Package ‘DBItest’

March 31, 2024

Title Testing DBI Backends
Version 1.8.1
Date 2024-03-31
Description A helper that tests DBI back ends for conformity to the interface.
License LGPL (>= 2.1)
BugReports https://github.com/r-dbi/DBItest/issues
Depends R (>= 3.2.0)
Imports blob (>= 1.2.0), callr, DBI (>= 1.2.1), desc, hms (>= 0.5.0), lubridate, magrittr, methods, nanoarrow, palmerpenguins, rlang (>= 0.2.0), testthat (>= 2.0.0), utils, withr
Suggests clipr, constructive, debugme, devtools, knitr, lintr, pkgload, rmarkdown, RSQLite
VignetteBuilder knitr

Description

A helper that tests DBI back ends for conformity to the interface.

Details

The two most important functions are `make_context()` and `test_all()`. The former tells the package how to connect to your DBI backend, the latter executes all tests of the test suite. More fine-grained test functions (all with prefix `test_`) are available.

See the package’s vignette for more details.

Author(s)

make_context

Test contexts

Description

Create a test context, set and query the default context.

Usage

make_context(
  drv,
  connect_args = NULL,
  set_as_default = TRUE,
  tweaks = NULL,
  name = NULL,
  default_skip = NULL,
)

set_default_context(ctx)

global_default_context()

Arguments

drv [DBIConnector]
An object of class DBIConnector that describes how to connect to the database.

connect_args [named list]
Deprecated.

set_as_default [logical(1)]
Should the created context be set as default context?

tweaks [DBItest_tweaks]
Tweaks as constructed by the tweaks() function.

name [character]
An optional name of the context which will be used in test messages.

default_skip [character]
Default value of skip argument to test_all() and other testing functions.

ctx [DBItest_context]
A test context.

Value

[DBItest_context]
A test context, for set_default_context the previous default context (invisibly) or NULL.
Examples

```r
make_context(
  new(
    "DBIConnector",
    .drv = RSQLite::SQLite(),
    .conn_args = list(dbname = tempfile("DBItest", fileext = ".sqlite")),
  ),
  tweaks = tweaks(
    constructor_relax_args = TRUE,
    placeholder_pattern = c("?", "$1", "$name", "::name"),
    date_cast = function(x) paste0("'\ Var", x, "'\ Var"),
    time_cast = function(x) paste0("'\ Var", x, "'\ Var"),
    timestamp_cast = function(x) paste0("'\ Var", x, "'\ Var"),
    logical_return = function(x) as.integer(x),
    date_typed = FALSE,
    time_typed = FALSE,
    timestamp_typed = FALSE
  ),
  default_skip = c("roundtrip_date", "roundtrip_timestamp")
)
```

Description

spec_arrow_append_table_arrow

Value
dbAppendTableArrow() returns a scalar numeric.

Failure modes

If the table does not exist, or the new data in values is not a data frame or has different column names, an error is raised; the remote table remains unchanged.

An error is raised when calling this method for a closed or invalid connection. An error is also raised if name cannot be processed with dbQuoteIdentifier() or if this results in a non-scalar.

Specification

SQL keywords can be used freely in table names, column names, and data. Quotes, commas, spaces, and other special characters such as newlines and tabs, can also be used in the data, and, if the database supports non-syntactic identifiers, also for table names and column names.

The following data types must be supported at least, and be read identically with dbReadTable():
spec_arrow_append_table_arrow

- integer
- numeric (the behavior for Inf and NaN is not specified)
- logical
- NA as NULL
- 64-bit values (using "bigint" as field type); the result can be
  - converted to a numeric, which may lose precision,
  - converted a character vector, which gives the full decimal representation
  - written to another table and read again unchanged
- character (in both UTF-8 and native encodings), supporting empty strings (before and after non-empty strings)
- factor (possibly returned as character)
- objects of type blob::blob (if supported by the database)
- date (if supported by the database; returned as Date) also for dates prior to 1970 or 1900 or after 2038
- time (if supported by the database; returned as objects that inherit from difftime)
- timestamp (if supported by the database; returned as POSIXct respecting the time zone but not necessarily preserving the input time zone), also for timestamps prior to 1970 or 1900 or after 2038 respecting the time zone but not necessarily preserving the input time zone)

Mixing column types in the same table is supported.

The name argument is processed as follows, to support databases that allow non-syntactic names for their objects:

- If an unquoted table name as string: dbAppendTableArrow() will do the quoting, perhaps by calling dbQuoteIdentifier(conn, x = name)
- If the result of a call to dbQuoteIdentifier(): no more quoting is done to support databases that allow non-syntactic names for their objects:

The value argument must be a data frame with a subset of the columns of the existing table. The order of the columns does not matter.

See Also

Other Arrow specifications: spec_arrow_create_table_arrow, spec_arrow_fetch_arrow, spec_arrow_fetch_arrow_chunk, spec_arrow_get_query_arrow, spec_arrow_read_table_arrow, spec_arrow_send_query_arrow, spec_arrow_write_table_arrow, spec_result_clear_result
Description

spec_arrow_create_table_arrow

Value

dbCreateTableArrow() returns TRUE, invisibly.

Failure modes

If the table exists, an error is raised; the remote table remains unchanged.

An error is raised when calling this method for a closed or invalid connection. An error is also raised if name cannot be processed with `dbQuoteIdentifier()` or if this results in a non-scalar. Invalid values for the temporary argument (non-scalars, unsupported data types, NA, incompatible values, duplicate names) also raise an error.

Additional arguments

The following arguments are not part of the `dbCreateTableArrow()` generic (to improve compatibility across backends) but are part of the DBI specification:

- temporary (default: FALSE)

They must be provided as named arguments. See the "Specification" and "Value" sections for details on their usage.

Specification

The name argument is processed as follows, to support databases that allow non-syntactic names for their objects:

- If an unquoted table name as string: `dbCreateTableArrow()` will do the quoting, perhaps by calling `dbQuoteIdentifier(conn, x = name)`
- If the result of a call to `dbQuoteIdentifier()`: no more quoting is done

The value argument can be:

- a data frame,
- a nanoarrow array
- a nanoarrow array stream (which will still contain the data after the call)
- a nanoarrow schema
If the temporary argument is TRUE, the table is not available in a second connection and is gone after reconnecting. Not all backends support this argument. A regular, non-temporary table is visible in a second connection, in a pre-existing connection, and after reconnecting to the database. SQL keywords can be used freely in table names, column names, and data. Quotes, commas, and spaces can also be used for table names and column names, if the database supports non-syntactic identifiers.

See Also

Other Arrow specifications: spec_arrow_append_table_arrow, spec_arrow_create_table_arrow, spec_arrow_fetch_arrow_chunk, spec_arrow_get_query_arrow, spec_arrow_read_table_arrow, spec_arrow_send_query_arrow, spec_arrow_write_table_arrow, spec_result_clear_result

dbFetchArrow() always returns an object coercible to a data.frame with as many rows as records were fetched and as many columns as fields in the result set, even if the result is a single value or has one or zero rows.

An attempt to fetch from a closed result set raises an error.

Fetching multi-row queries with one or more columns by default returns the entire result. The object returned by dbFetchArrow() can also be passed to nanoarrow::as_nanoarrow_array_stream() to create a nanoarrow array stream object that can be used to read the result set in batches. The chunk size is implementation-specific.

Other Arrow specifications: spec_arrow_append_table_arrow, spec_arrow_create_table_arrow, spec_arrow_fetch_arrow_chunk, spec_arrow_get_query_arrow, spec_arrow_read_table_arrow, spec_arrow_send_query_arrow, spec_arrow_write_table_arrow, spec_result_clear_result
spec_arrow_fetch_arrow_chunk

### Description
spec_arrow_fetch_arrow_chunk

### Value
dbFetchArrowChunk() always returns an object coercible to a data.frame with as many rows as records were fetched and as many columns as fields in the result set, even if the result is a single value or has one or zero rows.

### Failure modes
An attempt to fetch from a closed result set raises an error.

### Specification
Fetching multi-row queries with one or more columns returns the next chunk. The size of the chunk is implementation-specific. The object returned by dbFetchArrowChunk() can also be passed to nanoarrow::as_nanoarrow_array() to create a nanoarrow array object. The chunk size is implementation-specific.

### See Also
Other Arrow specifications: spec_arrow_append_table_arrow, spec_arrow_create_table_arrow, spec_arrow_fetch_arrow, spec_arrow_get_query_arrow, spec_arrow_read_table_arrow, spec_arrow_send_query, spec_arrow_write_table_arrow, spec_result_clear_result

---

dbGetQueryArrow() always returns an object coercible to a data.frame, with as many rows as records were fetched and as many columns as fields in the result set, even if the result is a single value or has one or zero rows.
Failure modes

An error is raised when issuing a query over a closed or invalid connection, if the syntax of the query is invalid, or if the query is not a non-NA string. The object returned by `dbGetQueryArrow()` can also be passed to `nanoarrow::as_nanoarrow_array_stream()` to create a nanoarrow array stream object that can be used to read the result set in batches. The chunk size is implementation-specific.

Additional arguments

The following arguments are not part of the `dbGetQueryArrow()` generic (to improve compatibility across backends) but are part of the DBI specification:

- `params` (default: NULL)
- `immediate` (default: NULL)

They must be provided as named arguments. See the "Specification" and "Value" sections for details on their usage.

The `param` argument allows passing query parameters, see `dbBind()` for details.

