Package ‘DT’

June 11, 2019

Type Package

Title A Wrapper of the JavaScript Library 'DataTables'

Version 0.7

Maintainer Yihui Xie <xie@yihui.name>

Description Data objects in R can be rendered as HTML tables using the
    JavaScript library 'DataTables' (typically via R Markdown or Shiny). The
    'DataTables' library has been included in this R package. The package name
    'DT' is an abbreviation of 'DataTables'.

coerceValue

Coerce a character string to the same type as a target value

Description

Create a new value from a character string based on an old value, e.g., if the old value is an integer, call as.integer() to coerce the string to an integer.

Usage

coerceValue(val, old)

Arguments

val A character string.
old An old value, whose type is the target type of val.

Details

This function only works with integer, double, date, time (POSIXt or POSIXct), and factor values. The date must be of the format %Y-%m-%dT%H:%M:%S. The factor value must be in the levels of old, otherwise it will be coerced to NA.

Value

A value of the same data type as old if possible.
### Examples

```r
library(DT)
coerceValue("100", 1L)
coerceValue("1.23", 3.1416)
coerceValue("2018-02-14", Sys.Date())
coerceValue("2018-02-14T22:18:52Z", Sys.time())
coerceValue("setosa", iris$Species)
coerceValue("setosa2", iris$Species) # NA
coerceValue("FALSE", TRUE) # not supported
```

### datatable

Create an HTML table widget using the DataTables library

### Description

This function creates an HTML widget to display rectangular data (a matrix or data frame) using the JavaScript library DataTables.

### Usage

```r
datatable(data, options = list(), class = "display", callback = JS("return table;"),
rownames, colnames, container, caption = NULL, filter = c("none", "bottom", "top"), escape = TRUE, style = "default", width = NULL,
height = NULL, elementId = NULL, fillContainer = getOption("DT.fillContainer", NULL),
autoHideNavigation = getOption("DT.autoHideNavigation", NULL),
selection = c("multiple", "single", "none"), extensions = list(),
plugins = NULL, editable = FALSE)
```

### Arguments

- **data**
  a data object (either a matrix or a data frame)
- **options**
  a list of initialization options (see [http://datatables.net/reference/option/](http://datatables.net/reference/option/)); the character options wrapped in JS() will be treated as literal JavaScript code instead of normal character strings; you can also set options globally via `options(DT.options = list(...))`, and global options will be merged into this options argument if set
- **class**
  the CSS class(es) of the table; see [http://datatables.net/manual/styling/classes](http://datatables.net/manual/styling/classes)
- **callback**
  the body of a JavaScript callback function with the argument `table` to be applied to the DataTables instance (i.e. `table`)
- **rownames**
  TRUE (show row names) or FALSE (hide row names) or a character vector of row names; by default, the row names are displayed in the first column of the table if exist (not NULL)
- **colnames**
  if missing, the column names of the data; otherwise it can be an unnamed character vector of names you want to show in the table header instead of the default data column names; alternatively, you can provide a named numeric or character vector of the form 'newName1' = i1,'newName2' = i2 or
c('newName1' = 'oldName1', 'newName2' = 'oldName2', ...), where
newName is the new name you want to show in the table, and i or oldName is the
index of the current column name
container a sketch of the HTML table to be filled with data cells; by default, it is generated
from htmltools::tags$table() with a table header consisting of the column
names of the data
caption the table caption; a character vector or a tag object generated from htmltools::tags$caption()
filter whether/where to use column filters; none: no filters; bottom/top: put col-
num filters at the bottom/top of the table; range sliders are used to filter nu-
meric/date/time columns, select lists are used for factor columns, and text input
boxes are used for character columns; if you want more control over the styles of
filters, you can provide a list to this argument of the form list(position = 'top', clear = TRUE, plain = FALSE), where clear indicates whether you want the clear buttons in the in-
put boxes, and plain means if you want to use Bootstrap form styles or plain
text input styles for the text input boxes
escape whether to escape HTML entities in the table: TRUE means to escape the whole
table, and FALSE means not to escape it; alternatively, you can specify numeric column
indices or column names to indicate which columns to escape, e.g. 1:5
(the first 5 columns), c(1, 3, 4), or c(-1, -3) (all columns except the first
and third), or c('Species', 'Sepal.Length')
style the style name (http://datatables.net/manual/styling/); currently only
'default' and 'bootstrap' are supported
width, height Width/Height in pixels (optional, defaults to automatic sizing)
elementId An id for the widget (a random string by default).
fillContainer TRUE to configure the table to automatically fill its containing element. If the
table can’t fit fully into its container then vertical and/or horizontal scrolling of
the table cells will occur.
autoHideNavigation TRUE to automatically hide navigational UI when the number of total records is
less than the page size.
selection the row/column selection mode (single or multiple selection or disable selection)
when a table widget is rendered in a Shiny app; alternatively, you can use a list of
the form list(mode = 'multiple', selected = c(1, 3, 8), target = 'row')
to pre-select rows; the element target in the list can be 'column' to enable
column selection, or 'row+column' to make it possible to select both rows and
columns (click on the footer to select columns), or 'cell' to select cells
extensions a character vector of the names of the DataTables extensions (https://datatables.
net/extensions/index)
plugins a character vector of the names of DataTables plug-ins (https://rstudio.
github.io/DT/plugins.html). Note that only those plugins supported by the
DT package can be used here.
editable FALSE to disable the table editor, or TRUE (or "cell") to enable editing a sin-
gle cell. Alternatively, you can set it to "row" to be able to edit a row, or
"column" to edit a column, or "all" to edit all cells on the current page of
the table. In all modes, start editing by doubleclicking on a cell. This argument can also be a list of the form `list(target = TARGET, disable = list(columns = INDICES))`, where `TARGET` can be `cell`, `row`, `column`, or `all`, and `INDICES` is an integer vector of column indices. Use the list form if you want to disable editing certain columns.

