engines implement transaction management, in which case these methods should not be implemented for the specific DBIConnection subclass.

Value

dbBegin(), dbCommit() and dbRollback() return TRUE, invisibly. The implementations are expected to raise an error in case of failure, but this is not tested. In any way, all generics throw an error with a closed or invalid connection. In addition, a call to dbCommit() or dbRollback() without a prior call to dbBegin() raises an error. Nested transactions are not supported by DBI, an attempt to call dbBegin() twice yields an error.

Specification

Actual support for transactions may vary between backends. A transaction is initiated by a call to dbBegin() and committed by a call to dbCommit(). Data written in a transaction must persist after the transaction is committed. For example, a record that is missing when the transaction is started but is created during the transaction must exist both during and after the transaction, and also in a new connection.

A transaction can also be aborted with dbRollback(). All data written in such a transaction must be removed after the transaction is rolled back. For example, a record that is missing when the transaction is started but is created during the transaction must not exist anymore after the rollback.

Disconnection from a connection with an open transaction effectively rolls back the transaction. All data written in such a transaction must be removed after the transaction is rolled back.

The behavior is not specified if other arguments are passed to these functions. In particular, RSQLite issues named transactions with support for nesting if the name argument is set.

The transaction isolation level is not specified by DBI.

Self-contained transactions: dbWithTransaction()
Examples

```r
c <- dbConnect(RSQLite::SQLite(), "memory:"

dbWriteTable(con, "cash", data.frame(amount = 100))
dbWriteTable(con, "account", data.frame(amount = 2000))

# All operations are carried out as logical unit:
dbBegin(con)
withdrawal <- 300
dbExecute(con, "UPDATE cash SET amount = amount + ?", list(withdrawal))
dbExecute(con, "UPDATE account SET amount = amount - ?", list(withdrawal))
dbCommit(con)

dbReadTable(con, "cash")
dbReadTable(con, "account")

# Rolling back after detecting negative value on account:
dbBegin(con)
withdrawal <- 5000
dbExecute(con, "UPDATE cash SET amount = amount + ?", list(withdrawal))
dbExecute(con, "UPDATE account SET amount = amount - ?", list(withdrawal))
if (dbReadTable(con, "account")$amount >= 0) {
  dbCommit(con)
} else {
  dbRollback(con)
}

dbReadTable(con, "cash")
dbReadTable(con, "account")

dbDisconnect(con)
