Package ‘HistData’

January 9, 2020

Type Package
Title Data Sets from the History of Statistics and Data Visualization
Version 0.8-6
Date 2020-01-06
Maintainer Michael Friendly <friendly@yorku.ca>
Description The ‘HistData’ package provides a collection of small data sets that are interesting and important in the history of statistics and data visualization. The goal of the package is to make these available, both for instructional use and for historical research. Some of these present interesting challenges for graphics or analysis in R.
Suggests gtools, KernSmooth, maps, ggplot2, scales, proto, grid, reshape, plyr, lattice, jpeg, car, gplots, sp, heplots, knitr, markdown, effects, lubridate, gridExtra, vcd, MASS
License GPL
LazyLoad yes
LazyData yes
VignetteBuilder knitr
RoxygenNote 5.0.1
NeedsCompilation no

HistData-package

Data sets from the History of Statistics and Data Visualization

Description

The HistData package provides a collection of data sets that are interesting and important in the history of statistics and data visualization. The goal of the package is to make these available, both for instructional use and for historical research.
Details

Package: HistData
Type: Package
Version: 0.8-6
Date: 2020-01-06
License: GPL
LazyLoad: yes
LazyData: yes

Some of the data sets have examples which reproduce an historical graph or analysis. These are meant mainly as starters for more extensive re-analysis or graphical elaboration. Some of these present graphical challenges to reproduce in R.

They are part of a program of research called statistical historiography, meaning the use of statistical methods to study problems and questions in the history of statistics and graphics.

Descriptions of each DataSet can be found using help(DataSet); example(DataSet) will likely show applications similar to the historical use.

Data sets included in the HistData package are:

**Arbuthnot** Arbuthnot’s data on male and female birth ratios in London from 1629-1710

**Armada** The Spanish Armada

**Bowley** Bowley’s data on values of British and Irish trade, 1855-1899

**Cavendish** Cavendish’s 1798 determinations of the density of the earth

**ChestSizes** Quetelet’s data on chest measurements of Scottish militiamen

**Cholera** William Farr’s Data on Cholera in London, 1849

**CushnyPeebles** Cushny-Peebles data: Soporific effects of scopolamine derivatives

**Dactyl** Edgeworth’s counts of dactyls in Virgil’s Aeneid

**DrinksWages** Elderton and Pearson’s (1910) data on drinking and wages

**Fingerprints** Waite’s data on Patterns in Fingerprints

**Galton** Galton’s data on the heights of parents and their children

**GaltonFamilies** Galton’s data on the heights of parents and their children, by family

**Guerry** Data from A.-M. Guerry, "Essay on the Moral Statistics of France"

**HalleyLifeTable** Halley’s Life Table

**Jevons** W. Stanley Jevons’ data on numerical discrimination

**Langren** van Langren’s data on longitude distance between Toledo and Rome

**Macdonell** Macdonell’s data on height and finger length of criminals, used by Gosset (1908)

**Michelson** Michelson’s 1879 determinations of the velocity of light

**Minard** Data from Minard’s famous graphic map of Napoleon’s march on Moscow

**Nightingale** Florence Nightingale’s data on deaths from various causes in the Crimean War

**OldMaps** Latitudes and Longitudes of 39 Points in 11 Old Maps
PearsonLee  Pearson and Lee’s 1896 data on the heights of parents and children classified by gender
PolioTrials  Polio Field Trials Data on the Salk vaccine
Prostitutes  Parent-Duchatelet’s time-series data on the number of prostitutes in Paris
Pyx  Trial of the Pyx
Quarrels  Statistics of Deadly Quarrels
Snow  John Snow’s map and data on the 1854 London Cholera outbreak
Virginis  J. F. W. Herschel’s data on the orbit of the twin star gamma Virginis
Wheat  Playfair’s data on wages and the price of wheat
Yeast  Student’s (1906) Yeast Cell Counts
ZeaMays  Darwin’s Heights of Cross- and Self-fertilized Zea May Pairs

Author(s)

Other packages containing data sets of historical interest include:
The Guerry-package, containing maps and other data sets related to Guerry’s (1833) Moral Statistics of France.
morsecodes from the (defunct) xgobi package for data from Rothkopf (1957) on errors in learning morse code, a classical example for MDS.
The **psych** package, containing Galton’s peas data.

The same data set is contained in **alr3** as **galtonpeas**.

The **agridat** contains a large number of data sets of agricultural data, including some extra data sets related to the classical barley data (**immer** and **barley**) from Immer (1934): **minnesota.barley.yield**, **minnesota.barley.weather**.

**Examples**

```r

```

## Description

John Arbuthnot (1710) used these time series data on the ratios of male to female christenings in London from 1629-1710 to carry out the first known significance test, comparing observed data to a null hypothesis. The data for these 81 years showed that in every year there were more male than female christenings.

On the assumption that male and female births were equally likely, he showed that the probability of observing 82 years with more males than females was vanishingly small ($4.14 \times 10^{-25}$). He used this to argue that a nearly constant birth ratio > 1 could be interpreted to show the guiding hand of a divine being. The data set adds variables of deaths from the plague and total mortality obtained by Campbell and from Creighton (1965).

## Usage

```r
data(Arbuthnot)
```

## Format

A data frame with 82 observations on the following 7 variables.

- **Year**  a numeric vector, 1629-1710
- **Males**  a numeric vector, number of male christenings
- **Females**  a numeric vector, number of female christenings
- **Plague**  a numeric vector, number of deaths from plague
- **Mortality**  a numeric vector, total mortality
- **Ratio**  a numeric vector, ratio of Males/Females
- **Total**  a numeric vector, total christenings in London (000s)
Details

Sandy Zabell (1976) pointed out several errors and inconsistencies in the Arbuthnot data. In particular, the values for 1674 and 1704 are identical, suggesting that the latter were copied erroneously from the former.

Jim Oeppen <joeppen@health.sdu.dk> points out that: "Arbuthnot’s data are annual counts of public baptisms, not births. Birth-baptism delay meant that infant deaths could occur before baptism. As male infants are more likely to die than females, the sex ratio at baptism might be expected to be lower than the ‘normal’ male- female birth ratio of 105:100. These effects were not constant as there were trends in birth-baptism delay, and in early infant mortality. In addition, the English Civil War and Commonwealth period 1642-1660 is thought to have been a period of both under-registration and lower fertility, but it is not clear whether these had sex-specific effects."

Armada

La Felicisima Armada

Description

The Spanish Armada (Spanish: Grande y Felicisima Armada, literally "Great and Most Fortunate Navy") was a Spanish fleet of 130 ships that sailed from La Coruna in August 1588. During its preparation, several accounts of its formidable strength were circulated to reassure allied powers of Spain or to intimidate its enemies. One such account was given by Paz Salas et Alvarez (1588).
The intent was bring the forces of Spain to invade England, overthrow Queen Elizabeth I, and re-establish Spanish control of the Netherlands. However the Armada was not as fortunate as hoped: it was all destroyed in one week’s fighting.

de Falguerolles (2008) reports the table given here as Armada as an early example of data to which multivariate methods might be applied.

Usage

data("Armada")

Format

A data frame with 10 observations on the following 11 variables.