Note
You are recommended to escape the table content for security reasons (e.g. XSS attacks) when using this function in Shiny or any other dynamic web applications.

References
See https://rstudio.github.io/DT for the full documentation.

Examples

```r
library(DT)

# see the package vignette for examples and the link to website
dataTable('DT', package = 'DT')

# some boring edge cases for testing purposes
m <- matrix(nrow = 0, ncol = 5, dimnames = list(NULL, letters[1:5]))
dataTable(m) # zero rows
dataTable(as.data.frame(m))

m <- matrix(1, dimnames = list(NULL, 'a'))
dataTable(m) # one row and one column
dataTable(as.data.frame(m))

m <- data.frame(a = 1, b = 2, c = 3)
dataTable(m)
dataTable(as.matrix(m))

# dates
dataTable(data.frame(
    date = seq(as.Date("2015-01-01"), by = "day", length.out = 5), x = 1:5
))
dataTable(data.frame(x = Sys.Date()))
dataTable(data.frame(x = Sys.time()))
```

**dataTableAjax**  
Register a data object in a shiny session for DataTables

**Description**

This function stores a data object in a shiny session and returns a URL that returns JSON data based on DataTables Ajax requests. The URL can be used as the `url` option inside the `ajax` option of the table. It is basically an implementation of server-side processing of DataTables in R. Filtering, sorting, and pagination are processed through R instead of JavaScript (client-side processing).
dataTableAjax

Usage

dataTableAjax(session, data, rownames, filter = dataTableAjaxFilter, outputId)

Arguments

session the session object in the shiny server function (function(input, output, session))
data a data object (will be coerced to a data frame internally)
rownames see datatable(); it must be consistent with what you use in datatable(), e.g. if the widget is generated by `datatable(rownames = FALSE)`, you must also use `dataTableAjax(rownames = FALSE)` here
filter (for expert use only) a function with two arguments `data` and `params` (Ajax parameters, a list of the form `list(search = list(value = 'FOO', regex = 'false'), length = 10, that return the filtered table result according to the DataTables Ajax request
outputId the output ID of the table (the same ID passed to `datatableOutput()`; if missing, a random string)

Details

Normally you should not need to call this function directly. It is called internally when a table widget is rendered in a Shiny app to configure the table option `ajax` automatically. If you are familiar with DataTables' server-side processing, and want to use a custom filter function, you may call this function to get an Ajax URL.

Value

A character string (an Ajax URL that can be queried by DataTables).

References

https://rstudio.github.io/DT/server.html

Examples

```r
DTApp <- function(data, ..., options = list()) {
  library(shiny)
  library(DT)
  shinyApp(
    ui = fluidPage(
      title = 'Server-side processing of DataTables',
      fluidRow(  
        DT::dataTableOutput('tbl')
      )
    ),
    server = function(input, output, session) {
      options(serverSide = TRUE
      options$ajax = list(url = dataTableAjax(session, data))
      # create a widget using an Ajax URL created above
      widget = datatable(data, ..., options = options)
      output$table = DT::renderDataTable(widget)
    }
  )
}
```
Helper functions for using DT in Shiny

Description

These two functions are like most fooOutput() and renderFoo() functions in the shiny package. The former is used to create a container for table, and the latter is used in the server logic to render the table.

