Package ‘Hmisc’

January 27, 2019

Version 4.2-0
Date 2019-01-25
Title Harrell Miscellaneous
Author Frank E Harrell Jr <f.harrell@vanderbilt.edu>, with
contributions from Charles Dupont and many others.
Maintainer Frank E Harrell Jr <f.harrell@vanderbilt.edu>
Depends lattice, survival (>= 2.40-1), Formula, ggplot2 (>= 2.2)
Imports methods, latticeExtra, cluster, rpart, nnet, acepack, foreign,
gtable, grid, gridExtra, data.table, htmlTable (>= 1.11.0),
viridis, htmltools, base64enc
Suggests chron, rms, mice, tables, knitr, ff, ffbase, plotly (>=
4.5.6), rlang
Description Contains many functions useful for data
analysis, high-level graphics, utility operations, functions for
computing sample size and power, importing and annotating datasets,
imputing missing values, advanced table making, variable clustering,
character string manipulation, conversion of R objects to LaTeX and html code,
and recoding variables.
License GPL (>= 2)
LazyLoad Yes
URL http://biostat.mc.vanderbilt.edu/Hmisc,

**Description**

Computes the mean and median of various absolute errors related to ordinary multiple regression models. The mean and median absolute errors correspond to the mean square due to regression, error, and total. The absolute errors computed are derived from \( \hat{Y} - \text{median}(\hat{Y}) \), \( \hat{Y} - Y \), and \( Y - \text{median}(Y) \). The function also computes ratios that correspond to \( R^2 \) and \( 1 - R^2 \) (but these ratios do not add to 1.0); the \( R^2 \) measure is the ratio of mean or median absolute \( \hat{Y} - \text{median}(\hat{Y}) \) to the mean or median absolute \( Y - \text{median}(Y) \). The \( 1 - R^2 \) or SSE/SST measure is the mean or median absolute \( \hat{Y} - Y \) divided by the mean or median absolute \( \hat{Y} - \text{median}(Y) \).

**Usage**

```r
abs.error.pred(fit, lp=NULL, y=NULL)
```

```r
## S3 method for class 'abs.error.pred'
print(x, ...)
```

**Arguments**

- `fit` a fit object typically from `lm` or `ols` that contains a `y` vector (i.e., you should have specified `y=TRUE` to the fitting function) unless the `y` argument is given to `abs.error.pred`. If you do not specify the `lp` argument, `fit` must contain `fitted.values` or `linear.predictors`. You must specify `fit` or both of `lp` and `y`.
- `lp` a vector of predicted values (\( \hat{Y} \) hat above) if `fit` is not given.
addMarginal

Description

Given a data frame and the names of variable, doubles the data frame for each variable with a new category "All" by default, or by the value of label. A new variable .marginal. is added to the resulting data frame, with value "" if the observation is an original one, and with value equal to the names of the variable being marginalized (separated by commas) otherwise. If there is another stratification variable besides the one in . . . , and that variable is nested inside the variable in . . . , specify nested=variable name to have the value of that variable set for label whenever marginal observations are created for . . . . See the state-city example below.
**all.is.numeric**

Check if All Elements in Character Vector are Numeric

**Description**

Tests, without issuing warnings, whether all elements of a character vector are legal numeric values, or optionally converts the vector to a numeric vector. Leading and trailing blanks in `x` are ignored.

**Usage**

```r
all.is.numeric(x, what = c("test", "vector"), extras=c('.', 'NA'))
```

**Arguments**

- `x` a character vector
- `what` specify what="vector" to return a numeric vector if it passes the test, or the original character vector otherwise
- `extras` a vector of character strings to count as numeric values, other than "".

---

**addMarginal**

Usage

```r
addMarginal(data, ..., label = "All", margloc=c('last', 'first'), nested)
```

**Arguments**

- `data` a data frame
- `...` a list of names of variables to marginalize
- `label` category name for added marginal observations
- `margloc` location for marginal category within factor variable specifying categories. Set to "first" to override the default - to put a category with value `label` as the first category.
- `nested` a single unquoted variable name if used

**Examples**

```r
d <- expand.grid(sex=c('female', 'male'), country=c('US', 'Romania'),
                 reps=1:2)
addMarginal(d, sex, country)

# Example of nested variables
x <- data.frame(state=c('AL', 'GA', 'GA', 'GA', 'GA'),
                 city=c('Montgomery', 'Valdosto',
                       'Augusta', 'Atlanta'),
                 x=1:5)
addMarginal(x, state, nested=city) # cite set to 'All' when state is
```
approxExtrap

Linear Extrapolation

Value

a logical value if what="test" or a vector otherwise

Author(s)

Frank Harrell

See Also

as.numeric

Examples

all.is.numeric(c('1','1.2','3'))
all.is.numeric(c('1','1.2','3a'))
all.is.numeric(c('1','1.2','3'),'vector')
all.is.numeric(c('1','1.2','3a'),'vector')
all.is.numeric(c('1','','.'),'vector')

approxExtrap

Description

Works in conjunction with the approx function to do linear extrapolation. approx in R does not support extrapolation at all, and it is buggy in S-Plus 6.

Usage

approxExtrap(x, y, xout, method = "linear", n = 50, rule = 2, f = 0, ties = "ordered", na.rm = FALSE)

Arguments

x, y, xout, method, n, rule, f

see approx

ties applies only to R. See approx

na.rm set to TRUE to remove NAs in x and y before proceeding

Details

Duplicates in x (and corresponding y elements) are removed before using approx.

Value

a vector the same length as xout
**areg**

**Author(s)**
Frank Harrell

**See Also**
approx

**Examples**

approxExtrp(1:3,1:3,xout=c(8,4))

---

**Description**

Expands continuous variables into restricted cubic spline bases and categorical variables into dummy variables and fits a multivariate equation using canonical variates. This finds optimum transformations that maximize $R^2$. Optionally, the bootstrap is used to estimate the covariance matrix of both left- and right-hand-side transformation parameters, and to estimate the bias in the $R^2$ due to over-fitting and compute the bootstrap optimism-corrected $R^2$. Cross-validation can also be used to get an unbiased estimate of $R^2$ but this is not as precise as the bootstrap estimate. The bootstrap and cross-validation may also be used to get estimates of mean and median absolute error in predicted values on the original $y$ scale. These two estimates are perhaps the best ones for gauging the accuracy of a flexible model, because it is difficult to compare $R^2$ under different $y$-transformations, and because $R^2$ allows for an out-of-sample recalibration (i.e., it only measures relative errors).

Note that uncertainty about the proper transformation of $y$ causes an enormous amount of model uncertainty. When the transformation for $y$ is estimated from the data a high variance in predicted values on the original $y$ scale may result, especially if the true transformation is linear. Comparing bootstrap or cross-validated mean absolute errors with and without restricted the $y$ transform to be linear (ytype='l') may help the analyst choose the proper model complexity.

**Usage**

```r
areg(x, y, xtype = NULL, ytype = NULL, nk = 4,
    B = 0, na.rm = TRUE, tolerance = NULL, crossval = NULL)
```

```r
# S3 method for class 'areg'
print(x, digits=4, ...)
```

```r
# S3 method for class 'areg'
plot(x, whichx = 1:ncol(x$x), ...)
```

```r
# S3 method for class 'areg'
predict(object, x, type=c('lp','fitted','x'),
    what=c('all','sample'), ...)
```
Arguments

- **x**: A single predictor or a matrix of predictors. Categorical predictors are required to be coded as integers (as factor does internally). For `predict`, `x` is a data matrix with the same integer codes that were originally used for categorical variables.

- **y**: a factor, categorical, character, or numeric response variable

- **xtype**: a vector of one-letter character codes specifying how each predictor is to be modeled, in order of columns of `x`. The codes are "s" for smooth function (using restricted cubic splines), "1" for no transformation (linear), or "c" for categorical (to cause expansion into dummy variables). Default is "s" if nk > 0 and "1" if nk=0.

- **ytype**: same coding as for xtype. Default is "s" for a numeric variable with more than two unique values, "1" for a binary numeric variable, and "c" for a factor, categorical, or character variable.

- **nk**: number of knots, 0 for linear, or 3 or more. Default is 4 which will fit 3 parameters to continuous variables (one linear term and two nonlinear terms)

- **B**: number of bootstrap resamples used to estimate covariance matrices of transformation parameters. Default is no bootstrapping.

- **na.rm**: set to FALSE if you are sure that observations with NAs have already been removed

- **tolerance**: singularity tolerance. List source code for `lm.fit.qr.bare` for details.

- **crossval**: set to a positive integer k to compute k-fold cross-validated R-squared (square of first canonical correlation) and mean and median absolute error of predictions on the original scale

- **digits**: number of digits to use in formatting for printing

- **object**: an object created by `areg`

- **whichx**: integer or character vector specifying which predictors are to have their transformations plotted (default is all). The y transformation is always plotted.

- **type**: tells predict whether to obtain predicted untransformed y (type='lp', the default) or predicted y on the original scale (type='fitted'), or the design matrix for the right-hand side (type='x').

- **what**: When the y-transform is non-monotonic you may specify what='sample' to predict to obtain a random sample of y values on the original scale instead of a matrix of all y-inverses. See `inverseFunction`.

... arguments passed to the plot function.

Details

`areg` is a competitor of `ace` in the `acepack` package. Transformations from `ace` are seldom smooth enough and are often overfitted. With `areg` the complexity can be controlled with the `nk` parameter, and predicted values are easy to obtain because parametric functions are fitted.

If one side of the equation has a categorical variable with more than two categories and the other side has a continuous variable not assumed to act linearly, larger sample sizes are needed to reliably estimate transformations, as it is difficult to optimally score categorical variables to maximize $R^2$ against a simultaneously optimally transformed continuous variable.
Value

a list of class "areg" containing many objects

**aregImpute**

Multiple Imputation using Additive Regression, Bootstrapping, and Predictive Mean Matching

**Description**

The `transcan` function creates flexible additive imputation models but provides only an approximation to true multiple imputation as the imputation models are fixed before all multiple imputations are drawn. This ignores variability caused by having to fit the imputation models. `aregImpute` takes all aspects of uncertainty in the imputations into account by using the bootstrap to approximate the process of drawing predicted values from a full Bayesian predictive distribution. Different bootstrap resamples are used for each of the multiple imputations, i.e., for the 1st imputation of a sometimes missing variable, a flexible additive model is fitted on a sample with replacement from the original data and this model is used to predict all of the original missing and non-missing values for the target variable.

`areg` is used to fit the imputation models. By default, linearity is assumed for target variables (variables being imputed) and nk=3 knots are assumed for continuous predictors transformed using restricted cubic splines. If nk is three or greater and tlinear is set to FALSE, `areg` simultaneously find transformations of the target variable and of all of the predictors, to get a good fit assuming additivity, maximizing $R^2$, using the same canonical correlation method as `transcan`. Flexible transformations may be overridden for specific variables by specifying the identity transformation for them. When a categorical variable is being predicted, the flexible transformation is Fisher’s optimum scoring method. Nonlinear transformations for continuous variables may be nonmonotonic. If nk is a vector, `areg`’s bootstrap and crossval=10 options will be used to help find the optimum validating value of nk over values of that vector, at the last imputation iteration. For the imputations, the minimum value of nk is used.

Instead of defaulting to taking random draws from fitted imputation models using random residuals as is done by `transcan`, `aregImpute` by default uses predictive mean matching with optional weighted probability sampling of donors rather than using only the closest match. Predictive mean matching works for binary, categorical, and continuous variables without the need for iterative
maximum likelihood fitting for binary and categorical variables, and without the need for computing residuals or for curtailing imputed values to be in the range of actual data. Predictive mean matching is especially attractive when the variable being imputed is also being transformed automatically. See Details below for more information about the algorithm. A “regression” method is also available that is similar to that used in transcan. This option should be used when mechanistic missingness requires the use of extrapolation during imputation.

A print method summarizes the results, and a plot method plots distributions of imputed values. Typically, fit.mult.impute will be called after aregImpute.

If a target variable is transformed nonlinearly (i.e., if nk is greater than zero and tlinear is set to FALSE) and the estimated target variable transformation is non-monotonic, imputed values are not unique. When type="regression", a random choice of possible inverse values is made.

The reformM function provides two ways of recreating a formula to give to aregImpute by reordering the variables in the formula. This is a modified version of a function written by Yong Hao Pua. One can specify nperm to obtain a list of nperm randomly permuted variables. The list is converted to a single ordinary formula if nperm=1. If nperm is omitted, variables are sorted in descending order of the number of NAs. reformM also prints a recommended number of multiple imputations to use, which is a minimum of 5 and the percent of incomplete observations.

Usage

```r
aregImpute(formula, data, subset, n.impute=5, group=NULL,
    nk=3, tlinear=TRUE, type=c('pmm', 'regression', 'normpmm'),
    pmmtype=1, match=c('weighted', 'closest', 'kclosest'),
    kclose=3, fweighted=0.2,
    curtail=TRUE, boot.method=c('simple', 'approximate bayesian'),
    burnin=3, x=FALSE, pr=TRUE, plotTrans=FALSE, tolerance=NULL, B=75)
```

```r
## S3 method for class 'aregImpute'
print(x, digits=3, ...)
```

```r
## S3 method for class 'aregImpute'
plot(x, nclass=NULL, type=c('ecdf', 'hist'),
    datadensity=c("hist", "none", "rug", "density"),
    diagnostics=FALSE, maxn=10, ...)
```

```r
reformM(formula, data, nperm)
```

Arguments

- `formula`: an S model formula. You can specify restrictions for transformations of variables. The function automatically determines which variables are categorical (i.e., factor, category, or character vectors). Binary variables are automatically restricted to be linear. Force linear transformations of continuous variables by enclosing variables by the identify function (I()). It is recommended that factor() or as.factor() do not appear in the formula but instead variables be converted to factors as needed and stored in the data frame. That way imputations for factor variables (done using impute.transcan for example) will be correct. Currently reformM does not handle variables that are enclosed in functions such as I().

- `x`: an object created by aregImpute. For aregImpute, set x to TRUE to save the data matrix containing the final (number n.impute) imputations in the result.
This is needed if you want to later do out-of-sample imputation. Categorical variables are coded as integers in this matrix.

data input raw data
subset These may be also be specified. You may not specify na.action as na.retain is always used.
n.impute number of multiple imputations. n.impute=5 is frequently recommended but 10 or more doesn’t hurt.
group a character or factor variable the same length as the number of observations in data and containing no NAs. When group is present, causes a bootstrap sample of the observations corresponding to non-NAs of a target variable to have the same frequency distribution of group as the that in the non-NAs of the original sample. This can handle k-sample problems as well as lower the chance that a bootstrap sample will have a missing cell when the original cell frequency was low.
nk number of knots to use for continuous variables. When both the target variable and the predictors are having optimum transformations estimated, there is more instability than with normal regression so the complexity of the model should decrease more sharply as the sample size decreases. Hence set nk to 0 (to force linearity for non-categorical variables) or 3 (minimum number of knots possible with a linear tail-restricted cubic spline) for small sample sizes. Simulated problems as in the examples section can assist in choosing nk. See nk to a vector to get bootstrap-validated and 10-fold cross-validated $R^2$ and mean and median absolute prediction errors for imputing each sometimes-missing variable, with nk ranging over the given vector. The errors are on the original untransformed scale. The mean absolute error is the recommended basis for choosing the number of knots (or linearity).

tlinear set to FALSE to allow a target variable (variable being imputed) to have a nonlinear left-hand-side transformation when nk is 3 or greater

type The default is "pmm" for predictive mean matching, which is a more nonparametric approach that will work for categorical as well as continuous predictors. Alternatively, use "regression" when all variables that are sometimes missing are continuous and the missingness mechanism is such that entire intervals of population values are unobserved. See the Details section for more information. Another method, type="normpmm", only works when variables containing NAs are continuous and tlinear is TRUE (the default), meaning that the variable being imputed is not transformed when it is on the left hand model side. normpmm assumes that the imputation regression parameter estimates are multivariately normally distributed and that the residual variance has a scaled chi-squared distribution. For each imputation a random draw of the estimates is taken and a random draw from sigma is combined with those to get a random draw from the posterior predicted value distribution. Predictive mean matching is then done matching these predicted values from incomplete observations with predicted values from complete potential donor observations, where the latter predictions are based on the imputation model least squares parameter estimates and not on random draws from the posterior. For the plot method, specify type="hist" to draw histograms of imputed values with rug plots at the top, or type="ecdf" (the default) to draw empirical CDFs with spike histograms at the bottom.
pmmttype: type of matching to be used for predictive mean matching when `type="pmm"`. `pmmttype=2` means that predicted values for both target incomplete and complete observations come from a fit from the same bootstrap sample. `pmmttype=1`, the default, means that predicted values for complete observations are based on additive regression fits on original complete observations (using last imputations for non-target variables as with the other methods), and using fits on a bootstrap sample to get predicted values for missing target variables. See van Buuren (2012) section 3.4.2 where `pmmttype=1` is said to work much better when the number of variables is small. `pmmttype=3` means that complete observation predicted values come from a bootstrap sample fit whereas target incomplete observation predicted values come from a sample with replacement from the bootstrap fit (approximate Bayesian bootstrap).

match: Defaults to `match="weighted"` to do weighted multinomial probability sampling using the tricube function (similar to lowess) as the weights. The argument of the tricube function is the absolute difference in transformed predicted values of all the donors and of the target predicted value, divided by a scaling factor. The scaling factor in the tricube function is `fweighted` times the mean absolute difference between the target predicted value and all the possible donor predicted values. Set `match="closest"` to find as the donor the observation having the closest predicted transformed value, even if that same donor is found repeatedly. Set `match="kclosset"` to use a slower implementation that finds, after jittering the complete case predicted values, the `kclosest` complete cases on the target variable being imputed, then takes a random sample of one of these `kclosest` cases.

kclosest: see `match`

fweighted: Smoothing parameter (multiple of mean absolute difference) used when `match="weighted"`, with a default value of 0.2. Set `fweighted` to a number between 0.02 and 0.2 to force the donor to have a predicted value closer to the target, and set `fweighted` to larger values (but seldom larger than 1.0) to allow donor values to be less tightly matched. See the examples below to learn how to study the relationship between `fweighted` and the standard deviation of multiple imputations within individuals.

curtail: applies if `type='regression'`, causing imputed values to be curtailed at the observed range of the target variable. Set to `FALSE` to allow extrapolation outside the data range.

boot.method: By default, simple bootstrapping is used in which the target variable is predicted using a sample with replacement from the observations with non-missing target variable. Specify `boot.method='approximate bayesian'` to build the imputation models from a sample with replacement from a sample with replacement of the observations with non-missing targets. Preliminary simulations have shown this results in good confidence coverage of the final model parameters when `type='regression'` is used. Not implemented when `group` is used.

burnin: `aregImpute` does `burnin + n.impute` iterations of the entire modeling process. The first `burnin` imputations are discarded. More burn-in iterations may be required when multiple variables are missing on the same observations. When only one variable is missing, no burn-ins are needed and `burnin` is set to zero if unspecified.
aregImpute

pr

set to FALSE to suppress printing of iteration messages

plotTrans

set to TRUE to plot ace or avas transformations for each variable for each of the multiple imputations. This is useful for determining whether transformations are reasonable. If transformations are too noisy or have long flat sections (resulting in "lumps" in the distribution of imputed values), it may be advisable to place restrictions on the transformations (monotonicity or linearity).

tolerance

singularity criterion; list the source code in the lm.fit.qr.bare function for details

B

number of bootstrap resamples to use ifnkis a vector

digits

number of digits for printing

nclass

number of bins to use in drawing histogram

datadensity

see Ecdf

diagnostics

Specify diagnostics=TRUE to draw plots of imputed values against sequential imputation numbers, separately for each missing observations and variable.

maxn

Maximum number of observations shown for diagnostics. Default is maxn=10, which limits the number of observations plotted to at most the first 10.

nperm

number of random formula permutations for reformm; omit to sort variables by descending missing count.

... other arguments that are ignored

Details

The sequence of steps used by the aregImpute algorithm is the following.

(1) For each variable containing m NAs where m > 0, initialize the NAs to values from a random sample (without replacement if a sufficient number of non-missing values exist) of size m from the non-missing values.

(2) For burnin+ni.mpute iterations do the following steps. The first burnin iterations provide a burn-in, and imputations are saved only from the last ni.mpute iterations.

(3) For each variable containing any NAs, draw a sample with replacement from the observations in the entire dataset in which the current variable being imputed is non-missing. Fit a flexible additive model to predict this target variable while finding the optimum transformation of it (unless the identity transformation is forced). Use this fitted flexible model to predict the target variable in all of the original observations. Impute each missing value of the target variable with the observed value whose predicted transformed value is closest to the predicted transformed value of the missing value (if match="closest" and type="pmm"), or use a draw from a multinomial distribution with probabilities derived from distance weights, if match="weighted" (the default).

(4) After these imputations are computed, use these random draw imputations the next time the current target variable is used as a predictor of other sometimes-missing variables.

When match="closest", predictive mean matching does not work well when fewer than 3 variables are used to predict the target variable, because many of the multiple imputations for an observation will be identical. In the extreme case of one right-hand-side variable and assuming that only monotonic transformations of left and right-side variables are allowed, every bootstrap resample will give predicted values of the target variable that are monotonically related to predicted values from every other bootstrap resample. The same is true for Bayesian predicted values. This causes predictive mean matching to always match on the same donor observation.
When the missingness mechanism for a variable is so systematic that the distribution of observed values is truncated, predictive mean matching does not work. It will only yield imputed values that are near observed values, so intervals in which no values are observed will not be populated by imputed values. For this case, the only hope is to make regression assumptions and use extrapolation. With type="regression", aregImpute will use linear extrapolation to obtain a (hopefully) reasonable distribution of imputed values. The "regression" option causes aregImpute to impute missing values by adding a random sample of residuals (with replacement if there are more NAs than measured values) on the transformed scale of the target variable. After random residuals are added, predicted random draws are obtained on the original untransformed scale using reverse linear interpolation on the table of original and transformed target values (linear extrapolation when a random residual is large enough to put the random draw prediction outside the range of observed values). The bootstrap is used as with type="pmm" to factor in the uncertainty of the imputation model.

As model uncertainty is high when the transformation of a target variable is unknown, tlinear defaults to TRUE to limit the variance in predicted values when nk is positive.

Value

a list of class "aregImpute" containing the following elements:

call the function call expression
formulathe formula specified to aregImpute
match the match argument
fweighted the fweighted argument
ntotal number of observations in input dataset
pnumber of variables
namatch argument
named vector containing the numbers of missing values in the data
typevector of types of transformations used for each variable ("s", "l", "c" for smooth spline, linear, or categorical with dummy variables)
tlinearvalue of tlinear parameter
nknumber of knots used for smooth transformations
cat.levels list containing character vectors specifying the levels of categorical variables
dfdegrees of freedom (number of parameters estimated) for each variable
nimpute number of multiple imputations per missing value
imputed a list containing matrices of imputed values in the same format as those created by transcan. Categorical variables are coded using their integer codes. Variables having no missing values will have NULL matrices in the list.
xif x is TRUE, the original data matrix with integer codes for categorical variables
rsqfor the last round of imputations, a vector containing the R-squares with which each sometimes-missing variable could be predicted from the others by ace or avas.

# Give result or one of the results as the first argument to aregImpute
**binconf**

*Confidence Intervals for Binomial Probabilities*

---

**Description**

Produces 1-alpha confidence intervals for binomial probabilities.

**Usage**

```r
binconf(x, n, alpha=0.05,
        method=c("wilson","exact","asymptotic","all"),
        include.x=FALSE, include.n=FALSE, return.df=FALSE)
```

**Arguments**

- `x`: vector containing the number of "successes" for binomial variates
- `n`: vector containing the numbers of corresponding observations
- `alpha`: probability of a type I error, so confidence coefficient = 1-alpha
- `method`: character string specifying which method to use. The "all" method only works when `x` and `n` are length 1. The "exact" method uses the F distribution to compute exact (based on the binomial cdf) intervals; the "wilson" interval is score-test-based; and the "asymptotic" is the text-book, asymptotic normal interval. Following Agresti and Coull, the Wilson interval is to be preferred and so is the default.
- `include.x`: logical flag to indicate whether `x` should be included in the returned matrix or data frame
- `include.n`: logical flag to indicate whether `n` should be included in the returned matrix or data frame
- `return.df`: logical flag to indicate that a data frame rather than a matrix be returned

**Value**

A matrix or data.frame containing the computed intervals and, optionally, `x` and `n`.

Examples

```r
binconf(0:10, 10, include.x=TRUE, include.n=TRUE)
binconf(46, 50, method="all")
```

Description

biVar is a generic function that accepts a formula and usual data, subset, and na.action parameters plus a list statinfo that specifies a function of two variables to compute along with information about labeling results for printing and plotting. The function is called separately with each right hand side variable and the same left hand variable. The result is a matrix of bivariate statistics and the statinfo list that drives printing and plotting. The plot method draws a dot plot with x-axis values by default sorted in order of one of the statistics computed by the function.

spearman2 computes the square of Spearman’s rho rank correlation and a generalization of it in which x can relate non-monotonically to y. This is done by computing the Spearman multiple rho-squared between \((\text{rank}(x), \text{rank}(x)^2)\) and y. When x is categorical, a different kind of Spearman correlation used in the Kruskal-Wallis test is computed (and spearman2 can do the Kruskal-Wallis test). This is done by computing the ordinary multiple \(R^2\) between \(k-1\) dummy variables and \(\text{rank}(y)\), where x has k categories. x can also be a formula, in which case each predictor is correlated separately with y, using non-missing observations for that predictor. biVar is used to do the looping and bookkeeping. By default the plot shows the adjusted \(\text{rho}^2\), using the same formula used for the ordinary adjusted \(R^2\). The F test uses the unadjusted \(R^2\).

spearman computes Spearman’s rho on non-missing values of two variables. spearman.test is a simple version of spearman2.default.

chiSquare is set up like spearman2 except it is intended for a categorical response variable. Separate Pearson chi-square tests are done for each predictor, with optional collapsing of infrequent categories. Numeric predictors having more than g levels are categorized into g quantile groups. chiSquare uses biVar.

Usage

```r
biVar(formula, statinfo, data=NULL, subset=NULL,
na.action=na.retain, exclude.imputed=TRUE, ...)
```
## Arguments

- **formula**: a formula with a single left side variable.
- **statinfo**: see `spearman2.formula` or `chisquare` code.
- **data**, **subset**, **na.action**, **exclude.imputed**: the usual options for models. Default for **na.action** is to retain all values, NA or not, so that NAs can be deleted in only a pairwise fashion.
- **exclude.imputed**: set to **FALSE** to include imputed values (created by `impute`) in the calculations.
- **...**: other arguments that are passed to the function used to compute the bivariate statistics or to `dotchart3` for plot.
- **na.rm**: logical; delete NA values?
- **x**: a numeric matrix with at least 5 rows and at least 2 columns (if **y** is absent). For `spearman2`, the first argument may be a vector of any type, including character or factor. The first argument may also be a formula, in which case all predictors are correlated individually with the response variable. **x** may be a formula for `spearman2` in which case `spearman2.formula` is invoked. Each predictor in the right hand side of the formula is separately correlated with the response variable. For print or plot, **x** is an object produced by `biVar`. For `spearman` and `spearman.test` **x** is a numeric vector, as is **y**. For `chisquare`, **x** is a formula.
- **y**: a numeric vector.
- **p**: for numeric variables, specifies the order of the Spearman $\rho^2$ to use. The default is **p=1** to compute the ordinary $\rho^2$. Use **p=2** to compute the quadratic.
rank generalization to allow non-monotonicity. p is ignored for categorical predictors.

minlev minimum relative frequency that a level of a categorical predictor should have before it is pooled with other categories (see combine.levels) in spearman2 and chiSquare (in which case it also applies to the response). The default, minlev=0 causes no pooling.

what specifies which statistic to plot. Possibilities include the column names that appear with the print method is used.
sort. set sort.=FALSE to suppress sorting variables by the statistic being plotted
main main title for plot. Default title shows the name of the response variable.
xlab x-axis label. Default constructed from what.
vnames set to "labels" to use variable labels in place of names for plotting. If a variable does not have a label the name is always used.

Details
Uses midranks in case of ties, as described by Hollander and Wolfe. P-values for Spearman, Wilcoxon, or Kruskal-Wallis tests are approximated by using the t or F distributions.

Value
spearman2.default (the function that is called for a single x, i.e., when there is no formula) returns a vector of statistics for the variable. biVar, spearman2.formula, and chiSquare return a matrix with rows corresponding to predictors.

**Bootstrap Kaplan-Meier Estimates**

**Description**

Bootstraps Kaplan-Meier estimate of the probability of survival to at least a fixed time (times variable) or the estimate of the q quantile of the survival distribution (e.g., median survival time, the default).

**Usage**

```r
bootkm(S, q=0.5, B=500, times, pr=TRUE)
```

**Arguments**

- `S` a Surv object for possibly right-censored survival time
- `q` quantile of survival time, default is 0.5 for median
- `B` number of bootstrap repetitions (default=500)
- `times` time vector (currently only a scalar is allowed) at which to compute survival estimates. You may specify only one of q and times, and if times is specified q is ignored.
- `pr` set to FALSE to suppress printing the iteration number every 10 iterations

**Details**

bootkm uses Therneau’s `survfitkm` function to efficiently compute Kaplan-Meier estimates.

**Value**

a vector containing B bootstrap estimates

**Side Effects**

updates `.Random.seed`, and, if pr=TRUE, prints progress of simulations

bpower

Power and Sample Size for Two-Sample Binomial Test

Description

Uses method of Fleiss, Tytun, and Ury (but without the continuity correction) to estimate the power
(or the sample size to achieve a given power) of a two-sided test for the difference in two propor-
tions. The two sample sizes are allowed to be unequal, but for bsamsize you must specify the
fraction of observations in group 1. For power calculations, one probability (p1) must be given,
and either the other probability (p2), an odds.ratio, or a percent.reduction must be given. For
bpower or bsamsize, any or all of the arguments may be vectors, in which case they return a vector
of powers or sample sizes. All vector arguments must have the same length.