Specification for the `immediate` argument

The `immediate` argument supports distinguishing between "direct" and "prepared" APIs offered by many database drivers. Passing `immediate = TRUE` leads to immediate execution of the query or statement, via the "direct" API (if supported by the driver). The default NULL means that the backend should choose whatever API makes the most sense for the database, and (if relevant) tries the other API if the first attempt fails. A successful second attempt should result in a message that suggests passing the correct `immediate` argument. Examples for possible behaviors:

1. DBI backend defaults to `immediate = TRUE` internally
   (a) A query without parameters is passed: query is executed
   (b) A query with parameters is passed:
      i. `params` not given: rejected immediately by the database because of a syntax error in the query, the backend tries `immediate = FALSE` (and gives a message)
      ii. `params` given: query is executed using `immediate = FALSE`

2. DBI backend defaults to `immediate = FALSE` internally
   (a) A query without parameters is passed:
      i. simple query: query is executed
      ii. "special" query (such as setting a config options): fails, the backend tries `immediate = TRUE` (and gives a message)
   (b) A query with parameters is passed:
      i. `params` not given: waiting for parameters via `dbBind()`
      ii. `params` given: query is executed

Other Arrow specifications: spec_arrow_append_table_arrow, spec_arrow_create_table_arrow, spec_arrow_fetch_arrow, spec_arrow_fetch_arrow_chunk, spec_arrow_read_table_arrow, spec_arrow_send_query_arrow, spec_arrow_write_table_arrow, spec_result_clear_result
spec_arrow_read_table_arrow

Description

spec_arrow_read_table_arrow

Value

dbReadTableArrow() returns an Arrow object that contains the complete data from the remote table, effectively the result of calling \texttt{dbGetQueryArrow()} with \texttt{SELECT * FROM <name>}. An empty table is returned as an Arrow object with zero rows.

Failure modes

An error is raised if the table does not exist.

An error is raised when calling this method for a closed or invalid connection. An error is raised if \texttt{name} cannot be processed with \texttt{dbQuoteIdentifier()} or if this results in a non-scalar.

Specification

The \texttt{name} argument is processed as follows, to support databases that allow non-syntactic names for their objects:

- If an unquoted table name as string: \texttt{dbReadTableArrow()} will do the quoting, perhaps by calling \texttt{dbQuoteIdentifier(conn, x = name)}
- If the result of a call to \texttt{dbQuoteIdentifier()}: no more quoting is done

See Also

Other Arrow specifications: \texttt{spec_arrow_append_table_arrow}, \texttt{spec_arrow_create_table_arrow}, \texttt{spec_arrow_fetch_arrow}, \texttt{spec_arrow_fetch_arrow_chunk}, \texttt{spec_arrow_get_query_arrow}, \texttt{spec_arrow_send_query_arrow}, \texttt{spec_arrow_write_table_arrow}, \texttt{spec_result_clear_result}

spec_result_send_query

Description

spec_result_send_query
Value

dbSendQueryArrow() returns an S4 object that inherits from DBIResultArrow. The result set can be used with dbFetchArrow() to extract records. Once you have finished using a result, make sure to clear it with dbClearResult().

Failure modes

An error is raised when issuing a query over a closed or invalid connection, or if the query is not a non-NA string. An error is also raised if the syntax of the query is invalid and all query parameters are given (by passing the params argument) or the immediate argument is set to TRUE.

Additional arguments

The following arguments are not part of the dbSendQueryArrow() generic (to improve compatibility across backends) but are part of the DBI specification:

- params (default: NULL)
- immediate (default: NULL)

They must be provided as named arguments. See the "Specification" sections for details on their usage.

Specification

No warnings occur under normal conditions. When done, the DBIResult object must be cleared with a call to dbClearResult(). Failure to clear the result set leads to a warning when the connection is closed.

If the backend supports only one open result set per connection, issuing a second query invalidates an already open result set and raises a warning. The newly opened result set is valid and must be cleared with dbClearResult().

The param argument allows passing query parameters, see dbBind() for details.

Specification for the immediate argument

The immediate argument supports distinguishing between "direct" and "prepared" APIs offered by many database drivers. Passing immediate = TRUE leads to immediate execution of the query or statement, via the "direct" API (if supported by the driver). The default NULL means that the backend should choose whatever API makes the most sense for the database, and (if relevant) tries the other API if the first attempt fails. A successful second attempt should result in a message that suggests passing the correct immediate argument. Examples for possible behaviors:

1. DBI backend defaults to immediate = TRUE internally
   (a) A query without parameters is passed: query is executed
   (b) A query with parameters is passed:
      i. params not given: rejected immediately by the database because of a syntax error in the query, the backend tries immediate = FALSE (and gives a message)
      ii. params given: query is executed using immediate = FALSE
2. DBI backend defaults to immediate = FALSE internally
(a) A query without parameters is passed:
   i. simple query: query is executed
   ii. "special" query (such as setting a config options): fails, the backend tries immediate
       = TRUE (and gives a message)
(b) A query with parameters is passed:
   i. params not given: waiting for parameters via dbBind()
   ii. params given: query is executed

See Also

Other Arrow specifications: spec_arrow_append_table_arrow, spec_arrow_create_table_arrow,
spec_arrow_fetch_arrow, spec_arrow_fetch_arrow_chunk, spec_arrow_get_query_arrow,
spec_arrow_read_table_arrow, spec_arrow_write_table_arrow, spec_result_clear_result

Description

spec_arrow_write_table_arrow

Value

dbWriteTableArrow() returns TRUE, invisibly.

Failure modes

If the table exists, and both append and overwrite arguments are unset, or append = TRUE and
the data frame with the new data has different column names, an error is raised; the remote table
remains unchanged.

An error is raised when calling this method for a closed or invalid connection. An error is also raised
if name cannot be processed with dbQuoteIdentifier() or if this results in a non-scalar. Invalid
values for the additional arguments overwrite, append, and temporary (non-scalars, unsupported
data types, NA, incompatible values, incompatible columns) also raise an error.

Additional arguments

The following arguments are not part of the dbWriteTableArrow() generic (to improve compati-

bility across backends) but are part of the DBI specification:

- overwrite (default: FALSE)
- append (default: FALSE)
- temporary (default: FALSE)

They must be provided as named arguments. See the "Specification" and "Value" sections for details
on their usage.
Specification

The name argument is processed as follows, to support databases that allow non-syntactic names for their objects:

• If an unquoted table name as string: `dbWriteTableArrow()` will do the quoting, perhaps by calling `dbQuoteIdentifier(conn, x = name)`

• If the result of a call to `dbQuoteIdentifier()`: no more quoting is done

The value argument must be a data frame with a subset of the columns of the existing table if `append = TRUE`. The order of the columns does not matter with `append = TRUE`.

If the `overwrite` argument is `TRUE`, an existing table of the same name will be overwritten. This argument doesn’t change behavior if the table does not exist yet.

If the `append` argument is `TRUE`, the rows in an existing table are preserved, and the new data are appended. If the table doesn’t exist yet, it is created.

If the `temporary` argument is `TRUE`, the table is not available in a second connection and is gone after reconnecting. Not all backends support this argument. A regular, non-temporary table is visible in a second connection, in a pre-existing connection, and after reconnecting to the database.

SQL keywords can be used freely in table names, column names, and data. Quotes, commas, spaces, and other special characters such as newlines and tabs, can also be used in the data, and, if the database supports non-syntactic identifiers, also for table names and column names.

The following data types must be supported at least, and be read identically with `dbReadTable()`:

• integer
• numeric (the behavior for `Inf` and `NaN` is not specified)
• logical
• `NA` as `NULL`
• 64-bit values (using "bigint" as field type); the result can be
  – converted to a numeric, which may lose precision,
  – converted a character vector, which gives the full decimal representation
  – written to another table and read again unchanged
• character (in both UTF-8 and native encodings), supporting empty strings before and after a non-empty string
• factor (possibly returned as character)
• objects of type `blob::blob` (if supported by the database)
• date (if supported by the database; returned as `Date`), also for dates prior to 1970 or 1900 or after 2038
• time (if supported by the database; returned as objects that inherit from `difftime`)
• `timestamp` (if supported by the database; returned as `POSIXct` respecting the time zone but not necessarily preserving the input time zone), also for timestamps prior to 1970 or 1900 or after 2038 respecting the time zone but not necessarily preserving the input time zone)

Mixing column types in the same table is supported.
Description

dbDisconnect() returns TRUE, invisibly.

Failure modes

A warning is issued on garbage collection when a connection has been released without calling dbDisconnect(), but this cannot be tested automatically. At least one warning is issued immediately when calling dbDisconnect() on an already disconnected or invalid connection.

See Also

Other connection specifications: spec_get_info
Description

spec_driver_connect

Value

dbConnect() returns an S4 object that inherits from DBIConnection. This object is used to communicate with the database engine.

A format() method is defined for the connection object. It returns a string that consists of a single line of text.

Specification

DBI recommends using the following argument names for authentication parameters, with NULL default:

- user for the user name (default: current user)
- password for the password
- host for the host name (default: local connection)
- port for the port number (default: local connection)
- dbname for the name of the database on the host, or the database file name

The defaults should provide reasonable behavior, in particular a local connection for host = NULL. For some DBMS (e.g., PostgreSQL), this is different to a TCP/IP connection to localhost.

In addition, DBI supports the bigint argument that governs how 64-bit integer data is returned. The following values are supported:

- "integer": always return as integer, silently overflow
- "numeric": always return as numeric, silently round
- "character": always return the decimal representation as character
- "integer64": return as a data type that can be coerced using as.integer() (with warning on overflow), as.numeric() and as.character()

See Also

Other driver specifications: spec_driver_constructor, spec_driver_data_type, spec_get_info
Description

spec_driver_constructor

Construction of the DBIDriver object

The backend must support creation of an instance of its DBIDriver subclass with a constructor function. By default, its name is the package name without the leading ‘R’ (if it exists), e.g., SQLite for the RSQLite package. However, backend authors may choose a different name. The constructor must be exported, and it must be a function that is callable without arguments. DBI recommends to define a constructor with an empty argument list.

See Also

Other driver specifications: spec_driver_connect, spec_driver_data_type, spec_get_info

Description

spec_driver_data_type

Value

dbDataType() returns the SQL type that corresponds to the obj argument as a non-empty character string. For data frames, a character vector with one element per column is returned.

Failure modes

An error is raised for invalid values for the obj argument such as a NULL value.

Specification

The backend can override the dbDataType() generic for its driver class.