Usage

dataTableOutput(outputId, width = "100\%", height = "auto")

DTOutput(outputId, width = "100\%", height = "auto")

renderDataTable(expr, server = TRUE, env = parent.frame(), quoted = FALSE,
                 funcFilter = dataTablesFilter, ...)

renderDT(expr, server = TRUE, env = parent.frame(), quoted = FALSE,
           funcFilter = dataTablesFilter, ...)

Arguments

- **outputId**: output variable to read the table from
- **width**: the width of the table container
- **height**: the height of the table container
- **expr**: an expression to create a table widget (normally via `datatable()`), or a data object to be passed to `datatable()` to create a table widget
- **server**: whether to use server-side processing. If TRUE, then the data is kept on the server and the browser requests a page at a time; if FALSE, then the entire data frame is sent to the browser at once. Highly recommended for medium to large data frames, which can cause browsers to slow down or crash.
- **env**: The environment in which to evaluate `expr`.
- **quoted**: Is `expr` a quoted expression (with `quote()`)? This is useful if you want to save an expression in a variable.
- **funcFilter**: (for expert use only) passed to the filter argument of `dataTableAjax()`
- **...**: ignored when `expr` returns a table widget, and passed as additional arguments to `datatable()` when `expr` returns a data object
dataTableProxy

**Description**

The function `dataTableProxy()` creates a proxy object that can be used to manipulate an existing DataTables instance in a Shiny app, e.g. select rows/columns, or add rows.

**Usage**

```r
dataTableProxy(outputId, session = shiny::getDefaultReactiveDomain(), deferUntilFlush = TRUE)

selectRows(proxy, selected)
selectColumns(proxy, selected)
selectCells(proxy, selected)
addRow(proxy, data)
clearSearch(proxy)
selectPage(proxy, page)
updateCaption(proxy, caption)
updateSearch(proxy, keywords = list(global = NULL, columns = NULL))
showCols(proxy, show, reset = FALSE)
```

**Examples**

```r
if (interactive()) {
  library(shiny)
  library(DT)
  shinyApp(
    ui = fluidPage(fluidRow(DTOutput('tbl'))),
    server = function(input, output) {
      output$tbl = renderDT(
        iris, options = list(lengthChange = FALSE)
      )
    }
  )
}
```
hideCols(proxy, hide, reset = FALSE)

colReorder(proxy, order, origOrder = FALSE)

reloadData(proxy, reset Paging = TRUE, clearSelection = c("all", "none", "row", "column", "cell"))

Arguments

outputId the id of the table to be manipulated (the same id as the one you used in `datatableOutput()`)  
session the Shiny session object (from the server function of the Shiny app)  
deferUntilFlush whether an action should be carried out right away, or should be held until after the next time all of the outputs are updated  
proxy a proxy object returned by `datatableProxy()`  
selected an integer vector of row/column indices, or a matrix of two columns (row and column indices, respectively) for cell indices; you may use NULL to clear existing selections  
data a single row of data to be added to the table; it can be a matrix or data frame of one row, or a vector or list of row data (in the latter case, please be cautious about the row name: if your table contains row names, here `data` must also contain the row name as the first element)  
page a number indicating the page to select  
caption a new table caption (see the `caption` argument of `datatable()`)  
keywords a list of two components: `global` is the global search keyword of a single character string (ignored if NULL); `columns` is a character vector of the search keywords for all columns (when the table has one column for the row names, this vector of keywords should contain one keyword for the row names as well)  
show a vector of column positions to show (the indexing starts at 0, but if `row.names` are visible, they are the first column).  
reset if TRUE, will only show/hide the columns indicated.  
hide a vector of column positions to hide  
order A numeric vector of column positions, starting from 0, and including the `row.names` as a column, if they are include. Must contain a value for all columns, regardless of whether they are visible or not. Also for column reordering to work, the `datatable` must have extension ‘ColReorder’ set as well as option ‘colReorder’ set to TRUE).  
origOrder Whether column reordering should be relative to the original order (the default is to compare to current order)  
reset Paging whether to reset the paging position  
clearSelection which existing selections to clear: it can be any combinations of `row`, `column`, and `cell`, or all for all three, or `none` to keep current selections (by default, all selections are cleared after the data is reloaded)
Note

addRow() only works for client-side tables. If you want to use it in a Shiny app, make sure to use renderDataTable(..., server = FALSE). Also note that the column filters (if used) of the table will not be automatically updated when a new row is added, e.g., the range of the slider of a column will stay the same even if you have added a value outside the range of the original data column.

reloadData() only works for tables in the server-side processing mode, e.g. tables rendered with renderDataTable(server = TRUE). The data to be reloaded (i.e. the one you pass to dataTableAjax()) must have exactly the same number of columns as the previous data object in the table.

editData

Edit a data object using the information from the editor in a DataTable

Description

When editing cells in a DataTable in a Shiny app, we know the row/column indices and values of the cells that were edited. With these information, we can update the data object behind the DataTable accordingly.