Given p1, p2, ballocation uses the method of Brittain and Schlesselman to compute the optimal
fraction of observations to be placed in group 1 that either (1) minimize the variance of the difference
in two proportions, (2) minimize the variance of the ratio of the two proportions, (3) minimize
the variance of the log odds ratio, or (4) maximize the power of the 2-tailed test for differences. For
(4) the total sample size must be given, or the fraction optimizing the power is not returned. The
fraction for (3) is one minus the fraction for (1).

bpower.sim estimates power by simulations, in minimal time. By using bpower.sim you can
see that the formulas without any continuity correction are quite accurate, and that the power of
a continuity-corrected test is significantly lower. That's why no continuity corrections are imple-
mented here.
Usage

bpower(p1, p2, odds.ratio, percent.reduction,
  n, n1, n2, alpha=0.05)

bsamsize(p1, p2, fraction=.5, alpha=.05, power=.8)

ballocation(p1, p2, n, alpha=.05)

bpower.sim(p1, p2, odds.ratio, percent.reduction,
  n, n1, n2,
  alpha=0.05, nsim=10000)

Arguments

p1  population probability in the group 1
p2  probability for group 2
odds.ratio
percent.reduction

n   total sample size over the two groups. If you omit this for ballocation, the
    fraction which optimizes power will not be returned.
n1
n2  the individual group sample sizes. For bpower, if n is given, n1 and n2 are set to n/2.
alpha  type I error
fraction  fraction of observations in group 1
power  the desired probability of detecting a difference
nsim  number of simulations of binomial responses

Details

For bpower.sim, all arguments must be of length one.

Value

for bpower, the power estimate; for bsamsize, a vector containing the sample sizes in the two
groups; for ballocation, a vector with 4 fractions of observations allocated to group 1, optimiz-
ing the four criteria mentioned above. For bpower.sim, a vector with three elements is returned,
corresponding to the simulated power and its lower and upper 0.95 confidence limits.

# n is varied also
pl <- seq(.01,.99,by=.01)
bpplot

Description

Produce side-by-side box-percentile plots from several vectors or a list of vectors.

Usage

bpplot(..., name=TRUE, main="Box-Percentile Plot", xlab="", ylab="", srtx=0, plotopts=NULL)

Arguments

... vectors or lists containing numeric components (e.g., the output of split).
name character vector of names for the groups. Default is TRUE to put names on the x-axis. Such names are taken from the data vectors or the names attribute of the first argument if it is a list. Set name to FALSE to suppress names. If a character vector is supplied the names in the vector are used to label the groups.
main main title for the plot.
xlabel x axis label.
ylabel y axis label.
srtx rotation angle for x-axis labels. Default is zero.
plotopts a list of other parameters to send to plot

Value

There are no returned values

Side Effects

A plot is created on the current graphics device.

BACKGROUND

Box-percentile plots are similar to boxplots, except box-percentile plots supply more information about the univariate distributions. At any height the width of the irregular "box" is proportional to the percentile of that height, up to the 50th percentile, and above the 50th percentile the width is proportional to 100 minus the percentile. Thus, the width at any given height is proportional to the percent of observations that are more extreme in that direction. As in boxplots, the median, 25th and 75th percentiles are marked with line segments across the box.

x3 <- abs(rnorm(500))-2
bpplot(x1, x2, x3)
g <- sample(1:2, 500, replace=TRUE)
bpplot(split(x2, g), name=c('Group 1','Group 2'))
rm(x1,x2,x3,g)
```

bystats

Statistics by Categories

Description

For any number of cross-classification variables, bystats returns a matrix with the sample size, number missing y, and fun(non-missing y), with the cross-classifications designated by rows. Uses Harrell's modification of the interaction function to produce cross-classifications. The default fun is mean, and if y is binary, the mean is labeled as Fraction. There is a print method as well as a latex method for objects created by bystats. bystats2 handles the special case in which there are 2 classification variables, and places the first one in rows and the second in columns. The print method for bystats2 uses the print.char.matrix function to organize statistics for cells into boxes.

Usage

```r
bystats(y, ..., fun, nmiss, subset)
## S3 method for class 'bystats'
print(x, ...)
## S3 method for class 'bystats'
latex(object, title, caption, rowlabel, ...)
bystats2(y, v, h, fun, nmiss, subset)
## S3 method for class 'bystats2'
print(x, abbreviate.dimnames=FALSE,
```
Arguments

\(y\) a binary, logical, or continuous variable or a matrix or data frame of such variables. If \(y\) is a data frame it is converted to a matrix. If \(y\) is a data frame or matrix, computations are done on subsets of the rows of \(y\), and you should specify \(fun\) so as to be able to operate on the matrix. For matrix \(y\), any column with a missing value causes the entire row to be considered missing, and the row is not passed to \(fun\).

\(...\)

For \texttt{bystats}, one or more classification variables separated by commas. For \texttt{print.bystats}, options passed to \texttt{print.default} such as \texttt{digits}. For \texttt{latex.bystats}, and \texttt{latex.bystats2}, options passed to \texttt{latex.default} such as \texttt{digits}. If you pass \texttt{cdec} to \texttt{latex.default}, keep in mind that the first one or two positions (depending on \texttt{nmiss}) should have zeros since these correspond with frequency counts.

\(v\) vertical variable for \texttt{bystats2}. Will be converted to \texttt{factor}.

\(h\) horizontal variable for \texttt{bystats2}. Will be converted to \texttt{factor}.

\(fun\) a function to compute on the non-missing \(y\) for a given subset. You must specify \(fun=\) in front of the function name or definition. \(fun\) may return a single number or a vector or matrix of any length. Matrix results are rolled out into a vector, with names preserved. When \(y\) is a matrix, a common \(fun\) is \texttt{function(y) apply(y, 2, ff)} where \(ff\) is the name of a function which operates on one column of \(y\).

\(nmiss\) A column containing a count of missing values is included if \texttt{nmiss=TRUE} or if there is at least one missing value.

\(subset\) a vector of subscripts or logical values indicating the subset of data to analyze

\(abbreviate.dimnames\) set to \texttt{TRUE} to abbreviate \texttt{dimnames} in output

\(prefix.width\) see \texttt{print.char.matrix}

\(title\) title to pass to \texttt{latex.default}. Default is the first word of the character string version of the first calling argument.

\(caption\) caption to pass to \texttt{latex.default}. Default is the heading attribute from the object produced by \texttt{bystats}.

\(rowlabel\) rowlabel to pass to \texttt{latex.default}. Default is the \texttt{byvarnames} attribute from the object produced by \texttt{bystats}. For \texttt{bystats2} the default is "".

\(x\) an object created by \texttt{bystats} or \texttt{bystats2}

\(object\) an object created by \texttt{bystats} or \texttt{bystats2}

Value

for \texttt{bystats}, a matrix with row names equal to the classification labels and column names \texttt{N, Missing, funlab}, where \texttt{funlab} is determined from \texttt{fun}. A row is added to the end with the summary statistics computed on all observations combined. The class of this matrix is \texttt{bystats}. For \texttt{bystats}, returns a
3-dimensional array with the last dimension corresponding to statistics being computed. The class of the array is `bystats2`.

**Side Effects**

`latex` produces a `.tex` file.

**capitalize**

*capitalize the first letter of a string*

**Description**

Capitalizes the first letter of each element of the string vector.
Usage

capitalize(string)

Arguments

string String to be capitalized

Value

Returns a vector of characters with the first letter capitalized

Author(s)

Charles Dupont

Examples

capitalize(c("Hello", "bob", "daN"))

ciapower(Power of Interaction Test for Exponential Survival)

Description

Uses the method of Peterson and George to compute the power of an interaction test in a 2 x 2 setup in which all 4 distributions are exponential. This will be the same as the power of the Cox model test if assumptions hold. The test is 2-tailed. The duration of accrual is specified (constant accrual is assumed), as is the minimum follow-up time. The maximum follow-up time is then accrual + tmin. Treatment allocation is assumed to be 1:1.

Usage

ciapower(tref, n1, n2, m1c, m2c, r1, r2, accrual, tmin,
alpha=0.05, pr=TRUE)

Arguments

tref time at which mortalities estimated
n1 total sample size, stratum 1
n2 total sample size, stratum 2
m1c tref-year mortality, stratum 1 control
m2c tref-year mortality, stratum 2 control
r1 % reduction in m1c by intervention, stratum 1
r2 % reduction in m2c by intervention, stratum 2
accrual duration of accrual period
ciapower

tmin  minimum follow-up time
alpha  type I error probability
pr    set to FALSE to suppress printing of details

Value

power

Side Effects

prints

cnvrt.coords  Convert between the 5 different coordinate systems on a graphical device

Description

Takes a set of coordinates in any of the 5 coordinate systems (usr, plt, fig, dev, or tdev) and returns the same points in all 5 coordinate systems.

Usage

cnvrt.coords(x, y = NULL, input = c("usr", "plt", "fig", "dev", "tdev"))

Arguments

x Vector, Matrix, or list of x coordinates (or x and y coordinates), NA's allowed.
y y coordinates (if x is a vector), NA's allowed.
input Character scalar indicating the coordinate system of the input points.

Details

Every plot has 5 coordinate systems:

usr (User): the coordinate system of the data, this is shown by the tick marks and axis labels.
plt (Plot): Plot area, coordinates range from 0 to 1 with 0 corresponding to the x and y axes and 1 corresponding to the top and right of the plot area. Margins of the plot correspond to plot coordinates less than 0 or greater than 1.
fig (Figure): Figure area, coordinates range from 0 to 1 with 0 corresponding to the bottom and left edges of the figure (including margins, label areas) and 1 corresponds to the top and right edges. fig and dev coordinates will be identical if there is only 1 figure area on the device (layout, mfrow, or mfcol has not been used).
dev (Device): Device area, coordinates range from 0 to 1 with 0 corresponding to the bottom and left of the device region within the outer margins and 1 is the top and right of the region within the outer margins. If the outer margins are all set to 0 then tdev and dev should be identical.
tdev (Total Device): Total Device area, coordinates range from 0 to 1 with 0 corresponding to the bottom and left edges of the device (piece of paper, window on screen) and 1 corresponds to the top and right edges.

Value

A list with 5 components, each component is a list with vectors named x and y. The 5 sublists are:

usr The coordinates of the input points in usr (User) coordinates.
plt The coordinates of the input points in plt (Plot) coordinates.
fig The coordinates of the input points in fig (Figure) coordinates.
dev The coordinates of the input points in dev (Device) coordinates.
tdev The coordinates of the input points in tdev (Total Device) coordinates.
Note

You must provide both x and y, but one of them may be NA.

This function is becoming deprecated with the new functions `grconvertX` and `grconvertY` in R version 2.7.0 and beyond. These new functions use the correct coordinate system names and have more coordinate systems available, you should start using them instead.

See Also

`par` specifically `usr`, `plt`, and `fig`. Also `xpd` for plotting outside of the plotting region and `mrow` and `mfcol` for multi figure plotting. `subplot`, `grconvertX` and `grconvertY` in R 2.7.0 and later

Examples

```r
old.par <- par(no.readonly=TRUE)

par(mfrow=c(2,2),xpd=NA)

# generate some sample data
tmp.x <- rnorm(25, 10, 2)
tmp.y <- rnorm(25, 50, 10)
tmp.z <- rnorm(25, 0, 1)

plot( tmp.x, tmp.y)

# draw a diagonal line across the plot area
tmp1 <- cnvrt.coords( c(0,1), c(0,1), input='plt' )
lines(tmp1$usr, col='blue')

# draw a diagonal line across figure region
tmp2 <- cnvrt.coords( c(0,1), c(1,0), input='fig' )
lines(tmp2$usr, col='red')

# save coordinate of point 1 and y value near top of plot for future plots
tmp.range1 <- cnvrt.coords(tmp.x[1], tmp.y[1])

# make a second plot and draw a line linking point 1 in each plot
plot(tmp.y, tmp.z)

tmp.range2 <- cnvrt.coords(tmp.range1$dev, input='dev')

# draw another plot and add rectangle showing same range in 2 plots
arrows( tmp.y[1], tmp.z[1], tmp.range2$usr$x, tmp.range2$usr$y, col='green')
```

**colorFacet**

```r
plot(tmp.x, tmp.z)
tmp.range2 <- cnvrt.coords(NA, 0.02, input='plt')
tmp.range3 <- cnvrt.coords(NA, tmp.range1$dev$y, input='dev')
rect(9, tmp.range2$usr$y, 11, tmp.range3$usr$y, border='yellow')

# put a label just to the right of the plot and
# near the top of the figure region.
text( cnvrt.coords(1.05, NA, input='plt')$usr$x,
cnvrt.coords(NA, 0.75, input='fig')$usr$y,
"Label", adj=0)

par(mfrow=c(1,1))

## create a subplot within another plot (see also subplot)

plot(1:10, 1:10)
tmp <- cnvrt.coords( c(1, 4, 6, 9), c(6, 9, 1, 4) )
par(plt = c(tmp$dev$x[1:2], tmp$dev$y[1:2]), new=TRUE)
hist(rnorm(100))
par(fig = c(tmp$dev$x[3:4], tmp$dev$y[3:4]), new=TRUE)
hist(rnorm(100))

par( old.par)
```

---

**colorFacet**

*Miscellaneous ggplot2 and grid Helper Functions*

**Description**

These functions are used on ggplot2 objects or as layers when building a ggplot2 object, and to facilitate use of gridExtra. `colorFacet` colors the thin rectangles used to separate panels created by `facet_grid` (and probably by `facet_wrap`). A better approach may be found at [http://stackoverflow.com/questions/28652284](http://stackoverflow.com/questions/28652284). `arrGrob` is a front-end to `gridExtra::arrangeGrob` that allows for proper printing. See [http://stackoverflow.com/questions/29062766/store-output-from-gridextra](http://stackoverflow.com/questions/29062766/store-output-from-gridextra). The `arrGrob` print method calls `grid::grid.draw`.

**Usage**

```r
colorFacet(g, col = adjustcolor("blue", alpha.f = 0.3))

arrGrob(...)

## S3 method for class 'arrGrob'
print(x, ...)
```
Arguments

- `g`: A ggplot2 object that used faceting.
- `col`: Color for facet separator rectangles.
- `...`: Passed to arrangeGrob.
- `x`: An object created by arrGrob.

Author(s)

Sandy Muspratt

Examples

```r
## Not run:
s <- summaryP(age + sex ~ region + treatment)
colorFacet(ggplot(s))  # prints directly
# arrGrob is called by rms::ggplot.Predict and others

## End(Not run)
```

### consolidate

**Element Merging**

Merges an object by the names of its elements. Inserting elements in `value` into `x` that do not exist in `x` and replacing elements in `x` that exist in `value` with `value` elements if `protect` is false.

**Usage**

```r
consolidate(x, value, protect, ...)
```

**Default S3 method:**

```r
consolidate(x, value, protect=FALSE, ...)
```

```r
consolidate(x, protect, ...) <- value
```

**Arguments**

- `x`: Named list or vector.
- `value`: Named list or vector.
- `protect`: Logical; should elements in `x` be kept instead of elements in `value`?
- `...`: Currently does nothing; included if ever want to make generic.

y # c(D=6,E=7,F=8,G=9,H=10)

consolidate(x, y) # c(A=1,B=2,C=3,D=6,E=7,F=8,G=9,H=10)
consolidate(x, y, protect=TRUE) # c(A=1,B=2,C=3,D=4,E=5,F=8,G=9,H=10)

## Metadata for a Data Frame

Description

contents is a generic method for which contents.data.frame is currently the only method. contents.data.frame creates an object containing the following attributes of the variables from a data frame: names, labels (if any), units (if any), number of factor levels (if any), factor levels, class, storage mode, and number of NAs. print.contents.data.frame will print the results, with options for sorting the variables. html.contents.data.frame creates HTML code for displaying the results. This code has hyperlinks so that if the user clicks on the number of levels the browser jumps to the correct part of a table of factor levels for all the factor variables. If long labels are present (~"longlabel" attributes on variables), these are printed at the bottom and the html method links to them through the regular labels. Variables having the same levels in the same order have the levels factored out for brevity.

contents.list prints a directory of datasets when sasxport.get imported more than one SAS dataset.

Usage

contents(object, ...)
## S3 method for class 'data.frame'
contents(object, sortlevels=FALSE, id=NULL,
          range=NULL, values=NULL, ...)
## S3 method for class 'contents.data.frame'
print(x,
          sort=c('none','names','labels','NAS'), prlevels=TRUE, maxlevels=Inf,
          number=FALSE, ...)
## S3 method for class 'contents.data.frame'
html(object,
        sort=c('none','names','labels','NAs'), prlevels=TRUE, maxlevels=Inf,
        leveltype=c('list','table'),
        number=FALSE, nshow=TRUE, ...)
## S3 method for class 'list'
contents(object, dslabels, ...)
## S3 method for class 'contents.list'
print(x,
        sort=c('none','names','labels','NAs','vars'), ...)

Arguments

object a data frame. For html is an object created by contents. For contents.list
         is a list of data frames.
sortlevels set to TRUE to sort levels of all factor variables into alphabetic order. This is
         especially useful when two variables use the same levels but in different orders. They will
         still be recognized by the html method as having identical levels if sorted.
id an optional subject ID variable name that if present in object will cause the
         number of unique IDs to be printed in the contents header
range an optional variable name that if present in object will cause its range to be
         printed in the contents header
values an optional variable name that if present in object will cause its unique values
         to be printed in the contents header
x an object created by contents
sort Default is to print the variables in their original order in the data frame. Specify
        one of "names", "labels", or "NAs" to sort the variables by, respectively, alphabetically
        by names, alphabetically by labels, or by increasing order of number of missing values. For
        contents.list, sort may also be the value "vars" to cause sorting by the number of variables in
        the dataset.
prlevels set to FALSE to not print all levels of factor variables
maxlevels maximum number of levels to print for a factor variable
number set to TRUE to have the print and latex methods number the variables by their
         order in the data frame
nshow set to FALSE to suppress outputting number of observations and number of NAs;
         useful when these counts would unblind information to blinded reviewers
leveltype By default, bullet lists of category levels are constructed in html. Set leveltype='table'
         to put levels in html table format.
... arguments passed from html to format.df, unused otherwise
dslabels named vector of SAS dataset labels, created for example by sasdsLabels

Value

an object of class "contents.data.frame" or "contents.list". For the html method is an html
character vector object.
cpower

Examples

```r
set.seed(1)
dfr <- data.frame(x=rnorm(400),y=sample(c('male','female'),400,TRUE))
contents(dfr)
dfr <- upData(dfr, labels=c(x='Label for x', y='Label for y'))
attr(dfr$x, 'longlabel') <-
'A very long label for x that can continue onto multiple long lines of text'

k <- contents(dfr)
print(k, sort='names', prlevels=FALSE)
## Not run:
html(k)
html(contents(dfr)) # same result
latex(k$contents) # latex.default just the main information

## End(Not run)
```

cpower  

Power of Cox/log-rank Two-Sample Test

Description
Assumes exponential distributions for both treatment groups. Uses the George-Desu method along with formulas of Schoenfeld that allow estimation of the expected number of events in the two groups. To allow for drop-ins (noncompliance to control therapy, crossover to intervention) and noncompliance of the intervention, the method of Lachin and Foulkes is used.

Usage
cpower(tref, n, mc, r, accrual, tmin, noncomp.c=0, noncomp.i=0,
alpha=0.05, nc, ni, pr=TRUE)

Arguments

- `tref`  
  time at which mortalities estimated
- `n`  
  total sample size (both groups combined). If allocation is unequal so that there are not n/2 observations in each group, you may specify the sample sizes in `nc` and `ni`.  

mc  tref-year mortality, control
r  % reduction in mc by intervention
accrual  duration of accrual period
tmin  minimum follow-up time
noncomp.c  % non-compliant in control group (drop-ins)
noncomp.i  % non-compliant in intervention group (non-adherers)
alpha  type I error probability. A 2-tailed test is assumed.
nc  number of subjects in control group
ni  number of subjects in intervention group. nc and ni are specified exclusive of n.
pr  set to FALSE to suppress printing of details

Details
For handling noncompliance, uses a modification of formula (5.4) of Lachin and Foulkes. Their method is based on a test for the difference in two hazard rates, whereas cpower is based on testing the difference in two log hazards. It is assumed here that the same correction factor can be approximately applied to the log hazard ratio as Lachin and Foulkes applied to the hazard difference.
Note that Schoenfeld approximates the variance of the log hazard ratio by \( \frac{4}{m} \), where \( m \) is the total number of events, whereas the George-Desu method uses the slightly better \( \frac{1}{m_1} + \frac{1}{m_2} \). Power from this function will thus differ slightly from that obtained with the SAS samsizc program.

Value
power

Side Effects
prints

Examples

In this example, 4 plots are drawn on one page, one plot for each combination of noncompliance percentage. Within a plot, the 5-year mortality % in the control group is on the x-axis, and separate curves are drawn for several % reductions in mortality with the intervention. The accrual period is 1.5y, with all patients followed at least 5y and some 6.5y.

```r
par(mfrow=c(2,2),oma=c(0,0,0,0))

morts <- seq(10,25,length=50)
red <- c(10,15,20,25)

for(noncomp in c(0,10,15,19)) {
  if(noncomp==0) nc.i <- nc.c <- noncomp else (nc.i <- 25; nc.c <- 15)
  z <- paste("Drop-in ",nc.c,"% Non-adherence ",nc.i,"%",sep="")
  plot(0,0,xlim=range(morts),ylim=c(0,1),
       xlab="5-year Mortality in Control Patients (%)",
       ylab="Power",type="n")
  title(z)
  cat(z,"\n")
  lty <- 0
  for(r in red) {
    lty <- lty+1
    power <- morts
    i <- 0
    for(m in morts) {
      i <- i+1
      power[i] <- cpower(5,14000,m/100,r,1.5,5,nc.c,nc.i,pr=FALSE)
    }

title(sub='alpha=0.05, 2-tailed', adj=0)

---

Cs

*Character strings from unquoted names*

**Description**

Makes a vector of character strings from a list of valid S names

**Usage**

`Cs(...)`

**Arguments**

...  
any number of names separated by commas

**Value**

character string vector

**See Also**

`sys.frame`, `deparse`

**Examples**

`Cs(a,cat,dog)`

# subset.data.frame <- data.frame[,Cs(age,sex,race,bloodpressure,height)]
### csv.get

**Read Comma-Separated Text Data Files**

#### Description

Read comma-separated text data files, allowing optional translation to lower case for variable names after making them valid S names. There is a facility for reading long variable labels as one of the rows. If labels are not specified and a final variable name is not the same as that in the header, the original variable name is saved as a variable label. Uses `read.csv` if the `data.table` package is not in effect, otherwise calls `fread`.

#### Usage

```r
csv.get(file, lowernames=FALSE, datevars=NULL, datetimevars=NULL, 
        dateformat='%', 
        fixdates=c('none', 'year'), comment.char='', autodates=TRUE, 
        allow=NULL, charfactor=FALSE, 
        sep=',', skip=0, vnames=NULL, labels=NULL, ...)
```

#### Arguments

- **file**: the file name for import.
- **lowernames**: set this to TRUE to change variable names to lower case.
- **datevars**: character vector of names (after `lowernames` is applied) of variables to consider as a factor or character vector containing dates in a format matching `dateformat`. The default is "%F" which uses the yyyy-mm-dd format.
- **datetimevars**: character vector of names (after `lowernames` is applied) of variables to consider to be date-time variables, with date formats as described under `datevars` followed by a space followed by time in hh:mm:ss format. `chron` is used to store such variables. If all times in the variable are 00:00:00 the variable will be converted to an ordinary date variable.
- **dateformat**: for `cleanup.import` is the input format (see `strptime`)
- **fixdates**: for any of the variables listed in `datevars` that have a `dateformat` that `cleanup.import` understands, specifying `fixdates` allows corrections of certain formatting inconsistencies before the fields are attempted to be converted to dates (the default is to assume that the dateformat is followed for all observation for `datevars`). Currently `fixdates='year'` is implemented, which will cause 2-digit or 4-digit years to be shifted to the alternate number of digits when `dateformat` is the default "%F" or is "%y-%m-%d", "%m/%d/%y", or "%m/%d/%Y". Two-digits years are padded with 0 on the left. Set `dateformat` to the desired format, not the exceptional format.
- **comment.char**: a character vector of length one containing a single character or an empty string. Use """" to turn off the interpretation of comments altogether.
- **autodates**: Set to true to allow function to guess at which variables are dates
allow  
a vector of characters allowed by R that should not be converted to periods in variable names. By default, underscores in variable names are converted to periods as with R before version 1.9.

charfactor  
set to TRUE to change character variables to factors if they have fewer than n/2 unique values. Blanks and null strings are converted to NAs.

sep  
field separator, defaults to comma

skip  
number of records to skip before data start. Required if vnames or labels is given.

vnames  
number of row containing variable names, default is one

labels  
number of row containing variable labels, default is no labels

...  
arguments to pass to read.csv other than skip and sep.

Details

csv.get reads comma-separated text data files, allowing optional translation to lower case for variable names after making them valid S names. Original possibly non-legal names are taken to be variable labels if labels is not specified. Character or factor variables containing dates can be converted to date variables. cleanup.import is invoked to finish the job.

Value

a new data frame.

Examples

```r
## Not run:
dat <- csv.get('myfile.csv')

# Read a csv file with junk in the first row, variable names in the 
# second, long variable labels in the third, and junk in the 4th row
dat <- csv.get('myfile.csv', vnames=2, labels=3, skip=4)

## End(Not run)
```
Description

curveRep finds representative curves from a relatively large collection of curves. The curves usually represent time-response profiles as in serial (longitudinal or repeated) data with possibly unequal time points and greatly varying sample sizes per subject. After excluding records containing missing x or y, records are first stratified into kn groups having similar sample sizes per curve (subject). Within these strata, curves are next stratified according to the distribution of x points per curve (typically measurement times per subject). The clara clustering/partitioning function is used to do this, clustering on one, two, or three x characteristics depending on the minimum sample size in the current interval of sample size. If the interval has a minimum number of unique values of one, clustering is done on the single x values. If the minimum number of unique x values is two, clustering is done to create groups that are similar on both min(x) and max(x). For groups containing no fewer than three unique x values, clustering is done on the trio of values min(x), max(x), and the longest gap between any successive x. Then within sample size and x distribution strata, clustering of time-response profiles is based on p values of y all evaluated at the same p equally-spaced x’s within the stratum. An option allows per-curve data to be smoothed with lowess before proceeding. Outer x values are taken as extremes of x across all curves within the stratum. Linear interpolation within curves is used to estimate y at the grid of x’s. For curves within the stratum that do not extend to the most extreme x values in that stratum, extrapolation uses flat lines from the observed extremes in the curve unless extrap=TRUE. The p y values are clustered using clara.

print and plot methods show results. By specifying an auxiliary idcol variable to plot, other variables such as treatment may be depicted to allow the analyst to determine for example whether subjects on different treatments are assigned to different time-response profiles. To write the frequencies of a variable such as treatment in the upper left corner of each panel (instead of the grand total number of clusters in that panel), specify freq.

curveSmooth takes a set of curves and smooths them using lowess. If the number of unique x points in a curve is less than p, the smooth is evaluated at the unique x values. Otherwise it is evaluated at an equally spaced set of x points over the observed range. If fewer than 3 unique x values are in a curve, those points are used and smoothing is not done.

Usage

curveRep(x, y, id, kn = 5, kxdist = 5, k = 5, p = 5,
force1 = TRUE, metric = c("euclidean", "manhattan"),
smooth=FALSE, extrap=FALSE, pr=FALSE)

## S3 method for class 'curveRep'
print(x, ...)

## S3 method for class 'curveRep'
plot(x, which=1:length(res), method=c('all','lattice'),
     m=NULL, probs=c(.5, .25, .75), nx=NULL, fill=TRUE,
idcol=NULL, freq=NULL, plotfreq=FALSE, 
xlim=range(x), ylim=range(y), 
xlab='x', ylab='y', colorfreq=FALSE, ...)
curveSmooth(x, y, id, p=NULL, pr=TRUE)

Arguments

x  a numeric vector, typically measurement times. For plot.curveRep is an object created by curveRep.

y  a numeric vector of response values

id a vector of curve (subject) identifiers, the same length as x and y

kn number of curve sample size groups to construct. curveRep tries to divide the data into equal numbers of curves across sample size intervals.

kxdist maximum number of x-distribution clusters to derive using clara

k maximum number of x-y profile clusters to derive using clara

p number of x points at which to interpolate y for profile clustering. For curveSmooth is the number of equally spaced points at which to evaluate the lowess smooth, and if p is omitted the smooth is evaluated at the original x values (which will allow curveRep to still know the x distribution

force1 By default if any curves have only one point, all curves consisting of one point will be placed in a separate stratum. To prevent this separation, set force1 = FALSE.

metric see clara

smooth By default, linear interpolation is used on raw data to obtain y values to cluster to determine x-y profiles. Specify smooth = TRUE to replace observed points with lowess before computing y points on the grid. Also, when smooth is used, it may be desirable to use extrap=TRUE.

extrap set to TRUE to use linear extrapolation to evaluate y points for x-y clustering. Not recommended unless smoothing has been or is being done.

pr set to TRUE to print progress notes

which an integer vector specifying which sample size intervals to plot. Must be specified if method='lattice' and must be a single number in that case.

method The default makes individual plots of possibly all x-distribution by sample size by cluster combinations. Fewer may be plotted by specifying which. Specify method='lattice' to show a lattice xyplot of a single sample size interval, with x distributions going across and clusters going down.

m the number of curves in a cluster to randomly sample if there are more than m in a cluster. Default is to draw all curves in a cluster. For method = "lattice" you can specify m = "quantiles" to use the xyplot function to show quantiles of y as a function of x, with the quantiles specified by the probs argument. This cannot be used to draw a group containing n = 1.

nx applies if m = "quantiles". See xyplot.

probs 3-vector of probabilities with the central quantile first. Default uses quartiles.
fill for method = "all", by default if a sample size x-distribution stratum did not have enough curves to stratify into k x-y profiles, empty graphs are drawn so that a matrix of graphs will have the next row starting with a different sample size range or x-distribution. See the example below.

idcol a named vector to be used as a table lookup for color assignments (does not apply when m = "quantile"). The names of this vector are curve ids and the values are color names or numbers.

freq a named vector to be used as a table lookup for a grouping variable such as treatment. The names are curve ids and values are any values useful for grouping in a frequency tabulation.

plotfreq set to TRUE to plot the frequencies from the freq variable as horizontal bars instead of printing them. Applies only to method = "lattice". By default the largest bar is 0.1 times the length of a panel’s x-axis. Specify plotfreq = 0.5 for example to make the longest bar half this long.

colorfreq set to TRUE to color the frequencies printed by plotfreq using the colors provided by idcol.

xlim, ylim, xlab, ylab plotting parameters. Default ranges are the ranges in the entire set of raw data given to curveRep.

... arguments passed to other functions.

Details

In the graph titles for the default graphic output, n refers to the minimum sample size, x refers to the sequential x-distribution cluster, and c refers to the sequential x-y profile cluster. Graphs from method = "lattice" are produced by xyplot and in the panel titles distribution refers to the x-distribution stratum and cluster refers to the x-y profile cluster.