Armada designation of the fleet, a factor with levels Andalucia Castilla Galeras Guipuscua Napoles Pataches Portugal Uantiscas Vizca Vrcas

ships number of ships, a numeric vector
tons total tons, a numeric vector
soldiers number of soldiers, a numeric vector
sailors number of sailors, a numeric vector
men total of soldiers plus sailors, a numeric vector
artillery a numeric vector
balls a numeric vector
gunpowder a numeric vector
lead a numeric vector
rope a numeric vector

Details

Note that men = soldiers + sailors

Bowley
Bowley’s data on values of British and Irish trade, 1855-1899

Description

In one of the first statistical textbooks, Arthur Bowley (1901) used these data to illustrate an arith-
metic and graphical analysis of time-series data using the total value of British and Irish exports
from 1855-1899. He presented a line graph of the time-series data, supplemented by overlaid line
graphs of 3-, 5- and 10-year moving averages. His goal was to show that while the initial series
showed wide variability, moving averages made the series progressively smoother.

Usage

data(Bowley)

Format

A data frame with 45 observations on the following 2 variables.

Year Year, from 1855-1899
Value total value of British and Irish exports (millions of Pounds)

Source

Digitized from Bowley’s graph.

Examples

data(Bowley)

# plot the data
with(Bowley,plot(Year, Value, type='b',
ylab="Value of British and Irish Exports",
main="Bowley’s example of the method of smoothing curves"))

# find moving averages-- use center alignment (requires width=ODD)
Henry Cavendish carried out a series of experiments in 1798 to determine the mean density of the earth, as an indirect means to calculate the gravitational constant, $G$, in Newton’s formula for the force ($f$) of gravitational attraction, $f = GmM/r^2$ between two bodies of mass $m$ and $M$.

Stigler (1977) used these data to illustrate properties of robust estimators with real, historical data. For these data sets, he found that trimmed means performed as well or better than more elaborate robust estimators.

**Usage**

`data(Cavendish)`

**Format**

A data frame with 29 observations on the following 3 variables.

- `density` Cavendish’s 29 determinations of the mean density of the earth
- `density2` same as `density`, with the third value (4.88) replaced by 5.88
- `density3` same as `density`, omitting the first 6 observations

**Details**

Density values (D) of the earth are given as relative to that of water. If the earth is regarded as a sphere of radius $R$, Newton’s law can be expressed as $GD = 3g/(4\pi R)$, where $g = 9.806m/s^2$ is the acceleration due to gravity; so $G$ is proportional to $1/D$.

`density` contains Cavendish’s measurements as analyzed, where he treated the value 4.88 as if it were 5.88. `density2` corrects this. Cavendish also changed his experimental apparatus after the sixth determination, using a stiffer wire in the torsion balance. `density3` replaces the first 6 values with NA.

The modern "true" value of $D$ is taken as 5.517. The gravitational constant can be expressed as $G = 6.674 \times 10^{-11} m^3/kg/s^2$. 

```R

```

Cholera

*William Farr's Data on Cholera in London, 1849*

Description

In 1852, William Farr, published a report of the Registrar-General on mortality due to cholera in England in the years 1848-1849, during which there was a large epidemic throughout the country. Farr initially believed that cholera arose from bad air (“miasma”) associated with low elevation above the River Thames. John Snow (1855) later showed that the disease was principally spread by contaminated water.

This data set comes from a paper by Brigham et al. (2003) that analyses some tables from Farr’s report to examine the prevalence of death from cholera in the districts of London in relation to the available predictors from Farr’s table.

Usage

```r
data("Cholera")
```

Format

A data frame with 38 observations on the following 15 variables.

district name of the district in London, a character vector
cholera_drate deaths from cholera in 1849 per 10,000 inhabitants, a numeric vector
cholera_deaths number of deaths registered from cholera in 1849, a numeric vector
popn population, in the middle of 1849, a numeric vector
elevation elevation, in feet above the high water mark, a numeric vector
region  a grouping of the London districts, a factor with levels West North Central South Kent
water  water supply region, a factor with levels Battersea New River Kew; see Details
annual_deaths  annual deaths from all causes, 1838-1844, a numeric vector
pop_dens  population density (persons per acre), a numeric vector
persons_house  persons per inhabited house, a numeric vector
house_valpp  average annual value of house, per person (pounds), a numeric vector
poor_rate  poor rate precept per pound of house value, a numeric vector
area  district area, a numeric vector
houses  number of houses, a numeric vector
house_val  total house values, a numeric vector

Details

The supply of water was classified as “Thames, between Battersea and Waterloo Bridges” (central London), “New River, Rivers Lea and Ravensbourne”, and “Thames, at Kew and Hammersmith” (western London). The factor levels use abbreviations for these.

The data frame is sorted by increasing elevation above the high water mark.

Cushny-Peebles Data: Soporific Effects of Scopolamine Derivatives

Description

Cushny and Peebles (1905) studied the effects of hydrobromides related to scopolamine and atropine in producing sleep. The sleep of mental patients was measured without hypnotic (Control) and after treatment with one of three drugs: L. hyoscyamine hydrobromide (L_hyoscyamine), L.
hyoscine hydrobromide (L-hyoscine), and a mixture (racemic) form, DL-hyoscine, called atropine. The L (levo) and D (detro) form of a given molecule are optical isomers (mirror images).

The drugs were given on alternate evenings, and the hours of sleep were compared with the intervening control night. Each of the drugs was tested in this manner a varying number of times in each subject. The average number of hours of sleep for each treatment is the response.

Student (1908) used these data to illustrate the paired-sample t-test in small samples, testing the hypothesis that the mean difference between a given drug and the control condition was zero. This data set became well known when used by Fisher (1925). Both Student and Fisher had problems labeling the drugs correctly (see Senn & Richardson (1994)), and consequently came to wrong conclusions.

But as well, the sample sizes (number of nights) for each mean differed widely, ranging from 3-9, and this was not taken into account in their analyses. To allow weighted analyses, the number of observations for each mean is contained in the data frame CushnyPeeblesN.

Usage

```r
data(CushnyPeebles)
data(CushnyPeeblesN)
```

Format

CushnyPeebles: A data frame with 11 observations on the following 4 variables.

- **Control**: a numeric vector: mean hours of sleep
- L_hyoscyamine: a numeric vector: mean hours of sleep
- L_hyoscine: a numeric vector: mean hours of sleep
- D_hyoscine: a numeric vector: mean hours of sleep

CushnyPeeblesN: A data frame with 11 observations on the following 4 variables.

- **Control**: a numeric vector: number of observations
- L_hyoscyamine: a numeric vector: number of observations
- L_hyoscine: a numeric vector: number of observations
- DL_hyoscine: a numeric vector: number of observations

Details

The last patient (11) has no Control observations, and so is often excluded in analyses or other versions of this data set.

Edgeworth’s counts of dactyls in Virgil’s Aeneid

Description
Edgeworth (1885) took the first 75 lines in Book XI of Virgil’s Aeneid and classified each of the first four “feet” of the line as a dactyl (one long syllable followed by two short ones) or not. Grouping the lines in blocks of five gave a 4 x 25 table of counts, represented here as a data frame with ordered factors, Foot and Lines. Edgeworth used this table in what was among the first examples of analysis of variance applied to a two-way classification.