Usage

editData(data, info, proxy = NULL, rownames = TRUE, resetPaging = FALSE, ...)
Arguments

- **data**: The original data object used in the DataTable.
- **info**: The information about the edited cells. It should be obtained from input$tableView$cell_edit from Shiny, and is a data frame containing columns row, column, and value.
- **proxy**, **resetPaging**, ...  
  (Optional) If proxy is provided, it must be either a character string of the output ID of the table or a proxy object created from `datatableProxy()`, and the rest of arguments are passed to `replaceData()` to update the data in a DataTable instance in a Shiny app.
- **rownames**: Whether row names are displayed in the table.

Value

The updated data object.

---

**formatCurrency**

**Format table columns**

Description

Format numeric columns in a table as currency (`formatCurrency()`) or percentages (`formatPercentage()`), or round numbers to a specified number of decimal places (`formatRound()`) or a specified number of significant figures (`formatSignif()`). The function `formatStyle()` applies CSS styles to table cells by column.

Usage

```r
formatCurrency(table, columns, currency = "$", interval = 3, mark = ",", digits = 2, dec.mark = getOption("OutDec"), before = TRUE)

formatString(table, columns, prefix = "", suffix = "")

formatPercentage(table, columns, digits = 0, interval = 3, mark = ",",
  dec.mark = getOption("OutDec"))

formatRound(table, columns, digits = 2, interval = 3, mark = ",",
  dec.mark = getOption("OutDec"))

formatSignif(table, columns, digits = 2, interval = 3, mark = ",",
  dec.mark = getOption("OutDec"))

formatDate(table, columns, method = "toDateElement", params = NULL)

formatStyle(table, columns, valueColumns = columns, target = c("cell", 
  "row"), fontWeight = NULL, color = NULL, backgroundColor = NULL, 
  background = NULL, ...)```
formatCurrency

Arguments

- **table**: a table object created from `datatable()`
- **columns**: the indices of the columns to be formatted (can be character, numeric, logical, or a formula of the form `~ V1 + V2`, which is equivalent to `c('V1', 'V2')`)
- **currency**: the currency symbol
- **interval**: put a marker after how many digits of the numbers
- **mark**: the marker after every interval decimals in the numbers
- **digits**: the number of decimal places to round to
- **dec.mark**: a character to indicate the decimal point
- **before**: whether to place the currency symbol before or after the values
- **prefix**: string to put in front of the column values
- **suffix**: string to put after the column values
- **method**: the method(s) to convert a date to string in JavaScript; see `DT::DateMethods` for a list of possible methods, and `http://mzl.la/1xGe99W` for a full reference
- **params**: a list parameters for the specific date conversion method, e.g., for the `toLocaleDateString()` method, your browser may support `params = list('ko-KR', list(year = 'numeric', month = 'long', 'numeric'))`
- **valueColumns**: indices of the columns from which the cell values are obtained; this can be different with the columns argument, e.g. you may style one column based on the values of a different column
- **target**: the target to apply the CSS styles to (the current cell or the full row)
- **fontWeight**: the font weight, e.g. 'bold' and 'normal'
- **color**: the font color, e.g. 'red' and '#ee00aa'
- **backgroundColor**: the background color of table cells
- **background**: the background of table cells
- **...**: other CSS properties, e.g. 'border', 'font-size', 'text-align', and so on; if you want to condition CSS styles on the cell values, you may use the helper functions such as `styleInterval()`; note the actual CSS property names are dash-separated, but you can use camelCase names in this function (otherwise you will have to use backticks to quote the names, e.g. `'font-size' = '12px'`), and this function will automatically convert camelCase names to dash-separated names (e.g. `'fontWeight'` will be converted to `'font-weight'` internally)

References

See [https://rstudio.github.io/DT/functions.html](https://rstudio.github.io/DT/functions.html) for detailed documentation and examples.
replaceData

Examples

library(DT)
m = cbind(matrix(rnorm(120, 1e5, 1e6), 40), runif(40), rnorm(40, 100))
colnames(m) = head(LETTERS, ncol(m))
m

# format the columns A and C as currency, and D as percentages
datatable(m) %>% formatCurrency(c('A', 'C')) %>% formatPercentage('D', 2)

# the first two columns are Euro currency, and round column E to 3 decimal places
datatable(m) %>% formatCurrency(1:2, '\\u20AC') %>% formatRound('E', 3)

# render vapor pressure with only two significant figures.
datatable(pressure) %>% formatSignif('pressure', 2)

# apply CSS styles to columns
datatable(iris) %>%
  formatStyle('Sepal.Length', fontWeight = styleInterval(5, c('bold', 'weight')))
  formatStyle('Sepal.Width',
    color = styleInterval(3:4, c('red', 'white')),
    backgroundColor = styleInterval(3:4, c('yellow', 'gray'))
)

replaceData

Replace data in an existing table

Description

Replace the data object of a table output and avoid regenerating the full table, in which case the
state of the current table will be preserved (sorting, filtering, and pagination) and applied to the
table with new data.

Usage

replaceData(proxy, data, ..., resetPaging = TRUE, clearSelection = "all")

Arguments

proxy a proxy object created by dataTableProxy()
data the new data object to be loaded in the table
... other arguments to be passed to dataTableAjax()
resetPaging, clearSelection passed to reloadData()
Note

When you replace the data in an existing table, please make sure the new data has the same number of columns as the current data. When you have enabled column filters, you should also make sure the attributes of every column remain the same, e.g. factor columns should have the same or fewer levels, and numeric columns should have the same or smaller range, otherwise the filters may never be able to reach certain rows in the data.

---

*styleInterval*  
*Conditional CSS styles*

**Description**

A few helper functions for the *formatStyle()* function to calculate CSS styles for table cells based on the cell values. Under the hood, they just generate JavaScript and CSS code from the values specified in R.

**Usage**