Value

a list of class "curveRep" with the following elements

res a hierarchical list first split by sample size intervals, then by x distribution clusters, then containing a vector of cluster numbers with id values as a names attribute

ns a table of frequencies of sample sizes per curve after removing NAs

nomit total number of records excluded due to NAs

missfreq a table of frequencies of number of NAs excluded per curve

ncuts cut points for sample size intervals

kn number of sample size intervals

kdist number of clusters on x distribution

k number of clusters of curves within sample size and distribution groups

p number of points at which to evaluate each curve for clustering

x

y
id input data after removing NAs

curveSmooth returns a list with elements x, y, id.

Note

The references describe other methods for deriving representative curves, but those methods were not used here. The last reference which used a cluster analysis on principal components motivated curveRep however. The km1 package does k-means clustering of longitudinal data with imputation.

---

### cut2

**Cut a Numeric Variable into Intervals**

**Description**

Function like `cut` but left endpoints are inclusive and labels are of the form `[lower, upper]`, except that last interval is `[lower, upper]`. If cuts are given, will by default make sure that cuts include entire range of `x`. Also, if cuts are not given, will cut `x` into quantile groups (`g` given) or groups with a given minimum number of observations (`m`). Whereas `cut` creates a category object, `cut2` creates a factor object.

**Usage**

```r
cut2(x, cuts, m=150, g, levels.mean=FALSE, digits, minmax=TRUE,
oneval=TRUE, onlycuts=FALSE, formatfun=format, ...)
```

**Arguments**

- `x`: numeric vector to classify into intervals
- `cuts`: cut points
- `m`: desired minimum number of observations in a group. The algorithm does not guarantee that all groups will have at least `m` observations.
- `g`: number of quantile groups
- `levels.mean`: set to `TRUE` to make the new categorical vector have levels attribute that is the group means of `x` instead of interval endpoint labels
- `digits`: number of significant digits to use in constructing levels. Default is 3 (5 if `levels.mean=TRUE`)
- `minmax`: if cuts is specified but `min(x)<min(cuts)` or `max(x)>max(cuts)`, augments cuts to include min and max `x`
if an interval contains only one unique value, the interval will be labeled with the formatted version of that value instead of the interval endpoints, unless oneval=FALSE

set to TRUE to only return the vector of computed cuts. This consists of the interior values plus outer ranges.

formatting function, supports formula notation (if rlang is installed)

additional arguments passed to formatfun

a factor variable with levels of the form [a,b) or formatted means (character strings) unless onlycuts is TRUE in which case a numeric vector is returned

cut, quantile

Examples

set.seed(1)
x <- runif(1000, 0, 100)
z <- cut2(x, c(10, 20, 30))
table(z)
table(cut2(x, g=10))  # quantile groups
table(cut2(x, m=50))  # group x into intervals with at least 50 obs.

Tips for Creating, Modifying, and Checking Data Frames

Description

This help file contains a template for importing data to create an R data frame, correcting some problems resulting from the import and making the data frame be stored more efficiently, modifying the data frame (including better annotating it and changing the names of some of its variables), and checking and inspecting the data frame for reasonableness of the values of its variables and to describe patterns of missing data. Various built-in functions and functions in the Hmisc library are used. At the end some methods for creating data frames “from scratch” within R are presented.

The examples below attempt to clarify the separation of operations that are done on a data frame as a whole, operations that are done on a small subset of its variables without attaching the whole data frame, and operations that are done on many variables after attaching the data frame in search position one. It also tries to clarify that for analyzing several separate variables using R commands that do not support a data argument, it is helpful to attach the data frame in a search position later than position one.

It is often useful to create, modify, and process datasets in the following order.
1. Import external data into a data frame (if the raw data do not contain column names, provide these during the import if possible)
2. Make global changes to a data frame (e.g., changing variable names)
3. Change attributes or values of variables within a data frame
4. Do analyses involving the whole data frame (without attaching it)
   (Data frame still in .Data)
5. Do analyses of individual variables (after attaching the data frame in search position two or later)

Details

The examples below use the FEV dataset from Rosner 1995. Almost any dataset would do. The jetable data are taken from Galobardes et al.

Presently, giving a variable the "units" attribute (using the Hmisc units function) only benefits the Hmisc describe function and the rms library’s version of the link[rms]{surv} function. Variables labels defined with the Hmisc label function are used by describe, summary.formula, and many of the plotting functions in Hmisc and rms.

Examples

```r
## Not run:
# First, we do steps that create or manipulate the data
# frame in its entirety. For S-Plus, these are done with
#.Data in search position one (the default at the
# start of the session).
#
# -----------------------------------------------
# Step 1: Create initial draft of data frame
#
# We usually begin by importing a dataset from
# # another application. ASCII files may be imported
# using the scan and read.table functions. SAS
# # datasets may be imported using the Hmisc sas.get
# # function (which will carry more attributes from
# # SAS than using File ... Import) from the GUI
# # menus. But for most applications (especially
```
# Excel), File ... Import will suffice. If using
# the GUI, it is often best to provide variable
# names during the import process, using the Options
# tab, rather than renaming all fields later of
# course, if the data to be imported already have
# field names (e.g., in Excel), let S use those
# automatically. If using S-Plus, you can use a
# command to execute File ... Import, e.g.:

import.data(FileName = "/windows/temp/fev.asc",
            FileType = "ASCII", DataFrame = "FEV")

# Here we name the new data frame FEV rather than
# fev, because we wanted to distinguish a variable
# in the data frame named fev from the data frame
# name. For S-Plus the command will look
# instead like the following:

FEV <- importData("/tmp/fev.asc")

# ----------------------------------------------------------------------
# Step 2: Clean up data frame / make it be more
# efficiently stored
#
# Unless using sas.get to import your dataset
# (sas.get already stores data efficiently), it is
# usually a good idea to run the data frame through
# the Hmisc cleanup.import function to change
# numeric variables that are always whole numbers to
# be stored as integers, the remaining numerics to
# single precision, strange values from Excel to
# NAs, and character variables that always contain
# legal numeric values to numeric variables.
# cleanup.import typically halves the size of the
# data frame. If you do not specify any parameters
# to cleanup.import, the function assumes that no
# numeric variable needs more than 7 significant
# digits of precision, so all non-integer-valued
# variables will be converted to single precision.

FEV <- cleanup.import(FEV)

# ----------------------------------------------------------------------
# Step 3: Make global changes to the data frame
#
# A data frame has attributes that are "external" to its variables. There are the vector of its
# variable names ("names" attribute), the observation identifiers ("row.names"), and the
# "class" (whose value is "data.frame"). The "names" attribute is the one most commonly in need
# of modification. If we had wanted to change all the variable names to lower case, we could have
# specified lowernames=TRUE to the cleanup.import # invocation above, or type

names(FEV) <- casefold(names(FEV))

# The upData function can also be used to change variable names in two ways (see below).
# To change names in a non-systematic way we use other options. Under Windows/NT the most
# straightforward approach is to change the names interactively. Click on the data frame in the
# left panel of the Object Browser, then in the right pane click twice (slowly) on a variable.
# Use the left arrow and other keys to edit the name. Click outside that name field to commit the
# change. You can also rename columns while in a Data Sheet. To instead use programming commands
# to change names, use something like:

names(FEV)[6] <- 'smoke'  # assumes you know the positions!
names(FEV)[names(FEV) == 'smoking'] <- 'smoke'
names(FEV) <- edit(names(FEV))

# The last example is useful if you are changing many names. But none of the interactive
# approaches such as edit() are handy if you will be re-importing the dataset after it is updated in
# its original application. This problem can be addressed by saving the new names in a permanent
# vector in .Data:

new.names <- names(FEV)

# Then if the data are re-imported, you can type

names(FEV) <- new.names
# to rename the variables.

# ------------------------------------------------------------------
# Step 4: Delete unneeded variables
# 
# To delete some of the variables, you can
# right-click on variable names in the Object
# Browser's right pane, then select Delete. You can
# also set variables to have NULL values, which
# causes the system to delete them. We don't need
# to delete any variables from FEV but suppose we
# did need to delete some from mydf.

mydf$x1 <- NULL
mydf$x2 <- NULL
mydf[cbind('age', 'sex')] <- NULL  # delete 2 variables
mydf[cbind('age', 'sex')] <- NULL  # same thing

# The last example uses the Hmisc short-cut quoting
# function Cs. See also the drop parameter to upData.

# ------------------------------------------------------------------
# Step 5: Make changes to individual variables
# within the data frame
#
# After importing data, the resulting variables are
# seldom self-documenting, so we commonly need to
# change or enhance attributes of individual
# variables within the data frame.
#
# If you are only changing a few variables, it is
# efficient to change them directly without
# attaching the entire data frame.

FEV$sex <- factor(FEV$sex, 0:1, c('female', 'male'))
FEV$smoke <- factor(FEV$smoke, 0:1, c('non-current smoker', 'current smoker'))
units(FEV$age) <- 'years'
units(FEV$fev) <- 'L'
label(FEV$fev) <- 'Forced Expiratory Volume'
units(FEV$height) <- 'inches'
# When changing more than one or two variables it is
# more convenient change the data frame using the
# Hmisc upData function.

FEV2 <- upData(FEV,
   rename=c(smoking='smoke'),
   # omit if renamed above
drop=c('var1','var2'),
   levels=list(sex =list(female=0,male=1),
               smoke=list('non-current smoker'=0,
                          'current smoker'=1)),
   units=list(age='years', fev='L', height='inches'),
   labels=list(fev='Forced Expiratory Volume'))

# An alternative to levels=list(...) is for example
# upData(FEV, sex=factor(sex,0:1,c('female','male'))).
# Note that we saved the changed data frame into a
# new data frame FEV2. If we were confident of the
# correctness of our changes we could have stored
# the new data frame on top of the old one, under
# the original name FEV.

# ------------------------------------------------------------------------
# Step 6: Check the data frame
#
# The Hmisc describe function is perhaps the first
# function that should be used on the new data
# frame. It provides documentation of all the
# variables and the frequency tabulation, counts of
# NAs, and 5 largest and smallest values are
# helpful in detecting data errors. Typing
# describe(FEV) will write the results to the
# current output window. To put the results in a
# new window that can persist, even upon exiting
# S, we use the page function. The describe
# output can be minimized to an icon but kept ready
# for guiding later steps of the analysis.

page(describe(FEV2), multi=TRUE)
# multi=TRUE allows that window to persist while
# control is returned to other windows

# The new data frame is OK. Store it on top of the
# old FEV and then use the graphical user interface
# to delete FEV2 (click on it and hit the Delete
# key) or type rm(FEV2) after the next statement.
FEV <- FEV2

# Next, we can use a variety of other functions to
# check and describe all of the variables. As we
# are analyzing all or almost all of the variables,
# this is best done without attaching the data
# frame. Note that plot.data.frame plots inverted
# CDFs for continuous variables and dot plots
# showing frequency distributions of categorical
# ones.

summary(FEV)
# basic summary function (summary.data.frame)

plot(FEV)  # plot.data.frame
datadensity(FEV)
# rug plots and freq. bar charts for all var.

hist.data.frame(FEV)
# for variables having > 2 values

by(FEV, FEV$smoke, summary)
# use basic summary function with stratification

# -----------------------------------------------
# Step 7: Do detailed analyses involving individual
# variables
#
# Analyses based on the formula language can use
# data= so attaching the data frame may not be
# required. This saves memory. Here we use the
# Hmisc summary.formula function to compute 5
# statistics on height, stratified separately by age
# quartile and by sex.

options(width=80)
summary(height ~ age + sex, data=FEV,
        fun=function(y)c(smean.sd(y),
                       smedian.hilow(y,conf.int=.5)))
# This computes mean height, S.D., median, outer quartiles
fit <- lm(height ~ age*sex, data=FEV)
summary(fit)

# For this analysis we could also have attached the
# data frame in search position 2. For other
# analyses, it is mandatory to attach the data frame
# unless FEV$ prefixes each variable name.
# Important: DO NOT USE attach(FEV, 1) or
# attach(FEV, pos=1, ...) if you are only analyzing
# and not changing the variables, unless you really
# need to avoid conflicts with variables in search
# position 1 that have the same names as the
# variables in FEV. Attaching into search position
# 1 will cause S-Plus to be more of a memory hog.

attach(FEV)
# Use e.g. attach(FEV[,Cs(age,sex)]) if you only
# want to analyze a small subset of the variables
# Use e.g. attach(FEV[FEV$sex=='male',]) to
# analyze a subset of the observations

summary(height ~ age + sex,
    fun=function(y)c(smean.sd(y),
                        smedian.hilow(y,conf.int=.5)))
fit <- lm(height ~ age*sex)

# Run generic summary function on height and fev,
# stratified by sex
by(data.frame(height,fev), sex, summary)

# Cross-classify into 4 sex x smoke groups
by(FEV, list(sex,smoke), summary)

# Plot 5 quantiles
s <- summary(fev ~ age + sex + height,
             fun=function(y)quantile(y,c(.1,.25,.5,.75,.9))
plot(s, which=1:5, pch=c(1,2,15,2,1), #pch=c(=',','[','o',']','='),
     main='A Discovery', xlab='FEV')

# Use the nonparametric bootstrap to compute a
# 0.95 confidence interval for the population mean fev
smean.cl.boot(fev)  # in Hmisc
# Use the Statistics ... Compare Samples ... One Sample
# keys to get a normal-theory-based C.I. Then do it
# more manually. The following method assumes that
# there are no NAs in fev

ds <- sqrt(var(fev))
xbar <- mean(fev)
xbar
sd
n <- length(fev)
qt(.975,n-1)
# prints 0.975 critical value of t dist. with n-1 d.f.

xbar + c(-1,1)*sd/sqrt(n)*qt(.975,n-1)
# prints confidence limits

# Fit a linear model
# fit <- lm(fev ~ other variables ...)

detach()

# The last command is only needed if you want to
# start operating on another data frame and you want
# to get FEV out of the way.

# --------------------------------------------------------------------------
# Creating data frames from scratch
#
# Data frames can be created from within S. To
# create a small data frame containing ordinary
# data, you can use something like

dframe <- data.frame(age=c(10,20,30),
                    sex=c('male','female','male'))

# You can also create a data frame using the Data
# Sheet. Create an empty data frame with the
# correct variable names and types, then edit in the
# data.

dd <- data.frame(age=numeric(0), sex=character(0))
# The sex variable will be stored as a factor, and
# levels will be automatically added to it as you
# define new values for sex in the Data Sheet's sex
# column.
#
# When the data frame you need to create is defined
# by systematically varying variables (e.g., all
# possible combinations of values of each variable),
# the expand.grid function is useful for quickly
# creating the data. Then you can add
# non-systematically-varying variables to the object
# created by expand.grid, using programming
# statements or editing the Data Sheet. This
# process is useful for creating a data frame
# representing all the values in a printed table.
# In what follows we create a data frame
# representing the combinations of values from an 8
# x 2 x 2 x 2 (event x method x sex x what) table,
# and add a non-systematic variable percent to the
# data.

jctable <- expand.grid(
  event=c('Wheezing at any time',
    'Wheezing and breathless',
    'Wheezing without a cold',
    'Waking with tightness in the chest',
    'Waking with shortness of breath',
    'Waking with an attack of cough',
    'Attack of asthma',
    'Use of medication'),
  method=c('Mail', 'Telephone'),
  sex=c('Male', 'Female'),
  what=c('Sensitivity', 'Specificity'))

jctable$percent <-
c(756, 618, 706, 422, 356, 578, 289, 333,
  576, 421, 789, 273, 273, 212, 212, 212,
  613, 763, 713, 403, 377, 541, 290, 226,
  613, 684, 632, 290, 387, 613, 258, 129,
  656, 597, 438, 780, 732, 679, 938, 919,
  714, 600, 494, 877, 850, 703, 963, 987,
  755, 420, 480, 794, 779, 647, 956, 941,
  766, 423, 500, 833, 833, 604, 955, 986) / 10

# In jctable, event varies most rapidly, then
# method, then sex, and what.

## End(Not run)
Representativeness of Observations in a Data Set

Description

These functions are intended to be used to describe how well a given set of new observations (e.g., new subjects) were represented in a dataset used to develop a predictive model. The `dataRep` function forms a data frame that contains all the unique combinations of variable values that existed in a given set of variable values. Cross-classifications of values are created using exact values of variables, so for continuous numeric variables it is often necessary to round them to the nearest v and to possibly curtail the values to some lower and upper limit before rounding. Here v denotes a numeric constant specifying the matching tolerance that will be used. `dataRep` also stores marginal distribution summaries for all the variables. For numeric variables, all 101 percentiles are stored, and for all variables, the frequency distributions are also stored (frequencies are computed after any rounding and curtailment of numeric variables). For the purposes of rounding and curtailing, the `roundN` function is provided. A print method will summarize the calculations made by `dataRep`, and if `long=TRUE` all unique combinations of values and their frequencies in the original dataset are printed.

The `predict` method for `dataRep` takes a new data frame having variables named the same as the original ones (but whose factor levels are not necessarily in the same order) and examines the collapsed cross-classifications created by `dataRep` to find how many observations were similar to each of the new observations after any rounding or curtailment of limits is done. `predict` also does some calculations to describe how the variable values of the new observations "stack up" against the marginal distributions of the original data. For categorical variables, the percent of observations having a given variable with the value of the new observation (after rounding for variables that were through `roundN` in the formula given to `dataRep`) is computed. For numeric variables, the percentile of the original distribution in which the current value falls will be computed. For this purpose, the data are not rounded because the 101 original percentiles were retained; linear interpolation is used to estimate percentiles for values between two tabulated percentiles. The lowest marginal frequency of matching values across all variables is also computed. For example, if an age, sex combination matches 10 subjects in the original dataset but the age value matches 100 ages (after rounding) and the sex value matches the sex code of 300 observations, the lowest marginal frequency is 100, which is a "best case" upper limit for multivariable matching. I.e., matching on all variables has to result on a lower frequency than this amount. A print method for the output of `predict.dataRep` prints all calculations done by `predict` by default. Calculations can be selectively suppressed.

Usage

dataRep(formula, data, subset, na.action)
roundN(x, tol=1, clip=NULL)

## S3 method for class 'dataRep'
print(x, long=FALSE, ...)

## S3 method for class 'dataRep'
predict(object, newdata, 

# S3 method for class 'predict.dataRep'
print(x, prdata=TRUE, prpct=TRUE, 

Arguments

formula a formula with no left-hand-side. Continuous numeric variables in need of rounding should appear in the formula as e.g. `roundN(x, 5)` to have a tolerance of e.g. +/- 2.5 in matching. Factor or character variables as well as numeric ones not passed through `roundN` are matched on exactly.

x a numeric vector or an object created by `dataRep`

object the object created by `dataRep` or `predict.dataRep`

data, subset, na.action standard modeling arguments. Default `na.action` is `na.delete`, i.e., observations in the original dataset having any variables missing are deleted up front.

tol rounding constant (tolerance is actually `tol/2` as values are rounded to the nearest `tol`)

clip a 2-vector specifying a lower and upper limit to curtail values of `x` before rounding

long set to `TRUE` to see all unique combinations and frequency count

newdata a data frame containing all the variables given to `dataRep` but not necessarily in the same order or having factor levels in the same order

prdata set to `FALSE` to suppress printing `newdata` and the count of matching observations (plus the worst-case marginal frequency).

prpct set to `FALSE` to not print percentiles and percents

... unused

Value

dataRep returns a list of class "dataRep" containing the collapsed data frame and frequency counts along with marginal distribution information. predict returns an object of class "predict.dataRep" containing information determined by matching observations in `newdata` with the original (collapsed) data.

Side Effects

print.dataRep prints.

  round, table

Examples

```r
set.seed(13)
num.symptoms <- sample(1:4, 1000, TRUE)
sex <- factor(sample(c('female', 'male'), 1000, TRUE))
x <- runif(1000)
x[1] <- NA
table(num.symptoms, sex, .25*round(x/.25))

d <- dataRep(~ num.symptoms + sex + roundN(x,.25))
print(d, long=TRUE)

predict(d, data.frame(num.symptoms = 1:3, sex = c('male', 'male', 'female'),
                      x = c(.03, .5, 1.5)))
```

deff  

**Design Effect and Intra-cluster Correlation**

Description

Computes the Kish design effect and corresponding intra-cluster correlation for a single cluster-sampled variable

Usage

deff(y, cluster)

Arguments

y  
variable to analyze

cluster  
a variable whose unique values indicate cluster membership. Any type of variable is allowed.

Value

a vector with named elements n (total number of non-missing observations), clusters (number of clusters after deleting missing data), rho(intra-cluster correlation), and deff (design effect).

clinic <- sample(letters, 1000, replace=TRUE)
deff(blood.pressure, clinic)
```

---

**Description**

`describe` is a generic method that invokes `describe.data.frame`, `describe.matrix`, `describe.vector`, or `describe.formula`. `describe.vector` is the basic function for handling a single variable. This function determines whether the variable is character, factor, category, binary, discrete numeric, and continuous numeric, and prints a concise statistical summary according to each. A numeric variable is deemed discrete if it has <= 10 distinct values. In this case, quantiles are not printed. A frequency table is printed for any non-binary variable if it has no more than 20 distinct values. For any variable for which the frequency table is not printed, the 5 lowest and highest values are printed. This behavior can be overriden for long character variables with many levels using the `listunique` parameter, to get a complete tabulation.

`describe` is especially useful for describing data frames created by `*get`, as labels, formats, value labels, and (in the case of `sas.get`) frequencies of special missing values are printed.

For a binary variable, the sum (number of 1’s) and mean (proportion of 1’s) are printed. If the first argument is a formula, a model frame is created and passed to `describe.data.frame`. If a variable is of class "impute", a count of the number of imputed values is printed. If a date variable has an attribute `partial.date` (this is set up by `sas.get`), counts of how many partial dates are actually present (missing month, missing day, missing both) are also presented. If a variable was created by the special-purpose function `substi` (which substitutes values of a second variable if the first variable is NA), the frequency table of substitutions is also printed.

For numeric variables, `describe` adds an item called `info` which is a relative information measure using the relative efficiency of a proportional odds/Wilcoxon test on the variable relative to the same test on a variable that has no ties. `Info` is related to how continuous the variable is, and ties are less harmful the more untied values there are. The formula for `Info` is one minus the sum of the cubes of relative frequencies of values divided by one minus the square of the reciprocal of the sample size. The lowest information comes from a variable having only one distinct value following by a highly skewed binary variable. `Info` is reported to two decimal places.

A `latex` method exists for converting the `describe` object to a LaTeX file. For numeric variables having more than 20 distinct values, `describe` saves in its returned object the frequencies of 100 evenly spaced bins running from minimum observed value to the maximum. When there are less than or equal to 20 distinct values, the original values are maintained. `latex` and `html` insert a spike histogram displaying these frequency counts in the tabular material using the LaTeX picture.
describe environment. For example output see http://biostat.mc.vanderbilt.edu/wiki/pub/Main/Hmisc/counties.pdf. Note that the latex method assumes you have the following styles installed in your latex installation: setspace and relsize.

The html method mimics the LaTeX output. This is useful in the context of Rmarkdown html and html notebook output.

The plot method is for describe objects run on data frames. It produces spike histograms for a graphic of continuous variables and a dot chart for categorical variables, showing category proportions. The graphic format is ggplot2 if the user has not set options(grType='plotly') or has set the grType option to something other than 'plotly'. Otherwise plotly graphics that are interactive are produced, and these can be placed into an Rmarkdown html notebook. The user must install the plotly package for this to work. When the use hovers the mouse over a bin for a raw data value, the actual value will pop-up (formatted using digits). When the user hovers over the minimum data value, most of the information calculated by describe will pop up. For each variable, the number of missing values is used to assign the color to the histogram or dot chart, and a legend is drawn. Color is not used if there are no missing values in any variable. For categorical variables, hovering over the leftmost point for a variable displays details, and for all points proportions, numerators, and denominators are displayed in the popup. If both continuous and categorical variables are present and which='both' is specified, the plot method returns an unclassed list containing two objects, named 'Categorical' and 'Continuous', in that order.

Sample weights may be specified to any of the functions, resulting in weighted means, quantiles, and frequency tables.

Note: As discussed in Cox and Longton (2008), Stata Technical Bulletin 8(4) pp. 557, the term "unique" has been replaced with "distinct" in the output (but not in parameter names).

When weights are not used, Gini’s mean difference is computed for numeric variables. This is a robust measure of dispersion that is the mean absolute difference between any pairs of observations. In the output Gini’s difference is labeled gmd.

formatdescribeSingle is a service function for latex, html, and print methods for single variables that is not intended to be called by the user.

Usage

```r
## S3 method for class 'vector'
describe(x, descript, exclude.missing=TRUE, digits=4,
    listunique=0, listnchar=NULL,
    weights=NULL, normwt=FALSE, minlength=NULL, ...)
## S3 method for class 'matrix'
describe(x, descript, exclude.missing=TRUE, digits=4, ...)
## S3 method for class 'data.frame'
describe(x, descript, exclude.missing=TRUE,
    digits=4, ...)
## S3 method for class 'formula'
describe(x, descript, data, subset, na.action,
    digits=4, weights, ...)
## S3 method for class 'describe'
print(x, ...)
## S3 method for class 'describe'
ltx(object, title=NULL,
Arguments

x a data frame, matrix, vector, or formula. For a data frame, the describe.data.frame function is automatically invoked. For a matrix, describe.matrix is called. For a formula, describe.data.frame(model.frame(x)) is invoked. The formula may or may not have a response variable. For print, latex, html, or formatdescribeSingle, x is an object created by describe.

descript optional title to print for x. The default is the name of the argument or the "label" attributes of individual variables. When the first argument is a formula, descript defaults to a character representation of the formula.

exclude.missing set to TRUE to print the names of variables that contain only missing values. This list appears at the bottom of the printout, and no space is taken up for such variables in the main listing.

digits number of significant digits to print. For plot.describe is the number of significant digits to put in hover text for plotly when showing raw variable values.

listunique For a character variable that is not an mChoice variable, that has its longest string length greater than listnchar, and that has no more than listunique distinct values, all values are listed in alphabetic order. Any value having more than one occurrence has the frequency of occurrence after it, in parentheses. Specify listunique equal to some value at least as large as the number of observations to ensure that all character variables will have all their values listed. For purposes of tabulating character strings, multiple white spaces of any kind are translated to a single space, leading and trailing white space are ignored, and case is ignored.

listnchar see listunique
weights | a numeric vector of frequencies or sample weights. Each observation will be treated as if it were sampled weights times.

minlength | value passed to summary.mChoice.

normwt | The default, normwt=FALSE results in the use of weights as weights in computing various statistics. In this case the sample size is assumed to be equal to the sum of weights. Specify normwt=TRUE to divide weights by a constant so that weights sum to the number of observations (length of vectors specified to describe). In this case the number of observations is taken to be the actual number of records given to describe.

object | a result of describe

title | unused

data | subset

na.action | These are used if a formula is specified. na.action defaults to na.retain which does not delete any NAs from the data frame. Use na.action=na.omit or na.delete to drop any observation with any NA before processing.

... | arguments passed to describe.default which are passed to calls to format for numeric variables. For example if using R POSIXct or Date date/time formats, specifying describe(d, format='%d%b%y') will print date/time variables as '01Jan2000'. This is useful for omitting the time component. See the help file for format.POSIXct or format.Date for more information. For plot methods, . . . is ignored. For html and latex methods, . . . is used to pass optional arguments to format.describeSingle, especially the condense argument.

file | name of output file (should have a suffix of .tex). Default name is formed from the first word of the descript element of the describe object, prefixed by "describe". Set file="" to send LaTeX code to standard output instead of a file.

append | set to TRUE to have latex append text to an existing file named file

size | LaTeX text size ("small", the default, or "normalsize", "tiny", "scriptsize", etc.) for the describe output in LaTeX. For html is the percent of the prevailing font size to use for the output.

tabular | set to FALSE to use verbatim rather than tabular (or html table) environment for the summary statistics output. By default, tabular is used if the output is not too wide.

greek | By default, the latex and html methods will change names of greek letters that appear in variable labels to appropriate LaTeX symbols in math mode, or html symbols, unless greek=FALSE.

spacing | By default, the latex method for describe run on a matrix or data frame uses the setspace LaTeX package with a line spacing of 0.7 so as to no waste space. Specify spacing=0 to suppress the use of the setspace's spacing environment, or specify another positive value to use this environment with a different spacing.

lspage | extra vertical space, in character size units (i.e., "ex" as appended to the space). When using certain font sizes, there is too much space left around LaTeX verbatim environments. This two-vector specifies space to remove (i.e., the values
are negated in forming the \texttt{vspace} command) before (first element) and after
(second element of \texttt{lspacen} verbatims

\textbf{scroll} \hspace{1cm} set to \texttt{TRUE} to create an html scrollable box for the html output

\textbf{rows, cols} \hspace{1cm} the number of rows or columns to allocate for the scrollable box

\textbf{vname} \hspace{1cm} unused argument in \texttt{latex.describe.single}

\textbf{which} \hspace{1cm} specifies whether to plot numeric continuous or binary/categorical variables, or both. When "both" a list with two elements is created. Each element is a \texttt{ggplot2} or \texttt{plotly} object. If there are no variables of a given type, a single \texttt{ggplot2} or \texttt{plotly} object is returned, ready to print.

\textbf{what} \hspace{1cm} character or numeric vector specifying which variables to plot; default is to plot all

\textbf{sort} \hspace{1cm} specifies how and whether variables are sorted in order of the proportion of positives when \texttt{which}="categorical". Specify \texttt{sort}="none" to leave variables in the order they appear in the original data.

\textbf{n.unique} \hspace{1cm} the minimum number of distinct values a numeric variable must have before \texttt{plot.describe} uses it in a continuous variable plot

\textbf{condense} \hspace{1cm} specifies whether to condense the output with regard to the 5 lowest and highest values ("extremes") and the frequency table

\textbf{lang} \hspace{1cm} specifies the markup language

\textbf{verb} \hspace{1cm} set to 1 if a verbatim environment is already in effect for \LaTeX

\textbf{Details}

If \texttt{options(na.detail.response=TRUE)} has been set and \texttt{na.action} is "\texttt{na.delete}" or "\texttt{na.keep}", summary statistics on the response variable are printed separately for missing and non-missing values of each predictor. The default summary function returns the number of non-missing response values and the mean of the last column of the response values, with a names attribute of \texttt{c("N","Mean")}. When the response is a \texttt{Surv} object and the mean is used, this will result in the crude proportion of events being used to summarize the response. The actual summary function can be designated through \texttt{options(na.fun.response = "function name")}.