Usage
```r
data(Dactyl)
```

Format
A data frame with 60 observations on the following 3 variables.

- **Foot**: an ordered factor with levels `1 < 2 < 3 < 4`
- **count**: number of dactyls

Source

<table>
<thead>
<tr>
<th>DrinksWages</th>
<th>Elderton and Pearson's (1910) data on drinking and wages</th>
</tr>
</thead>
</table>

Description

In 1910, Karl Pearson weighed in on the debate, fostered by the temperance movement, on the evils done by alcohol not only to drinkers, but to their families. The report "A first study of the influence of parental alcoholism on the physique and ability of their offspring" was an ambitious attempt to the new methods of statistics to bear on an important question of social policy, to see if the hypothesis that children were damaged by parental alcoholism would stand up to statistical scrutiny.

Working with his assistant, Ethel M. Elderton, Pearson collected voluminous data in Edinburgh and Manchester on many aspects of health, stature, intelligence, etc. of children classified according to the drinking habits of their parents. His conclusions where almost invariably negative: the tendency of parents to drink appeared unrelated to any thing he had measured.

The firestorm that this report set off is well described by Stigler (1999), Chapter 1. The data set DrinksWages is just one of Pearsons many tables, that he published in a letter to The Times, August 10, 1910.

Usage

data(DrinksWages)

Format

A data frame with 70 observations on the following 6 variables, giving the number of non-drinkers (sober) and drinkers (drinks) in various occupational categories (trade).

- class  wage class: a factor with levels A B C
- trade  a factor with levels baker barman billposter ... wellsinker wireworker
- sober  the number of non-drinkers, a numeric vector
- drinks the number of drinkers, a numeric vector
- wage  weekly wage (in shillings), a numeric vector
- n     total number, a numeric vector

Details

The data give Karl Pearson’s tabulation of the father’s trades from an Edinburgh sample, classified by whether they drink or are sober, and giving average weekly wage.

The wages are averages of the individuals’ nominal wages. Class A is those with wages under 2.5s.; B: those with wages 2.5s. to 30s.; C: wages over 30s.

EdgeworthDeaths

*Edgeworth’s Data on Death Rates in British Counties*

Description

In 1885, Francis Edgeworth published a paper, *On methods of ascertaining variations in the rate of births, deaths and marriages*. It contained among the first examples of two-way tables, analyzed to show variation among row and column factors, in a way that Fisher would later formulate as the Analysis of Variance.

Although the data are rates per 1000, they provide a good example of a two-way ANOVA with n=1 per cell, where an additive model fits reasonably well.

Treated as frequencies, the data is also a good example of a case where the independence model fits reasonably well.

Usage

data("EdgeworthDeaths")
EdgeworthDeaths

Format

A data frame with 42 observations on the following 3 variables.

- County  a factor with levels Berks Herts Bucks Oxford Bedford Cambridge
- year  an ordered factor with levels 1876 < 1877 < 1878 < 1879 < 1880 < 1881 < 1882
- Freq  a numeric vector, death rate per 1000 population

Details

Edgeworth’s data came from the Registrar General’s report for the final year, 1883. The Freq variable represents death rates per 1000 population in the six counties listed.

Source

The data were scanned from Table 5.2 in Stigler, S. M. (1999) Statistics on the Table: The History of Statistical Concepts and Methods, Harvard University Press.

Description

Waite (1915) was interested in analyzing the association of patterns in fingerprints, and produced a table of counts for 2000 right hands, classified by the number of fingers describable as a "whorl", a "small loop" (or neither). Because each hand contributes five fingers, the number of Whorls + Loops cannot exceed 5, so the contingency table is necessarily triangular.

Karl Pearson (1904) introduced the test for independence in contingency tables, and by 1913 had developed methods for "restricted contingency tables," such as the triangular table analyzed by Waite. The general formulation of such tests for association in restricted tables is now referred to as models for quasi-independence.

Usage

data(Fingerprints)

Format

A frequency data frame with 36 observations on the following 3 variables, representing a 6 x 6 table giving the cross-classification of the fingers on 2000 right hands as a whorl, small loop or neither.

Whorls  Number of whorls, an ordered factor with levels 0 < 1 < 2 < 3 < 4 < 5
Loops   Number of small loops, an ordered factor with levels 0 < 1 < 2 < 3 < 4 < 5
count   Number of hands

Details

Cells for which Whorls + Loops>5 have NA for count

Examples

data(Fingerprints)
xtabs(count ~ Whorls + Loops, data=Fingerprints)
Description

Galton (1886) presented these data in a table, showing a cross-tabulation of 928 adult children born to 205 fathers and mothers, by their height and their mid-parent’s height. He visually smoothed the bivariate frequency distribution and showed that the contours formed concentric and similar ellipses, thus setting the stage for correlation, regression and the bivariate normal distribution.

Usage

data(Galton)

Format

A data frame with 928 observations on the following 2 variables.

- `parent` a numeric vector: height of the mid-parent (average of father and mother)
- `child` a numeric vector: height of the child

Details

The data are recorded in class intervals of width 1.0 in. He used non-integer values for the center of each class interval because of the strong bias toward integral inches.

All of the heights of female children were multiplied by 1.08 before tabulation to compensate for sex differences. See Hanley (2004) for a reanalysis of Galton’s raw data questioning whether this was appropriate.

}

})
```

**GaltonFamilies**

*Galton’s data on the heights of parents and their children, by child*

**Description**

This data set lists the individual observations for 934 children in 205 families on which Galton (1886) based his cross-tabulation.

In addition to the question of the relation between heights of parents and their offspring, for which this data is mainly famous, Galton had another purpose which the data in this form allows to address: Does marriage selection indicate a relationship between the heights of husbands and wives, a topic he called *assortative mating*? Keen [p. 297-298](2010) provides a brief discussion of this topic.

**Usage**