```r
styleInterval(cuts, values)
styleEqual(levels, values, default = "")
styleColorBar(data, color, angle = 90)
```

**Arguments**

- `cuts`: a vector of cut points (sorted increasingly)
- `values`: a vector of CSS values
- `levels`: a character vector of data values to be mapped (one-to-one) to CSS values
- `default`: a string used as the default CSS value for values other than levels
- `data`: a numeric vector whose range will be used for scaling the table data from 0-100 before being represented as color bars. A vector of length 2 is acceptable here for specifying a range possibly wider or narrower than the range of the table data itself.
- `color`: the color of the bars
- `angle`: a number of degrees representing the direction to fill the gradient relative to a horizontal line and the gradient line, going counter-clockwise. For example, 90 fills right to left and -90 fills left to right.
Details

The function `styleInterval()` maps intervals to CSS values. Its argument values must be of length \( n + 1 \) where \( n = \text{length(cuts)} \). The right-closed interval \( '(\text{cuts}[i - 1], \text{cuts}[i])' \) is mapped to \( '\text{values}[i]' \) for \( i = 2, 3, \ldots, n \); \( '\text{values}[1]' \) is for the interval \( '(-\infty, \text{cuts}[1])' \), and \( '\text{values}[n + 1]' \) is for \( '(\text{cuts}[n], +\infty)' \). You can think of the order of cuts and values using this diagram: \( -\infty \rightarrow \text{values}[1] \rightarrow \text{cuts}[1] \rightarrow \text{values}[2] \rightarrow \text{cuts}[2] \rightarrow \ldots \rightarrow \text{values}[n] \rightarrow \text{cuts}[n] \rightarrow \text{values}[n + 1] \rightarrow +\infty \).

The function `styleEqual()` maps data values to CSS values in the one-to-one manner, i.e. \( \text{values}[i] \) is used when the table cell value is \( \text{levels}[i] \).

The function `styleColorBar()` can be used to draw background color bars behind table cells in a column, and the width of bars is proportional to the column values.

---

**tableHeader**  
*Generate a table header or footer from column names*

---

**Description**

Convenience functions to generate a table header ('<thead></thead>') or footer ('<tfoot></tfoot>') given the column names. They are basically wrappers of `htmltools::tags$th` applied to the column names.

**Usage**

```r
tableHeader(names, escape = TRUE)

tableFooter(names, escape = TRUE)
```

**Arguments**

- **names**  
a character vector of the column names of the table (if it is an object with column names, its column names will be used instead)

- **escape**  
whether to escape the names (see `datatable`)

**Value**  
A tag object generated by `htmltools::tags`.

**Examples**

```r
library(DT)

tableHeader(iris) # or equivalently,
tableHeader(colnames(iris))
tableFooter(iris) # footer

library(htmltools)
tags$_table(tableHeader(iris), tableFooter(iris))
```