If you are modifying \LaTeX\ parskip or certain other parameters, you may need to shrink the area around tabular and verbatim environments produced by \texttt{latex.describe}. You can do this using for example \texttt{\usepackage{etoolbox} \makeatletter \p@reto{\@verbatim}{\topsep=-1.4pt \partopsep=0pt} \p@reto{}{\parskip=0pt} \makeatother} in the \LaTeX\ preamble.

\textbf{Value}

a list containing elements \texttt{descript}, \texttt{counts}, \texttt{values}. The list is of class \texttt{describe}. If the input object was a matrix or a data frame, the list is a list of lists, one list for each variable analyzed. \texttt{latex} returns a standard \LaTeX\ object. For numeric variables having at least 20 distinct values, an additional component \texttt{intervalFreq}. This component is a list with two elements, \texttt{range} (containing two values) and \texttt{count}, a vector of 100 integer frequency counts.

discrete

**Discrete Vector tools**

**Description**

`discrete` creates a discrete vector which is distinct from a continuous vector, or a factor/ordered vector. The other function are tools for manipulating descrete vectors.

**Usage**

- `as.discrete(x, ...)`
  - # Default S3 method:
  - `as.discrete(x, ...)`
  - `discrete(x, levels = sort(unique.default(x), na.last = TRUE), exclude = NA)`
## S3 replacement method for class 'discrete'

```r
x[...] <- value
```

## S3 method for class 'discrete'

```r
x[...], drop = FALSE]
```

## S3 method for class 'discrete'

```r
x[[i]]
is.discrete(x)
```

## S3 replacement method for class 'discrete'

```r
is.na(x) <- value
```

## S3 replacement method for class 'discrete'

```r
length(x) <- value
```

### Arguments

- **x**: a vector
- **drop**: Should unused levels be dropped.
- **exclude**: logical: should NA be excluded.
- **i**: indexing vector
- **levels**: character: list of individual level values
- **value**: index of elements to set to NA
- **...**: arguments to be passed to other functions

### Details

- `as.discrete` converts a vector into a discrete vector.
- `discrete` creates a discrete vector from provided values.
- `is.discrete` tests to see if the vector is a discrete vector.

### Value

- `as.discrete`, `discrete` returns a vector of discrete type.
- `is.discrete` return logical TRUE if the vector is of class discrete otherwise it returns FALSE.

### Author(s)

Charles Dupont

`[`, `[, factor`

### Examples

```r
a <- discrete(1:25)
a

is.discrete(a)
```
b <- as.discrete(2:4)
b

---

**dotchart2**

*Enhanced Dot Chart*

---

**Description**

`dotchart2` is an enhanced version of the `dotchart` function with several new options.

**Usage**

```r
dotchart2(data, labels=names(data), groups=NULL, gdata=NA, horizontal=TRUE, pch=16,
           xlab='', ylab='', xlim=NULL, auxdata=NULL, auxgdata=NULL, auxtitle,
           lty=1, lines=TRUE, dotsize = .8,
           cex = par("cex"), cex.labels = cex,
           cex.group.labels = cex.labels*1.25, sort.=TRUE,
           add=FALSE, dotfont=par('font'), groupfont=2,
           reset.par=add, xaxis=TRUE, width.factor=1.1,
           lcolor='gray', leavepar=FALSE,
           axisat=NULL, axislabels=NULL, ...)
```

**Arguments**

- `data` a numeric vector whose values are shown on the x-axis
- `labels` a vector of labels for each point, corresponding to `x`. If omitted, `names(data)` are used, and if there are no names, integers prefixed by "#" are used.
- `groups` an optional categorical variable indicating how data values are grouped
- `gdata` data values for groups, typically summaries such as group medians
- `horizontal` set to `FALSE` to make the chart vertical instead of the default
- `pch` default character number or value for plotting dots in dot charts. The default is 16.
- `xlab` x-axis title
- `ylab` y-axis title
- `xlim` x-axis limits. Applies only to `horizontal=TRUE`.
- `auxdata` a vector of auxiliary data given to `dotchart2`, of the same length as the first (data) argument. If present, this vector of values will be printed outside the right margin of the dot chart. Usually `auxdata` represents cell sizes.
- `auxgdata` similar to `auxdata` but corresponding to the `gdata` argument. These usually represent overall sample sizes for each group of lines.
- `auxtitle` if `auxdata` is given, `auxtitle` specifies a column heading for the extra printed data in the chart, e.g., "N"
- `lty` line type for horizontal lines. Default is 1 for R, 2 for S-Plus
lines set to FALSE to suppress drawing of reference lines
dotsize cex value for drawing dots. Default is 0.8. Note that the original dotchart function used a default of 1.2.
cex see par
cex.labels cex parameter that applies only to the line labels for the dot chart cex parameter for major grouping labels for dotchart2. Defaults to cex.
cex.group.labels value of cex corresponding to gdata
sort. set to FALSE to keep dotchart2 from sorting the input data, i.e., it will assume that the data are already properly arranged. This is especially useful when you are using gdata and groups and you want to control the order that groups appear on the chart (from top to bottom).
add set to TRUE to add to an existing plot
dotfont font number of plotting dots. Default is one. Use -1 to use "outline" fonts. For example, pch=183, dotfont=-1 plots an open circle for UNIX on postscript. pch=1 makes an open octagon under Windows.
groupfont font number to use in drawing group labels for dotchart2. Default is 2 for boldface.
reset.par set to FALSE to cause dotchart2 to not reset the par parameters when finished. This is useful when add=TRUE is about to be used in another call. The default is to reset the par parameters if add=TRUE and not if add=FALSE, i.e., the program assumes that only one set of points will be added to an existing set. If you fail to use reset.par=TRUE for the first of a series of plots, the next call to plot with add=TRUE will result in distorted x-axis scaling.
xaxis set to FALSE to suppress drawing x-axis
width.factor When the calculated left margin turns out to be faulty, specify a factor by which to multiple the left margin as width.factor to get the appropriate space for labels on horizontal charts.
lcolor color for horizontal reference lines. Default is "gray" for R, par("col") for S-Plus.
leavepar set to TRUE to leave par() unchanged. This assumes the user has allocated sufficient left and right margins for a horizontal dot chart.
axisat a vector of tick mark locations to pass to axis. Useful if transforming the data axis
axislabels a vector of strings specifying axis tick mark labels. Useful if transforming the data axis
... arguments passed to plot.default

Side Effects

dotchart will leave par altered if reset.par=FALSE.

Examples

```r
set.seed(135)
maj <- factor(c(rep('North',13),rep('South',13)))
g <- paste('Category',rep(letters[1:13],2))
n <- sample(1:15000, 26, replace=TRUE)
y1 <- runif(26)
y2 <- pmax(0, y1 - runif(26, 0, 1))
dotchart2(y2, g, groups=maj, auxdata=n, auxtitle='n', xlab='Y')
dotchart2(y2, g, groups=maj, pch=17, add=TRUE)
## Compare with dotchart function (no superpositioning or auxdata allowed):
## dotchart(y1, g, groups=maj, xlab='Y')

## To plot using a transformed scale add for example
## axisat=sqrt(pretty(y)), axislabels=pretty(y)
```

---

dotchart3

**Enhanced Version of dotchart Function**

**Description**

These are adaptations of the R dotchart function that sorts categories top to bottom, adds auxdata and auxtitle arguments to put extra information in the right margin, and for dotchart3 adds arguments cex.labels, cex.group.labels, and groupfont. By default, group headings are in a larger, bold font. dotchart3 also cuts a bit of white space from the top and bottom of the chart. The most significant change, however, is in how x is interpreted. Columns of x no longer provide an alternate way to define groups. Instead, they define superpositioned values. This is useful for showing three quartiles, for example. Going along with this change, for dotchart3 pch can now be a vector specifying symbols to use going across columns of x. x was changed in this way because to put multiple points on a line (e.g., quartiles) and keeping track of par() parameters when dotchart2 was called with add=TRUE was cumbersome. dotchart3 changes the margins to account for horizontal labels.

dotchartp is a version of dotchart3 for making the chart with the plotly package.

summaryD creates aggregate data using `summarize` and calls dotchart3 with suitable arguments to summarize data by major and minor categories. If `options(grType='plotly')` is in effect and the plotly package is installed, summaryD uses dotchartp instead of dotchart3.
Usage

dotchart3(x, labels = NULL, groups = NULL, gdata = NULL, 
cex = par("cex"), pch = 21, gpch = pch, bg = par("bg"), 
color = par("fg"), gcolor = par("fg"), lcolor = "gray", 
xlim = range(c(x, gdata), na.rm=TRUE), main = NULL, xlab = NULL, 
ylab = NULL, auxdata = NULL, auxtitle = NULL, auxgdata=NULL, 
axisat=NULL, axislabels=NULL, 
cex.labels = cex, cex.group.labels = cex.labels * 1.25, 
cex.auxdata=cex, groupfont = 2, 
auxwhere=NULL, height=NULL, width=NULL, ...)

dotchartp(x, labels = NULL, groups = NULL, gdata = NULL, 
xlim = range(c(x, gdata), na.rm=TRUE), na.rm=TRUE), main=NOll, 
xlab = NULL, ylab = '\', auxdata=NULL, auxtitle=NULL, auxgdata=NULL, 
axisat=NULL, auxwhere=c('right', 'hover'), 
symbol='circle', col=colorspace::rainbow_hcl, 
legendgroup=NULL, 
axisat=NULL, axislabels=NULL, sort=TRUE, digits=4, dec=FALSE, 
height=NULL, width=700, layoutattr=FALSE, showlegend=TRUE, ...)

summaryD(formula, data=NULL, fun=mean, funm=fun, 
groupsummary=TRUE, auxvar=NULL, auxtitle='', 
auxwhere=c('hover', 'right'), 
vals=length(auxvar) > 0, fmtvals=format, 
symbol=if(use.plotly) 'circle' else 21, 
col=if(use.plotly) colorspace::rainbow_hcl else 1:10, 
legendgroup=NULL, 
cex.auxdata=.7, xlab=V[c], ylab=NULL, 
gridevery=NULL, gridcol=gray(.95), sort=TRUE, ...)

Arguments

x a numeric vector or matrix
labels labels for categories corresponding to rows of x. If not specified these are taken from row names of x.
groups, gdata, cex, pch, gpch, bg, color, gcolor, lcolor, xlim, main, xlab, ylab see dotchart

auxdata a vector of information to be put in the right margin, in the same order as x. May be numeric, character, or a vector of expressions containing plotmath markup. For dotchartp, auxdata may be a matrix to go along with the numeric x-axis variable, to result in point-specific hover text.
auxtitle a column heading for auxdata
auxgdata similar to auxdata but corresponding to the gdata argument. These usually represent overall sample sizes for each group of lines.
axisat a vector of tick mark locations to pass to axis. Useful if transforming the data axis
axislabels  a vector of strings specifying axis tick mark labels. Useful if transforming the
data axis
digits number of significant digits for formatting numeric data in hover text for dotchartp
dec for dotchartp only, overrides digits to specify the argument to round() for
rounding values for hover labels
cex.labels cex for labels
cex.group.labels cex for group labels
cex.auxdata cex for auxdata
groupfont font number for group headings
auxwhere for summaryD and dotchartp specifies whether auxdata and auxgdata are to
be placed on the far right of the chart, or should appear as pop-up tooltips when
hovering the mouse over the ordinary x data points on the chart. Ignored for
dotchart3.
... other arguments passed to some of the graphics functions, or to dotchart3 or
dotchartp from summaryD. The auxwhere='hover' option is a useful argu-
ment to pass from summaryD to dotchartp.
layoutattr set to TRUE to put plotly::layout information in a list as an attribute layout
of the returned plotly object instead of running the plotly object through the
layout function. This is useful if running dotchart multiple times to later
put together using plotly::subplot and only then running the result through
plotly::layout.
showlegend set to FALSE to suppress the plotly legend with dotchartp
formula a formula with one variable on the left hand side (the variable to compute sum-
mary statistics on), and one or two variables on the right hand side. If there are
two variables, the first is taken as the major grouping variable. If the left hand
side variable is a matrix it has to be a legal R variable name, not an expression,
and fun needs to be able to process a matrix.
data a data frame or list used to find the variables in formula. If omitted, the parent
environment is used.
fun a summarization function creating a single number from a vector. Default is the
mean.
funm applies if there are two right hand variables and groupsummary=TRUE and the
marginal summaries over just the first x variable need to be computed differently
than the summaries that are cross-classified by both variables. funm defaults to
fun and should have the same structure as fun.
groupsummary By default, when there are two right-hand variables, summarize(..., fun) is
called a second time without the use of the second variable, to obtain marginal
summaries for the major grouping variable and display the results as a dot (and
optionally in the right margin). Set groupsummary=FALSE to suppress this in-
formation.
auxvar when fun returns more than one statistic and the user names the elements in the
returned vector, you can specify auxvar as a single character string naming one
of them. This will cause the named element to be written in the right margin,
and that element to be deleted when plotting the statistics.
vals set to TRUE to show data values (dot locations) in the right margin. Defaults to TRUE if auxvar is specified.

fmtvals an optional function to format values before putting them in the right margin. Default is the format function.

symbol a scalar or vector of pch values for ordinary graphics or a character vector or scalar of plotly symbols. These correspond to columns of x or elements produced by fun.

col a function or vector of colors to assign to multiple points plotted in one line. If a function it will be evaluated with an argument equal to the number of groups/columns.

legendgroup see plotly documentation; corresponds to column names/fun output for plotly graphs only

gridevery specify a positive number to draw very faint vertical grid lines every gridevery x-axis units; for non-plotly charts

gridcol color for grid lines; default is very faint gray scale

sort specify sort=FALSE to plot data in the original order, from top to bottom on the dot chart. For dotchartp, set sort to ‘descending’ to sort in descending order of the first column of x, or ‘ascending’ to do the reverse. These do not make sense if groups is present.

height, width height and width in pixels for dotchartp if not using plotly defaults. Ignored for dotchart3. If set to "auto" the height is computed using hmisc::plotlyHeightDotchart.

Value the function returns invisibly

set.seed(135)
maj <- factor(c(rep('North',13),rep('South',13)))
g <- paste('Category',rep(letters[1:13],2))
n <- sample(1:15000, 26, replace=TRUE)
y1 <- runif(26)
y2 <- pmax(0, y1 - runif(26, 0, .1))
dotchart3(cbind(y1,y2), g, groups=maj, auxdata=n, auxtitle='n', xlab='Y', pch=c(1,17))
## Compare with dotchart function (no superpositioning or auxdata allowed):
## dotchart(y1, g, groups=maj, xlab='Y')
## Not run:
dotchartpl(cbind(y1, y2), g, groups=maj, auxdata=n, auxtitle='n',
    xlab='Y', gdata=cbind(c(0,.1), c(.23,.44)), auxgdata=c(-1,-2),
    symbol=c('circle', 'line-ns-open'))

## End(Not run)

## Put options(grType='plotly') to have the following use dotchartpl
## (rlegend will not apply)
## Add argument auxwhere='hover' to summaryD or dotchartpl to put
## aux info in hover text instead of right margin
summaryD(y1 ~ maj + g, xlab='Mean')
summaryD(y1 ~ maj + g, groupsummary=FALSE)
summaryD(Y ~ maj + g, fntvals=function(x) sprintf('%4.2f', x))
Y <- cbind(y1, y2)  # summaryD cannot handle cbind(...) - ...  
summaryD(Y ~ maj + g, fun=function(y) y[1,], symbol=c(1,17))
rlegend(.1, 26, c('y1','y2'), pch=c(1,17))

summaryD(y1 ~ maj, fun=function(y) c(Mean=mean(y), n=length(y)),
    auxvar='n', auxtitle='N')
Arguments

x  a numeric vector used for values on the x-axis
major  major vertical category, e.g., variable labels
minor  minor vertical category, e.g. category levels within variables
group  superpositioning variable such as treatment
mult  strata names for further subdivisions without groups
big  omit if all levels of mult are equally important or if mult is omitted. Otherwise denotes major (larger points, right on horizontal lines) vs. minor (smaller, transparent points slightly below the line).
htext  additional hover text per point
num  if x represents proportions, optionally specifies numerators to be used in fractions added to hover text. When num is given, x is automatically added to hover text, rounded to 3 digits after the decimal point.
denom  like num but for denominators
lower  lower limits for optional error bars
upper  upper limits for optional error bars
refgroup  if group is specified and there are exactly two groups, specify the character string for the reference group in computing difference in proportions. For example if refgroup='A' and the group levels are 'A', 'B', you will get B - A.
sortdiff  minor categories are sorted by descending values of the difference in proportions when refgroup is used, unless you specify sortdiff=FALSE
conf.int  confidence level for computing confidence intervals for the difference in two proportions. Specify conf.int=FALSE to suppress confidence intervals.
minkeep  if refgroup and minkeep are both given, observations that are at or above minkeep for at least one of the groups are retained. The defaults to to keep all observations.
xlim  x-axis limits
xlab  x-axis label
tracename  plotly trace name if group is not used
limitstracename  plotly trace name for lower and upper if group is not used
nonbigtracename  plotly trace name used for non-big elements, which usually represent stratified versions of the "big" observations
col  a function or vector of colors to assign to group. If a function it will be evaluated with an argument equal to the number of distinct groups.
width  width of plot in pixels
Value

A `plotly` object. An attribute `levelsRemoved` is added if `minkeep` is used and any categories were omitted from the plot as a result. This is a character vector with categories removed. If `major` is present, the strings are of the form `major:minor`.

\textit{Ecdf} \quad \textit{Empirical Cumulative Distribution Plot} \vspace{3ex}

\textbf{Description} \vspace{1ex}

Computes coordinates of cumulative distribution function of x, and by defaults plots it as a step function. A grouping variable may be specified so that stratified estimates are computed and (by default) plotted. If there is more than one group, the \texttt{labcurve} function is used (by default) to label the multiple step functions or to draw a legend defining line types, colors, or symbols by linking them with group labels. A weights vector may be specified to get weighted estimates. Specify \texttt{normwt} to make \texttt{weights} sum to the length of \texttt{x} (after removing NAs). Other wise the total sample size is taken to be the sum of the weights.

\texttt{Ecdf} is actually a method, and \texttt{Ecdf.default} is what’s called for a vector argument. \texttt{Ecdf.data.frame} is called when the first argument is a data frame. This function can automatically set up a matrix of ECDFs and wait for a mouse click if the matrix requires more than one page. Categorical variables, character variables, and variables having fewer than a set number of unique values are ignored. If \texttt{par(mfrow=...)} is not set up before \texttt{Ecdf.data.frame} is called, the function will try to figure the best layout depending on the number of variables in the data frame. Upon return the original \texttt{mfrow} is left intact.

When the first argument to \texttt{Ecdf} is a formula, a Trellis/Lattice function \texttt{Ecdf.formula} is called. This allows for multi-panel conditioning, superposition using a groups variable, and other Trellis features, along with the ability to easily plot transformed ECDFs using the \texttt{fun} argument. For example, if \texttt{fun=qnorm}, the inverse normal transformation will be used for the y-axis. If the transformed curves are linear this indicates normality. Like the \texttt{xyplot} function, \texttt{Ecdf} will create a function \texttt{key} if the groups variable is used. This function can be invoked by the user to define the keys for the groups.
Usage

Ecdf(x, ...)

## Default S3 method:
Ecdf(x, what=c('F','1-F','f','1-f'),
weights=rep(1, length(x)), normwt=FALSE,
xlab, ylab, q, pl=TRUE, add=FALSE, lty=1,
col=1, group=rep(1,length(x)), label.curves=TRUE, xlim,
subtitles=TRUE, datadensity=c('none','rug','hist','density'),
side=1,
frac=switch(datadensity,none=NA,rug=.03,hist=.1,density=.1),
dens.opts=NULL, lwd=1, log=' ', ...)

## S3 method for class 'data.frame'
Ecdf(x, group=rep(1,nrows),
weights=rep(1, nrows), normwt=FALSE,
label.curves=TRUE, n.unique=10, na.big=FALSE, subtitles=TRUE,
vnames=c('labels','names'),...)

## S3 method for class 'formula'
Ecdf(x, data=sys.frame(sys.parent()), groups=NULL,
prepanel=prepanel.Ecdf, panel=panel.Ecdf, ..., xlab,
ylab, fun=function(x)x, what=c('F','1-F','f','1-f'), subset=TRUE)

Arguments

x a numeric vector, data frame, or Trellis/Lattice formula
what The default is "F" which results in plotting the fraction of values <= x. Set to "1-F" to plot the fraction > x or "f" to plot the cumulative frequency of values <= x. Use "1-f" to plot the cumulative frequency of values >= x.
weights numeric vector of weights. Omit or specify a zero-length vector or NULL to get unweighted estimates.
normwt see above
xlab x-axis label. Default is label(x) or name of calling argument. For Ecdf.formula, xlab defaults to the label attribute of the x-axis variable.
ylab y-axis label. Default is "Proportion <= x", "Proportion > x", or "Frequency <= x" depending on value of what.
q a vector for quantiles for which to draw reference lines on the plot. Default is not to draw any.
pl set to F to omit the plot, to just return estimates
add set to TRUE to add the cdf to an existing plot. Does not apply if using lattice graphics (i.e., if a formula is given as the first argument).
lty integer line type for plot. If group is specified, this can be a vector.
lwd line width for plot. Can be a vector corresponding to groups.
log  
see plot. Set log='x' to use log scale for x-axis.

col  
color for step function. Can be a vector.

group  
a numeric, character, or factor categorical variable used for stratifying estimates. If group is present, as many ECDFs are drawn as there are non–missing group levels.

label.curves  
applies if more than one group exists. Default is TRUE to use labcurve to label curves where they are farthest apart. Set label.curves to a list to specify options to labcurve, e.g., label.curves=list(method="arrow", cex=.8). These option names may be abbreviated in the usual way arguments are abbreviated. Use for example label.curves=list(keys=1:5) to draw symbols periodically (as in pch=1:5 - see points) on the curves and automatically position a legend in the most empty part of the plot. Set label.curves=FALSE to suppress drawing curve labels. The col, lty, and type parameters are automatically passed to labcurve, although you can override them here. You can set label.curves=list(keys="lines") to have different line types defined in an automatically positioned key.

xlim  
x-axis limits. Default is entire range of x.

subtitles  
set to FALSE to suppress putting a subtitle at the bottom left of each plot. The subtitle indicates the numbers of non-missing and missing observations, which are labeled n, m.

datadensity  
If datadensity is not "none", either scatQd or histSpike is called to add a rug plot (datadensity="rug"), spike histogram (datadensity="hist"), or smooth density estimate ("density") to the bottom or top of the ECDF.

side  
If datadensity is not "none", the default is to place the additional information on top of the x-axis (side=1). Use side=3 to place at the top of the graph.

frac  
passed to histSpike

dens.opts  
a list of optional arguments for histSpike

...  
other parameters passed to plot if add=F. For data frames, other parameters to pass to Ecdf.default. For Ecdf.formula, if groups is not used, you can also add data density information to each panel's ECDF by specifying the datadensity and optional frac, side, dens.opts arguments.

n.unique  
minimum number of unique values before an ECDF is drawn for a variable in a data frame. Default is 10.

na.big  
set to TRUE to draw the number of NAs in larger letters in the middle of the plot for Ecdf.data.frame

vnames  
By default, variable labels are used to label x-axes. Set vnames="names" to instead use variable names.

method  
method for computing the empirical cumulative distribution. See wtd.Ecdf. The default is to use the standard "i/n" method as is used by the non-Trellis versions of Ecdf.

fun  
a function to transform the cumulative proportions, for the Trellis-type usage of Ecdf

data, groups, subset,prepanel, panel  
the usual Trellis/Lattice parameters, with groups causing Ecdf.formula to overlay multiple ECDFs on one panel.
Value

for \texttt{Ecdf.default} an invisible list with elements \texttt{x} and \texttt{y} giving the coordinates of the cdf. If there is more than one group, a list of such lists is returned. An attribute, \texttt{N}, is in the returned object. It contains the elements \texttt{n} and \texttt{m}, the number of non-missing and missing observations, respectively.

Side Effects

plots

Examples

```r
set.seed(1)
ch <- rnorm(1000, 200, 40)
Ecdf(ch, xlab="Serum Cholesterol")
scat1d(ch)                      # add rug plot
histSpike(ch, add=TRUE, frac=.15) # add spike histogram
# Better: add a data density display automatically:
Ecdf(ch, datadensity='density')

label(ch) <- "Serum Cholesterol"
Ecdf(ch)
other.ch <- rnorm(500, 220, 20)
Ecdf(other.ch, add=TRUE, lty=2)

sex <- factor(sample(c('female','male'), 1000, TRUE))
Ecdf(ch, q=c(.25,.5,.75))   # show quartiles
Ecdf(ch, group=sex,        
   label.curves=list(method='arrow'))

# Example showing how to draw multiple ECDFs from paired data
pre.test <- rnorm(100,50,10)
post.test <- rnorm(100,55,10)
x <- c(pre.test, post.test)
g <- c(rep('Pre',length(pre.test)),rep('Post',length(post.test)))
Ecdf(x, group=g, xlab='Test Results', label.curves=list(keys=1:2))
# keys=1:2 causes symbols to be drawn periodically on top of curves
```
# Draw a matrix of ECDFs for a data frame
m <- data.frame(pre.test, post.test,
  sex=sample(c('male','female'),100,TRUE))
Ecdf(m, group=m$sex, datadensity='rug')

defrods <- sample(1:10, 1000, TRUE)
Ecdf(ch, weights=freqs) # weighted estimates

# Trellis/Lattice examples:

region <- factor(sample(c('Europe','USA','Australia'),100,TRUE))
year <- factor(sample(2001:2002,1000,TRUE))
Ecdf(~ch | region*year, groups=sex)
Key() # draw a key for sex at the default location
# Key(locator(1)) # user-specified positioning of key
age <- rnorm(1000, 50, 10)
Ecdf(~ch | equal.count(age), groups=sex) # use overlapping shingles
Ecdf(~ch | sex, datadensity='hist', side=3) # add spike histogram at top

---

**equalBins**  
*Multicolumn Formatting*

**Description**

Expands the width either supercolumns or the subcolumns so that the sum of the supercolumn widths is the same as the sum of the subcolumn widths.

**Usage**

equalBins(widths, subwidths)

**Arguments**

- **widths**: widths of the supercolumns.
- **subwidths**: list of widths of the subcolumns for each supercolumn.

**Details**

This determines the correct subwidths of each of various columns in a table for printing. The correct width of the multicolumns is determined by summing the widths of its subcolumns.

**Value**

widths of the columns for a table.
Add vertical error bars to an existing plot or makes a new plot with error bars.