```r
data(GaltonFamilies)
```
Format

A data frame with 934 observations on the following 8 variables.

family  family ID, a factor with levels 001-204
father  height of father
mother  height of mother
midparentHeight  mid-parent height, calculated as (father + 1.08*mother)/2
children  number of children in this family
childNum  number of this child within family. Children are listed in decreasing order of height for boys followed by girls
gender  child gender, a factor with levels female male
childHeight  height of child

Details

Galton’s notebook lists 963 children in 205 families ranging from 1-15 adult children. Of these, 29 had non-numeric heights recorded and are not included here.

Families are largely listed in descending order of fathers and mothers height.

# Description

Data from A.-M. Guerry, "Essay on the Moral Statistics of France"

Description

Andre-Michel Guerry (1833) was the first to systematically collect and analyze social data on such things as crime, literacy and suicide with the view to determining social laws and the relations among these variables.

The Guerry data frame comprises a collection of 'moral variables' on the 86 departments of France around 1830. A few additional variables have been added from other sources.

Usage

data(Guerry)

Format

A data frame with 86 observations (the departments of France) on the following 23 variables.

department  Department ID: Standard numbers for the departments, except for Corsica (200)

Department Department name: Departments are named according to usage in 1830, but without accents. A factor with levels Ain Aisne Allier ... Vosges Yonne

Crime_pers Population per Crime against persons. Source: A2 (Compte general, 1825-1830)

Crime_prop Population per Crime against property. Source: A2 (Compte general, 1825-1830)

Literacy Percent Read & Write: Percent of military conscripts who can read and write. Source: A2

Donations Donations to the poor. Source: A2 (Bulletin des lois)

Infants Population per illegitimate birth. Source: A2 (Bureauau des Longitudes, 1817-1821)

Suicides Population per suicide. Source: A2 (Compte general, 1827-1830)

MainCity Size of principal city (‘1:Sm’, ‘2:Med’, ‘3:Lg’), used as a surrogate for population density. Large refers to the top 10, small to the bottom 10; all the rest are classed Medium. Source: A1. An ordered factor with levels 1:Sm < 2:Med < 3:Lg

Wealth Per capita tax on personal property. A ranked index based on taxes on personal and movable property per inhabitant. Source: A1

Commerce Commerce and Industry, measured by the rank of the number of patents / population. Source: A1

Clergy Distribution of clergy, measured by the rank of the number of Catholic priests in active service / population. Source: A1 (Almanach officiel du clergy, 1829)

Crime_parents Crimes against parents, measured by the rank of the ratio of crimes against parents to all crimes— Average for the years 1825-1830. Source: A1 (Compte general)

Infanticide Infanticides per capita. A ranked ratio of number of infanticides to population— Average for the years 1825-1830. Source: A1 (Compte general)

Donation_clergy Donations to the clergy. A ranked ratio of the number of bequests and donations inter vivios to population— Average for the years 1815-1824. Source: A1 (Bull. des lois, ordunn. d’autorisation)

Lottery Per capita wager on Royal Lottery. Ranked ratio of the proceeds bet on the royal lottery to population— Average for the years 1822-1826. Source: A1 (Compte rendus par le ministre des finances)

Desertion Military disertion, ratio of the number of young soldiers accused of desertion to the force of the military contingent, minus the deficit produced by the insufficiency of available billets— Average of the years 1825-1827. Source: A1 (Compte du ministere du guerre, 1829 etat V)

Instruction Instruction. Ranks recorded from Guerry’s map of Instruction. Note: this is inversely related to Literacy (as defined here)

Prostitutes Prostitutes in Paris. Number of prostitutes registered in Paris from 1816 to 1834, classified by the department of their birth Source: Parent-Duchatelet (1836), De la prostitution en Paris

Distance Distance to Paris (km). Distance of each department centroid to the centroid of the Seine (Paris) Source: calculated from department centroids

Area Area (1000 km^2). Source: Angeville (1836)

Pop1831 1831 population. Population in 1831, taken from Angeville (1836), Essai sur la Statistique de la Population fra?ais, in 1000s
Details

Note that most of the variables (e.g., Crime_pers) are scaled so that 'more is better' morally.

Values for the quantitative variables displayed on Guerry’s maps were taken from Table A2 in the English translation of Guerry (1833) by Whitt and Reinking. Values for the ranked variables were taken from Table A1, with some corrections applied. The maximum is indicated by rank 1, and the minimum by rank 86.

HalleyLifeTable

**Halley’s Life Table**

Description

In 1693 the famous English astronomer Edmond Halley studied the birth and death records of the city of Breslau, which had been transmitted to the Royal Society by Caspar Neumann. He produced a life table showing the number of people surviving to any age from a cohort born the same year. He also used his table to compute the price of life annuities.
Usage

data("HalleyLifeTable")

Format

A data frame with 84 observations on the following 4 variables.

age  a numeric vector

deads number of deaths, \( D_k \), among people of age \( k \), a numeric vector

number size of the population, \( P_k \) surviving until this age, a numeric vector

ratio the ratio \( \frac{P_{k+1}}{P_k} \), the conditional probability of surviving until age \( k + 1 \) given that one had already reached age \( k \), a numeric vector

Details

Halley’s table contained only age and number. For people aged over 84 years, Halley just noted that their total number was 107. This value is not included in the data set.

The data from Breslau had a mean of 1,238 births per year: this is the value that Halley took for the size, \( P_0 \) of the population cohort at age 0. From the data, he could compute the annual mean \( D_k \) of the number of deaths among people aged \( k \) for all \( k \geq 0 \). From this, he calculated the number \( P_{k+1} \) surviving one more year,

\[
P_{k+1} = P_k - D_k
\]

This method had the great advantage of not requiring a general census but only knowledge of the number of births and deaths and of the age at which people died during a few years.

Jevons

W. Stanley Jevons' data on numerical discrimination

Description

In a remarkable brief note in *Nature*, 1871, W. Stanley Jevons described the results of an experiment he had conducted on himself to determine the limits of the number of objects an observer could comprehend immediately without counting them. This was an important philosophical question: How many objects can the mind embrace at once?

He carried out 1027 trials in which he tossed an "uncertain number" of uniform black beans into a box and immediately attempted to estimate the number "without the least hesitation". His questions, procedure and analysis anticipated by 75 years one of the most influential papers in modern cognitive psychology by George Miller (1956), "The magical number 7 plus or minus 2: Some limits on ..." For Jevons, the magical number was 4.5, representing an empirical law of complete accuracy.

Usage

data(Jevons)

Format

A frequency data frame with 50 observations on the following 4 variables.

actual Actual number: a numeric vector
estimated Estimated number: a numeric vector
frequency Frequency of this combination of (actual, estimated): a numeric vector
total-number-estimated-estimated: a numeric vector
Details

The original data were presented in a two-way, 13 x 13 frequency table, estimated (3:15) x actual (3:15).

van Langren’s Data on Longitude Distance between Toledo and Rome

Description

Michael Florent van Langren (1598-1675) was a Dutch mathematician and astronomer, who served as a royal mathematician to King Phillip IV of Spain, and who worked on one of the most significant problems of his time—the accurate determination of longitude, particularly for navigation at sea.

In order to convince the Spanish court of the seriousness of the problem (often resulting in great losses through ship wrecks), he prepared a 1-dimensional line graph, showing all the available estimates of the distance in longitude between Toledo and Rome, which showed large errors, for even this modest distance. This 1D line graph, from Langren (1644), is believed to be the first known graph of statistical data (Friendly et al., 2010). It provides a compelling example of the notions of statistical variability and bias.

The data frame Langren1644 gives the estimates and other information derived from the previously known 1644 graph. It turns out that van Langren produced other versions of this graph, as early as 1628. The data frame Langren.all gives the estimates derived from all known versions of this graph.

Usage

data(Langren1644)
data(Langren.all)

Format

Langren1644: A data frame with 12 observations on the following 9 variables, giving determinations of the distance in longitude between Toledo and Rome, from the 1644 graph.

Name The name of the person giving a determination, a factor with levels A. Argelius ... T. Brahe
Longitude Estimated value of the longitude distance between Toledo and Rome
Year Year associated with this determination
Longname A longer version of the Name, where appropriate; a factor with levels Andrea Argoli Christoph Clavius Tycho Brahe
City The principal city where this person worked; a factor with levels Alexandria Amsterdam Bamberg Bologna Frankfurt Hven Leuven Middelburg Nuremberg Padua Paris Rome
Country The country where this person worked; a factor with levels Belgium Denmark Egypt Flanders France Germany Italy Italy
Latitude Latitude of this City; a numeric vector
Source Likely source for this determination of Longitude; a factor with levels Astron Map
Gap A numeric vector indicating whether the Longitude value is below or above the median

Langren.all: A data frame with 61 observations on the following 4 variables, giving determinations of Longitude between Toledo and Rome from all known versions of van Langren’s graph.
Author  Author of the graph, a factor with levels Langren Lelewel
Year  Year of publication
Name  The name of the person giving a determination, a factor with levels Algunos1 Algunos2 Apianus ... Schonerus
Longitude  Estimated value of the longitude distance between Toledo and Rome

Details
In all the graphs, Toledo is implicitly at the origin and Rome is located relatively at the value of Longitude. To judge correspondence with an actual map, the positions in (lat, long) are
\[
\text{toledo} <- c(39.86, -4.03); \text{rome} <- c(41.89, 12.5)
\]

Source
The longitude values were digitized from images of the various graphs, which may be found on the Supplementary materials page for Friendly et al. (2009).

Macdonell

Macdonell's Data on Height and Finger Length of Criminals, used by Gosset (1908)

Description

In the second issue of *Biometrika*, W. R. Macdonell (1902) published an extensive paper, *On Criminal Anthropometry and the Identification of Criminals* in which he included numerous tables of physical characteristics 3000 non-habitual male criminals serving their sentences in England and Wales. His Table III (p. 216) recorded a bivariate frequency distribution of height by finger length. His main purpose was to show that Scotland Yard could have indexed their material more efficiently, and find a given profile more quickly.

W. S. Gosset (aka "Student") used these data in two classic papers in 1908, in which he derived various characteristics of the sampling distributions of the mean, standard deviation and Pearson’s r. He said, "Before I had succeeded in solving my problem analytically, I had endeavoured to do so empirically." Among his experiments, he randomly shuffled the 3000 observations from Macdonell’s table, and then grouped them into samples of size 4, 8, ..., calculating the sample means, standard deviations and correlations for each sample.

Usage

data(Macdonell)
data(MacdonellDF)

Format

Macdonell: A frequency data frame with 924 observations on the following 3 variables giving the bivariate frequency distribution of height and finger.

height lower class boundaries of height, in decimal ft.
finger length of the left middle finger, in mm.
frequency frequency of this combination of height and finger

MacdonellDF: A data frame with 3000 observations on the following 2 variables.

height a numeric vector
finger a numeric vector

Details

Class intervals for height in Macdonell’s table were given in 1 in. ranges, from (4’ 7" 9/16 - 4’ 8" 9/16), to (6’ 4" 9/16 - 6’ 5" 9/16). The values of height are taken as the lower class boundaries.

For convenience, the data frame MacdonellDF presents the same data, in expanded form, with each combination of height and finger replicated frequency times.

Source

The data used here were obtained from:

Description

The data frame Michelson gives Albert Michelson's measurements of the velocity of light in air, made from June 5 to July 2, 1879, reported in Michelson (1882). The given values + 299,000 are Michelson's measurements in km/sec. The number of cases is 100 and the "true" value on this scale is 734.5.

Stigler (1977) used these data to illustrate properties of robust estimators with real, historical data. For this purpose, he divided the 100 measurements into 5 sets of 20 each. These are contained in MichelsonSets.

Usage

data(Michelson)
data(MichelsonSets)

Format

Michelson: A data frame with 100 observations on the following variable, given in time order of data collection

velocity a numeric vector

MichelsonSets: A 20 x 5 matrix, with format int [1:20, 1:5] 850 850 1000 810 960 800 830 830 880 720 ... - attr(*, "dimnames")=List of 2 ..$ : NULL ..$ : chr [1:5] "ds12" "ds13" "ds14" "ds15" ...

Details

The "true" value is taken to be 734.5, arrived at by taking the "true" speed of light in a vacuum to be 299,792.5 km/sec, and adjusting for the velocity in air.

The data values are recorded in order, and so may also be taken as a time series.