This generic expects an arbitrary object as second argument. To query the values returned by the default implementation, run example(dbDataType, package = "DBI"). If the backend needs to override this generic, it must accept all basic R data types as its second argument, namely logical, integer, numeric, character, dates (see Dates), date-time (see DateTimeClasses), and difftime. If the database supports blobs, this method also must accept lists of raw vectors, and blob::blob objects. As-is objects (i.e., wrapped by I()) must be supported and return the same results as their unwrapped counterparts. The SQL data type for factor and ordered is the same as for character. The behavior for other object types is not specified.
Description

A DBI backend is an R package which imports the DBI and methods packages. For better or worse, the names of many existing backends start with ‘R’, e.g., RSQLite, RMySQL, RSQLServer; it is up to the backend author to adopt this convention or not.

Value

For objects of class DBIDriver, dbGetInfo() returns a named list that contains at least the following components:

- driver.version: the package version of the DBI backend,
- client.version: the version of the DBMS client library.

For objects of class DBIConnection, dbGetInfo() returns a named list that contains at least the following components:

- db.version: version of the database server,
- dbname: database name,
- username: username to connect to the database,
- host: hostname of the database server,
- port: port on the database server. It must not contain a password component. Components that are not applicable should be set to NA.
For objects of class DBIResult, dbGetInfo() returns a named list that contains at least the following components:

- `statement`: the statement used with `dbSendQuery()` or `dbExecute()`, as returned by `dbGetStatement()`.
- `row.count`: the number of rows fetched so far (for queries), as returned by `dbGetRowCount()`.
- `rows.affected`: the number of rows affected (for statements), as returned by `dbGetRowsAffected()`.
- `has.completed`: a logical that indicates if the query or statement has completed, as returned by `dbHasCompleted()`.

### See Also

- Other driver specifications: `spec_driver_connect`, `spec_driver_constructor`, `spec_driver_data_type`
- Other connection specifications: `spec_connection_disconnect`
- Other meta specifications: `spec_meta_bind`, `spec_meta_column_info`, `spec_meta_get_row_count`, `spec_meta_get_rows_affected`, `spec_meta_get_statement`, `spec_meta_has_completed`, `spec_meta_is_valid`

---

**Description**

- `spec_meta_bind`
- `spec_meta_bind`
- `spec_meta_bind`

**Value**

`dbBind()` returns the result set, invisibly, for queries issued by `dbSendQuery()` or `dbSendQueryArrow()` and also for data manipulation statements issued by `dbSendStatement()`.

**Specification**

**DBI** clients execute parametrized statements as follows:

1. Call `dbSendQuery()`, `dbSendQueryArrow()` or `dbSendStatement()` with a query or statement that contains placeholders, store the returned `DBIResult` object in a variable. Mixing placeholders (in particular, named and unnamed ones) is not recommended. It is good practice to register a call to `dbClearResult()` via `on.exit()` right after calling `dbSendQuery()` or `dbSendStatement()` (see the last enumeration item). Until `dbBind()` or `dbBindArrow()` have been called, the returned result set object has the following behavior:
   - `dbFetch()` raises an error (for `dbSendQuery()` and `dbSendQueryArrow()`)
   - `dbGetRowCount()` returns zero (for `dbSendQuery()` and `dbSendQueryArrow()`)
   - `dbGetRowsAffected()` returns an integer NA (for `dbSendStatement()`)
   - `dbIsValid()` returns TRUE
   - `dbHasCompleted()` returns FALSE
2. Call \texttt{dbBind()} or \texttt{dbBindArrow()}:
   - For \texttt{dbBind()}, the \texttt{params} argument must be a list where all elements have the same lengths and contain values supported by the backend. A \texttt{data.frame} is internally stored as such a list.
   - For \texttt{dbBindArrow()}, the \texttt{params} argument must be a nanoarrow array stream, with one column per query parameter.

3. Retrieve the data or the number of affected rows from the \texttt{DBIResult} object.
   - For queries issued by \texttt{dbSendQuery()} or \texttt{dbSendQueryArrow()}, call \texttt{dbFetch()}.
   - For statements issued by \texttt{dbSendStatements()}, call \texttt{dbGetRowsAffected()}. (Execution begins immediately after the \texttt{dbBind()} call, the statement is processed entirely before the function returns.)

4. Repeat 2. and 3. as necessary.

5. Close the result set via \texttt{dbClearResult()}. 

The elements of the \texttt{params} argument do not need to be scalars, vectors of arbitrary length (including length 0) are supported. For queries, calling \texttt{dbFetch()} binding such parameters returns concatenated results, equivalent to binding and fetching for each set of values and connecting via \texttt{rbind()}. For data manipulation statements, \texttt{dbGetRowsAffected()} returns the total number of rows affected if binding non-scalar parameters. \texttt{dbBind()} also accepts repeated calls on the same result set for both queries and data manipulation statements, even if no results are fetched between calls to \texttt{dbBind()}, for both queries and data manipulation statements.

If the placeholders in the query are named, their order in the \texttt{params} argument is not important. At least the following data types are accepted on input (including \texttt{NA}):

- integer
- numeric
- logical for Boolean values
- character (also with special characters such as spaces, newlines, quotes, and backslashes)
- factor (bound as character, with warning)
- \texttt{Date} (also when stored internally as integer)
- \texttt{POSIXct} timestamps
- \texttt{POSIXlt} timestamps
- \texttt{difftime} values (also with units other than seconds and with the value stored as integer)
- lists of \texttt{raw} for blobs (with \texttt{NULL} entries for SQL NULL values)
- objects of type \texttt{blob::blob}

\textbf{Failure modes}

Calling \texttt{dbBind()} for a query without parameters raises an error.

Binding too many or not enough values, or parameters with wrong names or unequal length, also raises an error. If the placeholders in the query are named, all parameter values must have names (which must not be empty or \texttt{NA}), and vice versa, otherwise an error is raised. The behavior for mixing placeholders of different types (in particular mixing positional and named placeholders) is not specified.

Calling \texttt{dbBind()} on a result set already cleared by \texttt{dbClearResult()} also raises an error.
Description

spec_meta_column_info

Value

dbColumnInfo() returns a data frame with at least two columns "name" and "type" (in that order) (and optional columns that start with a dot). The "name" and "type" columns contain the names and types of the R columns of the data frame that is returned from dbFetch(). The "type" column is of type character and only for information. Do not compute on the "type" column, instead use dbFetch(res, n = 0) to create a zero-row data frame initialized with the correct data types.

Failure modes

An attempt to query columns for a closed result set raises an error.

Specification

A column named row_names is treated like any other column. The column names are always consistent with the data returned by dbFetch(). If the query returns unnamed columns, non-empty and non-NA names are assigned. Column names that correspond to SQL or R keywords are left unchanged.

See Also

Other meta specifications: spec_get_info, spec_meta_bind, spec_meta_get_row_count, spec_meta_get_rows_affected, spec_meta_get_statement, spec_meta_has_completed, spec_meta_is_valid
Description

spec_meta_get_rows_affected

Value

dbGetRowsAffected() returns a scalar number (integer or numeric), the number of rows affected by a data manipulation statement issued with dbSendStatement(). The value is available directly after the call and does not change after calling dbFetch(). NA_integer_ or NA_numeric_ are allowed if the number of rows affected is not known.

For queries issued with dbSendQuery(), zero is returned before and after the call to dbFetch(). NA values are not allowed.

Failure modes

Attempting to get the rows affected for a result set cleared with dbClearResult() gives an error.

See Also

Other meta specifications: spec_get_info, spec_meta_bind, spec_meta_column_info, spec_meta_get_row_count, spec_meta_get_statement, spec_meta_has_completed, spec_meta_is_valid

Description

spec_meta_get_row_count

Value

dbGetRowCount() returns a scalar number (integer or numeric), the number of rows fetched so far. After calling dbSendQuery(), the row count is initially zero. After a call to dbFetch() without limit, the row count matches the total number of rows returned. Fetching a limited number of rows increases the number of rows by the number of rows returned, even if fetching past the end of the result set. For queries with an empty result set, zero is returned even after fetching. For data manipulation statements issued with dbSendStatement(), zero is returned before and after calling dbFetch().
Failure modes

Attempting to get the row count for a result set cleared with `dbClearResult()` gives an error.

See Also

Other meta specifications: `spec_get_info`, `spec_meta_bind`, `spec_meta_column_info`, `spec_meta_get_row_count`, `spec_meta_get_row_count`, `spec_meta_get_rows_affected`, `spec_meta_has_completed`, `spec_meta_is_valid`

---

**Description**

`spec_meta_get_statement`

**Value**

`dbGetStatement()` returns a string, the query used in either `dbSendQuery()` or `dbSendStatement()`.

Failure modes

Attempting to query the statement for a result set cleared with `dbClearResult()` gives an error.

See Also

Other meta specifications: `spec_get_info`, `spec_meta_bind`, `spec_meta_column_info`, `spec_meta_get_row_count`, `spec_meta_get_rows_affected`, `spec_meta_has_completed`, `spec_meta_is_valid`

---

**Description**

`spec_meta_has_completed`

**Value**

`dbHasCompleted()` returns a logical scalar. For a query initiated by `dbSendQuery()` with non-empty result set, `dbHasCompleted()` returns FALSE initially and TRUE after calling `dbFetch()` without limit. For a query initiated by `dbSendStatement()`, `dbHasCompleted()` always returns TRUE.
Failure modes

Attempting to query completion status for a result set cleared with `dbClearResult()` gives an error.

Specification

The completion status for a query is only guaranteed to be set to FALSE after attempting to fetch past the end of the entire result. Therefore, for a query with an empty result set, the initial return value is unspecified, but the result value is TRUE after trying to fetch only one row.

Similarly, for a query with a result set of length n, the return value is unspecified after fetching n rows, but the result value is TRUE after trying to fetch only one more row.