Usage

```r
errbar(x, y, yplus, yminus, cap=0.015, main = NULL, sub=NULL, xlab=as.character(substitute(x)), ylab=if(is.factor(x) || is.character(x)) "" else as.character(substitute(y)), add=FALSE, lty=1, type='p', ylim=NULL, lwd=1, pch=16, errbar.col, Type=rep(1, length(y)), ...)```

Arguments

- `x`: vector of numeric x-axis values (for vertical error bars) or a factor or character variable (for horizontal error bars, x representing the group labels)
- `y`: vector of y-axis values.
- `yplus`: vector of y-axis values: the tops of the error bars.
- `yminus`: vector of y-axis values: the bottoms of the error bars.
- `cap`: the width of the little lines at the tops and bottoms of the error bars in units of the width of the plot. Defaults to 0.015.
- `main`: a main title for the plot, passed to `plot`, see also `title`.
errbar

sub          a sub title for the plot, passed to plot
xlab         optional x-axis labels if add=FALSE.
ylab         optional y-axis labels if add=FALSE. Defaults to blank for horizontal charts.
add           set to TRUE to add bars to an existing plot (available only for vertical error bars)
lty           type of line for error bars
type          type of point. Use type="b" to connect dots.
ylim          y-axis limits. Default is to use range of y, yminus, and yplus. For horizontal charts, ylim is really the x-axis range, excluding differences.
lwd           line width for line segments (not main line)
pch           character to use as the point.
errbar.col    color to use for drawing error bars.
Type          used for horizontal bars only. Is an integer vector with values 1 if corresponding values represent simple estimates, 2 if they represent differences.
...           other parameters passed to all graphics functions.

Details

errbar adds vertical error bars to an existing plot or makes a new plot with error bars. It can also make a horizontal error bar plot that shows error bars for group differences as well as bars for groups. For the latter type of plot, the lower x-axis scale corresponds to group estimates and the upper scale corresponds to differences. The spacings of the two scales are identical but the scale for differences has its origin shifted so that zero may be included. If at least one of the confidence intervals includes zero, a vertical dotted reference line at zero is drawn.

Author(s)

Charles Geyer, University of Chicago. Modified by Frank Harrell, Vanderbilt University, to handle missing data, to add the parameters add and lty, and to implement horizontal charts with differences.

Examples

```
set.seed(1)
x <- 1:10
y <- x + rnorm(10)
delta <- runif(10)
errbar( x, y, y + delta, y - delta )
```

```
# Show bootstrap nonparametric CLs for 3 group means and for
# pairwise differences on same graph

group <- sample(c('a','b','d'), 200, TRUE)
y <- runif(200) + .25*(group=='b') + .5*(group=='d')
cla <- smean.cl.boot(y[group=='a'],B=1000,reps=TRUE)  # usually B=1000
a   <- attr(cla,'reps')
clb <- smean.cl.boot(y[group=='b'],B=1000,reps=TRUE)
b   <- attr(clb,'reps')
```
cld <- smean.cl.boot(y[group=='d'],B=100, reps=TRUE)
 d <- attr(cld, 'reps')
 a.b <- quantile(a-b,c(.025,.975))
 a.d <- quantile(a-d,c(.025,.975))
 b.d <- quantile(b-d,c(.025,.975))
 errbar(c('a','b','d','a - b','a - d','b - d'),
        c(cla[1],clb[1],cld[1],cla[1]-clb[1],cla[1]-cld[1],clb[1]-cld[1]),
        c(cla[3],clb[3],cld[3],a.b[2],a.d[2],b.d[2]),
        c(cla[2],clb[2],cld[2],a.b[1],a.d[1],b.d[1]),
        type=c(1,1,2,2,2), xlab='', ylab='')

---

**escapeRegex**

Escapes any characters that would have special meaning in a regular expression.

**Description**

Escapes any characters that would have special meaning in a regular expression.

**Usage**

```r
escapeRegex(string)
 escapeBS(string)
```

**Arguments**

- `string`  
  string being operated on.

**Details**

`escapeRegex` will escape any characters that would have special meaning in a regular expression. For any string `grep(regexpEscape(string), string)` will always be true.

`escapeBS` will escape any backslash `\` in a string.

**Value**

The value of the string with any characters that would have special meaning in a regular expression escaped.

**Author(s)**

Charles Dupont  
Department of Biostatistics  
Vanderbilt University

**See Also**

`grep`
Examples

```r
string <- "this\\(system\) \{is\} [full]."
escapeRegex(string)
escapeBS(string)
```

---

**event.chart**

*Flexible Event Chart for Time-to-Event Data*

**Description**

Creates an event chart on the current graphics device. Also, allows user to plot legend on plot area or on separate page. Contains features useful for plotting data with time-to-event outcomes which arise in a variety of studies including randomized clinical trials and non-randomized cohort studies. This function can use as input a matrix or a data frame, although greater utility and ease of use will be seen with a data frame.

**Usage**

```r
event.chart(data, subset.r = 1:dim(data)[1], subset.c = 1:dim(data)[2],

  sort.by = NA, sort.ascending = TRUE,
  sort.na.last = TRUE, sort.after.subset = TRUE,
  y.var = NA, y.var.type = "n",
  y.jitter = FALSE, y.jitter.factor = 1,
  y.renum = FALSE, NA.rm = FALSE, x.reference = NA,
  now = max(data[, subset.c], NA.rm = TRUE),
  now.line = FALSE, now.line.lty = 2,
  now.line.lwd = 1, now.line.col = 1, pty = "m",
  date.orig = c(1, 1, 1960), titl = "Event Chart",

  y.idlabels = NA, y.axis = "auto",
  y.axis.custom.at = NA, y.axis.custom.labels = NA,
  y.julian = FALSE, y.lim.extend = c(0, 0),
  y.lab = ifelse(is.na(y.idlabels), "", as.character(y.idlabels)),

  x.axis.all = TRUE, x.axis = "auto",
  x.axis.custom.at = NA, x.axis.custom.labels = NA,
  x.julian = FALSE, x.lim.extend = c(0, 0), x.scale = 1,
  x.lab = ifelse(x.julian, "Follow-up Time", "Study Date"),

  line.by = NA, line.lty = 1, line.lwd = 1, line.col = 1,
  line.add = NA, line.add.lty = NA,
  line.add.lwd = NA, line.add.col = NA,
  point.pch = 1:length(subset.c),
```
point.cex = rep(0.6, length(subset.c)),
point.col = rep(1, length(subset.c)),
point.cex.mult = 1., point.cex.mult.var = NA,
extra.points.no.mult = rep(NA, length(subset.c)),

legend.plot = FALSE, legend.location = "o", legend.titl = titl,
legend.titl.cex = 3, legend.titl.line = 1,
legend.point.at = list(x = c(5, 95), y = c(95, 30)),
legend.point.pch = point.pch,
legend.point.text = ifelse(rep(is.data.frame(data), length(subset.c)),
  names(data[, subset.c]),
  subset.c),
legend.cex = 2.5, legend.bty = "n",
legend.line.at = list(x = c(5, 95), y = c(20, 5)),
legend.line.text = names(table(as.character(data[, line.by])),
  exclude = c("", "NA")),
legend.line.lwd = line.lwd, legend.loc.num = 1,

...)

Arguments

data a matrix or data frame with rows corresponding to subjects and columns corresponding to variables. Note that for a data frame or matrix containing multiple time-to-event data (e.g., time to recurrence, time to death, and time to last follow-up), one column is required for each specific event.

subset.r subset of rows of original matrix or data frame to place in event chart. Logical arguments may be used here (e.g., `subset.r = 'a'`, if the data frame, data, has been attached to the search directory; otherwise, `data$subset.r = 'a'`).

subset.c subset of columns of original matrix or data frame to place in event chart; if working with a data frame, a vector of data frame variable names may be used for subsetting purposes (e.g., `c('randdate', 'event')`).

sort.by column(s) or data frame variable name(s) with which to sort the chart’s output. The default is `NA`, whereby resulting in a chart sorted by original row number.

sort.ascending logical flag (which takes effect only if the argument `sort.by` is utilized). If `TRUE` (default), sorting is done in ascending order; if `FALSE`, descending order.

sort.na.last logical flag (which takes effect only if the argument `sort.by` is utilized). If `TRUE` (default), `NA` values are considered as last values in ordering.

sort.after.subset logical flag (which takes effect only if the argument `sort.by` is utilized). If `FALSE`, sorting data (via `sort.by` specified variables or columns) will be performed prior to row subsetting (via `subset.r`); if `TRUE` (default), row subsetting of original data will be done before sorting.

y.var variable name or column number of original matrix or data frame with which to scale y-axis. Default is `NA`, which will result in equally spaced lines on y-axis.
(based on original data or sorted data if requested by sort.by). Otherwise, location of lines on y-axis will be dictated by specified variable or column. Examples of specified variables may be date of an event or a physiological covariate. Any observation which has a missing value for the y.var variable will not appear on the graph.

**y.var.type**

Type of variable specified in y.var (which will only take effect if argument y.var is utilized). If “d”, specified variable is a date (either numeric julian date or an S-Plus dates object); if “n”, specified variable is numeric (e.g., systolic blood pressure level) although not a julian date.

**y.jitter**

Logical flag (which takes effect only if the argument y.var is utilized). Due to potential ties in y.var variable, y.jitter (when TRUE) will jitter the data to allow discrimination between observations at the possible cost of producing slightly inaccurate dates or covariate values; if FALSE (the default), no jittering will be performed. The y.jitter algorithm assumes a uniform distribution of observations across the range of y.var. The algorithm is as follows:

\[
\text{size.jitter} = \left( \frac{\text{diff(range(y.var))}}{2 \times (\text{length(y.var)} - 1)} \right) \times \text{y.jitter.factor}
\]

The default of y.jitter.factor is 1. The entire product is then used as an argument into runif: y.var <- y.var + runif(length(y.var), -size.jitter, size.jitter)

**y.jitter.factor**

An argument used with the y.jitter function to scale the range of added noise. Default is 1.

**y.renum**

Logical flag. If TRUE, subset observations are listed on y-axis from 1 to length(subset.r); if FALSE (default), subset observations are listed on y-axis in original form. As an example, if subset.r = 301:340 and y.renum ==TRUE, y-axis will be shown as 1 through 40. However, if y.renum ==FALSE, y-axis will be shown as 301 through 340. The above examples assume the following argument, NA.rm, is set to FALSE.

**NA.rm**

Logical flag. If TRUE, subset observations which have NA for each variable specified in subset.c will not have an entry on the y-axis. Also, if the following argument, x.reference, is specified, observations with missing x.reference values will also not have an entry on the y-axis. If FALSE (default), user can identify those observations which do have NA for every variable specified in subset.c (or, if x.reference is specified, also those observations which are missing only the x.reference value); this can easily be done by examining the resulting y-axis and recognizing the observations without any plotting symbols.

**x.reference**

Column of original matrix or data frame with which to reference the x-axis. That is, if specified, all columns specified in subset.c will be subtracted by x.reference. An example may be to see the timing of events before and after treatment or to see time-to-event after entry into study. The event times will be aligned using the x.reference argument as the reference point.

**now**

The “now” date which will be used for top of y-axis when creating the Goldman eventchart (see reference below). Default is max(data[, subset.c], na.rm =TRUE).

**now.line**

Logical flag. A feature utilized by the Goldman Eventchart. When x.reference is specified as the start of follow-up and y.var = x.reference, then the Goldman chart can be created. This argument, if TRUE, will cause the plot region to
be square, and will draw a line with a slope of -1 from the top of the y-axis to the right end of the x-axis. Essentially, it denotes end of current follow-up period for looking at the time-to-event data. Default is FALSE.

- **now.line.lty** line type of now.line.
- **now.line.lwd** line width of now.line.
- **now.line.col** color of now.line.
- **pty** graph option. pty='m' is the default; use pty='s' for the square looking Goldman's event chart.
- **date.orig** date of origin to consider if dates are in julian, SAS, or S-Plus dates object format; default is January 1, 1960 (which is the default origin used by both S-Plus and SAS). Utilized when either y.julian = FALSE or x.julian = FALSE.
- **title** title for event chart. Default is 'Event Chart'.
- **y.idlabels** column or data frame variable name used for y-axis labels. For example, if c('pt.no') is specified, patient ID (stored in pt.no) will be seen on y-axis labels instead of sequence specified by subset.r. This argument takes precedence over both y.axis = 'auto' and y.axis = 'custom' (see below). NOTE: Program will issue warning if this argument is specified and if is.na(y.var) == FALSE; y.idlabels will not be used in this situation. Also, attempting to plot too many patients on a single event chart will cause undesirable plotting of y.idlabels.
- **y.axis** character string specifying whether program will control labelling of y-axis (with argument "auto"), or if user will control labelling (with argument "custom"). If "custom" is chosen, user must specify location and text of labels using y.axis.custom.at and y.axis.custom.labels arguments, respectively, listed below. This argument will not be utilized if y.idlabels is specified.
- **y.axis.custom.at** user-specified vector of y-axis label locations. Must be used when y.axis = "custom"; will not be used otherwise.
- **y.axis.custom.labels** user-specified vector of y-axis labels. Must be used when y.axis = "custom"; will not be used otherwise.
- **y.julian** logical flag (which will only be considered if y.axis == "auto" and (!is.na(y.var) & y.var.type==
If FALSE (default), will convert julian numeric dates or S-Plus dates objects into "mm/dd/yy" format for the y-axis labels. If TRUE, dates will be printed in julian (numeric) format.
- **y.lim.extend** two-dimensional vector representing the number of units that the user wants to increase ylim on bottom and top of y-axis, respectively. Default c(0, 0). This argument will not take effect if the Goldman chart is utilized.
- **y.lab** single label to be used for entire y-axis. Default will be the variable name or column number of y.idlabels (if non-missing) and blank otherwise.
- **x.axis.all** logical flag. If TRUE (default), lower and upper limits of x-axis will be based on all observations (rows) in matrix or data frame. If FALSE, lower and upper limits will be based only on those observations specified by subset.r (either before or after sorting depending on specification of sort.by and value of sort.after.subset).
event.chart

x.axis character string specifying whether program will control labelling of x-axis (with argument "auto"), or if user will control labelling (with argument "custom"). If "custom" is chosen, user must specify location and text of labels using x.axis.custom.at and x.axis.custom.labels arguments, respectively, listed below.

x.axis.custom.at user-specified vector of x-axis label locations. Must be used when x.axis == "custom"; will not be used otherwise.

x.axis.custom.labels user-specified vector of x-axis labels. Must be used when x.axis == "custom"; will not be used otherwise.

x.julian logical flag (which will only be considered if x.axis == "auto"). If FALSE (default), will convert julian dates or S-plus dates objects into “mm/dd/yy” format for the x-axis labels. If TRUE, dates will be printed in julian (numeric) format. NOTE: This argument should remain TRUE if x.reference is specified.

x.lim.extend two-dimensional vector representing the number of time units (usually in days) that the user wants to increase xlim on left-hand side and right-hand side of x-axis, respectively. Default is c(0,0). This argument will not take effect if the Goldman chart is utilized.

x.scale a factor whose reciprocal is multiplied to original units of the x-axis. For example, if the original data frame is in units of days, x.scale = 365 will result in units of years (notwithstanding leap years). Default is 1.

x.lab single label to be used for entire x-axis. Default will be “On Study Date” if x.julian = FALSE and “Time on Study” if x.julian = TRUE.

line.by column or data frame variable name for plotting unique lines by unique values of vector (e.g., specify c('arm') to plot unique lines by treatment arm). Can take at most one column or variable name. Default is NA which produces identical lines for each patient.

line.lty vector of line types corresponding to ascending order of line.by values. If line.by is specified, the vector should be the length of the number of unique values of line.by. If line.by is NA, only line.lty[1] will be used. The default is 1.

line.lwd vector of line widths corresponding to ascending order of line.by values. If line.by is specified, the vector should be the length of the number of unique values of line.by. If line.by is NA, only line.lwd[1] will be used. The default is 1.

line.col vector of line colors corresponding to ascending order of line.by values. If line.by is specified, the vector should be the length of the number of unique values of line.by. If line.by is NA, only line.col[1] will be used. The default is 1.

line.add a 2xk matrix with k=number of pairs of additional line segments to add. For example, if it is of interest to draw additional line segments connecting events one and two, and three, and four and five, (possibly with different colors), an appropriate line.add argument would be matrix(c('first.event', 'second.event', 'second.event', 'third.event', 'fourth.event', and a second line segment would be drawn between second.event and third.event, and a third line segment would be drawn between fourth.event and fifth.event.)
Different line types, widths and colors can be specified (in arguments listed just below).

The convention use of subset.c and line.add must match (i.e., column name must be used for both or column number must be used for both).

If line.add != NA, length of line.add.lty, line.add.lwd, and line.add.col must be the same as number of pairs of additional line segments to add.

NOTE: The drawing of the original default line may be suppressed (with line.col = NA), and line.add can be used to do all the line plotting for the event chart.

- **line.add.lty**: a kx1 vector corresponding to the columns of line.add; specifies the line types for the k line segments.
- **line.add.lwd**: a kx1 vector corresponding to the columns of line.add; specifies the line widths for the k line segments.
- **line.add.col**: a kx1 vector corresponding to the columns of line.add; specifies the line colors for the k line segments.

- **point.pch**: vector of pch values for points representing each event. If similar events are listed in multiple columns (e.g., regular visits or a recurrent event), repeated pch values may be listed in the vector (e.g., c(2,4,rep(183,3))). If length(point.pch) < length(subset.c), point.pch will be repeated until lengths are equal; a warning message will verify this condition.

- **point.cex**: vector of size of points representing each event. If length(point.cex) < length(subset.c), point.cex will be repeated until lengths are equal; a warning message will verify this condition.

- **point.col**: vector of colors of points representing each event. If length(point.col) < length(subset.c), point.col will be repeated until lengths are equal; a warning message will verify this condition.

- **point.cex.mult**: a single number (may be non-integer), which is the base multiplier for the value of the cex of the plotted points, when interest lies in a variable size allowed for certain points, as a function of the quantity of the variable(s) in the dataset specified in the point.cex.mult.var argument; multiplied by original point.cex value and then the value of interest (for an individual) from the point.cex.mult.var argument; used only when non-NA arguments are provided to point.cex.mult.var; default is 1.

- **point.cex.mult.var**: vector of variables to be used in determining what point.cex.mult is multiplied by for determining size of plotted points from (possibly a subset of) subset.c variables, when interest lies in a variable size allowed for certain points, as a function of the level of some variable(s) in the dataset; default is NA.

- **extra.points.no.mult**: vector of variables in the dataset to ignore for purposes of using point.cex.mult; for example, for some variables there may be interest in allowing a variable size allowed for the plotting of the points, whereas other variables (e.g., dropout time), there may be no interest in such manipulation; the vector should be the same size as the number of variables specified in subset.c, with NA entries where variable point size is of interest and the variable name (or location in subset.c) specified when the variable point size is not of interest; in this latter case, the associated argument in point.cex is instead used as the point cex;
used only when non-NA arguments are provided to `point.cex.mult.var`; default is NA

`legend.plot` logical flag; if `TRUE`, a legend will be plotted. Location of legend will be based on specification of `legend.location` along with values of other arguments listed below. Default is `FALSE` (i.e., no legend plotting).

`legend.location` will be used only if `legend.plot = TRUE`. If "o" (default), a one-page legend will precede the output of the chart. The user will need to hit enter in order for the event chart to be displayed. This feature is possible due to the `dev.ask` option. If "i", an internal legend will be placed in the plot region based on `legend.point.at`. If "l", a legend will be placed in the plot region using the `locator` option. Legend will map points to events (via column names, by default) and, if `line.by` is specified, lines to groups (based on levels of `line.by`).

`legend.title` title for the legend; default is title to be used for main plot. Only used when `legend.location = "o"`.

`legend.title.cex` size of text for legend title. Only used when `legend.location = "o"`.

`legend.title.line` line location of legend title dictated by `mtext` function with `outer = FALSE` option; default is 1.0. Only used when `legend.location = "o"`.

`legend.point.at` location of upper left and lower right corners of legend area to be utilized for describing events via points and text.

`legend.point.pch` vector of `pch` values for points representing each event in the legend. Default is `point.pch`.

`legend.point.text` text to be used for describing events; the default is setup for a data frame, as it will print the names of the columns specified by `subset.c`.

`legend.cex` size of text for points and event descriptions. Default is 2.5 which is setup for `legend.location = "o"`. A much smaller `cex` is recommended (possibly 0.75) for use with `legend.location = "i"` or `legend.location = "l"`.

`legend.bty` option to put a box around the legend(s); default is to have no box (`legend.bty = "n"`). Option `legend.bty = "o"` will produce a legend box.

`legend.line.at` if `line.by` was specified (with `legend.location = "o"` or `legend.location = "i"`), this argument will dictate the location of the upper left and lower right corners of legend area to be utilized for describing the different `line.by` values (e.g., `treatment.arm`). The default is setup for `legend.location = "o"`.

`legend.line.text` text to be used for describing `line.by` values; the default are the names of the unique non-missing `line.by` values as produced from the `table` function.

`legend.line.lwd` vector of line widths corresponding to `line.by` values.

`legend.loc.num` number used for locator argument when `legend.locator = "1"`. If 1 (default), user is to locate only the top left corner of the legend box. If 2, user is to locate
both the top left corner and the lower right corner. This will be done twice when line.by is specified (once for points and once for lines).

... additional par arguments for use in main plot.

**Details**

if you want to put, say, two eventcharts side-by-side, in a plot region, you should not set up `par(mfrow=c(1,2))` before running the first plot. Instead, you should add the argument `mfg=c(1,1,1,2)` to the first plot call followed by the argument `mfg=c(1,2,1,2)` to the second plot call.

if dates in original data frame are in a specialized form (e.g., mm/dd/yy) of mode CHARACTER, the user must convert those columns to become class dates or julian numeric mode (see `Date` for more information). For example, in a data frame called `testdata`, with specialized dates in columns 4 thru 10, the following code could be used: `as.numeric(dates(testdata[,4:10]))`. This will convert the columns to numeric julian dates based on the function’s default origin of January 1, 1960. If original dates are in class dates or julian form, no extra work is necessary.

In the survival analysis, the data typically come in two columns: one column containing survival time and the other containing censoring indicator or event code. The `event.convert` function converts this type of data into multiple columns of event times, one column of each event type, suitable for the `event.chart` function.

**Side Effects**

an event chart is created on the current graphics device. If legend.plot = TRUE and legend.location = 'o', a one-page legend will precede the event chart. Please note that par parameters on completion of function will be reset to par parameters existing prior to start of function.

Examples

# The sample data set is an augmented CDC AIDS dataset (ASCII)
# which is used in the examples in the help file. This dataset is
# described in Kalbfleisch and Lawless (JASA, 1989).
# Here, we have included only children 4 years old and younger.
# We have also added a new field, dethdate, which
# represents a fictitious death date for each patient. There was
# no recording of death date on the original dataset. In addition, we have
# added a fictitious viral load reading (copies/ml) for each patient at time of AIDS diagnosis,
# noting viral load was also not part of the original dataset.
#
# All dates are julian with julian=0 being
# January 1, 1960, and julian=14000 being 14000 days beyond
# January 1, 1960 (i.e., May 1, 1998).

event.data <- event.convert(surv.data)
event.chart(cbind(rep(0,5),event.data),x.julian=TRUE,x.reference=1)

---

**Description**

Convert a two-column data matrix with event time and event code into multiple column event time with one event in each column
Usage

event.convert(data2, event.time = 1, event.code = 2)

Arguments

data2 a matrix or dataframe with at least 2 columns; by default, the first column contains the event time and the second column contains the k event codes (e.g. 1=dead, 0=censored)
event.time the column number in data contains the event time
event.code the column number in data contains the event code

Details

In the survival analysis, the data typically come in two columns: one column containing survival time and the other containing censoring indicator or event code. The `event.convert` function converts this type of data into multiple columns of event times, one column of each event type, suitable for the `event.chart` function.

Examples

# To convert coded time-to-event data, then, draw an event chart:
surv.time <- c(5,6,3,1,2)
cens.ind <- c(1,0,1,1,0)
surv.data <- cbind(surv.time,cens.ind)
event.data <- event.convert(surv.data)
event.chart(cbind(rep(0,5),event.data),x.julian=TRUE,x.reference=1)
Description

Produces an event history graph for right-censored survival data, including time-dependent covariate status, as described in Dubin, Muller, and Wang (2001). Effectively, a Kaplan-Meier curve is produced with supplementary information regarding individual survival information, censoring information, and status over time of an individual time-dependent covariate or time-dependent covariate function for both uncensored and censored individuals.

Usage

```
event.history(data, survtime.col, surv.col,
               surv.ind = c(1, 0), subset.rows = NULL,
               covtime.cols = NULL, cov.cols = NULL,
               num.colors = 1, cut.cov = NULL, colors = 1,
               cens.density = 10, mult.end.cens = 1.05,
               cens.mark.right = FALSE, cens.mark = "-",
               cens.mark.ahead = 0.5, cens.mark.cutoff = -1e-08,
               cens.mark.cex = 1,
               x.lab = "time under observation",
               y.lab = "estimated survival probability",
               title = "event history graph", ...)
```

Arguments

data | A matrix or data frame with rows corresponding to units (often individuals) and columns corresponding to survival time, event/censoring indicator. Also, multiple columns may be devoted to time-dependent covariate level and time change.
survtime.col | Column (in data) representing minimum of time-to-event or right-censoring time for individual.
surv.col | Column (in data) representing event indicator for an individual. Though, traditionally, such an indicator will be 1 for an event and 0 for a censored observation, this indicator can be represented by any two numbers, made explicit by the surv.ind argument.
surv.ind | Two-element vector representing, respectively, the number for an event, as listed in surv.col, followed by the number for a censored observation. Default is traditional survival data representation, i.e., c(1, 0).
subset.rows | Subset of rows of original matrix or data frame (data) to place in event history graph. Logical arguments may be used here (e.g., treatment.arm == "a", if the data frame, data, has been attached to the search directory;
covtime.cols | Column(s) (in data) representing the time when change of time-dependent covariate (or time-dependent covariate function) occurs. There should be a unique
non-NA entry in the column for each such change (along with corresponding
cov.cols column entry representing the value of the covariate or function at
that change time). Default is NULL, meaning no time-dependent covariate infor-
mation will be presented in the graph.

cov.cols Column(s) (in data) representing the level of the time-dependent covariate (or
time-dependent covariate function). There should be a unique non-NA column
entry representing each change in the level (along with a corresponding cov-
time.cols column entry representing the time of the change). Default is NULL,
meaning no time-dependent covariate information will be presented in the graph.

num.colors Colors are utilized for the time-dependent covariate level for an individual. This
argument provides the number of unique covariate levels which will be dis-
played by mapping the number of colors (via num.colors) to the number of
desired covariate levels. This will divide the covariate span into roughly equally-
sized intervals, via the S-Plus cut function. Default is one color, meaning no
time-dependent information will be presented in the graph. Note that this argu-
ment will be ignored/superceded if a non-NULL argument is provided for the
cut.cov parameter.

cut.cov This argument allows the user to explicitly state how to define the intervals for
the time-dependent covariate, such that different colors will be allocated to the
user-defined covariate levels. For example, for plotting five colors, six ordered
points within the span of the data’s covariate levels should be provided. Default
is NULL, meaning that the num.colors argument value will dictate the number of
breakpoints, with the covariate span defined into roughly equally-sized intervals
via the S-Plus cut function. However, if is.null(cut.cov) == FALSE, then
this argument supercedes any entry for the num.colors argument.

colors This is a vector argument defining the actual colors used for the time-dependent
covariate levels in the plot, with the index of this vector corresponding to the
ordered levels of the covariate. The number of colors (i.e., the length of the
colors vector) should correspond to the value provided to the num.colors argu-
ment or the number of ordered points - 1 as defined in the cut.cov argument
(with cut.cov superceding num.colors if is.null(cut.cov) == FALSE). The
function, as currently written, allows for as much as twenty distinct colors. This
argument effectively feeds into the col argument for the S-Plus polygon func-
tion. Default is colors = 1. See the col argument for the both the S-Plus par
function and polygon function for more information.

cens.density This will provide the shading density at the end of the individual bars for those
who are censored. For more information on shading density, see the density
argument in the S-Plus polygon function. Default is cens.density=10.

mult.end.cens This is a multiplier that extends the length of the longest surviving individual
bar (or bars, if a tie exists) if right-censored, presuming that no event times
eventually follow this final censored time. Default extends the length 5 percent
beyond the length of the observed right-censored survival time.

cens.mark.right A logical argument that states whether an explicit mark should be placed to
the right of the individual right-censored survival bars. This argument is most
useful for large sample sizes, where it may be hard to detect the special shading
via cens.density, particularly for the short-term survivors.
cens.mark Character argument which describes the censored mark that should be used if cens.mark.right = TRUE. Default is "-".

cens.mark.ahead A numeric argument, which specifies the absolute distance to be placed between the individual right-censored survival bars and the mark as defined in the above cens.mark argument. Default is 0.5 (that is, a half of day, if survival time is measured in days), but may very well need adjusting depending on the maximum survival time observed in the dataset.

cens.mark.cutoff A negative number very close to 0 (by default cens.mark.cutoff = -1e-8) to ensure that the censoring marks get plotted correctly. See event.history code in order to see its usage. This argument typically will not need adjustment.

cens.mark.cex Numeric argument defining the size of the mark defined in the cens.mark argument above. See more information by viewing the cex argument for the S-Plus par function. Default is cens.mark.cex = 1.0.

x.lab Single label to be used for entire x-axis. Default is "time under observation".

y.lab Single label to be used for entire y-axis. Default is "estimated survival probability".

title Title for the event history graph. Default is "event history graph".

... This allows arguments to the plot function call within the event.history function. So, for example, the axes representations can be manipulated with appropriate arguments, or particular areas of the event.history graph can be "zoomed". See the details section for more comments about zooming.

Details

In order to focus on a particular area of the event history graph, zooming can be performed. This is best done by specifying appropriate xlim and ylim arguments at the end of the event.history function call, taking advantage of the ... argument link to the plot function. An example of zooming can be seen in Plate 4 of the paper referenced below.

Please read the reference below to understand how the individual covariate and survival information is provided in the plot, how ties are handled, how right-censoring is handled, etc.

WARNING

This function has been tested thoroughly, but only within a restricted version and environment, i.e., only within S-Plus 2000, Version 3, and within S-Plus 6.0, version 2, both on a Windows 2000 machine. Hence, we cannot currently vouch for the function’s effectiveness in other versions of S-Plus (e.g., S-Plus 3.4) nor in other operating environments (e.g., Windows 95, Linux or Unix). The function has also been verified to work on R under Linux.

Note

The authors have found better control of the use of color by producing the graphs via the postscript plotting device in S-Plus. In fact, the provided examples utilize the postscript function. However, your past experiences may be different, and you may prefer to control color directly (to the graphsheet in Windows environment, for example). The event.history function will work with either approach.

### ffCompress

**Transform Data Frame Into a Compact ff Object**

**Description**

The ff package implements a wide variety of atomic data types down to 2 bits, allowing for compact storage of large datasets and requiring memory usage in R for only those rows and columns of the dataset that are needed at one time. It is best to create a compact ffdf data frame object while initially reading the external data file, using for example an input .csv file and specifying the ff vmode for all the columns. If you can get enough memory to read the entire dataset into an R data.frame you can use ffCompress after the fact to analyze the data frame and use the most compact data representation possible. This entails using single precision for floating point numbers (which can be easily overridden to use R’s usual double precision) and a variety of integer types depend on the number of bits used by the maximum absolute value of the variable, whether or not NAs exist in the data, and whether or not negative values are possible.

Since ff does not allow variable labels and units, any such attributes are stripped off of variables and stored as attributes on the entire ffdf object. An as.data.frame and subscripting method retrieves these attributes and restores them to individual variables when needed.
Usage

```r
ffCompress(obj, float=c('single', 'double'), print=FALSE)
```

## S3 method for class 'ffdflabel'
as.data.frame(x, ...)

Arguments

- **obj**: a data frame
- **float**: representation to use for floating point vectors. The default is single precision (4 bytes, 7 significant digits). Specify `float='double'` to use double precision (8 bytes, 15 significant digits)
- **print**: set to TRUE to get progress output and passed as the VERB0SE argument to ff functions
- **x**: an ffdf object
- **...**: ignored

Value

an ffdf object for ffCompress, a data.frame for as.data.frame, and either one of these for subscripting. If subscripting results in a single variable and `drop=FALSE` is not specified, the result is of ff type.

---

**find.matches**

**Find Close Matches**

**Description**

Compares each row in x against all the rows in y, finding rows in y with all columns within a tolerance of the values a given row of x. The default tolerance tol is zero, i.e., an exact match is required on all columns. For qualifying matches, a distance measure is computed. This is the sum of squares of differences between x and y after scaling the columns. The default scaling values are tol, and for columns with tol=1 the scale values are set to 1.0 (since they are ignored anyway). Matches (up to maxmatch of them) are stored and listed in order of increasing distance.

The summary method prints a frequency distribution of the number of matches per observation in x, the median of the minimum distances for all matches per x, as a function of the number of matches, and the frequency of selection of duplicate observations as those having the smallest distance. The print method prints the entire matches and distance components of the result from find.matches.

matchCases finds all controls that match cases on a single variable x within a tolerance of tol. This is intended for prospective cohort studies that use matching for confounder adjustment (even though regression models usually work better).

**Usage**

find.matches(x, y, tol=rep(0, ncol(y)), scale=tol, maxmatch=10)
## S3 method for class 'find.matches'

**summary**

```r
summary(object, ...)  
```

## S3 method for class 'find.matches'

**print**