```

Description

Charles Joseph Minard’s graphic depiction of the fate of Napoleon’s Grand Army in the Russian campaign of 1815 has been called the "greatest statistical graphic ever drawn" (Tuft, 1983). Friendly (2002) describes some background for this graphic, and presented it as Minard’s Challenge: to reproduce it using modern statistical or graphic software, in a way that showed the elegance of some computer language to both describe and produce this graphic.

Usage

```r
data(Minard.troops)
data(Minard.cities)
data(Minard.temp)
```
Format

Minard.troops: A data frame with 51 observations on the following 5 variables giving the number of surviving troops.

long Longitude
lat Latitude
survivors Number of surviving troops, a numeric vector
direction a factor with levels A ("Advance") R ("Retreat")
group a numeric vector

Minard.cities: A data frame with 20 observations on the following 3 variables giving the locations of various places along the path of Napoleon's army.

long Longitude
lat Latitude
city City name: a factor with levels Bobr Chjat ... Witebsk Wixma

Minard.temp: A data frame with 9 observations on the following 4 variables, giving the temperature at various places along the march of retreat from Moscow.

long Longitude
temp Temperature
days Number of days on the retreat march
date a factor with levels Dec01 Dec06 Dec07 Nov09 Nov14 Nov28 Oct18 Oct24

Details

date in Minard.temp should be made a real date in 1815.

Nightingale

Florence Nightingale's data on deaths from various causes in the Crimean War
**Description**

In the history of data visualization, Florence Nightingale is best remembered for her role as a social activist and her view that statistical data, presented in charts and diagrams, could be used as powerful arguments for medical reform.

After witnessing deplorable sanitary conditions in the Crimea, she wrote several influential texts (Nightingale, 1858, 1859), including polar-area graphs (sometimes called "Coxcombs" or rose diagrams), showing the number of deaths in the Crimean from battle compared to disease or preventable causes that could be reduced by better battlefield nursing care.

Her *Diagram of the Causes of Mortality in the Army in the East* showed that most of the British soldiers who died during the Crimean War died of sickness rather than of wounds or other causes. It also showed that the death rate was higher in the first year of the war, before a Sanitary Commissioners arrived in March 1855 to improve hygiene in the camps and hospitals.

**Usage**

data(Nightingale)

**Format**

A data frame with 24 observations on the following 10 variables.

- **Date** a Date, composed as `as.Date(paste(Year,Month,1,sep='-',"%Y-%b-%d")`  
- **Month** Month of the Crimean War, an ordered factor  
- **Year** Year of the Crimean War  
- **Army** Estimated average monthly strength of the British army  
- **Disease** Number of deaths from preventable or mitagable zymotic diseases  
- **Wounds** Number of deaths directly from battle wounds  
- **Other** Number of deaths from other causes  
- **Disease.rate** Annual rate of deaths from preventable or mitagable zymotic diseases, per 1000  
- **Wounds.rate** Annual rate of deaths directly from battle wounds, per 1000  
- **Other.rate** Annual rate of deaths from other causes, per 1000

**Details**

For a given cause of death, D, annual rates per 1000 are calculated as $12 \times 1000 \times D / \text{Army}$, rounded to 1 decimal.