See Also

Other meta specifications: `spec_get_info`, `spec_meta_bind`, `spec_meta_column_info`, `spec_meta_get_row_count`, `spec_meta_get_rows_affected`, `spec_meta_get_statement`, `spec_meta_is_valid`

---

Description

`spec_meta_is_valid`

Value

dbIsValid() returns a logical scalar, TRUE if the object specified by `dbObj` is valid, FALSE otherwise. A `DBIConnection` object is initially valid, and becomes invalid after disconnecting with `dbDisconnect()`. For an invalid connection object (e.g., for some drivers if the object is saved to a file and then restored), the method also returns FALSE. A `DBIResult` object is valid after a call to `dbSendQuery()`, and stays valid even after all rows have been fetched; only clearing it with `dbClearResult()` invalidates it. A `DBIResult` object is also valid after a call to `dbSendStatement()`, and stays valid after querying the number of rows affected; only clearing it with `dbClearResult()` invalidates it. If the connection to the database system is dropped (e.g., due to connectivity problems, server failure, etc.), `dbIsValid()` should return FALSE. This is not tested automatically.

Other meta specifications: `spec_get_info`, `spec_meta_bind`, `spec_meta_column_info`, `spec_meta_get_row_count`, `spec_meta_get_rows_affected`, `spec_meta_get_statement`, `spec_meta_has_completed`
spec_result_clear_result

Description
spec_result_clear_result

Value
dbClearResult() returns TRUE, invisibly, for result sets obtained from dbSendQuery(), dbSendStatement(), or dbSendQueryArrow().

Failure modes
An attempt to close an already closed result set issues a warning for dbSendQuery(), dbSendStatement(), and dbSendQueryArrow().

Specification
dbClearResult() frees all resources associated with retrieving the result of a query or update operation. The DBI backend can expect a call to dbClearResult() for each dbSendQuery() or dbSendStatement() call.

See Also
Other result specifications: spec_result_create_table_with_data_type, spec_result_execute, spec_result_fetch, spec_result_get_query, spec_result_roundtrip, spec_result_send_query, spec_result_send_statement

Other Arrow specifications: spec_arrow_append_table_arrow, spec_arrow_create_table_arrow, spec_arrow_fetch_arrow, spec_arrow_fetch_arrow_chunk, spec_arrow_get_query_arrow, spec_arrow_read_table_arrow, spec_arrow_send_query_arrow, spec_arrow_write_table_arrow

spec_result_create_table_with_data_type

Description
spec_result_create_table_with_data_type

Specification
All data types returned by dbDataType() are usable in an SQL statement of the form “CREATE TABLE test (a ...)”.
See Also

Other result specifications: spec_result_clear_result, spec_result_execute, spec_result_fetch, spec_result_get_query, spec_result_roundtrip, spec_result_send_query, spec_result_send_statement

---

Description

spec_result_execute

Value
dbExecute() always returns a scalar numeric that specifies the number of rows affected by the statement.

Failure modes

An error is raised when issuing a statement over a closed or invalid connection, if the syntax of the statement is invalid, or if the statement is not a non-NA string.

Additional arguments

The following arguments are not part of the dbExecute() generic (to improve compatibility across backends) but are part of the DBI specification:

- params (default: NULL)
- immediate (default: NULL)

They must be provided as named arguments. See the "Specification" sections for details on their usage.

Specification

The params argument allows passing query parameters, see dbBind() for details.

Specification for the immediate argument

The immediate argument supports distinguishing between "direct" and "prepared" APIs offered by many database drivers. Passing immediate = TRUE leads to immediate execution of the query or statement, via the "direct" API (if supported by the driver). The default NULL means that the backend should choose whatever API makes the most sense for the database, and (if relevant) tries the other API if the first attempt fails. A successful second attempt should result in a message that suggests passing the correct immediate argument. Examples for possible behaviors:

1. DBI backend defaults to immediate = TRUE internally
   (a) A query without parameters is passed: query is executed
   (b) A query with parameters is passed:
i. params not given: rejected immediately by the database because of a syntax error in the query, the backend tries immediate = FALSE (and gives a message)
ii. params given: query is executed using immediate = FALSE

2. DBI backend defaults to immediate = FALSE internally
   (a) A query without parameters is passed:
      i. simple query: query is executed
      ii. "special" query (such as setting a config options): fails, the backend tries immediate = TRUE (and gives a message)
   (b) A query with parameters is passed:
      i. params not given: waiting for parameters via dbBind()
      ii. params given: query is executed

See Also

Other result specifications: spec_result_clear_result, spec_result_create_table_with_data_type, spec_result_fetch, spec_result_get_query, spec_result_roundtrip, spec_result_send_query, spec_result_send_statement

Description

spec_result_fetch

Value

dbFetch() always returns a data.frame with as many rows as records were fetched and as many columns as fields in the result set, even if the result is a single value or has one or zero rows. Passing n = NA is supported and returns an arbitrary number of rows (at least one) as specified by the driver, but at most the remaining rows in the result set.

Failure modes

An attempt to fetch from a closed result set raises an error. If the n argument is not an atomic whole number greater or equal to -1 or Inf, an error is raised, but a subsequent call to dbFetch() with proper n argument succeeds.

Calling dbFetch() on a result set from a data manipulation query created by dbSendStatement() can be fetched and return an empty data frame, with a warning.
**Specification**

Fetching multi-row queries with one or more columns by default returns the entire result. Multi-row queries can also be fetched progressively by passing a whole number (integer or numeric) as the `n` argument. A value of `Inf` for the `n` argument is supported and also returns the full result. If more rows than available are fetched, the result is returned in full without warning. If fewer rows than requested are returned, further fetches will return a data frame with zero rows. If zero rows are fetched, the columns of the data frame are still fully typed. Fetching fewer rows than available is permitted, no warning is issued when clearing the result set.

A column named `row_names` is treated like any other column.

**See Also**

Other result specifications: spec_result_clear_result, spec_result_create_table_with_data_type, spec_result_execute, spec_result_get_query, spec_result_roundtrip, spec_result_send_query, spec_result_send_statement

---

**Description**

spec_result_get_query

**Value**

dbGetQuery() always returns a data.frame, with as many rows as records were fetched and as many columns as fields in the result set, even if the result is a single value or has one or zero rows.

**Failure modes**

An error is raised when issuing a query over a closed or invalid connection, if the syntax of the query is invalid, or if the query is not a non-NA string. If the `n` argument is not an atomic whole number greater or equal to -1 or Inf, an error is raised, but a subsequent call to dbGetQuery() with proper `n` argument succeeds.

**Additional arguments**

The following arguments are not part of the dbGetQuery() generic (to improve compatibility across backends) but are part of the DBI specification:

- `n` (default: -1)
- `params` (default: NULL)
- `immediate` (default: NULL)

They must be provided as named arguments. See the "Specification" and "Value" sections for details on their usage.
Specification

A column named `row_names` is treated like any other column.

The `n` argument specifies the number of rows to be fetched. If omitted, fetching multi-row queries with one or more columns returns the entire result. A value of `Inf` for the `n` argument is supported and also returns the full result. If more rows than available are fetched (by passing a too large value for `n`), the result is returned in full without warning. If zero rows are requested, the columns of the data frame are still fully typed. Fetching fewer rows than available is permitted, no warning is issued.

The `param` argument allows passing query parameters, see `dbBind()` for details.

Specification for the `immediate` argument

The `immediate` argument supports distinguishing between "direct" and "prepared" APIs offered by many database drivers. Passing `immediate = TRUE` leads to immediate execution of the query or statement, via the "direct" API (if supported by the driver). The default `NULL` means that the backend should choose whatever API makes the most sense for the database, and (if relevant) tries the other API if the first attempt fails. A successful second attempt should result in a message that suggests passing the correct `immediate` argument. Examples for possible behaviors:

1. DBI backend defaults to `immediate = TRUE` internally
   (a) A query without parameters is passed: query is executed
   (b) A query with parameters is passed:
      i. `params` not given: rejected immediately by the database because of a syntax error in the query, the backend tries `immediate = FALSE` (and gives a message)
      ii. `params` given: query is executed using `immediate = FALSE`

2. DBI backend defaults to `immediate = FALSE` internally
   (a) A query without parameters is passed:
      i. simple query: query is executed
      ii. "special" query (such as setting a config options): fails, the backend tries `immediate = TRUE` (and gives a message)
   (b) A query with parameters is passed:
      i. `params` not given: waiting for parameters via `dbBind()`
      ii. `params` given: query is executed

See Also

Other result specifications: `spec_result_clear_result`, `spec_result_create_table_with_data_type`, `spec_result_execute`, `spec_result_fetch`, `spec_result_roundtrip`, `spec_result_send_query`, `spec_result_send_statement`
Description

spec_result_roundtrip

Specification

The column types of the returned data frame depend on the data returned:

- **integer** (or coercible to an integer) for integer values between \(-2^{31}\) and \(2^{31} - 1\), with **NA** for SQL **NULL** values
- **numeric** for numbers with a fractional component, with **NA** for SQL **NULL** values
- **logical** for Boolean values (some backends may return an integer); with **NA** for SQL **NULL** values
- **character** for text, with **NA** for SQL **NULL** values
- lists of **raw** for blobs with **NULL** entries for SQL **NULL** values
- coercible using `as.Date()` for dates, with **NA** for SQL **NULL** values (also applies to the return value of the SQL function `current_date`)
- coercible using `hms::as_hms()` for times, with **NA** for SQL **NULL** values (also applies to the return value of the SQL function `current_time`)
- coercible using `as.POSIXct()` for timestamps, with **NA** for SQL **NULL** values (also applies to the return value of the SQL function `current_timestamp`)

If dates and timestamps are supported by the backend, the following R types are used:

- **Date** for dates (also applies to the return value of the SQL function `current_date`)
- **POSIXct** for timestamps (also applies to the return value of the SQL function `current_timestamp`)

R has no built-in type with lossless support for the full range of 64-bit or larger integers. If 64-bit integers are returned from a query, the following rules apply:

- Values are returned in a container with support for the full range of valid 64-bit values (such as the `integer64` class of the `bit64` package)
- Coercion to numeric always returns a number that is as close as possible to the true value
- Loss of precision when converting to numeric gives a warning
- Conversion to character always returns a lossless decimal representation of the data

See Also

Other result specifications: `spec_result_clear_result`, `spec_result_create_table_with_data_type`, `spec_result_execute`, `spec_result_fetch`, `spec_result_get_query`, `spec_result_send_query`, `spec_result_send_statement`
Description

spec_result_send_query

Value

dbSendQuery() returns an S4 object that inherits from DBIResult. The result set can be used with 
dbFetch() to extract records. Once you have finished using a result, make sure to clear it with 
dbClearResult().