```r
print(x, digits, ...)  
```

**matchCases**

```r
matchCases(xcase, ycase, idcase=names(ycase),  
xcontrol, ycontrol, idcontrol=names(ycontrol),  
tol=NULL,  
maxobs=max(length(ycase),length(ycontrol))*10,  
maxmatch=20, which=c('closest','random'))  
```

### Arguments

- **x**: a numeric matrix or the result of `find.matches`
- **y**: a numeric matrix with same number of columns as `x`
- **xcase**: vectors, not necessarily of the same length, specifying a numeric variable used to match cases and control
- **xcontrol**: vectors, not necessarily of the same length, specifying a numeric variable used to match cases and control
- **ycase**: vectors or matrices, not necessarily having the same number of rows, specifying a variable to carry along from cases and matching controls. If you instead want to carry along rows from a data frame, let `ycase` and `ycontrol` be non-overlapping integer subscripts of the donor data frame.
- **ycontrol**: vectors or matrices, not necessarily having the same number of rows, specifying a variable to carry along from cases and matching controls. If you instead want to carry along rows from a data frame, let `ycase` and `ycontrol` be non-overlapping integer subscripts of the donor data frame.
- **tol**: a vector of tolerances with number of elements the same as the number of columns of `y`, for `find.matches`. For `matchCases` is a scalar tolerance.
- **scale**: a vector of scaling constants with number of elements the same as the number of columns of `y`.
- **maxmatch**: maximum number of matches to allow. For `matchCases`, maximum number of controls to match with a case (default is 20). If more than `maxmatch` matching controls are available, a random sample without replacement of `maxmatch` controls is used (if `which`="random").
- **object**: an object created by `find.matches`
- **digits**: number of digits to use in printing distances
- **idcase**: vectors the same length as `xcase` and `xcontrol` respectively, specifying the id of cases and controls. Defaults are integers specifying original element positions within each of cases and controls.
- **idcontrol**: vectors the same length as `xcase` and `xcontrol` respectively, specifying the id of cases and controls. Defaults are integers specifying original element positions within each of cases and controls.
- **maxobs**: maximum number of cases and all matching controls combined (maximum dimension of data frame resulting from `matchControls`). Default is ten times the maximum of the number of cases and number of controls. `maxobs` is used to allocate space for the resulting data frame.
- **which**: set to "closest" (the default) to match cases with up to `maxmatch` controls that most closely match on `x`. Set `which`="random" to use randomly chosen controls. In either case, only those controls within `tol` on `x` are allowed to be used.

... unused
find.matches

Value

find.matches returns a list of class find.matches with elements matches and distance. Both elements are matrices with the number of rows equal to the number of rows in x, and with k columns, where k is the maximum number of matches (\( \leq \) maxmatch) that occurred. The elements of matches are row identifiers of y that match, with zeros if fewer than maxmatch matches are found (blanks if y had row names). matchCases returns a data frame with variables idcase (id of case currently being matched), type (factor variable with levels "case" and "control"), id (id of case if case row, or id of matching case), and y.

describe(ors)

---

**Description**

`first.word` finds the first word in an expression. A word is defined by unlisting the elements of the expression found by the S parser and then accepting any elements whose first character is either a letter or period. The principal intended use is for the automatic generation of temporary file names where it is important to exclude special characters from the file name. For Microsoft Windows, periods in names are deleted and only up to the first 8 characters of the word is returned.

**Usage**

`first.word(x, i=1, expr=substitute(x))`
Arguments

- **x**: any scalar character string
- **i**: word number, default value = 1. Used when the second or ith word is wanted. Currently only the i=1 case is implemented.
- **expr**: any S object of mode expression.

Value

a character string

Examples

```
first.word(expr=expression(y - x + log(w)))
```

---

format.df

Format a Data Frame or Matrix for LaTeX or HTML

Description

format.df does appropriate rounding and decimal alignment, and outputs a character matrix containing the formatted data. If **x** is a data.frame, then do each component separately. If **x** is a matrix, but not a data.frame, make it a data.frame with individual components for the columns. If a component **x[i]** is a matrix, then do all columns the same.

Usage

```
format.df(x, digits, dec=NULL, rdec=NULL, cdec=NULL, numeric.dollar=!dcolumn, na.blank=FALSE, na.dot=FALSE, blank.dot=FALSE, col.just=NULL, cdot=FALSE, dcolumn=FALSE, matrix.sep=',', scientific=c(-4,4), math.row.names=FALSE, already.math.row.names=FALSE, math.col.names=FALSE, already.math.col.names=FALSE, double.slash=FALSE, format.Date="%m/%d/%Y", format.POSIXt="%m/%d/%Y %H:%M:%OS", ...)
```
Arguments

\textbf{x} \hspace{1cm} a matrix (usually numeric) or data frame

\textit{digits} \hspace{1cm} causes all values in the table to be formatted to \textit{digits} significant digits. \textit{dec} is usually preferred.

\textit{dec} \hspace{1cm} If \textit{dec} is a scalar, all elements of the matrix will be rounded to \textit{dec} decimal places to the right of the decimal. \textit{dec} can also be a matrix whose elements correspond to \textit{x}, for customized rounding of each element. A matrix \textit{dec} must have number of columns equal to number of columns of input \textit{x}. A scalar \textit{dec} is expanded to a vector \textit{cdec} with number of items equal to number of columns of input \textit{x}.

\textit{rdec} \hspace{1cm} a vector specifying the number of decimal places to the right for each row (\textit{cdec} is more commonly used than \textit{rdec}). A vector \textit{rdec} must have number of items equal to number of rows of input \textit{x}. \textit{rdec} is expanded to matrix \textit{dec}.

\textit{cdec} \hspace{1cm} a vector specifying the number of decimal places for each column. The vector must have number of items equal to number of columns or components of input \textit{x}.

\textit{cdott} \hspace{1cm} Set to \textbf{TRUE} to use centered dots rather than ordinary periods in numbers. The output uses a syntax appropriate for \textit{latex}.

\textit{na.blank} \hspace{1cm} Set to \textbf{TRUE} to use blanks rather than \texttt{NA} for missing values. This usually looks better in \textit{latex}.

\textit{dcolumn} \hspace{1cm} Set to \textbf{TRUE} to use David Carlisle's \texttt{dcolumn} style for decimal alignment in \textit{latex}. Default is \textbf{FALSE}. You will probably want to use \textit{dcolumn} if you use \textit{rdec}, as a column may then contain varying number of places to the right of the decimal. \textit{dcolumn} can line up all such numbers on the decimal point, with integer values right justified at the decimal point location of numbers that actually contain decimal places. When you use \textit{dcolumn} = \textbf{TRUE}, \textit{numeric.dollar} is set by default to \textbf{FALSE}. When you use \textit{dcolumn} = \textbf{TRUE}, the object attribute "style" set to 'dcolumn' as the \textit{latex} \textit{usepackage} must reference [dcolumn]. The three files 'dcolumn.sty', 'newarray.sty', and 'array.sty' will need to be in a directory in your \texttt{TEXINPUTS} path. When you use \textit{dcolumn}=\textbf{TRUE}, \textit{numeric.dollar} should be set to \textbf{FALSE}.

\textit{numeric.dollar} \hspace{1cm} logical, default !\texttt{dcolumn}. Set to \textbf{TRUE} to place dollar signs around numeric values when \textit{dcolumn} = \textbf{FALSE}. This assures that \texttt{latex} will use minus signs rather than hyphens to indicate negative numbers. Set to \textbf{FALSE} when \textit{dcolumn} = \textbf{TRUE}, as \texttt{dcolumn.sty} automatically uses minus signs.

\textit{math.row.names} \hspace{1cm} logical, set true to place dollar signs around the row names.

\textit{already.math.row.names} \hspace{1cm} set to \textbf{TRUE} to prevent any math mode changes to row names

\textit{math.col.names} \hspace{1cm} logical, set true to place dollar signs around the column names.

\textit{already.math.col.names} \hspace{1cm} set to \textbf{TRUE} to prevent any math mode changes to column names

\textit{na.dot} \hspace{1cm} Set to \textbf{TRUE} to use periods rather than \texttt{NA} for missing numeric values. This works with the \texttt{SAS} convention that periods indicate missing values.
blank.dot  Set to TRUE to use periods rather than blanks for missing character values. This works with the SAS convention that periods indicate missing values.

col.just  Input vector col.just must have number of columns equal to number of columns of the output matrix. When NULL, the default, the col.just attribute of the result is set to ‘l’ for character columns and to ‘r’ for numeric columns. The user can override the default by an argument vector whose length is equal to the number of columns of the result matrix. When format.df is called by latex.default, the col.just is used as the cols argument to the tabular environment and the letters ‘l’, ‘r’, and ‘c’ are valid values. When format.df is called by SAS, the col.just is used to determine whether a ‘$’ is needed on the ‘input’ line of the ‘sysin’ file, and the letters ‘l’ and ‘r’ are valid values. You can pass specifications other than l,r,c in col.just, e.g., “p{3in}” to get paragraph-formatted columns from latex().

matrix.sep  When x is a data frame containing a matrix, so that new column names are constructed from the name of the matrix object and the names of the individual columns of the matrix, matrix.sep specifies the character to use to separate object names from individual column names.

scientific  specifies ranges of exponents (or a logical vector) specifying values not to convert to scientific notation. See format.default for details.

double.slash  should escaping backslashes be themselves escaped.

format.Date  String used to format objects of the Date class.

format.POSIXt  String used to format objects of the POSIXt class.

...  other arguments are accepted and passed to format.default. For latexVerbatim these arguments are passed to the print function.

Value

da character matrix with character images of properly rounded x. Matrix components of input x are now just sets of columns of character matrix. Object attribute "col.just" repeats the value of the argument col.just when provided, otherwise, it includes the recommended justification for columns of output. See the discussion of the argument col.just. The default justification is ‘l’ for characters and factors, ‘r’ for numeric. When dcolumn==TRUE, numerics will have ‘.’ as the justification character.

**format.pval**

*Format P Values*

Description

`format.pval` is intended for formatting p-values.

Usage

```r
format.pval(x, pv=x, digits = max(1, .Options$digits - 2),
eps = .Machine$double.eps, na.form = "NA", ...)
```

Arguments

- `pv`: a numeric vector.
- `x`: argument for method compliance.
- `digits`: how many significant digits are to be used.
- `eps`: a numerical tolerance: see Details.
- `na.form`: character representation of NAs.
- `...`: arguments passed to `format` in the `format.pval` function body.

Details

`format.pval` is mainly an auxiliary function for `print.summary.lm` etc., and does separate formatting for fixed, floating point and very small values; those less than `eps` are formatted as “’< [eps]’” (where “’[eps]’” stands for `format(eps, digits)`).

Value

A character vector.

Note

This is the base `format.pval` function with the ability to pass the `nsmall` argument to `format`
Examples

```r
format.pval(c(runif(5), pi^100, NA))
format.pval(c(0.1, 0.0001, 1e-27))
format.pval(c(0.1, 1e-27), nsmall=3)
```

---

**Description**

gbayes derives the (Gaussian) posterior and optionally the predictive distribution when both the prior and the likelihood are Gaussian, and when the statistic of interest comes from a 2-sample problem. This function is especially useful in obtaining the expected power of a statistical test, averaging over the distribution of the population effect parameter (e.g., log hazard ratio) that is obtained using pilot data. gbayes is also useful for summarizing studies for which the statistic of interest is approximately Gaussian with known variance. An example is given for comparing two proportions using the angular transformation, for which the variance is independent of unknown parameters except for very extreme probabilities. A plot method is also given. This plots the prior, posterior, and predictive distributions on a single graph using a nice default for the x-axis limits and using the labcurve function for automatic labeling of the curves.

gbayes2 uses the method of Spiegelhalter and Freedman (1986) to compute the probability of correctly concluding that a new treatment is superior to a control. By this we mean that a 1-alpha normal theory-based confidence interval for the new minus old treatment effect lies wholly to the right of `delta.w`, where `delta.w` is the minimally worthwhile treatment effect (which can be zero to be consistent with ordinary null hypothesis testing, a method not always making sense). This kind of power function is averaged over a prior distribution for the unknown treatment effect. This procedure is applicable to the situation where a prior distribution is not to be used in constructing the test statistic or confidence interval, but is only used for specifying the distribution of `delta`, the parameter of interest.

Even though gbayes2 assumes that the test statistic has a normal distribution with known variance (which is strongly a function of the sample size in the two treatment groups), the prior distribution function can be completely general. Instead of using a step-function for the prior distribution as Spiegelhalter and Freedman used in their appendix, gbayes2 uses the built-in integrate function for numerical integration. gbayes2 also allows the variance of the test statistic to be general as long as it is evaluated by the user. The conditional power given the parameter of interest `delta` is

```r
1 - pnorm(((delta.w - delta)/sd + z), where z is the normal critical value corresponding to 1-alpha/2.
```

gbayesMixPredNoData derives the predictive distribution of a statistic that is Gaussian given `delta` when no data have yet been observed and when the prior is a mixture of two Gaussians.

gbayesMixPost derives the posterior density, cdf, or posterior mean of `delta` given the statistic `x`, when the prior for `delta` is a mixture of two Gaussians and when `x` is Gaussian given `delta`.

gbayesMixPowerNP computes the power for a test for `delta > delta.w` for the case where (1) a Gaussian prior or mixture of two Gaussian priors is used as the prior distribution, (2) this prior is used in forming the statistical test or credible interval, (3) no prior is used for the distribution of `delta` for computing power but instead a fixed single `delta` is given (as in traditional frequentist
hypothesis tests), and (4) the test statistic has a Gaussian likelihood with known variance (and mean equal to the specified \( \delta \)). \texttt{gbayesMixPowerNP} is handy where you want to use an earlier study in testing for treatment effects in a new study, but you want to mix with this prior a non-informative prior. The mixing probability \( \text{mix} \) can be thought of as the "applicability" of the previous study. As with \texttt{gbayes2}, power here means the probability that the new study will yield a left credible interval that is to the right of \( \delta_w \). \texttt{gbayes1PowerNP} is a special case of \texttt{gbayesMixPowerNP} when the prior is a single Gaussian.

**Usage**

\[
\texttt{gbayes(mean.prior, var.prior, m1, m2, stat, var.stat, n1, n2, cut.prior, cut.prob.prior=0.025)}
\]

\[
\# S3 method for class 'gbayes'
\]

\[
\texttt{plot(x, xlim, ylim, name.stat='z', ...)}
\]

\[
\texttt{gbayes2(sd, prior, delta.w=0, alpha=0.05, upper=Inf, prior.aux)}
\]

\[
\texttt{gbayesMixPredNoData(mix=NA, d0=NA, v0=NA, d1=NA, v1=NA, what=c('density','cdf'))}
\]

\[
\texttt{gbayesMixPost(x=NA, v=NA, mix=1, d0=NA, v0=NA, d1=NA, v1=NA, what=c('density','cdf','postmean'))}
\]

\[
\texttt{gbayesMixPowerNP(pcdf, delta, v, delta.w=0, mix, interval, nsim=0, alpha=0.05)}
\]

\[
\texttt{gbayes1PowerNP(d0, v0, delta, v, delta.w=0, alpha=0.05)}
\]

**Arguments**

- **mean.prior**: mean of the prior distribution
- **cut.prior**, **cut.prob.prior**, **var.prior**: variance of the prior. Use a large number such as 10000 to effectively use a flat (noninformative) prior. Sometimes it is useful to compute the variance so that the prior probability that \( \text{stat} \) is greater than some impressive value \( u \) is only \( \alpha \). The correct \( \text{var.prior} \) to use is then \((u-\text{mean.prior})/\text{qnorm}(1-\alpha))^2\). You can specify \( \text{cut.prior=}\alpha \) and \( \text{cut.prob.prior=}\alpha \) (whose default is 0.025) in place of \( \text{var.prior} \) to have \texttt{gbayes} compute the prior variance in this manner.
- **m1**: sample size in group 1
- **m2**: sample size in group 2
- **stat**: statistic comparing groups 1 and 2, e.g., log hazard ratio, difference in means, difference in angular transformations of proportions
- **var.stat**: variance of \( \text{stat} \), assumed to be known. \( \text{var.stat} \) should either be a constant (allowed if \( n1 \) is not specified), or a function of two arguments which specify the sample sizes in groups 1 and 2. Calculations will be approximate when the variance is estimated from the data.
**x** an object returned by `gbayes` or the value of the statistic which is an estimator of delta, the parameter of interest

**sd** the standard deviation of the treatment effect

**prior** a function of possibly a vector of unknown treatment effects, returning the prior density at those values

**pcdf** a function computing the posterior CDF of the treatment effect `delta`, such as a function created by `gbayesMixPost` with `what=c("cdf")`.

**delta** a true unknown single treatment effect to detect

**v** the variance of the statistic `x`, e.g., `s^2 * (1/n1 + 1/n2)`. Neither `x` nor `v` need to be defined to `gbayesMixPost`, as they can be defined at run time to the function created by `gbayesMixPost`.

**n1** number of future observations in group 1, for obtaining a predictive distribution

**n2** number of future observations in group 2

**xlim** vector of 2 x-axis limits. Default is the mean of the posterior plus or minus 6 standard deviations of the posterior.

**ylim** vector of 2 y-axis limits. Default is the range over combined prior and posterior densities.

**name.stat** label for x-axis. Default is "z".

... optional arguments passed to `labcurve` from `plot.gbayes`

**delta.w** the minimum worthwhile treatment difference to detect. The default is zero for a plain uninteresting null hypothesis.

**alpha** type I error, or more accurately one minus the confidence level for a two-sided confidence limit for the treatment effect

**upper** upper limit of integration over the prior distribution multiplied by the normal likelihood for the treatment effect statistic. Default is infinity.

**prior.aux** argument to pass to `prior` from `integrate` through `gbayes2`. Inside of `power` the argument must be named `prior.aux` if it exists. You can pass multiple parameters by passing `prior.aux` as a list and pulling off elements of the list inside `prior`. This setup was used because of difficulties in passing ... arguments through `integrate` for some situations.

**mix** mixing probability or weight for the Gaussian prior having mean `d0` and variance `v0`. `mix` must be between 0 and 1, inclusive.

**d0** mean of the first Gaussian distribution (only Gaussian for `gbayes1PowerNP` and is a required argument)

**v0** variance of the first Gaussian (only Gaussian for `gbayes1PowerNP` and is a required argument)

**d1** mean of the second Gaussian (if `mix < 1`)

**v1** variance of the second Gaussian (if `mix < 1`). Any of these last 5 arguments can be omitted to `gbayesMixPredNoData` as they can be provided at run time to the function created by `gbayesMixPredNoData`.

**what** specifies whether the predictive density or the CDF is to be computed. Default is "density".
interval

A 2-vector containing the lower and upper limit for possible values of the test statistic \( x \) that would result in a left credible interval exceeding \( \text{delta.w} \) with probability \( 1-\alpha/2 \).

`nsim`

Defaults to zero, causing `gbayesMixPowerNP` to solve numerically for the critical value of \( x \), then to compute the power accordingly. Specify a nonzero number such as 20000 for `nsim` to instead have the function estimate power by simulation. In this case 0.95 confidence limits on the estimated power are also computed. This approach is sometimes necessary if `uniroot` can't solve the equation for the critical value.

**Value**

`gbayes` returns a list of class "`gbayes`" containing the following names elements: `mean.prior`, `var.prior`, `mean.post`, `var.post`, and if `n1` is specified, `mean.pred` and `var.pred`. Note that `mean.pred` is identical to `mean.post`. `gbayes2` returns a single number which is the probability of correctly rejecting the null hypothesis in favor of the new treatment. `gbayesMixPredNoData` returns a function that can be used to evaluate the predictive density or cumulative distribution. `gbayesMixPost` returns a function that can be used to evaluate the posterior density or cdf. `gbayesMixPowerNP` returns a vector containing two values if `nsim = 0`. The first value is the critical value for the test statistic that will make the left credible interval > `delta.w`, and the second value is the power. If `nsim > 0`, it returns the power estimate and confidence limits for it if `nsim > 0`. The examples show how to use these functions.

**Examples**

```r
# Compare 2 proportions using the var stabilizing transformation  
# arcsin(sqrt((x+3/8)/(n+3/4))) (Anscombe), which has variance  
# 1/[(4{n+.5] 

m1 <- 100;  
m2 <- 150
```
```r
deads1 <- 10; deaths2 <- 30

f <- function(events,n) asin(sqrt((events+3/8)/(n+3/4)))
stat <- f(deaths1, m1) - f(deaths2, m2)
var.stat <- function(m1, m2) 1/4/(m1+.5) + 1/4/(m2+.5)
cat("Test statistic:", format(stat," s.d.: ",
     format(sqrt(var.stat(m1, m2))), "\n")
#Use unbiased prior with variance 1000 (almost flat)
b <- gbayes(0, 1000, m1, m2, stat, var.stat, 2*m1, 2*m2)
print(b)
plot(b)
#To get posterior Prob[parameter > w] use
#1-pnorm(w, b$mean.post, sqrt(b$var.post))

#If g(effect, n1, n2) is the power function to
#detect an effect of 'effect' with samples size for groups 1 and 2
#of n1,n2, estimate the expected power by getting 1000 random
#draws from the posterior distribution, computing power for
#each value of the population effect, and averaging the 1000 powers
#This code assumes that g will accept vector-valued 'effect'
#For the 2-sample proportion problem just addressed, 'effect'
#could be taken approximately as the change in the arcsin of
#the square root of the probability of the event

g <- function(effect, n1, n2, alpha=.05) {
  sd <- sqrt(var.stat(n1, n2))
z <- qnorm(1 - alpha/2)
effect <- abs(effect)
  1 - pnorm(z - effect/sd) + pnorm(-z - effect/sd)
}
effects <- rnorm(1000, b$mean.post, sqrt(b$var.post))
powers <- g(effects, 500, 500)
hist(powers, nclass=35, xlab='Power')
describe(powers)

# gbayes2 examples
# First consider a study with a binary response where the
# sample size is n1=500 in the new treatment arm and n2=300
# in the control arm.  The parameter of interest is the
# treated:control log odds ratio, which has variance
# 1/[n1 p1 (1-p1)] + 1/[n2 p2 (1-p2)].  This is not
# really constant so we average the variance over plausible
# values of the probabilities of response p1 and p2.  We
# think that these are between .4 and .6 and we take a
# further short cut
```
v <- function(n1, n2, p1, p2) 1/(n1*p1*(1-p1)) + 1/(n2*p2*(1-p2))
n1 <- 500; n2 <- 300
ps <- seq(.4, .6, length=100)
vguess <- quantile(v(n1, n2, ps, ps), .75)
vguess
#  75%
# 0.2183459

# The minimally interesting treatment effect is an odds ratio
# of 1.1. The prior distribution on the log odds ratio is
# a 50:50 mixture of a vague Gaussian (mean 0, sd 100) and
# an informative prior from a previous study (mean 1, sd 1)

prior <- function(delta)
  0.5*dnorm(delta, 0, 100)+0.5*dnorm(delta, 1, 1)
deltas <- seq(-5, 5, length=150)
plot(deltas, prior(deltas), type='l')

# Now compute the power, averaged over this prior
gbayes2(sqrt(vguess), prior, log(1.1))
# [1] 0.6133338

# See how much power is lost by ignoring the previous
# study completely

gbayes2(sqrt(vguess), function(delta)dnorm(delta, 0, 100), log(1.1))
# [1] 0.4984588

# What happens to the power if we really don't believe the treatment
# is very effective? Let's use a prior distribution for the log
# odds ratio that is uniform between log(1.2) and log(1.3).
# Also check the power against a true null hypothesis

prior2 <- function(delta) dunif(delta, log(1.2), log(1.3))
gbayes2(sqrt(vguess), prior2, log(1.1))
# [1] 0.1385113

gbayes2(sqrt(vguess), prior2, 0)
# [1] 0.3264065

# Compare this with the power of a two-sample binomial test to
# detect an odds ratio of 1.25
For the original prior, consider a new study with equal sample sizes \( n \) in the two arms. Solve for \( n \) to get a power of 0.9. For the variance of the log odds ratio assume a common \( p \) in the center of a range of suspected probabilities of response, 0.3. For this example we use a zero null value and the uniform prior above.

\[
\begin{align*}
v & \leftarrow \text{function}(n) \frac{2}{(n^{.3} \times .7)} \\
pow & \leftarrow \text{function}(n) \ \text{gbayes2}(\text{sqrt}(v(n)), \text{prior2}) \\
\text{uniroot(}\text{function}(n) \ \text{pow}(n)=0.9, c(50,10000)) \ \\
\text{[1]} & \ 2119.675 \\
\text{# Check this value} \\
\text{pow}(2119.675) & \ \\
\text{[1]} & \ 0.9
\end{align*}
\]

Get the posterior density when there is a mixture of two priors, with mixing probability 0.5. The first prior is almost non-informative (normal with mean 0 and variance 10000) and the second has mean 2 and variance 0.3. The test statistic has a value of 3 with variance 0.4.

\[
\begin{align*}
f & \leftarrow \text{gbayesMixPost}(3, 4, \text{mix}=0.5, \ d0=0, \ v0=10000, \ d1=2, \ v1=0.3)
\end{align*}
\]

\text{args}(f)

# Plot this density
\[
\begin{align*}
delta & \leftarrow \text{seq}(-2, 6, \text{length}=150) \\
\text{plot}(\delta, f(\delta), \text{type}='l')
\end{align*}
\]

# Add to the plot the posterior density that used only the almost non-informative prior
lines(\delta, f(\delta, \text{mix}=1), \text{lty}=2)

# The same but for an observed statistic of zero
lines(\delta, f(\delta, \text{mix}=1, \ x=0), \text{lty}=3)

# Derive the CDF instead of the density
\[
\begin{align*}
g & \leftarrow \text{gbayesMixPost}(3, 4, \text{mix}=0.5, \ d0=0, \ v0=10000, \ d1=2, \ v1=0.3, \\
& \quad \text{what='cdf'})
\end{align*}
\]

# Had mix=0 or 1, \text{gbayes1PowerNP} could have been used instead
# of \text{gbayesMixPowerNP} below
# Compute the power to detect an effect of delta=1 if the variance
# of the test statistic is 0.2
gbayesMixPowerNP(g, 1, 0.2, interval=c(-10,12))

# Do the same thing by simulation
gbayesMixPowerNP(g, 1, 0.2, interval=c(-10,12), nsim=20000)

# Compute by what factor the sample size needs to be larger
# (the variance needs to be smaller) so that the power is 0.9
ratios <- seq(1, 4, length=50)
pow <- single(50)
for(i in 1:50)
  pow[i] <- gbayesMixPowerNP(g, 1, 0.2/ratios[i], interval=c(-10,12))[2]

# Solve for ratio using reverse linear interpolation
approx(pow, ratios, xout=0.9)
y

# Check this by computing power
gbayesMixPowerNP(g, 1, 0.2/2.1, interval=c(-10,12))
# So the study will have to be 2.1 times as large as earlier thought

description getsHdata

getHdata

Download and Install Datasets for Hmisc, rms, and Statistical Modeling

Description

This function downloads and makes ready to use datasets from the main web site for the Hmisc and rms libraries. For R, the datasets were stored in compressed save format and getHdata makes them available by running load after download. For S-Plus, the datasets were stored in data.dump format and are made available by running data.restore after import. The dataset is run through the cleanup.import function. Calling getHdata with no file argument provides a character vector of names of available datasets that are currently on the web site. For R, R’s default browser can optionally be launched to view html files that were already prepared using the Hmisc command html(contents()) or to view ‘.txt’ or ‘.html’ data description files when available.

Usage

gethdata(file, what = c("data", "contents", "description", "all"),
         where="http://biostat.mc.vanderbilt.edu/wiki/pub/Main/DataSets")
Arguments

file  an unquoted name of a dataset on the web site, e.g. `prostate`. Omit file to obtain a list of available datasets.
what  specify what="contents" to browse the contents (metadata) for the dataset rather than fetching the data themselves. Specify what="description" to browse a data description file if available. Specify what="all" to retrieve the data and see the metadata and description.
where  URL containing the data and metadata files

Value

gethdata() without a file argument returns a character vector of dataset base names. When a dataset is downloaded, the data frame is placed in search position one and is not returned as value of getHdata.

Examples

```r
## Not run:
getHdata()  # download list of available datasets
gethdata(prostate)  # downloads, load( ) or data.restore( )
                   # runs cleanup.import for S-Plus 6
gethdata(valung, "contents")  # open browser (options(browser="whatever"))
                   # after downloading valung.html
                   # (result of html(contains()))
gethdata(support, "all")  # download and open one browser window
dataDensity(support)
attach(support)  # make individual variables available
gethdata(plasma, "all")  # download and open two browser windows
                   # (description file is available for plasma)

## End(Not run)
```
getRs

Description

The github rscripts project at https://github.com/harrelfe/rscripts contains R scripts that are primarily analysis templates for teaching with RStudio. This function allows the user to print an organized list of available scripts, to download a script and load it into an RStudio script editor window, to list scripts whose major category contains a given string (ignoring case), or to list all major and minor categories.

Usage

getRs(file=NULL, guser='harrelfe', grepo='rscripts', gdir='raw/master', dir=NULL, browse=c('local', 'browser'), cats=FALSE, put=c('rstudio', 'source'))

Arguments

- **file**: a character string containing a script file name. Omit file to obtain a list of available scripts with major and minor categories.
- **guser**: GitHub user name, default is 'harrelfe'
- **grepo**: Github repository name, default is 'rscripts'
- **gdir**: Github directory under which to find retrievable files
- **dir**: directory under grepo in which to find files
- **browse**: When showing the rscripts contents directory, the default is to list in tabular form in the console. Specify browse='browser' to open the online contents in a web browser.
- **cats**: Leave at the default (FALSE) to list whole contents or download a script. Specify cats=TRUE to list major and minor categories available. Specify a character string to list all scripts whose major category contains the string (ignoring case).
- **put**: Leave at the default ('rstudio') to load file into the RStudio script editor window. Use put='source' to source() the file. This is useful when the file just defines a function you want to use in the session.

Value

a data frame or list, depending on arguments

Examples

```r
## Not run:
getRs()  # list available scripts
scripts <- getRs()  # likewise, but store in an object that can easily
                   # be viewed on demand in RStudio
getRs('introda.r')  # download introda.r and put in script editor
getRs(cats=TRUE)    # list available major and minor categories
categories <- getRs(cats=TRUE)
# likewise but store results in a list for later viewing
getRs(cats='reg')   # list all scripts in a major category containing 'reg'
getRs('importREDCap.r', put='source')  # source() to define a function
# source() a new version of the Hmisc package's cut2 function:
getRs('cut2.s', grep='Hmisc', dir='R', put='source')

## End(Not run)
```

getZip

Open a Zip File From a URL.

Description

Allows downloading and reading of a zip file containing one file

Usage

```r
getZip(url, password=NULL)
```

Arguments

- `url` either a path to a local file or a valid URL.
- `password` required to decode password-protected zip files

Details

Allows downloading and reading of zip file containing one file. The file may be password protected.

If a password is needed then one will be requested unless given.

Note: to make password-protected zip file z.zip, do `zip -e z myfile`

Value

Returns a file O/I pipe.

### ggfreqScatter

**Frequency Scatterplot**

**Description**

Uses ggplot2 to plot a scatterplot or dot-like chart for the case where there is a very large number of overlapping values. This works for continuous and categorical x and y. For continuous variables it serves the same purpose as hexagonal binning. Counts for overlapping points are grouped into quantile groups and level of transparency and rainbow colors are used to provide count information. The result can also be passed to `ggplotly`. Actual cell frequencies are added to the hover text in that case.

**Usage**