The two panels of Nightingale’s Coxcomb correspond to dates before and after March 1855

**Source**

The data were obtained from:

OldMaps

OldMaps

Latitudes and Longitudes of 39 Points in 11 Old Maps

Description

The data set is concerned with the problem of aligning the coordinates of points read from old maps
(1688 - 1818) of the Great Lakes area. 39 easily identifiable points were selected in the Great Lakes
area, and their (lat, long) coordinates were recorded using a grid overlaid on each of 11 old maps,
and using linear interpolation.

It was conjectured that maps might be systematically in error in five key ways: (a) constant error
in latitude; (b) constant error in longitude; (c) proportional error in latitude; (d) proportional error in
longitude; (e) angular error from a non-zero difference between true North and the map’s North.

One challenge from these data is to produce useful analyses and graphical displays that relate to
these characteristics or to other aspects of the data.

Usage

data(OldMaps)

Format

A data frame with 468 observations on the following 6 variables, giving the latitude and longitude
of 39 points recorded from 12 sources (Actual + 11 maps).

point  a numeric vector
col  Column in the table a numeric vector
name  Name of the map maker, using Actual for the true coordinates of the points. A factor with levels Actual Arrowsmith Belin Cary Coronelli D'Anville Del'Isle Lattre Melish Mitchell Popple.

year  Year of the map

lat  Latitude

long  Longitude

Details

Some of the latitude and longitude values are inexplicably negative. It is probable that this is an error in type setting, because the table footnote says "* denotes that interpolation accuracy is not good," yet no "*"s appear in the body of the table.

| PearsonLee | Pearson and Lee's data on the heights of parents and children classified by gender |

Description

Wachsmuth et. al (2003) noticed that a loess smooth through Galton's data on heights of mid-parents and their offspring exhibited a slightly non-linear trend, and asked whether this might be due to Galton having pooled the heights of fathers and mothers and sons and daughters in constructing his tables and graphs.

To answer this question, they used analogous data from English families at about the same time, tabulated by Karl Pearson and Alice Lee (1896, 1903), but where the heights of parents and children were each classified by gender of the parent.

Usage

data(PearsonLee)
Format

A frequency data frame with 746 observations on the following 6 variables.

child  child height in inches, a numeric vector
parent  parent height in inches, a numeric vector
frequency  a numeric vector
gp  a factor with levels fd fs md ms
par  a factor with levels Father Mother
chl  a factor with levels Daughter Son

Details

The variables gp, par and chl are provided to allow stratifying the data according to the gender of the father/mother and son/daughter.

The data frame PolioTrials gives the results of the 1954 field trials to test the Salk polio vaccine (named for the developer, Jonas Salk), conducted by the National Foundation for Infantile Paralysis (NFIP). It is adapted from data in the article by Francis et al. (1955). There were actually two clinical trials, corresponding to two statistical designs (Experiment), discussed by Brownlee (1955). The comparison of designs and results represented a milestone in the development of randomized clinical trials.
Usage

data(PolioTrials)

Format

A data frame with 8 observations on the following 6 variables.

Experiment a factor with levels ObservedControl RandomizedControl
Group a factor with levels Controls Grade2NotInoculated IncompleteVaccinations NotInoculated Placebo Vaccinated
Population the size of the population in each group in each experiment
Paralytic the number of cases of paralytic polio observed in that group
NonParalytic the number of cases of paralytic polio observed in that group
FalseReports the number of cases initially reported as polio, but later determined not to be polio in that group

Details

The data frame is in the form of a single table, but actually comprises the results of two separate field trials, given by Experiment. Each should be analyzed separately, because the designs differ markedly.

The original design (Experiment == "ObservedControl") called for vaccination of second-graders at selected schools in selected areas of the country (with the consent of the children’s parents, of course). The Vaccinated second-graders formed the treatment group. The first and third-graders at the schools were not given the vaccination, and formed the Controls group.

In the second design (Experiment == “RandomizedControl”) children were selected (again in various schools in various areas), all of whose parents consented to vaccination. The sample was randomly divided into treatment (Group == "Vaccinated"), given the real polio vaccination, and control groups (Group == "Placebo"), a placebo dose that looked just like the real vaccine. The experiment was also double blind: neither the parents of a child in the study nor the doctors treating the child knew which group the child belonged to.

In both experiments, NotInnoculated refers to children who did not participate in the experiment. IncompleteVaccinations refers to children who received one or two, but not all three administrations of the vaccine.

Prostitutes

Parent-Duchatelet's time-series data on the number of prostitutes in Paris

Description

A table indicating month by month, for the years 1812-1854, the number of prostitutes on the registers of the administration of the city of Paris.

Usage

data(Prostitutes)

Format

A data frame with 516 observations on the following 5 variables.

Year  a numeric vector
month  a factor with levels Apr Aug Dec Feb Jan Jul Jun Mar May Nov Oct Sep
count  a numeric vector: number of prostitutes
mon    a numeric vector: numeric month
date   a Date

Details

The data table was digitally scanned with OCR, and errors were corrected by comparing the yearly totals recorded in the table to the row sums of the scanned data.

Source

Examples

data(Prostitutes)
## maybe str(Prostitutes) ; plot(Prostitutes) ...
Description

Stigler (1997, 1999) recounts the history of one of the oldest continuous schemes of sampling inspection carried out by the Royal Mint in London for about eight centuries. The Trial of the Pyx was the final, ceremonial stage in a process designed to ensure that the weight and quality of gold and silver coins from the mint met the standards for coinage.

At regular intervals, coins would be taken from production and deposited into a box called the Pyx. When a Trial of the Pyx was called, the contents of the Pyx would be counted, weighed and assayed for content, and the results would be compared with the standard set for the Royal Mint.

The data frame Pyx gives the results for the year 1848 (Great Britain, 1848) in which 10,000 gold sovereigns were assayed. The coins in each bag were classified according to the deviation from the standard content of gold for each coin, called the Remedy, R = 123 * (12/5760) = .25625, in grains, for a single sovereign.

Usage

data(Pyx)

Format

A frequency data frame with 72 observations on the following 4 variables giving the distribution of 10,000 sovereigns, classified according to the Bags in which they were collected and the Deviation from the standard weight.

- Bags: an ordered factor with levels 1 and 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9 < 10
- Group: an ordered factor with levels below std < near std < above std
- Deviation: an ordered factor with levels Below -R < (-R to -.2) < (-.2 to -.1) < (-.1 to 0) < (0 to .1) < (.1 to .2) < (.2 to R) < Above R
- count: number of sovereigns

Details

Bags 1-4 were selected as "near to standard", bags 5-7 as below standard, bags 8-10 as above standard. This classification is reflected in Group.

**Description**

*The Statistics Of Deadly Quarrels* by Lewis Fry Richardson (1960) is one of the earlier attempts at quantification of historical conflict behavior.

The data set contains 779 dyadic deadly quarrels that cover a time period from 1809 to 1949. A quarrel consists of one pair of belligerents, and is identified by its beginning date and magnitude (log 10 of the number of deaths). Neither actor in a quarrel is identified by name.

Because Richardson took a dyad of belligerents as his unit, a given war, such as World War I or World War II comprises multiple observations, for all pairs of belligerents. For example, there are forty-four pairs of belligerents coded for World War I.

For each quarrel, the nominal variables include the type of quarrel, as well as political, cultural, and economic similarities and dissimilarities between the pair of combatants.