Failure modes

An error is raised when issuing a query over a closed or invalid connection, or if the query is not a 
non-NA string. An error is also raised if the syntax of the query is invalid and all query parameters 
are given (by passing the params argument) or the immediate argument is set to TRUE.

Additional arguments

The following arguments are not part of the dbSendQuery() generic (to improve compatibility 
across backends) but are part of the DBI specification:

- params (default: NULL)
- immediate (default: NULL)

They must be provided as named arguments. See the "Specification" sections for details on their 
usage.

Specification

No warnings occur under normal conditions. When done, the DBIResult object must be cleared with 
a call to dbClearResult(). Failure to clear the result set leads to a warning when the connection 
is closed.

If the backend supports only one open result set per connection, issuing a second query invalidates 
an already open result set and raises a warning. The newly opened result set is valid and must be 
cleared with dbClearResult().

The param argument allows passing query parameters, see dbBind() for details.

Specification for the immediate argument

The immediate argument supports distinguishing between "direct" and "prepared" APIs offered 
by many database drivers. Passing immediate = TRUE leads to immediate execution of the query 
or statement, via the "direct" API (if supported by the driver). The default NULL means that the 
backend should choose whatever API makes the most sense for the database, and (if relevant) tries
the other API if the first attempt fails. A successful second attempt should result in a message that suggests passing the correct `immediate` argument. Examples for possible behaviors:

1. DBI backend defaults to `immediate = TRUE` internally
   (a) A query without parameters is passed: query is executed
   (b) A query with parameters is passed:
      i. `params` not given: rejected immediately by the database because of a syntax error in the query, the backend tries `immediate = FALSE` (and gives a message)
      ii. `params` given: query is executed using `immediate = FALSE`

2. DBI backend defaults to `immediate = FALSE` internally
   (a) A query without parameters is passed:
      i. simple query: query is executed
      ii. "special" query (such as setting a config options): fails, the backend tries `immediate = TRUE` (and gives a message)
   (b) A query with parameters is passed:
      i. `params` not given: waiting for parameters via `dbBind()`
      ii. `params` given: query is executed

See Also

Other result specifications: `spec_result_clear_result, spec_result_create_table_with_data_type, spec_result_execute, spec_result_fetch, spec_result_get_query, spec_result_roundtrip, spec_result_send_statement`

Description

`spec_result_send_statement`

Value

dbSendStatement() returns an S4 object that inherits from `DBIResult`. The result set can be used with `dbGetRowsAffected()` to determine the number of rows affected by the query. Once you have finished using a result, make sure to clear it with `dbClearResult()`.

Failure modes

An error is raised when issuing a statement over a closed or invalid connection, or if the statement is not a non-NA string. An error is also raised if the syntax of the query is invalid and all query parameters are given (by passing the `params` argument) or the `immediate` argument is set to `TRUE`. 
Specification

No warnings occur under normal conditions. When done, the DBIResult object must be cleared with a call to `dbClearResult()`. Failure to clear the result set leads to a warning when the connection is closed. If the backend supports only one open result set per connection, issuing a second query invalidates an already open result set and raises a warning. The newly opened result set is valid and must be cleared with `dbClearResult()`.

The `param` argument allows passing query parameters, see `dbBind()` for details.

Additional arguments

The following arguments are not part of the `dbSendStatement()` generic (to improve compatibility across backends) but are part of the DBI specification:

- `params` (default: `NULL`)
- `immediate` (default: `NULL`)

They must be provided as named arguments. See the "Specification" sections for details on their usage.

Specification for the `immediate` argument

The `immediate` argument supports distinguishing between "direct" and "prepared" APIs offered by many database drivers. Passing `immediate = TRUE` leads to immediate execution of the query or statement, via the "direct" API (if supported by the driver). The default `NULL` means that the backend should choose whatever API makes the most sense for the database, and (if relevant) tries the other API if the first attempt fails. A successful second attempt should result in a message that suggests passing the correct `immediate` argument. Examples for possible behaviors:

1. DBI backend defaults to `immediate = TRUE` internally
   (a) A query without parameters is passed: query is executed
   (b) A query with parameters is passed:
      i. `params` not given: rejected immediately by the database because of a syntax error in the query, the backend tries `immediate = FALSE` (and gives a message)
      ii. `params` given: query is executed using `immediate = FALSE`

2. DBI backend defaults to `immediate = FALSE` internally
   (a) A query without parameters is passed:
      i. simple query: query is executed
      ii. "special" query (such as setting a config options): fails, the backend tries `immediate = TRUE` (and gives a message)
   (b) A query with parameters is passed:
      i. `params` not given: waiting for parameters via `dbBind()`
      ii. `params` given: query is executed

See Also

Other result specifications: `spec_result_clear_result`, `spec_result_create_table_with_data_type`, `spec_result_execute`, `spec_result_fetch`, `spec_result_get_query`, `spec_result_roundtrip`, `spec_result_send_query`
Description
spec_sql_append_table

Value
dbAppendTable() returns a scalar numeric.

Failure modes
If the table does not exist, or the new data in values is not a data frame or has different column names, an error is raised; the remote table remains unchanged.

An error is raised when calling this method for a closed or invalid connection. An error is also raised if name cannot be processed with dbQuoteIdentifier() or if this results in a non-scalar. Invalid values for the row.names argument (non-scalars, unsupported data types, NA) also raise an error.

Passing a value argument different to NULL to the row.names argument (in particular TRUE, NA, and a string) raises an error.

Specification
SQL keywords can be used freely in table names, column names, and data. Quotes, commas, spaces, and other special characters such as newlines and tabs, can also be used in the data, and, if the database supports non-syntactic identifiers, also for table names and column names.

The following data types must be supported at least, and be read identically with dbReadTable():

- integer
- numeric (the behavior for Inf and NaN is not specified)
- logical
- NA as NULL
- 64-bit values (using "bigint" as field type); the result can be
  - converted to a numeric, which may lose precision,
  - converted a character vector, which gives the full decimal representation
  - written to another table and read again unchanged
- character (in both UTF-8 and native encodings), supporting empty strings (before and after non-empty strings)
- factor (returned as character, with a warning)
- list of raw (if supported by the database)
- objects of type blob::blob (if supported by the database)
• date (if supported by the database; returned as Date) also for dates prior to 1970 or 1900 or after 2038
• time (if supported by the database; returned as objects that inherit from difftime)
• timestamp (if supported by the database; returned as POSIXct respecting the time zone but not necessarily preserving the input time zone), also for timestamps prior to 1970 or 1900 or after 2038 respecting the time zone but not necessarily preserving the input time zone)

Mixing column types in the same table is supported.

The name argument is processed as follows, to support databases that allow non-syntactic names for their objects:

• If an unquoted table name as string: dbAppendTable() will do the quoting, perhaps by calling dbQuoteIdentifier(conn, x = name)
• If the result of a call to dbQuoteIdentifier(): no more quoting is done to support databases that allow non-syntactic names for their objects:

The row.names argument must be NULL, the default value. Row names are ignored.

The value argument must be a data frame with a subset of the columns of the existing table. The order of the columns does not matter.

See Also

Other sql specifications: spec_sql_create_table, spec_sql_exists_table, spec_sql_list_fields, spec_sql_list_objects, spec_sql_list_tables, spec_sql_quote_identifier, spec_sql_quote_literal, spec_sql_quote_string, spec_sql_read_table, spec_sql_remove_table, spec_sql_unquote_identifier, spec_sql_write_table

---

Description

spec_sql_create_table

Value

dbCreateTable() returns TRUE, invisibly.

Failure modes

If the table exists, an error is raised; the remote table remains unchanged.

An error is raised when calling this method for a closed or invalid connection. An error is also raised if name cannot be processed with dbQuoteIdentifier() or if this results in a non-scalar. Invalid values for the row.names and temporary arguments (non-scalars, unsupported data types, NA, incompatible values, duplicate names) also raise an error.
Additional arguments

The following arguments are not part of the `dbCreateTable()` generic (to improve compatibility across backends) but are part of the DBI specification:

- temporary (default: FALSE)

They must be provided as named arguments. See the "Specification" and "Value" sections for details on their usage.

Specification

The name argument is processed as follows, to support databases that allow non-syntactic names for their objects:

- If an unquoted table name as string: `dbCreateTable()` will do the quoting, perhaps by calling `dbQuoteIdentifier(conn, x = name)`
- If the result of a call to `dbQuoteIdentifier()`: no more quoting is done

The value argument can be:

- a data frame,
- a named list of SQL types

If the temporary argument is TRUE, the table is not available in a second connection and is gone after reconnecting. Not all backends support this argument. A regular, non-temporary table is visible in a second connection, in a pre-existing connection, and after reconnecting to the database.

SQL keywords can be used freely in table names, column names, and data. Quotes, commas, and spaces can also be used for table names and column names, if the database supports non-syntactic identifiers.

The row.names argument must be missing or NULL, the default value. All other values for the row.names argument (in particular TRUE, NA, and a string) raise an error.

See Also

Other sql specifications: `spec_sql_append_table`, `spec_sql_exists_table`, `spec_sql_list_fields`, `spec_sql_list_objects`, `spec_sql_list_tables`, `spec_sql_quote_identifier`, `spec_sql_quote_literal`, `spec_sql_quote_string`, `spec_sql_read_table`, `spec_sql_remove_table`, `spec_sql_unquote_identifier`, `spec_sql_write_table`
Value

dbExistsTable() returns a logical scalar, TRUE if the table or view specified by the name argument exists, FALSE otherwise.

This includes temporary tables if supported by the database.

Failure modes

An error is raised when calling this method for a closed or invalid connection. An error is also raised if name cannot be processed with dbQuoteIdentifier() or if this results in a non-scalar.