```r
ggfreqscatter(x, y, bins=50, g=10, cuts=NULL,
               xtrans = function(x) x,
               ytrans = function(y) y,
               xbreaks = pretty(x, 10),
               ybreaks = pretty(y, 10),
               xminor = NULL, yminor = NULL,
               xlab = as.character(substitute(x)),
               ylab = as.character(substitute(y)),
               fcolors = viridis::viridis(10), nsize=FALSE,
               html=FALSE, prfreq=FALSE, ...)
```

**Arguments**

- `x`: x-variable
- `y`: y-variable
- `bins`: for continuous x or y is the number of bins to create by rounding. Ignored for categorical variables. If a 2-vector, the first element corresponds to x and the second to y.
- `g`: number of quantile groups to make for frequency counts. Use g=0 to use frequencies continuously for color and alpha coding. This is recommended only when using `plotly`.
- `cuts`: instead of using g, specify cuts to provide the vector of cuts for categorizing frequencies for assignment to colors
- `xtrans, ytrans`: functions specifying transformations to be made before binning and plotting
xbreaks, ybreaks
vectors of values to label on axis, on original scale
xminor, yminor
values at which to put minor tick marks, on original scale
xlab, ylab
axis labels. If not specified and variable has a label, that label will be used.
fcolors
colors argument to pass to scale_color_gradientn to color code frequencies
nsize
set to TRUE to not vary color or transparency but instead to size the symbols in
relation to the number of points. Best with both x and y are discrete. ggplot2
size is taken as the fourth root of the frequency. If there are 15 or unique
frequencies all the unique frequencies are used, otherwise g quantile groups of
frequencies are used.
html
set to TRUE to use html in axis labels instead of plotmath
prfreq
set to TRUE to print the frequency distributions of the binned coordinate frequen-
cies
... arguments to pass to geom_point such as shape and size

Value
a ggplot object

# Try with y categorical
y1 <- sample(LETTERS[1:10], length(x), TRUE)
**GiniMd**

**Description**

GiniMd computes Gini’s mean difference on a numeric vector. This index is defined as the mean absolute difference between any two distinct elements of a vector. For a Bernoulli (binary) variable with proportion of ones equal to \( p \) and sample size \( n \), Gini’s mean difference is \( \frac{2n}{n-1}p(1-p) \). For a trinomial variable (e.g., predicted values for a 3-level categorical predictor using two dummy variables) having (predicted) values \( A, B, C \) with corresponding proportions \( a, b, c \), Gini’s mean difference is \( \frac{2n}{n-1}[ab|A - B| + ac|A - C| + bc|B - C|] \).

**Usage**

```r
GiniMd(x, na.rm=FALSE)
```

**Arguments**

- **x**
  - a numeric vector (for GiniMd)
- **na.rm**
  - set to TRUE if you suspect there may be NAs in \( x \); these will then be removed. Otherwise an error will result.

**Value**

a scalar numeric

GiniMd(xx)
2*(a*b*abs(A-B) + a*c*abs(A-C) + b*c*abs(B-C))/n/(n-1)

hdquantile  

Harrell-Davis Distribution-Free Quantile Estimator

Description

Computes the Harrell-Davis (1982) quantile estimator and jackknife standard errors of quantiles. The quantile estimator is a weighted linear combination or order statistics in which the order statistics used in traditional nonparametric quantile estimators are given the greatest weight. In small samples the H-D estimator is more efficient than traditional ones, and the two methods are asymptotically equivalent. The H-D estimator is the limit of a bootstrap average as the number of bootstrap resamples becomes infinitely large.

Usage

hdquantile(x, probs = seq(0, 1, .25),
  se = FALSE, na.rm = FALSE, names = TRUE, weights=FALSE)

Arguments

x  
a numeric vector

probs  
vector of quantiles to compute

se  
set to TRUE to also compute standard errors

na.rm  
set to TRUE to remove NAs from x before computing quantiles

names  
set to FALSE to prevent names attributions from being added to quantiles and standard errors
weights set to TRUE to return a "weights" attribution with the matrix of weights used in the H-D estimator corresponding to order statistics, with columns corresponding to quantiles.

Details

A Fortran routine is used to compute the jackknife leave-out-one quantile estimates. Standard errors are not computed for quantiles 0 or 1 (NAs are returned).

Value

A vector of quantiles. If se=TRUE this vector will have an attribute se added to it, containing the standard errors. If weights=TRUE, also has a "weights" attribute which is a matrix.

Examples

set.seed(1)
x <- runif(100)
hdquantile(x, (1:3)/4, se=TRUE)

## Not run:
# Compare jackknife standard errors with those from the bootstrap library(boot)
boot(x, function(x,i) hdquantile(x[i], probs=(1:3)/4), R=400)

## End(Not run)
**hidingTOC**

Moving and Hiding Table of Contents

**Description**

Moving and hiding table of contents for Rmd HTML documents

**Usage**

```r
hidingTOC(buttonLabel = "Contents", levels = 3, tocSide = c("right", "left"), buttonSide = c("right", "left"), posCollapse = c("margin", "top", "bottom"), hidden = FALSE)
```

**Arguments**

- **buttonLabel** the text on the button that hides and unhide the table of contents. Defaults to Contents.
- **levels** the max depth of the table of contents that it is desired to have control over the display of. (defaults to 3)
- **tocSide** which side of the page should the table of contents be placed on. Can be either 'right' or 'left'. Defaults to 'right'
- **buttonSide** which side of the page should the button that hides the TOC be placed on. Can be either 'right' or 'left'. Defaults to 'right'
- **posCollapse** if 'margin' then display the depth select buttons vertically along the side of the page choosen by buttonSide. If 'top' then display the depth select buttons horizontally under the button that hides the TOC. Defaults to 'margin'. 'bottom' is currently unimplemented.
- **hidden** Logical should the table of contents be hidden at page load Defaults to FALSE

**Details**

hidingTOC creates a table of contents in a Rmd document that can be hidden at the press of a button. It also generate buttons that allow the hiding or unhiding of the different level depths of the table of contents.

**Value**

a HTML formatted text string to be inserted into an markdown document

**Author(s)**

Thomas Dupont
Examples

```r
## Not run:
hidingTOC()

## End(Not run)
```

### Description

This function tries to compute the maximum number of histograms that will fit on one page, then it draws a matrix of histograms. If there are more qualifying variables than will fit on a page, the function waits for a mouse click before drawing the next page.

#### Usage

```r
## S3 method for class 'data.frame'
hist(x, n.unique = 3, nclass = "compute",
    na.big = FALSE, rugs = FALSE, freq=TRUE, mtitl = FALSE, ...)
```

#### Arguments

- **x**: a data frame
- **n.unique**: minimum number of unique values a variable must have before a histogram is drawn
- **nclass**: number of bins. Default is \( \max(2, \text{trunc}(\min(n/10, 25 \times \log(n, 10))/2)) \), where \( n \) is the number of non-missing values for a variable.
- **na.big**: set to TRUE to draw the number of missing values on the top of the histogram in addition to in a subtitle. In the subtitle, \( n \) is the number of non-missing values and \( m \) is the number of missing values
- **rugs**: set to TRUE to add rug plots at the top of each histogram
- **freq**: see `hist`. Default is to show frequencies.
- **mtitl**: set to a character string to set aside extra outside top margin and to use the string for an overall title

#### Value

the number of pages drawn

#### Author(s)

hist, scat1d

Examples

d <- data.frame(a=runif(200), b=rnorm(200),
                w=sample(c('green', 'red', 'blue'), 200, TRUE))
hist.data.frame(d)  # in R, just say hist(d)

histbackback

Back to Back Histograms

Description

Takes two vectors or a list with x and y components, and produces back to back histograms of the two datasets.

Usage

histbackback(x, y, brks=NULL, xlab=NULL, axes=TRUE, probability=FALSE,
             xlim=NULL, ylab='', ...)

Arguments

x, y
  either two vectors or a list given as x with two components. If the components have names, they will be used to label the axis (modification FEH).

brks
  vector of the desired breakpoints for the histograms.

xlab
  a vector of two character strings naming the two datasets.

axes
  logical flag stating whether or not to label the axes.

probability
  logical flag: if TRUE, then the x-axis corresponds to the units for a density. If FALSE, then the units are counts.

xlim
  x-axis limits. First value must be negative, as the left histogram is placed at negative x-values. Second value must be positive, for the right histogram. To make the limits symmetric, use e.g. ylim=c(-20, 20).

ylab
  label for y-axis. Default is no label.

... additional graphics parameters may be given.

Value

A list is returned invisibly with the following components:

left
  the counts for the dataset plotted on the left.

right
  the counts for the dataset plotted on the right.

breaks
  the breakpoints used.
histboxp

Side Effects

A plot is produced on the current graphics device.

Examples

options(digits=3)
set.seed(1)
histbackback(rnorm(20), rnorm(30))

fool <- list(x=rnorm(40), y=rnorm(40))
histbackback(fool)
age <- rnorm(1000,50,10)
sex <- sample(c('female','male'),1000,TRUE)
histbackback(split(age, sex))
agef <- age[sex=='female']; agem <- age[sex=='male']
histbackback(list(Female=agef,Male=agem), probability=TRUE, xlim=c(-.06,.06))

Description

Uses plotly to draw horizontal spike histograms stratified by group, plus the mean (solid dot) and vertical bars for these quantiles: 0.05 (red, short), 0.25 (blue, medium), 0.50 (black, long), 0.75 (blue, medium), and 0.95 (red, short). The robust dispersion measure Gini’s mean difference and the SD may optionally be added. These are shown as horizontal lines starting at the minimum value of x having a length equal to the mean difference or SD. Even when Gini’s and SD are computed, they are not drawn unless the user clicks on their legend entry.

Spike histograms have the advantage of effectively showing the raw data for both small and huge datasets, and unlike box plots allow multi-modality to be easily seen.

histboxpm plots multiple histograms stacked vertically, for variables in a data frame having a common group variable (if any) and combined using plotly::subplot.

dhistboxp is like histboxp but no plotly graphics are actually drawn. Instead, a data frame suitable for use with plotly::subplot is returned. For dhistboxp an additional level of stratification strata is implemented. group causes a different result here to produce back-to-back histograms (in the case of two groups) for each level of strata.
Usage

\[
\text{histboxp}(p = \text{plotly}\!:\!\text{plot}\_\!\text{ly}(height=height), x, group = \text{NULL}, \\
\quad \text{xlab}=\text{NULL}, \text{gmd}=\text{TRUE}, \text{sd}=\text{FALSE}, \text{bins} = 100, \text{wmax}=190, \text{mult}=7, \\
\quad \text{connect}=\text{TRUE}, \text{showlegend}=\text{TRUE})
\]

\[
\text{dhistboxp}(x, \text{group} = \text{NULL}, \text{strata}=\text{NULL}, \text{xlab}=\text{NULL}, \\
\quad \text{gmd}=\text{FALSE}, \text{sd}=\text{FALSE}, \text{bins} = 100, \text{nmin}=5, \text{ff1}=1, \text{ff2}=1)
\]

\[
\text{histboxpM}(p=\text{plotly}\!:\!\text{plot}\_\!\text{ly}(height=height), x, \text{group}=\text{NULL}, \\
\quad \text{gmd}=\text{TRUE}, \text{sd}=\text{FALSE}, \text{nrows}=\text{NULL}, \text{ncols}=\text{NULL}, \ldots)
\]

Arguments

- \text{p} \quad \text{plotly} \text{ graphics object if already begun}
- \text{x} \quad \text{a numeric vector, or for histboxpM a numeric vector or a data frame of numeric vectors, hopefully with label and units attributes}
- \text{group} \quad \text{a discrete grouping variable. If omitted, defaults to a vector of ones}
- \text{strata} \quad \text{a discrete numeric stratification variable. Values are also used to space out different spike histograms. Defaults to a vector of ones.}
- \text{xlab} \quad \text{x-axis label, defaults to labelled version include units of measurement if any}
- \text{gmd} \quad \text{set to FALSE to not compute Gini’s mean difference}
- \text{sd} \quad \text{set to TRUE to compute the SD}
- \text{nrows} \quad \text{number of rows for layout of multiple plots}
- \text{ncols} \quad \text{number of columns for layout of multiple plots. At most one of nrows, ncols should be specified.}
- \text{bins} \quad \text{number of equal-width bins to use for spike histogram. If the number of distinct values of x is less than bins, the actual values of x are used.}
- \text{nmin} \quad \text{minimum number of non-missing observations for a group-stratum combination before the spike histogram and quantiles are drawn}
- \text{ff1, ff2} \quad \text{fudge factors for position and bar length for spike histograms}
- \text{wmax, mult} \quad \text{tweaks for margin to allocate}
- \text{connect} \quad \text{set to FALSE to suppress lines connecting quantiles}
- \text{showlegend} \quad \text{used if producing multiple plots to be combined with subplot; set to FALSE for all but one plot}
- \ldots \quad \text{other arguments for histboxpM that are passed to histboxp}

Value

- \text{a plotly object. For dhistboxp a data frame as expected by plotlyM}

### Description

The Hmisc library contains many functions useful for data analysis, high-level graphics, utility operations, functions for computing sample size and power, translating SAS datasets into R, imputing missing values, advanced table making, variable clustering, character string manipulation, conversion of R objects to LaTeX code, recoding variables, and bootstrap repeated measures analysis. Most of these functions were written by F Harrell, but a few were collected from statlib and from s-news; other authors are indicated below. This collection of functions includes all of Harrell’s submissions to statlib other than the functions in the `rms` and display libraries. A few of the functions do not have “Help” documentation.

To make Hmisc load silently, issue `options(hverbose=FALSE)` before `library(Hmisc)`.

</tbody>
</table>
(narrower!) score stat.-based Wilson interval
(Rollin Brant, mod. FEH)

bootkm Bootstrap Kaplan-Meier survival or quantile estimates
bpower Approximate power of 2-sided test for 2 proportions
Includes bpower.sim for exact power by simulation
bpplot Box-Percentile plot
(Jeffrey Banfield, <umsfjban@bill.oscs.montana.edu>)
bpplotM Chart extended box plots for multiple variables
bsamsize Sample size requirements for test of 2 proportions
bystats Statistics on a single variable by levels of >=1 factors
bystats2 2-way statistics
character.table Shows numeric equivalents of all latin characters
Useful for putting many special chars. in graph titles
(Pierre Joyet, <pierre.joyet@bluewin.ch>)
ciapower Power of Cox interaction test
cleanup.import More compactly store variables in a data frame, and clean up
problem data when e.g. Excel spreadsheet had a non-
umeric value in a numeric column
combine.levels Combine infrequent levels of a categorical variable
confbar Draws confidence bars on an existing plot using multiple
confidence levels distinguished using color or gray scale
contents Print the contents (variables, labels, etc.) of a data frame
cpower Power of Cox 2-sample test allowing for noncompliance
Cs Vector of character strings from list of unquoted names
csv.get Enhanced importing of comma separated files labels
cut2 Like cut with better endpoint label construction and allows
construction of quantile groups or groups with given n
datadensity Snapshot graph of distributions of all variables in
a data frame. For continuous variables uses scat1d.
dataRep Quantify representation of new observations in a database
ddmmmyy SAS “date7” output format for a chron object
deff Kish design effect and intra-cluster correlation
describe Function to describe different classes of objects.
Invoke by saying describe(object). It calls one of the
following:
describe.data.frame Describe all variables in a data frame (generalization
of SAS UNIVARIATE)
describe.default Describe a variable (generalization of SAS UNIVARIATE)
dotplot3 A more flexible version of dotplot
Dotplot Enhancement of Trellis dotplot allowing for matrix
x-var., auto generation of Key function, superposition
drawPlot Simple mouse-driven drawing program, including a function
for fitting Bezier curves
Ecdf Empirical cumulative distribution function plot
errbar Plot with error bars (Charles Geyer, U. Chi., mod FEH)
event.chart Plot general event charts (Jack Lee, <jjlee@mdanderson.org>,
Ken Hess, Joel Dubin; Am Statistician 54:63-70,2000)
event.history Event history chart with time-dependent cov. status
find.matches Find matches (with tolerances) between columns of 2 matrices
first.word Find the first word in an \texttt{R} expression (R Heiberger)
fit.mult.impute Fit most regression models over multiple transcan imputations, compute imputation-adjusted variances and avg. betas
format.df Format a matrix or data frame with much user control (R Heiberger and FE Harrell)
ftupwr Power of 2-sample binomial test using Fleiss, Tytun, Ury
ftuss Sample size for 2-sample binomial test using "Fleiss, Tytun, Ury"

(Both by Dan Heitjan, <dheitjan@biostats.hmc.psu.edu>)

gbayes Bayesian posterior and predictive distributions when both the prior and the likelihood are Gaussian
getHdata Fetch and list datasets on our web site
hdquantile Harrell-Davis nonparametric quantile estimator with s.e.
histbackback Back-to-back histograms (Pat Burns, Salomon Smith Barney, London, <pburns@dorado.sbi.com>)
hist.data.frame Matrix of histograms for all numeric vars. in data frame
Use \texttt{hist.data.frame(data.frame.name)}
histSpike Add high-resolution spike histograms or density estimates to an existing plot
hoeffd Hoeffding’s D test (omnibus test of independence of X and Y)
impute Impute missing data (generic method)
interaction More flexible version of \texttt{builtin} function
is.present Tests for non-blank character values or non-NA numeric values
james.stein James-Stein shrinkage estimates of cell means from raw data
labcurve Optimally label a set of curves that have been drawn on an existing plot, on the basis of gaps between curves.
Also position legends automatically at emptiest rectangle.
label Set or fetch a label for an \texttt{R}-object
Lag Lag a vector, padding on the left with NA or ""
llatex Convert an \texttt{R} object to LaTeX (R Heiberger & FE Harrell)
list.tree Pretty-print the structure of any data object (Alan Zaslavsky, <zaslavsky@hcp.med.harvard.edu>)
Load Enhancement of \texttt{load}
mask 8-bit logical representation of a short integer value (Rick Becker)
matchCases Match each case on one continuous variable
matxv Fast matrix * vector, handling intercept(s) and NAs
mgp.axis Version of \texttt{axis}() that uses appropriate \texttt{mgp} from \texttt{mgp.axis.labels} and gets around bug in \texttt{axis(2, ...)} that causes it to assume las=1
mgp.axis.labels Used by \texttt{survplot} and \texttt{plot} in \texttt{rms} library (and other functions in the future) so that different spacing between tick marks and axis tick mark labels may be specified for x- and y-axes.
Use \texttt{mgp.axis.labels("default")} to set defaults.
Users can set values manually using \texttt{mgp.axis.labels(x,y)} where x and y are 2nd value of
par('mgp') to use. Use mgp.axis.labels(type=w) to
retrieve values, where w='x', 'y', 'x and y', 'xy',
to get 3 mgp values (first 3 types) or 2 mgp.axis.labels.
minor.tick Add minor tick marks to an existing plot
mtitle Add outer titles and subtitles to a multiple plot layout
multLines Draw multiple vertical lines at each x
in a line plot
%nin% Opposite of %in%
nobsY Compute no. non-NA observations for left hand formula side
nomiss Return a matrix after excluding any row with an NA
panel.bpplot Panel function for trellis bwplot - box-percentile plots
panel.plsmo Panel function for trellis xyplot - uses plsmo
pBlock Block variables for certain lattice charts
pc1 Compute first prin. component and get coefficients on
original scale of variables
plotCorrPrecision Plot precision of estimate of correlation coefficient
plsmo Plot smoothed x vs. y with labeling and exclusion of NAs
Also allows a grouping variable and plots unsmoothed data
popower Power and sample size calculations for ordinal responses
(two treatments, proportional odds model)
prn prn(expression) does print(expression) but titles the
output with 'expression'. Do prn(expression,txt) to add
a heading ('txt') before the 'expression' title
pstamp Stamp a plot with date in lower right corner (pstamp())
Add ,pwd=T and/or ,time=T to add current directory
name or time
Put additional text for label as first argument, e.g.
pstamp('Figure 1') will draw 'Figure 1 date'
putKey Different way to use key()
putKeyEmpty Put key at most empty part of existing plot
rcorr Pearson or Spearman correlation matrix with pairwise deletion
of missing data
rcorr.cens Somers’ Dxy rank correlation with censored data
rcorrp.cens Assess difference in concordance for paired predictors
rcspline.eval Evaluate restricted cubic spline design matrix
rcspline.plot Plot spline fit with nonparametric smooth and grouped estimates
rcspline.restate Restate restricted cubic spline in unrestricted form, and
create TeX expression to print the fitted function
reShape Reshape a matrix into 3 vectors, reshape serial data
rm.boot Bootstrap spline fit to repeated measurements model,
with simultaneous confidence region - least
squares using spline function in time
rMultinom Generate multinomial random variables with varying prob.
samplesize.bin Sample size for 2-sample binomial problem
(Rick Chappell, <chappell@stat.wisc.edu>)
sas.get Convert SAS dataset to S data frame
sasxport.get Enhanced importing of SAS transport dataset in R
Save Enhancement of save
scat1d  Add 1-dimensional scatterplot to an axis of an existing plot
   (like bar-codes, FEH/Martin Maechler,
   <maechler@stat.math.ethz.ch>/Jens Oehlschlaegel-Akiyoshi,
   <oehl@psyres-stuttgart.de>)
score.binary Construct a score from a series of binary variables or
   expressions
sedit A set of character handling functions written entirely
   in R. sedit() does much of what the UNIX sed
   program does. Other functions included are
   substring.location, substring<-, replace.string.wild,
   and functions to check if a string is numeric or
   contains only the digits 0-9
setTrellis Set Trellis graphics to use blank conditioning panel strips,
   line thickness 1 for dot plot reference lines:
   setTrellis(); 3 optional arguments
show.col Show colors corresponding to col=0,1,...,99
show.pch Show all plotting characters specified by pch=.
   Just type show.pch() to draw the table on the
   current device.
showPsfrag Use LaTeX to compile, and dvips and ghostview to
   display a postscript graphic containing psfrag strings
solvet Version of solve with argument tol passed to qr
somers2 Somers’ rank correlation and c-index for binary y
spearman Spearman rank correlation coefficient spearman(x,y)
spearman.test Spearman 1 d.f. and 2 d.f. rank correlation test
spearman2 Spearman multiple d.f. $\rho^2$, adjusted $\rho^2$, Wilcoxon-Kruskal-
   Wallis test, for multiple predictors
spower Simulate power of 2-sample test for survival under
   complex conditions
   Also contains the Gompertz2,Weibull2,Lognorm2 functions.
spss.get Enhanced importing of SPSS files using read.spss function
src src(name) = source("name.s") with memory
store store an object permanently (easy interface to assign function)
strmatch Shortest unique identifier match
   (Terry Therneau, <therneau@mayo.edu>)
subset More easily subset a data frame
substi Substitute one var for another when observations NA
summarize Generate a data frame containing stratified summary
   statistics. Useful for passing to trellis.
summary.formula General table making and plotting functions for summarizing
   data
summaryD Summarizing using user-provided formula and dotchart3
summaryM Replacement for summary.formula(..., method='reverse')
summaryP Multi-panel dot chart for summarizing proportions
summaryS Summarize multiple response variables for multi-panel
   dot chart or scatterplot
summaryRc Summary for continuous variables using lowess
symbol.freq X-Y Frequency plot with circles’ area prop. to frequency
sys
Execute unix() or dos() depending on what's running

tabulr
Front-end to tabular function in the tables package

tex
Enclose a string with the correct syntax for using
with the LaTeX psfrag package, for postscript graphics

transace
ace() packaged for easily automatically transforming all
variables in a matrix

transcan
automatic transformation and imputation of NAs for a
series of predictor variables

trap.rule
Area under curve defined by arbitrary x and y vectors,
using trapezoidal rule

trellis.strip.blank
To make the strip titles in trellis more visible, you can
make the backgrounds blank by saying trellis.strip.blank().
Use before opening the graphics device.

t.test.cluster
2-sample t-test for cluster-randomized observations

unbind
Form individual variables from a matrix

upData
Update a data frame (change names, labels, remove vars, etc.)

units
Set or fetch "units" attribute - units of measurement for var.

varclus
Graph hierarchical clustering of variables using squared
Pearson or Spearman correlations or Hoeffding D as similarities
Also includes the naclus function for examining similarities in
patterns of missing values across variables.

wtd.mean

wtd.var

wtd.quantile

wtd.Ecdf

wtd.table

wtd.rank

wtd.loess.noiter

num.denom.setup
Set of function for obtaining weighted estimates

xy.group
Compute mean x vs. function of y by groups of x

xyplot
Like trellis xyplot but supports error bars and multiple
response variables that are connected as separate lines

ynbind
Combine a series of yes/no true/false present/absent variables into a matrix

zoom
Zoom in on any graphical display
(Bill Dunlap, <bill@statsci.com>)

hoeffd

Matrix of Hoeffding’s D Statistics

Description

Computes a matrix of Hoeffding’s (1948) D statistics for all possible pairs of columns of a matrix. D is a measure of the distance between F(x, y) and G(x)H(y), where F(x, y) is the joint CDF of x and y, and G and H are marginal CDFs. Missing values are deleted in pairs rather than deleting all rows of x having any missing variables. The D statistic is robust against a wide variety of alternatives to independence, such as non-monotonic relationships. The larger the value of D, the more dependent are x and y (for many types of dependencies). D used here is 30 times Hoeffding’s original D, and ranges from -0.5 to 1.0 if there are no ties in the data. print.hoeffd prints the information derived by hoeffd. The higher the value of D, the more dependent are x and y. hoeffd also computes the mean and maximum absolute values of the difference between the joint empirical CDF and the product of the marginal empirical CDFs.

Usage

hoeffd(x, y)

# S3 method for class 'hoeffd'
print(x, ...)

Usage

hoeffd(x, y)

# S3 method for class 'hoeffd'
print(x, ...)

Usage

hoeffd(x, y)

# S3 method for class 'hoeffd'
print(x, ...)
Arguments

x  a numeric matrix with at least 5 rows and at least 2 columns (if y is absent), or an object created by hoeffd
y  a numeric vector or matrix which will be concatenated to x
... ignored

Details

Uses midranks in case of ties, as described by Hollander and Wolfe. P-values are approximated by linear interpolation on the table in Hollander and Wolfe, which uses the asymptotically equivalent Blum-Kiefer-Rosenblatt statistic. For $P < .0001$ or $> .5$, P values are computed using a well-fitting linear regression function in $\log P$ vs. the test statistic. Ranks (but not bivariate ranks) are computed using efficient algorithms (see reference 3).

Value

a list with elements $D$, the matrix of D statistics, $n$ the matrix of number of observations used in analyzing each pair of variables, and $P$, the asymptotic P-values. Pairs with fewer than 5 non-missing values have the D statistic set to NA. The diagonals of $n$ are the number of non-NAs for the single variable corresponding to that row and column.

**html**

*Convert an S object to HTML*

**Description**

html is a generic function, for which only two methods are currently implemented, `html.latex` and a rudimentary `html.data.frame`. The former uses the HeVeA LaTeX to HTML translator by Maranget to create an HTML file from a LaTeX file like the one produced by `latex`. `html.default` just runs `html.data.frame`. `htmlVerbatim` prints all of its arguments to the console in an html verbatim environment, using a specified percent of the prevailing character size. This is useful for R Markdown with knitr.

Most of the html-producing functions in the Hmisc and rms packages return a character vector passed through `htmltools::html` so that knitr will correctly format the result without the need for the user putting `results='asis'` in the chunk header.

**Usage**