Details

In the original data set obtained from ICPSR, variables were named V1-V84. These were renamed to make them more meaningful. V84, renamed ID was moved to the first position, but otherwise the order of variables is the same.

In many of the factor variables, 0 is used to indicate "irrelevant to quarrel". This refers to those relations that Richardson found absent or irrelevant to the particular quarrel, and did not subsequently mention.

See the original codebook at http://www.icpsr.umich.edu/cgi-bin/file?comp=none&study=5407&ds=1&file_id=652814 for details not contained here.

Snow John Snow's Map and Data on the 1854 London Cholera Outbreak

Description

The Snow data consists of the relevant 1854 London streets, the location of 578 deaths from cholera, and the position of 13 water pumps (wells) that can be used to re-create John Snow’s map showing deaths from cholera in the area surrounding Broad Street, London in the 1854 outbreak. Another data frame provides boundaries of a tessellation of the map into Thiessen (Voronoi) regions which include all cholera deaths nearer to a given pump than to any other.

The apocryphal story of the significance of Snow’s map is that, by closing the Broad Street pump (by removing its handle), Dr. Snow stopped the epidemic, and demonstrated that cholera is a water borne disease. The method of contagion of cholera was not previously understood. Snow’s map is the most famous and classical example in the field of medical cartography, even if it didn’t happen exactly this way. (the apocryphal part is that the epidemic ended when the pump handle was removed.) At any rate, the map, together with various statistical annotations, is compelling because it points to the Broad Street pump as the source of the outbreak.
Usage

data(Snow.deaths)
data(Snow.pumps)
data(Snow.streets)
data(Snow.polygons)
data(Snow.dates)

Format

Snow.deaths: A data frame with 578 observations on the following 3 variables, giving the address of a person who died from cholera. When many points are associated with a single street address, they are "stacked" in a line away from the street so that they are more easily visualized. This is how they are displayed on John Snow's original map. The dates of the deaths are not individually recorded in this data set.

case  Sequential case number, in some arbitrary, randomized order
x    x coordinate
y    y coordinate

Snow.pumps: A data frame with 13 observations on the following 4 variables, giving the locations of water pumps within the boundaries of the map.

pump  pump number
label pump label: Briddle St Broad St ... Warwick
x    x coordinate
y    y coordinate

Snow.streets: A data frame with 1241 observations on the following 4 variables, giving coordinates used to draw the 528 street segment lines within the boundaries of the map. The map is created by drawing lines connecting the n points in each street segment.

street street segment number: 1:528
n    number of points in this street line segment
x    x coordinate
y    y coordinate

Snow.polygons: A list of 13 data frames, giving the vertices of Thiessen (Voronoi) polygons containing each pump. Their boundaries define the area that is closest to each pump relative to all other pumps. They are mathematically defined by the perpendicular bisectors of the lines between all pumps. Each data frame contains:

x    x coordinate
y    y coordinate

Snow.deaths2: An alternative version of Snow.deaths correcting some possible duplicate and missing cases, as described in vignette("Snow_deaths-duplicates").

Snow.dates: A data frame of 44 observations and 3 variables from Table 1 of Snow (1855), giving the number of fatal attacks and number of deaths by date from Aug. 19 – Sept. 30, 1854. There are a total of 616 deaths represented in both columns attacks and deaths; of these, the date of the attack is unknown for 45 cases.
Details

The scale of the source map is approx. 1:2000. The \((x, y)\) coordinate units are 100 meters, with an arbitrary origin.

Of the data in the `Snow.dates` table, Snow says, “The deaths in the above table are compiled from the sources mentioned above in describing the map; but some deaths which were omitted from the map on account of the number of the house not being known, are included in the table.”

One limitation of these data sets is the lack of exact street addresses. Another is the lack of any data that would serve as a population denominator to allow for a comparison of mortality rates in the Broad Street pump area as opposed to others. See Koch (2000), Koch (2004), Koch \& Denike (2009) and Tufte (1999), p. 27-37, for further discussion.

Source

The data in these files were first digitized in 1992 by Rusty Dodson of the NCGIA, Santa Barbara, from the map included in the book by John Snow: "Snow on Cholera...", London, Oxford University Press, 1936.

## Plot deaths over time
require(lubridate)
clr <- ifelse(Snow.dates$date < mdy("09/08/1854"), "red", "darkgreen")
The main function \texttt{SnowMap} draws versions of John Snow's map of cholera deaths in the South London area surrounding the Broad Street pump during the 1854 outbreak.

It is a wrapper for the various subfunctions also listed here:

\texttt{Splot} sets up the basic plot

\texttt{Sstreets} draws the streets
SnowMap plots the deaths
Sdeaths plots the pump locations
Sscale draws the scale
Spolygons draws the boundaries of the Voronoi polygons separating the pumps
Sdensity draws and fills contours of the 2D density of deaths

Usage

```r
SnowMap(xlim = c(3, 20), ylim = c(3, 20),
axis.labels = FALSE, main = "Snow's Cholera Map of London",
scale = TRUE, polygons = FALSE, density=FALSE,
streets.args = list(col = "grey", lwd = 1),
deaths.args = list(col = "red", pch = 15, cex = 0.6),
pumps.args = list(col = "blue", pch = 17, cex = 1.5, cex.lab = 0.9),
scale.args = list(xs = 3.5, ys = 19.7),
polygons.args = list(col=NA, border="brown", lwd=2, lty=1),
density.args=list(bandwidth=c(0.5,0.5),
    col1=rgb(0,1,0.5),
    col2=rgb(1,0,0,.8))
)
```

```r
Splot(xlim = c(3, 20), ylim = c(3, 20),
  xlab = "", ylab = "",
  axis.labels = FALSE,
  main = "Snow's Cholera Map of London")
```

```r
Sdeaths(col = "red", pch = 15, cex = 0.6)
```

```r
Spumps(col = "blue", pch = 17, cex = 1.5, cex.lab = 0.9)
```

```r
Sstreets(col = "gray", lwd = 1)
```

```r
Sscale(xs = 3.5, ys = 19.7)
```

```r
Spolygons(col=NA, border="brown", lwd=2, lty=1)
```

```r
Sdensity(bandwidth = c(0.5, 0.5), col1 = rgb(0, 1, 0, 0), col2 = rgb(1, 0, 0.8))
```

Arguments

- `xlim`: Limit for the horizontal axis. Specify ranges smaller than the defaults to zoom the plot.
- `ylim`: Limit for the vertical axis.
- `axis.labels`: Logical. Show axis tick mark labels?
- `main`: Plot title
- `scale`: Logical; draw a scale (in meters) on the plot
- `polygons`: Logical; Use Spolygons to draw the Snow.polygons on the plot?
density Logical; Use Sdensity to draw the 2D bivariate density of deaths on the plot?

streets.args List of arguments passed to Sstreets

deaths.args List of arguments passed to Sdeaths

pumps.args List of arguments passed to Spumps

scale.args List of arguments passed to Sscale

polygons.args List of arguments passed to Spolygons. Note that col here now refers to the fill colors, passed to polygon. The col argument here can be a vector of up to 13 colors, one for each pump region.

density.args List of arguments passed to Sdensity

xlab Label for horizontal axis

ylab Label for vertical axis

col Color of points and lines used by various functions

pch Point character used by various functions

cex Character size used by various functions

cex.lab Character size for labels used by Spumps

lwd Line width used by various functions

border Color of border lines used by Spolygons

xs x location of the scale used by Sscale

ys y location of the scale used by Sscale

lty Line type used by various functions

bandwidth Bandwidth used by bkde2D in Sdensity

col1 Lower level of color range used by colorRampPalette in Sdensity

col2 Upper level of color range used by colorRampPalette in Sdensity

Value

None

John F. W. Herschel's Data on the Orbit of the Twin Stars γ Virginis

Description

In 1833 J. F. W. Herschel published two papers in the Memoirs of the Royal Astronomical Society detailing his investigations of calculating the orbits of twin stars from observations of their relative position angle and angular distance.