Specification

The name argument is processed as follows, to support databases that allow non-syntactic names for their objects:

- If an unquoted table name as string: dbExistsTable() will do the quoting, perhaps by calling dbQuoteIdentifier(conn, x = name)
- If the result of a call to dbQuoteIdentifier(): no more quoting is done

For all tables listed by dbListTables(), dbExistsTable() returns TRUE.

See Also

Other sql specifications: spec_sql_append_table, spec_sql_create_table, spec_sql_list_fields, spec_sql_list_objects, spec_sql_list_tables, spec_sql_quote_identifier, spec_sql_quote_literal, spec_sql_quote_string, spec_sql_read_table, spec_sql_remove_table, spec_sql_unquote_identifier, spec_sql_write_table
Specification

The name argument can be

- a string
- the return value of `dbQuoteIdentifier()`
- a value from the table column from the return value of `dbListObjects()` where is_prefix is FALSE

A column named row_names is treated like any other column.

See Also

Other sql specifications: `spec_sql_append_table`, `spec_sql_create_table`, `spec_sql_exists_table`, `spec_sql_list_objects`, `spec_sql_list_tables`, `spec_sql_quote_identifier`, `spec_sql_quote_literal`, `spec_sql_quote_string`, `spec_sql_read_table`, `spec_sql_remove_table`, `spec_sql_unquote_identifier`, `spec_sql_write_table`

---

Description

`spec_sql_list_objects`

Value

`dbListObjects()` returns a data frame with columns table and is_prefix (in that order), optionally with other columns with a dot (. ) prefix. The table column is of type list. Each object in this list is suitable for use as argument in `dbQuoteIdentifier()`. The is_prefix column is a logical. This data frame contains one row for each object (schema, table and view) accessible from the prefix (if passed) or from the global namespace (if prefix is omitted). Tables added with `dbWriteTable()` are part of the data frame. As soon a table is removed from the database, it is also removed from the data frame of database objects.

The same applies to temporary objects if supported by the database.

The returned names are suitable for quoting with `dbQuoteIdentifier()`.

Failure modes

An error is raised when calling this method for a closed or invalid connection.
spec_sql_list_tables

Specification

The prefix column indicates if the table value refers to a table or a prefix. For a call with the default prefix = NULL, the table values that have is_prefix == FALSE correspond to the tables returned from \texttt{dbListTables()},

The table object can be quoted with \texttt{dbQuoteIdentifier()}. The result of quoting can be passed to \texttt{dbUnquoteIdentifier()}. (For backends it may be convenient to use the \texttt{Id} class, but this is not required.)

Values in table column that have is_prefix == TRUE can be passed as the prefix argument to another call to \texttt{dbListObjects()}. For the data frame returned from a \texttt{dbListObject()} call with the prefix argument set, all table values where is_prefix is FALSE can be used in a call to \texttt{dbExistsTable()} which returns TRUE.

Other sql specifications: \texttt{spec_sql_append_table,spec_sql_create_table,spec_sql_exists_table, spec_sql_list_fields,spec_sql_list_tables,spec_sql_quote_identifier,spec_sql_quote_literal, spec_sql_quote_string,spec_sql_read_table,spec_sql_remove_table,spec_sql_unquote_identifier, spec_sql_write_table}

---

des

spec_sql_list_tables

---

Description

spec_sql_list_tables

Value

\texttt{dbListTables()} returns a character vector that enumerates all tables and views in the database. Tables added with \texttt{dbWriteTable()} are part of the list. As soon a table is removed from the database, it is also removed from the list of database tables.

The same applies to temporary tables if supported by the database.

The returned names are suitable for quoting with \texttt{dbQuoteIdentifier()}.

Failure modes

An error is raised when calling this method for a closed or invalid connection.

See Also

Other sql specifications: \texttt{spec_sql_append_table,spec_sql_create_table,spec_sql_exists_table, spec_sql_list_fields,spec_sql_list_objects,spec_sql_quote_identifier,spec_sql_quote_literal, spec_sql_quote_string,spec_sql_read_table,spec_sql_remove_table,spec_sql_unquote_identifier, spec_sql_write_table}
Description

spec_sql_quote_identifier

Value

dbQuoteIdentifier() returns an object that can be coerced to character, of the same length as the input. For an empty character vector this function returns a length-0 object. The names of the input argument are preserved in the output. When passing the returned object again to dbQuoteIdentifier() as x argument, it is returned unchanged. Passing objects of class SQL should also return them unchanged. (For backends it may be most convenient to return SQL objects to achieve this behavior, but this is not required.)

Failure modes

An error is raised if the input contains NA, but not for an empty string.

Specification

Calling dbGetQuery() for a query of the format SELECT 1 AS ... returns a data frame with the identifier, unquoted, as column name. Quoted identifiers can be used as table and column names in SQL queries, in particular in queries like SELECT 1 AS ... and SELECT * FROM (SELECT 1) .... The method must use a quoting mechanism that is unambiguously different from the quoting mechanism used for strings, so that a query like SELECT ... FROM (SELECT 1 AS ...) throws an error if the column names do not match.

The method can quote column names that contain special characters such as a space, a dot, a comma, or quotes used to mark strings or identifiers, if the database supports this. In any case, checking the validity of the identifier should be performed only when executing a query, and not by dbQuoteIdentifier().

Other sql specifications: spec_sql_append_table, spec_sql_create_table, spec_sql_exists_table, spec_sql_list_fields, spec_sql_list_objects, spec_sql_list_tables, spec_sql_quote_literal, spec_sql_quote_string, spec_sql_read_table, spec_sql_remove_table, spec_sql_unquote_identifier, spec_sql_write_table
spec_sql_quote_literal

Description

spec_sql_quote_literal

Value

dbQuoteLiteral() returns an object that can be coerced to character, of the same length as the input. For an empty integer, numeric, character, logical, date, time, or blob vector, this function returns a length-0 object.

When passing the returned object again to dbQuoteLiteral() as x argument, it is returned unchanged. Passing objects of class SQL should also return them unchanged. (For backends it may be most convenient to return SQL objects to achieve this behavior, but this is not required.)

Specification

The returned expression can be used in a SELECT ... query, and the value of dbGetQuery(paste0("SELECT ", dbQuoteLiteral(x)))[[1]] must be equal to x for any scalar integer, numeric, string, and logical. If x is NA, the result must merely satisfy is.na(). The literals "NA" or "NULL" are not treated specially.

NA should be translated to an unquoted SQL NULL, so that the query SELECT * FROM (SELECT 1) a WHERE ... IS NULL returns one row.

Failure modes

Passing a list for the x argument raises an error.

See Also

Other sql specifications: spec_sql_append_table, spec_sql_create_table, spec_sql_exists_table, spec_sql_list_fields, spec_sql_list_objects, spec_sql_list_tables, spec_sql_quote_identifier, spec_sql_quote_string, spec_sql_read_table, spec_sql_remove_table, spec_sql_unquote_identifier, spec_sql_write_table
Description

Value

dbQuoteString() returns an object that can be coerced to character, of the same length as the input. For an empty character vector this function returns a length-0 object.

When passing the returned object again to dbQuoteString() as x argument, it is returned unchanged. Passing objects of class SQL should also return them unchanged. (For backends it may be most convenient to return SQL objects to achieve this behavior, but this is not required.)

Specification

The returned expression can be used in a SELECT ... query, and for any scalar character x the value of dbGetQuery(paste0("SELECT ", dbQuoteString(x))[1]) must be identical to x, even if x contains spaces, tabs, quotes (single or double), backticks, or newlines (in any combination) or is itself the result of a dbQuoteString() call coerced back to character (even repeatedly). If x is NA, the result must merely satisfy is.na(). The strings "NA" or "NULL" are not treated specially.

NA should be translated to an unquoted SQL NULL, so that the query SELECT * FROM (SELECT 1) a WHERE ... IS NULL returns one row.

Failure modes

Passing a numeric, integer, logical, or raw vector, or a list for the x argument raises an error.

See Also

Other sql specifications: spec_sql_append_table, spec_sql_create_table, spec_sql_exists_table, spec_sql_list_fields, spec_sql_list_objects, spec_sql_list_tables, spec_sql_quote_identifier, spec_sql_quote_literal, spec_sql_read_table, spec_sql_remove_table, spec_sql_unquote_identifier, spec_sql_write_table
Value

dbReadTable() returns a data frame that contains the complete data from the remote table, effectively the result of calling dbGetQuery() with SELECT * FROM <name>.

An empty table is returned as a data frame with zero rows.

The presence of rownames depends on the row.names argument, see sqlColumnToRownames() for details:

• If FALSE or NULL, the returned data frame doesn’t have row names.
• If TRUE, a column named "row_names" is converted to row names.
• If NA, a column named "row_names" is converted to row names if it exists, otherwise no translation occurs.
• If a string, this specifies the name of the column in the remote table that contains the row names.

The default is row.names = FALSE.

If the database supports identifiers with special characters, the columns in the returned data frame are converted to valid R identifiers if the check.names argument is TRUE. If check.names = FALSE, the returned table has non-syntactic column names without quotes.

Failure modes

An error is raised if the table does not exist.
An error is raised if row.names is TRUE and no "row_names" column exists,
An error is raised if row.names is set to a string and no corresponding column exists.
An error is raised when calling this method for a closed or invalid connection. An error is raised if name cannot be processed with dbQuoteIdentifier() or if this results in a non-scalar. Unsupported values for row.names and check.names (non-scalars, unsupported data types, NA for check.names) also raise an error.

Additional arguments

The following arguments are not part of the dbReadTable() generic (to improve compatibility across backends) but are part of the DBI specification:

• row.names (default: FALSE)
• check.names

They must be provided as named arguments. See the "Value" section for details on their usage.

Specification

The name argument is processed as follows, to support databases that allow non-syntactic names for their objects:

• If an unquoted table name as string: dbReadTable() will do the quoting, perhaps by calling dbQuoteIdentifier(conn, x = name)
• If the result of a call to dbQuoteIdentifier(): no more quoting is done
Description

spec_sql_remove_table

Value

dbRemoveTable() returns TRUE, invisibly.

Failure modes

If the table does not exist, an error is raised. An attempt to remove a view with this function may result in an error.

An error is raised when calling this method for a closed or invalid connection. An error is also raised if name cannot be processed with dbQuoteIdentifier() or if this results in a non-scalar.

Additional arguments

The following arguments are not part of the dbRemoveTable() generic (to improve compatibility across backends) but are part of the DBI specification:

• temporary (default: FALSE)
• fail_if_missing (default: TRUE)

These arguments must be provided as named arguments.

If temporary is TRUE, the call to dbRemoveTable() will consider only temporary tables. Not all backends support this argument. In particular, permanent tables of the same name are left untouched.

If fail_if_missing is FALSE, the call to dbRemoveTable() succeeds if the table does not exist.

Specification

A table removed by dbRemoveTable() doesn’t appear in the list of tables returned by dbListTables(), and dbExistsTable() returns FALSE. The removal propagates immediately to other connections to the same database. This function can also be used to remove a temporary table.

The name argument is processed as follows, to support databases that allow non-syntactic names for their objects:

• If an unquoted table name as string: dbRemoveTable() will do the quoting, perhaps by calling dbQuoteIdentifier(conn, x = name)
• If the result of a call to dbQuoteIdentifier(): no more quoting is done
See Also

Other sql specifications: spec_sql_append_table, spec_sql_create_table, spec_sql_exists_table, spec_sql_list_fields, spec_sql_list_objects, spec_sql_list_tables, spec_sql_quote_identifier, spec_sql_quote_literal, spec_sql_quote_string, spec_sql_read_table, spec_sql_unquote_identifier, spec_sql_write_table

---

dbUnquoteIdentifier() returns a list of objects of the same length as the input. For an empty vector, this function returns a length-0 object. The names of the input argument are preserved in the output. If x is a value returned by dbUnquoteIdentifier(), calling dbUnquoteIdentifier(..., dbQuoteIdentifier(..., x)) returns list(x). If x is an object of class Id, calling dbUnquoteIdentifier(..., x) returns list(x). (For backends it may be most convenient to return Id objects to achieve this behavior, but this is not required.)

Plain character vectors can also be passed to dbUnquoteIdentifier().

Failure modes

An error is raised if a character vectors with a missing value is passed as the x argument.

Specification

For any character vector of length one, quoting (with dbQuoteIdentifier()) then unquoting then quoting the first element is identical to just quoting. This is also true for strings that contain special characters such as a space, a dot, a comma, or quotes used to mark strings or identifiers, if the database supports this.

Unquoting simple strings (consisting of only letters) wrapped with SQL() and then quoting via dbQuoteIdentifier() gives the same result as just quoting the string. Similarly, unquoting expressions of the form SQL("schema.table") and then quoting gives the same result as quoting the identifier constructed by Id("schema", "table").

See Also

Other sql specifications: spec_sql_append_table, spec_sql_create_table, spec_sql_exists_table, spec_sql_list_fields, spec_sql_list_objects, spec_sql_list_tables, spec_sql_quote_identifier, spec_sql_quote_literal, spec_sql_quote_string, spec_sql_read_table, spec_sql_remove_table, spec_sql_write_table
Description

spec_sql_write_table

Value

dbWriteTable() returns TRUE, invisibly.

Failure modes

If the table exists, and both append and overwrite arguments are unset, or append = TRUE and the data frame with the new data has different column names, an error is raised; the remote table remains unchanged.

An error is raised when calling this method for a closed or invalid connection. An error is also raised if name cannot be processed with dbQuoteIdentifier() or if this results in a non-scalar. Invalid values for the additional arguments row.names, overwrite, append, field.types, and temporary (non-scalars, unsupported data types, NA, incompatible values, duplicate or missing names, incompatible columns) also raise an error.

Additional arguments

The following arguments are not part of the dbWriteTable() generic (to improve compatibility across backends) but are part of the DBI specification:

- row.names (default: FALSE)
- overwrite (default: FALSE)
- append (default: FALSE)
- field.types (default: NULL)
- temporary (default: FALSE)

They must be provided as named arguments. See the "Specification" and "Value" sections for details on their usage.

Specification

The name argument is processed as follows, to support databases that allow non-syntactic names for their objects:

- If an unquoted table name as string: dbWriteTable() will do the quoting, perhaps by calling dbQuoteIdentifier(conn, x = name)
- If the result of a call to dbQuoteIdentifier(): no more quoting is done
The value argument must be a data frame with a subset of the columns of the existing table if `append = TRUE`. The order of the columns does not matter with `append = TRUE`.

If the `overwrite` argument is `TRUE`, an existing table of the same name will be overwritten. This argument doesn’t change behavior if the table does not exist yet.

If the `append` argument is `TRUE`, the rows in an existing table are preserved, and the new data are appended. If the table doesn’t exist yet, it is created.

If the `temporary` argument is `TRUE`, the table is not available in a second connection and is gone after reconnecting. Not all backends support this argument. A regular, non-temporary table is visible in a second connection, in a pre-existing connection, and after reconnecting to the database.

SQL keywords can be used freely in table names, column names, and data. Quotes, commas, spaces, and other special characters such as newlines and tabs, can also be used in the data, and, if the database supports non-syntactic identifiers, also for table names and column names.

The following data types must be supported at least, and be read identically with `dbReadTable()`:

- integer
- numeric (the behavior for Inf and NaN is not specified)
- logical
- NA as NULL
- 64-bit values (using "bigint" as field type); the result can be
  - converted to a numeric, which may lose precision,
  - converted a character vector, which gives the full decimal representation
  - written to another table and read again unchanged
- character (in both UTF-8 and native encodings), supporting empty strings before and after a non-empty string
- factor (returned as character)
- list of raw (if supported by the database)
- objects of type `blob::blob` (if supported by the database)
- date (if supported by the database; returned as `Date`), also for dates prior to 1970 or 1900 or after 2038
- time (if supported by the database; returned as objects that inherit from `difftime`)
- timestamp (if supported by the database; returned as ` POSIXct` respecting the time zone but not necessarily preserving the input time zone), also for timestamps prior to 1970 or 1900 or after 2038 respecting the time zone but not necessarily preserving the input time zone)

Mixing column types in the same table is supported.

The `field.types` argument must be a named character vector with at most one entry for each column. It indicates the SQL data type to be used for a new column. If a column is missed from `field.types`, the type is inferred from the input data with `dbDataType()`.

The interpretation of `rownames` depends on the `row.names` argument, see `sqlRownamesToColumn()` for details:

- If FALSE or NULL, row names are ignored.
• If TRUE, row names are converted to a column named "row_names", even if the input data frame only has natural row names from 1 to nrow(...).
• If NA, a column named "row_names" is created if the data has custom row names, no extra column is created in the case of natural row names.
• If a string, this specifies the name of the column in the remote table that contains the row names, even if the input data frame only has natural row names.

The default is row.names = FALSE.

Other sql specifications: spec_sql_append_table, spec_sql_create_table, spec_sql_exists_table, spec_sql_list_fields, spec_sql_list_objects, spec_sql_list_tables, spec_sql_quote_identifier, spec_sql_quote_literal, spec_sql_quote_string, spec_sql_read_table, spec_sql_remove_table, spec_sql_unquote_identifier
The behavior is not specified if other arguments are passed to these functions. In particular, \texttt{RSQLite} issues named transactions with support for nesting if the \texttt{name} argument is set.

The transaction isolation level is not specified by DBI.

\textbf{See Also}

Other transaction specifications: \texttt{spec\_transaction\_with\_transaction}

\begin{verbatim}
spec_transaction_with_transaction

Description

\texttt{spec\_transaction\_with\_transaction}

Value

\texttt{dbWithTransaction()} returns the value of the executed code.

Failure modes

Failure to initiate the transaction (e.g., if the connection is closed or invalid or if \texttt{dbBegin()} has been called already) gives an error.

Specification

\texttt{dbWithTransaction()} initiates a transaction with \texttt{dbBegin()}, executes the code given in the code argument, and commits the transaction with \texttt{dbCommit()}. If the code raises an error, the transaction is instead aborted with \texttt{dbRollback()}, and the error is propagated. If the code calls \texttt{dbBreak()}, execution of the code stops and the transaction is silently aborted. All side effects caused by the code (such as the creation of new variables) propagate to the calling environment.

\textbf{See Also}

Other transaction specifications: \texttt{spec\_transaction\_begin\_commit\_rollback}
\end{verbatim}
Description

test_all() calls all tests defined in this package (see the section "Tests" below). This function supports running only one test by setting an environment variable, e.g., set the DBITEST_ONLY_RESULT to a nonempty value to run only test_result().
test_some() allows testing one or more tests.

Usage

test_all(skip = NULL, run_only = NULL, ctx = get_default_context())
test_some(test, ctx = get_default_context())

Arguments

skip [character()]
A vector of regular expressions to match against test names; skip test if matching any. The regular expressions are matched against the entire test name minus a possible suffix _N where N is a number. For example, skip = "exists_table" will skip both "exists_table_1" and "exists_table_2".

run_only [character()]
A vector of regular expressions to match against test names; run only these tests. The regular expressions are matched against the entire test name.

test [character]
A character vector of regular expressions describing the tests to run. The regular expressions are matched against the entire test name.

details

Internally ^ and $ are used as prefix and suffix around the regular expressions passed in the skip and run_only arguments.

Tests

This function runs the following tests, except the stress tests:
test_getting_started(): Getting started with testing
test_driver(): Test the "Driver" class
test_connection(): Test the "Connection" class
test_result(): Test the "Result" class
test_sql(): Test SQL methods
test_meta(): Test metadata functions

test_transaction(): Test transaction functions

test_arrow(): Test Arrow methods

test_compliance(): Test full compliance to DBI

test_stress(): Stress tests (not tested with test_all)

---

**Description**

Test Arrow methods

**Usage**

test_arrow(skip = NULL, run_only = NULL, ctx = get_default_context())

**Arguments**

- **skip** [character()]
  A vector of regular expressions to match against test names; skip test if matching any. The regular expressions are matched against the entire test name minus a possible suffix _N where N is a number. For example, skip = "exists_table" will skip both "exists_table_1" and "exists_table_2".