In the process, he invented the scatterplot, and the use of visual smoothing to obtain a reliable curve that surpassed the accuracy of individual observations (Friendly & Denis, 2005). His data on the recordings of the twin stars γ Virginis provide an accessible example of his methods.

Usage

data("Virginis")
data("Virginis.interp")

Format

Virgins: A data frame with 18 observations on the following 6 variables giving the measurements of position angle and angular distance between the central (brightest) star and its twin, recorded by various observers over more than 100 years.

year  year ("epoch") of the observation, a decimal numeric vector
posangle  recorded position angle between the two stars, a numeric vector
distance  separation distance between the two stars, a numeric vector
weight  a subjective weight attributed to the accuracy of this observation, a numeric vector
notes  Herschel's notes on this observation, a character vector
authority  A simplified version of the notes giving just the attribution of authority of the observation, a character vector
Virginis.interp: A data frame with 14 observations on the following 4 variables, giving the position angles and angular distance that Herschel interpolated from his smoothed curve.

- **year**: year ("epoch") of the observation, a decimal numeric vector
- **posangle**: recorded position angle between the two stars, a numeric vector
- **distance**: separation distance, calculated $1/\sqrt{\text{velocity}}$
- **velocity**: angular velocity, calculated as the instantaneous slopes of tangents to the smoothed curve, a numeric vector

**Details**

The data in Virginis come from the table on p. 35 of the "Micrometrical Measures" paper.

The weight variable was assigned by the package author, reflecting Herschel’s comments and for use in any weighted analysis.

In the notes and authority variables, "H" refers to William Herschel (John’s farther, the discoverer of the planet Uranus), "h" refers to John Herschel himself, and "Sigma", rendered Σ in the table on p. 35 refers to Joseph Fraunhofer.

The data in Virginis.interp come from Table 1 on p. 190 of the supplementary paper.

Playfair’s Data on Wages and the Price of Wheat

Description

Playfair (1821) used a graph, showing parallel time-series of the price of wheat and the typical weekly wage for a "good mechanic" from 1565 to 1821 to argue that working men had never been as well-off in terms of purchasing power as they had become toward the end of this period.

His graph is a classic in the history of data visualization, but commits the sin of showing two non-commensurable Y variables on different axes. Scatterplots of wages vs. price or plots of ratios (e.g., wages/price) are in some ways better, but both of these ideas were unknown in 1821.

In this version, information on the reigns of British monarchs is provided in a separate data.frame, Wheat.monarchs.

Usage

data(Wheat)
data(Wheat.monarchs)

Format

Wheat
A data frame with 53 observations on the following 3 variables.
Year  Year, in intervals of 5 from 1565 to 1821: a numeric vector
Wheat  Price of Wheat (Shillings/Quarter bushel): a numeric vector
Wages  Weekly wage (Shillings): a numeric vector

Wheat.monarchs
A data frame with 12 observations on the following 4 variables.
name  Reigning monarch, a factor with levels Anne Charles I Charles II Cromwell Elizabeth
      George I George II George III George IV James I James II W&M
start  Starting year of reign, a numeric vector
end    Starting year of reign, a numeric vector
commonwealth  A binary variable indicating the period of the Commonwealth under Cromwell

Yeast

Student's (1906) Yeast Cell Counts

Description

Counts of the number of yeast cells were made each of 400 regions in a 20 x 20 grid on a microscope slide, comprising a 1 sq. mm. area. This experiment was repeated four times, giving samples A, B, C and D.

Student (1906) used these data to investigate the errors in random sampling. He says "there are two sources of error: (a) the drop taken may not be representative of the bulk of the liquid; (b) the distribution of the cells over the area which is examined is never exactly uniform, so that there is an 'error of random sampling.'"

The data in the paper are provided in the form of discrete frequency distributions for the four samples. Each shows the frequency distribution squares containing a count of 0, 1, 2, ... yeast cells. These are combined here in Yeast. In addition, he gives a table (Table I) showing the actual number of yeast cells counted in the 20 x 20 grid for sample D, given here as YeastD.mat.

Usage

data(Yeast)
data(YeastD.mat)
Yeast

Format

Yeast: A frequency data frame with 36 observations on the following 3 variables, giving the frequencies of

sample  Sample identifier, a factor with levels A B C D
count   The number of yeast cells counted in a square
freq    The number of squares with the given count

YeastD.mat: A 20 x 20 matrix containing the count of yeast cells in each square for sample D.

Details

Student considers the distribution of a total of $Nm$ particles distributed over $N$ unit areas with an average of $m$ particles per unit area. With uniform mixing, for a given particle, the probability of it falling on any one area is $p = 1/N$, and not falling on that area is $q = 1 - 1/N$. He derives the probability distribution of 0, 1, 2, 3, ... particles on a single unit area from the binomial expansion of $(p + q)^{mN}$.

Description

Darwin (1876) studied the growth of pairs of zea may (aka corn) seedlings, one produced by cross-fertilization and the other produced by self-fertilization, but otherwise grown under identical conditions. His goal was to demonstrate the greater vigour of the cross-fertilized plants. The data recorded are the final height (inches, to the nearest 1/8th) of the plants in each pair.

In the Design of Experiments, Fisher (1935) used these data to illustrate a paired t-test (well, a one-sample test on the mean difference, cross - self). Later in the book (section 21), he used this data to illustrate an early example of a non-parametric permutation test, treating each paired difference as having (randomly) either a positive or negative sign.

Usage

data(ZeaMays)

Format

A data frame with 15 observations on the following 4 variables.

- pair: pair number, a numeric vector
- pot: pot, a factor with levels 1 2 3 4
- cross: height of cross fertilized plant, a numeric vector
- self: height of self fertilized plant, a numeric vector
- diff: cross - self for each pair

Details

In addition to the standard paired t-test, several types of non-parametric tests can be contemplated:

(a) Permutation test, where the values of, say self are permuted and diff=cross - self is calculated for each permutation. There are 15! permutations, but a reasonably large number of random permutations would suffice. But this doesn’t take the paired samples into account.

(b) Permutation test based on assigning each abs(diff) a + or - sign, and calculating the mean(diff). There are 2^{15} such possible values. This is essentially what Fisher proposed. The p-value for the test is the proportion of absolute mean differences under such randomization which exceed the observed mean difference.

(c) Wilcoxon signed rank test: tests the hypothesis that the median signed rank of the diff is zero, or that the distribution of diff is symmetric about 0, vs. a location shifted alternative.