- **run_only** [character()]
  A vector of regular expressions to match against test names; run only these tests. The regular expressions are matched against the entire test name.

- **ctx** [DBItest_context]
  A test context as created by make_context().

**See Also**

Other tests: test_compliance(), test_connection(), test_driver(), test_getting_started(),

test_meta(), test_result(), test_sql(), test_stress(), test_transaction()
**test_compliance**

*Test full compliance to DBI*

**Description**

Test full compliance to DBI

**Usage**

```r
test_compliance(skip = NULL, run_only = NULL, ctx = get_default_context())
```

**Arguments**

- `skip` [character()]
  
  A vector of regular expressions to match against test names; skip test if matching any. The regular expressions are matched against the entire test name minus a possible suffix \_N where N is a number. For example, `skip = "exists_table"` will skip both "exists_table_1" and "exists_table_2".

- `run_only` [character()]
  
  A vector of regular expressions to match against test names; run only these tests. The regular expressions are matched against the entire test name.

- `ctx` [DBItest_context]
  
  A test context as created by `make_context()`.

**See Also**

**test_connection**

*Test the "Connection" class*

**Description**

Test the "Connection" class

**Usage**

```r
test_connection(skip = NULL, run_only = NULL, ctx = get_default_context())
```
test_driver

Test the "Driver" class

Usage

test_driver(skip = NULL, run_only = NULL, ctx = get_default_context())

Arguments

skip [character()]
A vector of regular expressions to match against test names; skip test if matching
any. The regular expressions are matched against the entire test name minus a
possible suffix _N where N is a number. For example, skip = "exists_table"
will skip both "exists_table_1" and "exists_table_2".

run_only [character()]
A vector of regular expressions to match against test names; run only these tests.
The regular expressions are matched against the entire test name.

cxt [DBItest_context]
A test context as created by make_context().

Other tests: test_arrow(), test_compliance(), test_driver(), test_getting_started(),
test_meta(), test_result(), test_sql(), test_stress(), test_transaction()
### test_getting_started

**Getting started with testing**

**Description**

Tests very basic features of a DBI driver package, to support testing and test-first development right from the start.

**Usage**

```r
test_getting_started(skip = NULL, run_only = NULL, ctx = get_default_context())
```

**Arguments**

- **skip** [character()]
  A vector of regular expressions to match against test names; skip test if matching any. The regular expressions are matched against the entire test name minus a possible suffix `_N` where `N` is a number. For example, `skip = "exists_table"` will skip both "exists_table_1" and "exists_table_2".

- **run_only** [character()]
  A vector of regular expressions to match against test names; run only these tests. The regular expressions are matched against the entire test name.

- **ctx** [DBItest_context]
  A test context as created by `make_context()`.

**See Also**

Other tests: `test_arrow()`, `test_compliance()`, `test_connection()`, `test_driver()`, `test_meta()`, `test_result()`, `test_sql()`, `test_stress()`, `test_transaction()`

### test_meta

**Test metadata functions**

**Description**

Test metadata functions

**Usage**

```r
test_meta(skip = NULL, run_only = NULL, ctx = get_default_context())
```
Arguments

- **skip** [character()]
  A vector of regular expressions to match against test names; skip test if matching any. The regular expressions are matched against the entire test name minus a possible suffix \_N where N is a number. For example, `skip = "exists_table"` will skip both "exists_table_1" and "exists_table_2".

- **run_only** [character()]
  A vector of regular expressions to match against test names; run only these tests. The regular expressions are matched against the entire test name.

- **ctx** [DBItest_context]
  A test context as created by `make_context()`.

See Also

Other tests: `test_arrow()`, `test_compliance()`, `test_connection()`, `test_driver()`, `test_getting_started()`, `test_result()`, `test_sql()`, `test_stress()`, `test_transaction()`

test_result

Test the "Result" class

Description

Test the "Result" class

Usage

test_result(skip = NULL, run_only = NULL, ctx = get_default_context())

Arguments

- **skip** [character()]
  A vector of regular expressions to match against test names; skip test if matching any. The regular expressions are matched against the entire test name minus a possible suffix \_N where N is a number. For example, `skip = "exists_table"` will skip both "exists_table_1" and "exists_table_2".

- **run_only** [character()]
  A vector of regular expressions to match against test names; run only these tests. The regular expressions are matched against the entire test name.

- **ctx** [DBItest_context]
  A test context as created by `make_context()`.

See Also

Other tests: `test_arrow()`, `test_compliance()`, `test_connection()`, `test_driver()`, `test_getting_started()`, `test_meta()`, `test_sql()`, `test_stress()`, `test_transaction()`
### test_sql

**Description**
Test SQL methods

**Usage**
```
test_sql(skip = NULL, run_only = NULL, ctx = get_default_context())
```

**Arguments**

- `skip` [character()]
  A vector of regular expressions to match against test names; skip test if matching any. The regular expressions are matched against the entire test name minus a possible suffix `_N` where `N` is a number. For example, `skip = "exists_table"` will skip both "exists_table_1" and "exists_table_2".

- `run_only` [character()]
  A vector of regular expressions to match against test names; run only these tests. The regular expressions are matched against the entire test name.

- `ctx` [DBItest_context]
  A test context as created by `make_context()`.

**See Also**
Other tests: `test_arrow()`, `test_compliance()`, `test_connection()`, `test_driver()`, `test_getting_started()`, `test_meta()`, `test_result()`, `test_stress()`, `test_transaction()`

### test_transaction

**Description**
Test transaction functions

**Usage**
```
test_transaction(skip = NULL, run_only = NULL, ctx = get_default_context())
```
tweaks

Arguments

skip [character()]
A vector of regular expressions to match against test names; skip test if matching any. The regular expressions are matched against the entire test name minus a possible suffix _N where N is a number. For example, skip = "exists_table" will skip both "exists_table_1" and "exists_table_2".

run_only [character()]
A vector of regular expressions to match against test names; run only these tests. The regular expressions are matched against the entire test name.

cxt [DBItest_context]
A test context as created by make_context().

See Also

Other tests: test_arrow(), test_compliance(), test_connection(), test_driver(), test_getting_started(), test_meta(), test_result(), test_sql(), test_stress()

tweaks Tweaks for DBI tests

Description

The tweaks are a way to control the behavior of certain tests. Currently, you need to search the DBItest source code to understand which tests are affected by which tweaks. This function is usually called to set the tweaks argument in a make_context() call.

Usage

tweaks(
  ..., 
  constructor_name = NULL,
  constructor_relax_args = FALSE,
  strict_identifier = FALSE,
  omit_blob_tests = FALSE,
  current_needs_parens = FALSE,
  union = function(x) paste(x, collapse = " UNION "),
  placeholder_pattern = NULL,
  logical_return = identity,
  date_cast = function(x) paste0("date(’", x, ")"),
  time_cast = function(x) paste0("time(’", x, ")"),
  timestamp_cast = function(x) paste0("timestamp(’", x, ")"),
  blob_cast = identity,
  date_typed = TRUE,
  time_typed = TRUE,
  timestamp_typed = TRUE,
  temporary_tables = TRUE,
)
list_temporary_tables = TRUE,
allow_na_rows_affected = FALSE,
is_null_check = function(x) paste0("(", x, " IS NULL")
create_table_as = function(table_name, query) paste0("CREATE TABLE ", table_name, " AS ", query),
dbitest_version = "1.7.1"
)

Arguments

... [any]
Unknown tweaks are accepted, with a warning. The ellipsis also makes sure that you only can pass named arguments.

constructor_name
[character(1)]
Name of the function that constructs the Driver object.

creator_relay_args
[logical(1)]
If TRUE, allow a driver constructor with default values for all arguments; otherwise, require a constructor with empty argument list (default).

strict_identifier
[logical(1)]
Set to TRUE if the DBMS does not support arbitrarily-named identifiers even when quoting is used.

omit_blob_tests
[logical(1)]
Set to TRUE if the DBMS does not support a BLOB data type.

current_needs_parens
[logical(1)]
Set to TRUE if the SQL functions current_date, current_time, and current_timestamp require parentheses.

union [function(character)]
Function that combines several subqueries into one so that the resulting query returns the concatenated results of the subqueries.

placeholder_pattern
[character]
A pattern for placeholders used in `dbBind()`, e.g., "?", "$1", or ":name". See `make_placeholder_fun()` for details.

logical_return [function(logical)]
A vectorized function that converts logical values to the data type returned by the DBI backend.

date_cast [function(character)]
A vectorized function that creates an SQL expression for coercing a string to a date value.

time_cast [function(character)]
A vectorized function that creates an SQL expression for coercing a string to a time value.
timestamp_cast [function(character)]
A vectorized function that creates an SQL expression for coercing a string to a
timestamp value.

blob_cast [function(character)]
A vectorized function that creates an SQL expression for coercing a string to a
blob value.

date_typed [logical(1L)]
Set to FALSE if the DBMS doesn’t support a dedicated type for dates.

time_typed [logical(1L)]
Set to FALSE if the DBMS doesn’t support a dedicated type for times.

timestamp_typed [logical(1L)]
Set to FALSE if the DBMS doesn’t support a dedicated type for timestamps.

temporary_tables [logical(1L)]
Set to FALSE if the DBMS doesn’t support temporary tables.

list_temporary_tables [logical(1L)]
Set to FALSE if the DBMS doesn’t support listing temporary tables.

allow_na_rows_affected [logical(1L)]
Set to TRUE to allow dbGetRowsAffected() to return NA.

is_null_check [function(character)]
A vectorized function that creates an SQL expression for checking if a value is
NULL.

create_table_as [function(character(1), character(1))]
A function that creates an SQL expression for creating a table from an SQL
expression.

dbitest_version [character(1)]
Compatible DBItest version, default: "1.7.1".

Examples

```r
## Not run:
make_context(..., tweaks = tweaks(strict_identifier = TRUE))
```

## End(Not run)