```r
html(object, ...)  
## S3 method for class 'latex'
html(object, file, where=c('cwd', 'tmp'),  
     method=c('hevea', 'htlatex'),  
     rmarkdown=FALSE, cleanup=TRUE, ...)
## S3 method for class 'data.frame'
html(object,  
     file=paste(first.word(deparse(substitute(object))),'html',sep='.'), header,  
     caption=NULL, rownames=FALSE, align='r', align.header='c',  
     bold.header=TRUE, col.header='Black',  
     border=2, width=NULL, size=100, translate=FALSE,  
     append=FALSE, link=NULL, linkCol=1,  
     linkType=c('href','name'), ...)
## Default S3 method:
html(object,  
     file=paste(first.word(deparse(substitute(object))),'html',sep='.'),  
     append=FALSE, link=NULL, linkCol=1, linkType=c('href','name'), ...)
htmlVerbatim(, size=75, width=85, scroll=FALSE, rows=10, cols=100,  
     propts=NULL, omit1b=FALSE)
```
Arguments

object  a data frame or an object created by \texttt{latex}. For the generic \texttt{html} is any object for which an \texttt{html} method exists.

file  name of the file to create. The default file name is \texttt{object.html} where \texttt{object} is the first word in the name of the argument for \texttt{object}. For \texttt{html.latex} specify \texttt{file=''} or \texttt{file=character(0)} to print html code to the console, as when using \texttt{knitr}. For the \texttt{data.frame} method, \texttt{file} may be set to \texttt{FALSE} which causes a character vector enclosed in \texttt{htmltools::HTML} to be returned instead of writing to the console.

where  for \texttt{html}. Default is to put output files in current working directory. Specify \texttt{where='tmp'} to put in a system temporary directory area.

method  default is to use system command \texttt{hevea} to convert from \LaTeX{} to html. Specify \texttt{method='htlatex'} to use system command \texttt{htlatex}, assuming the system package \texttt{TeX4ht} is installed.

rmarkdown  set to \texttt{TRUE} if using RMarkdown (usually under \texttt{knitr} and RStudio). This causes \texttt{html} to be packaged for RMarkdown and output to go into the console stream. \texttt{file} is ignored when \texttt{rmarkdown=TRUE}.

cleanup  if using \texttt{method='htlatex'} set to \texttt{FALSE} if \texttt{where='cwd'} to prevent deletion of auxiliary files created by \texttt{htlatex} that are not needed when using the final \texttt{html} document (only the \texttt{.css} file is needed in addition to \texttt{.html}). If using \texttt{method='hevea'}, \texttt{cleanup=TRUE} causes deletion of the generated \texttt{.haux} file.

header  vector of column names. Defaults to names in \texttt{object}. Set to \texttt{NULL} to suppress column names.

caption  a character string to be used as a caption before the table

rownames  set to \texttt{FALSE} to ignore row names even if they are present

align  alignment for table columns (all are assumed to have the same if is a scalar). Specify "c", "r", "l" for center, right, or left alignment.

align.header  same coding as for \texttt{align} but pertains to header

bold.header  set to \texttt{FALSE} to not bold face column headers

col.header  color for column headers

border  set to 0 to not include table cell borders, 1 to include only outer borders, or 2 (the default) to put borders around cells too

translate  set to \texttt{TRUE} to run header and table cell text through the \texttt{htmlTranslate} function

width  optional table width for \texttt{html.data.frame}. For full page width use \texttt{width="100\%"}, for use in \texttt{options()} for printing objects.

size  a number between 0 and 100 representing the percent of the prevailing character size to be used by \texttt{htmlVerbatim} and the data frame method.

append  set to \texttt{TRUE} to append to an existing file

link  character vector specifying hyperlink names to attach to selected elements of the matrix or data frame. No hyperlinks are used if \texttt{link} is omitted or for elements of \texttt{link} that are "". To allow multiple links per \texttt{link}, \texttt{link} may also be a character matrix shaped as \texttt{object} in which case \texttt{linkCol} is ignored.
linkCol  column number of object to which hyperlinks are attached. Defaults to first column.

linkType  defaults to "href"

... ignored except for htmlVerbatim - is a list of objects to print()

scroll  set to TRUE to put the html in a scrollable textarea

rows,cols  the number of rows and columns to devote to the visible part of the scrollable box

propts  options, besides quote=FALSE to pass to the print method, for htmlVerbatim

omit1b  for htmlVerbatim if TRUE causes an initial line of output that is all blank to be deleted

Generic Functions and Methods for Imputation

Description

These functions do simple and transcan imputation and print, summarize, and subscript variables that have NAs filled-in with imputed values. The simple imputation method involves filling in NAs with constants, with a specified single-valued function of the non-NAs, or from a sample (with replacement) from the non-NA values (this is useful in multiple imputation). More complex imputations can be done with the transcan function, which also works with the generic methods shown here, i.e., impute can take a transcan object and use the imputed values created by transcan (with imputed=TRUE) to fill in NAs. The print method places * after variable values that were imputed. The summary method summarizes all imputed values and then uses the next summary method available for the variable. The subscript method preserves attributes of the variable and subsets the list of imputed values corresponding with how the variable was subsetted. The is.imputed function is for checking if observations are imputed.

Usage

impute(x, ...)

## Default S3 method:
impute(x, fun=median, ...)

## S3 method for class 'impute'
print(x, ...)

## S3 method for class 'impute'
summary(object, ...)

is.imputed(x)

Arguments

x a vector or an object created by transcan, or a vector needing basic unconditional imputation. If there are no NAs and x is a vector, it is returned unchanged.

fun the name of a function to use in computing the (single) imputed value from the non-NAs. The default is median. If instead of specifying a function as fun, a single value or vector (numeric, or character if object is a factor) is specified, those values are used for insertion. fun can also be the character string "random" to draw random values for imputation, with the random values not forced to be the same if there are multiple NAs. For a vector of constants, the vector must be of length one (indicating the same value replaces all NAs) or must be as long as the number of NAs, in which case the values correspond to consecutive NAs to replace. For a factor object, constants for imputation may include character values not in the current levels of object. In that case new levels are added. If
object is of class "factor", fun is ignored and the most frequent category is used for imputation.

object an object of class "impute"

Value

a vector with class "impute" placed in front of existing classes. For is.imputed, a vector of logical values is returned (all TRUE if object is not of class impute).

Examples

age <- c(1,2,NA,4)
age.i <- impute(age)
# Could have used impute(age,2.5), impute(age,mean), impute(age,"random")
age.i
summary(age.i)
is.imputed(age.i)

knitrSet Sets up knitr to use better default parameters for base graphics, better code formatting, and to allow several arguments to be passed from code chunk headers, such as bty, mfrow, ps, bot (extra bottom margin for base graphics), top (extra top margin), left (extra left margin), rt (extra right margin), lwd, mgp, las, tcl, axes, xpd, h (usually fig.height in knitr), w (usually fig.width in knitr), wo (out.width in knitr), ho (out.height in knitr), cap (character string containing figure caption), scap (character string containing short figure caption for table of figures).

plotlySave saves a plotly graphic with name foo.png where foo is the name of the current chunk. You must have a free plotly account from plot.ly to use this function, and you must have run Sys.setenv(plotly_username="your_plotly_username") and Sys.setenv(plotly_api_key="your_api_key"). The API key can be found in one’s profile settings.
Usage

knitrSet(basename=NULL, w=if(! bd) 4, h=if(! bd) 3, wo=NULL, ho=NULL,
fig.path=if(length(basename)) basename else '',
fig.align=if(! bd) 'center', fig.show='hold',
fig.pos=if(! bd) 'htbp',
fig.lp=if(! bd) paste('fig', basename, sep=':'),
dev=switch(lang, latex='pdf', markdown='png', blogdown=NULL),
tidy=FALSE, error=FALSE,
messages=c('messages.txt', 'console'),
width=61, decinline=5, size=NULL, cache=FALSE,
echo=TRUE, results='markup', lang=c('latex','markdown','blogdown'))

plotlySave(x, ...)

Arguments

basename base name to be added in front of graphics file names. basename is followed by a minus sign.
w, h default figure width and height in inches
wo, ho default figure rendering width and height, in integer pixels or percent as a character string, e.g. '40%'
fig.path path for figures. To put figures in a subdirectory specify e.g. fig.path='folder/' Ignored for blogdown.
fig.align, fig.show, fig.pos, fig.lp, tidy, cache, echo, results, error, size see knitr documentation
dev graphics device, with default figured from lang
messages By default warning and other messages such as those from loading packages are sent to file 'messages.txt' in the current working directory. You can specify messages='console' to send them directly to the console.
width text output width for R code and output
decinline number of digits to the right of the decimal point to round numeric values appearing inside Sexpr
lang Default is 'latex' to use LaTeX. Set to 'markdown' when using R Markdown or 'blogdown'. For 'blogdown' par and knitr graphics-related hooks are not called as this would prevent blogdown from putting graphics files in the correct directory for the blog system.
x a plotly graphics object or a named list of such objects. The resulting png file will go in the file path given by the knitr fig.path value, and have a base name equal to the current knitr chunk name. If x is a list, a minus sign followed by the chunk name are inserted before .png.
...
additional arguments passed to plotly::plotly_IMAGE

labcurve

Label Curves, Make Keys, and Interactively Draw Points and Curves

Description

labcurve optionally draws a set of curves then labels the curves. A variety of methods for drawing labels are implemented, ranging from positioning using the mouse to automatic labeling to automatic placement of key symbols with manual placement of key legends to automatic placement of legends. For automatic positioning of labels or keys, a curve is labeled at a point that is maximally separated from all of the other curves. Gaps occurring when curves do not start or end at the same x-coordinates are given preference for positioning labels. If labels are offset from the curves (the default behaviour), if the closest curve to curve i is above curve i, curve i is labeled below its line. If the closest curve is below curve i, curve i is labeled above its line. These directions are reversed if the resulting labels would appear outside the plot region.

Both ordinary lines and step functions are handled, and there is an option to draw the labels at the same angle as the curve within a local window.

Unless the mouse is used to position labels or plotting symbols are placed along the curves to distinguish them, curves are examined at 100 (by default) equally spaced points over the range of x-coordinates in the current plot area. Linear interpolation is used to get y-coordinates to line up (step function or constant interpolation is used for step functions). There is an option to instead examine all curves at the set of unique x-coordinates found by unioning the x-coordinates of all the curves. This option is especially useful when plotting step functions. By setting adj="auto" you can have labcurve try to optimally left- or right-justify labels depending on the slope of the curves.
at the points at which labels would be centered (plus a vertical offset). This is especially useful when labels must be placed on steep curve sections.

You can use the on top method to write (short) curve names directly on the curves (centered on the y-coordinate). This is especially useful when there are many curves whose full labels would run into each other. You can plot letters or numbers on the curves, for example (using the keys option), and have labcurve use the key function to provide long labels for these short ones (see the end of the example). There is another option for connecting labels to curves using arrows. When keys is a vector of integers, it is taken to represent plotting symbols (pch's), and these symbols are plotted at equally-spaced x-coordinates on each curve (by default, using 5 points per curve). The points are offset in the x-direction between curves so as to minimize the chance of collisions.

To add a legend defining line types, colors, or line widths with no symbols, specify keys="lines", e.g., labcurve(curves, keys="lines", lty=1:2).

putKey provides a different way to use key() by allowing the user to specify vectors for labels, line types, plotting characters, etc. Elements that do not apply (e.g., pch for lines (type="1")) may be NA. When a series of points is represented by both a symbol and a line, the corresponding elements of both pch and lty, col., or lwd will be non-missing.

putKeyEmpty, given vectors of all the x-y coordinates that have been plotted, uses largest.empty to find the largest empty rectangle large enough to hold the key, and draws the key using putKey.

drawPlot is a simple mouse-driven function for drawing series of lines, step functions, polynomials, Bezier curves, and points, and automatically labeling the point groups using labcurve or putKeyEmpty. When drawPlot is invoked it creates temporary functions Points, Curve, and abline. The user calls these functions inside the call to drawPlot to define groups of points in the order they are defined with the mouse. abline is used to call abline and not actually great a group of points. For some curve types, the curve generated to represent the corresponding series of points is drawn after all points are entered for that series, and this curve may be different than the simple curve obtained by connecting points at the mouse clicks. For example, to draw a general smooth Bezier curve the user need only click on a few points, and she must overshoot the final curve coordinates to define the curve. The originally entered points are not erased once the curve is drawn. The same goes for step functions and polynomials. If you plot() the object returned by drawPlot, however, only final curves will be shown. The last examples show how to use drawPlot.

The largest.empty function finds the largest rectangle that is large enough to hold a rectangle of a given height and width, such that the rectangle does not contain any of a given set of points. This is used by labcurve and putKeyEmpty to position keys at the most empty part of an existing plot. The default method was created by Hans Borchers.

Usage

labcurve(curves, labels=names(curves),
            method=NULL, keys=NULL, key.loc=c("auto","none"),
            type="1", step.type=c("left","right"),
            xmethod=if(any(type=="s")) "unique" else "grid",
            offset=NULL, xlim=NULL,
            tilt=FALSE, window=NULL, npts=100, cex=NULL,
            adj="auto", angle.adj.auto=30,
            lty=pr$lty, lwd=pr$lwd, col.=pr$col, transparent=TRUE,
            arrow.factor=1, point.inc=NULL, opts=NULL, key.opts=NULL,
            empty.method=c("area",'maxdim' ), numbins=25,
Arguments

curves a list of lists, each of which have at least two components: a vector of x values and a vector of corresponding y values. curves is mandatory except when method=“mouse” or “locator”, in which case labels is mandatory. Each list in curves may optionally have any of the parameters type, lty, lwd, or col for that curve, as defined below (see one of the last examples).
z

For `labcurve`, a vector of character strings used to label curves (which may contain newline characters to stack labels vertically). The default labels are taken from the names of the curves list. Setting `labels=FALSE` will suppress drawing any labels (for `labcurve` only). For `putKey` and `putKeyEmpty` is a vector of character strings specifying group labels.

x

y

For `putKeyEmpty` and `largest.empty`, x and y are same-length vectors specifying points that have been plotted. x can also be an object created by `drawPlot`.

... For `drawPlot` is a series of invocations of `Points` and `Curve` (see example). Any number of point groups can be defined in this way. For `Abline` these may be any arguments to `abline`. For `labcurve`, other parameters to pass to `text`.

width

height

for `largest.empty`, specifies the minimum allowable width in x units and the minimum allowable height in y units.

method

"offset" (the default) offsets labels at largest gaps between curves, and draws labels beside curves. "on top" draws labels on top of the curves (especially good when using keys). "arrow" draws arrows connecting labels to the curves. "mouse" or "locator" positions labels according to mouse clicks. If keys is specified and is an integer vector or is "lines", method defaults to "on top". If keys is character, method defaults to "offset". Set `method="none"` to suppress all curve labeling and key drawing, which is useful when `pl=TRUE` and you only need `labcurve` to draw the curves and the rest of the basic graph.

For `largest.empty` specifies the method a rectangle that does not collide with any of the (x, y) points. The default method, 'exhaustive', uses a Fortran translation of an R function and algorithm developed by Hans Borchers. The same result, more slowly, may be obtained by using pure R code by specifying `method='rexhaustive'`. The original algorithms using binning (and the only methods supported for S-Plus) are still available. For all methods, screening of candidate rectangles having at least a given width in x-units of width or having at least a given height in y-units of height is possible. Use `method="area"` to use the binning method to find the rectangle having the largest area, or `method="maxdim"` to use the binning method to return with last rectangle searched that had both the largest width and largest height over all previous rectangles.

keys

This causes keys (symbols or short text) to be drawn on or beside curves, and if `keyloc` is not equal to "none", a legend to be automatically drawn. The legend links keys with full curve labels and optionally with colors and line types. Set keys to a vector of character strings, or a vector of integers specifying plotting character (pch values - see `points`). For the latter case, the default behavior is to plot the symbols periodically, at equally spaced x-coordinates.

keyloc

When `keys` is specified, `keyloc` specifies how the legend is to be positioned for drawing using the `key` function in `trellis`. The default is "auto", for which the `largest.empty` function to used to find the most empty part of the plot. If no empty rectangle large enough to hold the key is found, no key will be
drawn. Specify keyloc="none" to suppress drawing a legend, or set keyloc
to a 2-element list containing the x and y coordinates for the center of the
legend. For example, use keyloc=locator(1) to click the mouse at the cen-
ter. keyloc specifies the coordinates of the center of the key to be drawn with
plot.drawPlot when key=TRUE.

**type**

for labcurve, a scalar or vector of character strings specifying the method that
the points in the curves were connected. "1" means ordinary connections be-
tween points and "s" means step functions. For putKey and putKeyEmpty is a
vector of plotting types, "1" for regular line, "p" for point, "b" for both point
and line, and "n" for none. For Points is either "p" (the default) for regular
points, or "r" for rugplot (one-dimensional scatter diagram to be drawn using
the scatPlot function). For Curve, type is "bezier" (the default) for drawing
a smooth Bezier curves (which can represent a non-1-to-1 function such as a
circle), "polygon" for originary line segments, "linear" for a straight line de-
defined by two endpoints, "pol" for a degree-degree polynomial to be fitted to the
mouse-clicked points, "step" for a left-step-function, "gauss" to plot a Gauss-
ian density fitted to 3 clicked points, "loess" to use the lowess function to
smooth the clicked points, or a function to draw a user-specified function, evaluated
at evaluation points spanning the whole x-axis. For the density the user
must click in the left tail, at the highest value (at the mean), and in the right tail,
with the two tail values being approximately equidistant from the mean. The
density is scaled to fit in the highest value regardless of its area.

**step.type**

type of step functions used (default is "left")

**xmethod**

method for generating the unique set of x-coordinates to examine (see above).
Default is "grid" for type="1" or "unique" for type="s".

**offset**

distance in y-units between the center of the label and the line being labeled.
Default is 0.75 times the height of an "m" that would be drawn in a label.
For R grid/lattice you must specify offset using the grid unit function, e.g.,
offset=unit(2,"native") or offset=unit(.25,"cm") ("native" means data
units)

**xlim**

limits for searching for label positions, and is also used to set up plots when
pl=TRUE and add=FALSE. Default is total x-axis range for current plot (par("usr")[1:2]).
For largest.empty, xlim limits the search for largest rectangles, but it has the
same default as above. For pl=TRUE, add=FALSE you may want to extend xlim
somewhat to allow large keys to fit, when using keyloc="auto". For drawPlot
default is c(0,1). When using largest.empty with ggplot2, xlim and ylim
are mandatory.

**tilt**

set to TRUE to tilt labels to follow the curves, for method="offset" when keys
is not given.

**window**

width of a window, in x-units, to use in determining the local slope for tilting
labels. Default is 0.5 times number of characters in the label times the x-width
of an "m" in the current character size and font.

**npts**

number of points to use if xmethod="grid"

**cex**

character size to pass to text and key. Default is current par("cex"). For
putKey, putKeyEmpty, and Points is the size of the plotting symbol.
adj Default is "auto" which has labcurve figure justification automatically when method="offset". This will cause centering to be used when the local angle of the curve is less than angle.adj.auto in absolute value, left justification if the angle is larger and either the label is under a curve of positive slope or over a curve of negative slope, and right justification otherwise. For step functions, left justification is used when the label is above the curve and right justification otherwise. Set adj=.5 to center labels at computed coordinates. Set to 0 for left-justification, 1 for right. Set adj to a vector to vary adjustments over the curves.

angle.adj.auto see adj. Does not apply to step functions.

lty vector of line types which were used to draw the curves. This is only used when keys are drawn. If all of the line types, line widths, and line colors are the same, lines are not drawn in the key.

lwd vector of line widths which were used to draw the curves. This is only used when keys are drawn. See lty also.

col. col vector of integer color numbers for use in curve labels, symbols, lines, and legends. Default is par("col") for all curves. See lty also.

transparent Default is TRUE to make key draw transparent legends, i.e., to suppress drawing a solid rectangle background for the legend. Set to FALSE otherwise.

arrow.factor factor by which to multiply default arrow lengths

point.inc When keys is a vector of integers, point.inc specifies the x-increment between the point symbols that are overlaid periodically on the curves. By default, point.inc is equal to the range for the x-axis divided by 5.

opts an optional list which can be used to specify any of the options to labcurve, with the usual element name abbreviations allowed. This is useful when labcurve is being called from another function. Example: opts=list(method="arrow", cex=.8, np=200). For drawPlot a list of labcurve options to pass as labcurve(..., opts=).

key.opts a list of extra arguments you wish to pass to key(), e.g., key.opts=list(background=1, between=3). The argument names must be spelled out in full.

empty.method numbins These two arguments are passed to the largest.empty function's method and numbins arguments (see below). For largest.empty specifies the number of bins in which to discretize both the x and y directions for searching for rectangles. Default is 25.

pl set to TRUE (or specify add) to cause the curves in curves to be drawn, under the control of type,lty,lwd,col parameters defined either in the curves lists or in the separate arguments given to labcurve or through opts. For largest.empty, set pl=TRUE to show the rectangle the function found by drawing it with a solid color. May not be used under ggplot2.

add By default, when curves are actually drawn by labcurve a new plot is started. To add to an existing plot, set add=TRUE.

ylim When a plot has already been started, ylim defaults to par("usr")[3:4]. When pl=TRUE, ylim and xlim are determined from the ranges of the data. Specify
ylim yourself to take control of the plot construction. In some cases it is advisable to make ylim larger than usual to allow for automatically-positioned keys. For largest.empty, ylim specifies the limits on the y-axis to limit the search for rectangle. Here ylim defaults to the same as above, i.e., the range of the y-axis of an open plot from par. For drawPlot the default is c(0, 1).

xlab

ylab

x-axis and y-axis labels when pl=TRUE and add=FALSE or for drawPlot. Defaults to "" unless the first curve has names for its first two elements, in which case the names of these elements are taken as xlab and ylab.

whichLabel

integer vector corresponding to curves specifying which curves are to be labelled or have a legend

grid

set to TRUE if the R grid package was used to draw the current plot. This prevents labcurve from using par("usr") etc. If using R grid you can pass coordinates and lengths having arbitrary units, as documented in the unit function. This is especially useful for offset.

xrestrict

When having labcurve label curves where they are most separated, you can restrict the search for this separation point to a range of the x-axis, specified as a 2-vector xrestrict. This is useful when one part of the curve is very steep. Even though steep regions may have maximum separation, the labels will collide when curves are steep.

pch

vector of plotting characters for putKey and putKeyEmpty. Can be any value including NA when only a line is used to indentify the group. Is a single plotting character for Points, with the default being the next unused value from among 1, 2, 3, 4, 16, 17, 5, 6, 15, 18, 19.

plot

set to FALSE to keep putKey or putKeyEmpty from actually drawing the key. Instead, the size of the key will be return by putKey, or the coordinates of the key by putKeyEmpty.

ticks

tells drawPlot which axes to draw tick marks and tick labels. Default is "none".

key

for drawPlot and plot.drawPlot. Default is FALSE so that labcurve is used to label points or curves. Set to TRUE to use putKeyEmpty.

Details

The internal functions Points, Curve, Abline have unique arguments as follows.

label: for Points and Curve is a single character string to label that group of points

n: number of points to accept from the mouse. Default is to input points until a right mouse click.

rug: for Points. Default is "none" to not show the marginal x or y distributions as rug plots, for the points entered. Other possibilities are used to execute scat1d to show the marginal distribution of x, y, or both as rug plots.

ymean: for Points, subtracts a constant from each y-coordinate entered to make the overall mean ymean

degree: degree of polynomial to fit to points by Curve

evaluation: number of points at which to evaluate Bezier curves, polynomials, and other functions in Curve
ask: set ask=TRUE to give the user the opportunity to try again at specifying points for Bezier curves, step functions, and polynomials.

The `labcurve` function used some code from the function `plot.multicurve` written by Rod Tjoelker of The Boeing Company (<tjoelker@espresso.rt.cs.boeing.com>).

If there is only one curve, a label is placed at the middle x-value, and no fancy features such as angle or positive/negative offsets are used.

`key` is called once (with the argument `plot=FALSE`) to find the key dimensions. Then an empty rectangle with at least these dimensions is searched for using `largest.empty`. Then `key` is called again to draw the key there, using the argument `corner=cn(.5,.5)` so that the center of the rectangle can be specified to `key`.

If you want to plot the data, an easier way to use `labcurve` is through `xyplot` as shown in some of its examples.

**Value**

`labcurve` returns an invisible list with components `x`, `y`, `offset`, `adj`, `cex`, `col`, and if `tilt=TRUE`, `angle`. `offset` is the amount to add to `y` to draw a label. `offset` is negative if the label is drawn below the line. `adj` is a vector containing the values 0, .5, 1.

`largest.empty` returns a list with elements `x` and `y` specifying the coordinates of the center of the rectangle which was found, and element `rect` containing the 4 `x` and `y` coordinates of the corners of the found empty rectangle. The `area` of the rectangle is also returned.

**label**

*Label Attribute of an Object*
Description

label(x) retrieves the label attribute of x. label(x) <- "a label" stores the label attribute, and also puts the class labelled as the first class of x (for S-Plus this class is not used and methods for handling this class are not defined so the "label" and "units" attributes are lost upon subsetting). The reason for having this class is so that the subscripting method for labelled, [.labelled, can preserve the label attribute in S. Also, the print method for labelled objects prefaces the print with the object's label and units if there). If the variable is also given a "units" attribute using the units function, subsetting the variable (using [.labelled) will also retain the "units" attribute.

label can optionally append a "units" attribute to the string, and it can optionally return a string or expression (for R's plotmath facility) suitable for plotting. labelPlotmath is a function that also has this function, when the input arguments are the 'label' and 'units' rather than a vector having those attributes. When plotmath mode is used to construct labels, the 'label' or 'units' may contain math expressions but they are typed verbatim if they contain percent signs, blanks, or underscores. labelPlotmath can optionally create the expression as a character string, which is useful in building ggplot commands.

For Surv objects, label first looks to see if there is an overall "label" attribute for the object, then it looks for saved attributes that Surv put in the "inputAttributes" object, looking first at the event variable, then time2, and finally time. You can restrict the looking by specifying type.

labelLatex constructs suitable LaTeX labels a variable or from the label and units arguments, optionally right-justifying units if hfill=TRUE. This is useful when making tables when the variable in question is not a column heading. If x is specified, label and units values are extracted from its attributes instead of from the other arguments.

Label (actually Label.data.frame) is a function which generates S source code that makes the labels in all the variables in a data frame easy to edit.

l1list is like list except that it preserves the names or labels of the component variables in the variables label attribute. This can be useful when looping over variables or using sapply or lapply. By using l1list instead of list one can annotate the output with the current variable's name or label. l1list also defines a names attribute for the list and pulls the names from the arguments' expressions for non-named arguments.

prlist prints a list with element names (without the dollar sign as in default list printing) and if an element of the list is an unclassed list with a name, all of those elements are printed, with titles of the form "primary list name : inner list name". This is especially useful for Rmarkdown html notebooks when a user-written function creates multiple html and graphical outputs to all be printed in a code chunk. Optionally the names can be printed after the object, and the htmlfig option provides more capabilities when making html reports. prList does not work for regular html documents.

putHfig is similar to prList but for a single graphical object that is rendered with a print method, making it easy to specify long captions, and short captions for the table of contents in HTML documents. Table of contents entries are generated with the short caption, which is taken as the long caption if there is none. One can optionally not make a table of contents entry. If argument table=TRUE table captions will be produced instead. Using expcoll, markupspecs html function expcoll will be used to make tables expand upon clicking an arrow rather than always appear.

putHcap is like putHfig except it is for figures only, and assumes that users render the graphics outside of the putHcap call. This allows things to work in ordinary html documents.
plotmathTranslate is a simple function that translates certain character strings to character strings that can be used as part of \texttt{R} plotmath expressions. If the input string has a space or percent inside, the string is surrounded by a call to plotmath’s paste function.

\texttt{as.data.frame.labelled} is a utility function that is called by \texttt{[.data.frame}. It is just a copy of \texttt{as.data.frame.vector}. \texttt{data.frame.labelled} is another utility function, that adds a class “labelled” to every variable in a data frame that has a "label" attribute but not a "labelled" class.

\texttt{relevel.labelled} is a method for preserving labels with the \texttt{relevel} function.

\texttt{reLabelled} is used to add a 'labelled' class back to variables in data frame that have a 'label' attribute but no 'labelled' class. Useful for changing \texttt{cleanup.import()}’d S-Plus data frames back to general form for \texttt{R} and old versions of S-Plus.

**Usage**

\begin{verbatim}
label(x, default=NULL, ...)  
  ## Default S3 method:
  label(x, default=NULL, units=plot, plot=FALSE, 
        grid=FALSE, html=FALSE, ...)  

  ## S3 method for class 'Surv'
  label(x, default=NULL, units=plot, plot=FALSE, 
        grid=FALSE, html=FALSE, type=c('any', 'time', 'event'), ...)  

  ## S3 method for class 'data.frame'
  label(x, default=NULL, self=FALSE, ...)  

  label(x, ...) <- value  
  ## Default S3 replacement method:
  label(x, ...) <- value  

  ## S3 replacement method for class 'data.frame'
  label(x, self=TRUE, ...) <- value  

  labelPlotmath(label, units=NULL, plotmath=TRUE, html=FALSE, grid=FALSE, 
                chexpr=FALSE)  

  labelLatex(x=NULL, label='', units='', size='smaller[2]', 
             hfill=FALSE, bold=FALSE, default='', double=FALSE)  

  ## S3 method for class 'labelled'
  print(x, ...)  ## or x <- calls print.labelled  

  Label(object, ...)  

  ## S3 method for class 'data.frame'
  Label(object, file='', append=FALSE, ...)  
\end{verbatim}
Arguments

x any object (for plotmathTranslate is a character string). For relevel is a factor variable. For prList is a named list. For putHfig is a graphical object for which a print method will render the graphic (e.g., a ggplot2 or plotly object).

self logical, where to interact with the object or its components

units set to TRUE to append the 'units' attribute (if present) to the returned label. The 'units' are surrounded by brackets. For labelPlotmath and labelLatex is a character string containing the units of measurement. When plot is TRUE, units defaults to TRUE.

plot set to TRUE to return a label suitable for R’s plotmath facility (returns an expression instead of a character string) if R is in effect. If units is also TRUE, and if both 'label' and 'units' attributes are present, the 'units' will appear after the label but in smaller type and will not be surrounded by brackets.

default if x does not have a 'label' attribute and default (a character string) is specified, the label will be taken as default. For labelLatex the default is the name of the first argument if it is a variable and not a label.

grid Currently R’s lattice and grid functions do not support plotmath expressions for xlab and ylab arguments. When using lattice functions in R, set the argument grid to TRUE so that labelPlotmath can return an ordinary character string instead of an expression.

html set to TRUE to use HTML formatting instead of plotmath expressions for constructing labels with units
type

a character string containing a variable's label

label

type for Surv objects specifies the type of element for which to restrict the search for a label

plotmath

set to TRUE to have labelMathplot return an expression for plotting using R's plotmath facility. If R is not in effect, an ordinary character string is returned.

chexpr

set to TRUE to have labelPlotmath return a character string of the form "expression(...)"

size

LaTeX size for units. Default is two sizes smaller than label, which assumes that the LaTeX relsize package is in use.

hfill

set to TRUE to right-justify units in the field. This is useful when multiple labels are being put into rows in a LaTeX tabular environment, and will cause a problem if the label is used in an environment where hfill is not appropriate.

bold

set to TRUE to have labelLatex put the label in bold face.

double

set to TRUE to represent backslash in LaTeX as four backslashes in place of two. This is needed if, for example, you need to convert the result using as.formula.

value

the label of the object, or ""

object

a data frame

... a list of variables or expressions to be formed into a list. Ignored for print.labelled. For relevel is the level (a single character string) to become the new reference (first) category. For putHfig and putHcap represents one or more character strings that are pasted together, separated by a blank.

file

the name of a file to which to write S source code. Default is "", meaning standard output. For putHcap, set file to FALSE to return a character vector instead of writing to file.

append

set to TRUE to append code generated by Label to file file. Also used for putHfig, putHcap.

labels

set to FALSE to make llist ignore the variables' label attribute and use the variables' names.

lcap

an optional vector of character strings corresponding to elements in x for prList. These contain long captions that do not appear in the table of contents but which are printed right after the short caption in the body, in the same font.

htmlfig

for prList set to 1 to use HTML markup by running the object names through markupSpecs$html$cap for figure captions. Set htmlfig=2 to also preface the figure caption with "### " so that it will appear in the table of contents.

after

set to TRUE to have prList put names after the printed object instead of before

scap

a character string specifying the short (or possibly only) caption.

extra

an optional vector of character strings. When present the long caption will be put in the first column of an HTML table and the elements of extra in subsequent columns. This allows extra information to appear in the long caption in a way that is right-justified to the right of the flowing caption text.

subsub

set to FALSE to suppress "### " from being placed in front of the short caption.

hr

applies if a caption is present. Specify FALSE to not put a horizontal line before the caption and figure.
table set to TRUE to produce table captions instead of figure captions

expcoll character string to be visible, with a clickable arrow following to allow initial hiding of a table and its captions. Cannot be used with `table=FALSE`.

Value

label returns the label attribute of `x`, if any; otherwise, "". `label` is used most often for the individual variables in data frames. The function `sas.get` copies labels over from SAS if they exist.

See Also

`sas.get`, `describe`

Examples

```r
age <- c(21, 65, 43)
y <- 1:3
label(age) <- "Age in Years"
plot(age, y, xlab=label(age))

data <- data.frame(age=age, y=y)
label(data)

label(data, self=TRUE) <- "A data frame"
label(data, self=TRUE)

x1 <- 1:10
x2 <- 10:1
label(x2) <- 'Label for x2'
units(x2) <- 'mmHg'
x2
x2[1:5]
dframe <- data.frame(x1, x2)
Label(dframe)

labellatex(x2, hfill=TRUE, bold=TRUE)
labellatex(label='Velocity', units='m/s')

## In these examples of `llist`, note that labels are printed after
## variable names, because of `print.labelled`

a <- 1:3
b <- 4:6
label(b) <- 'B Label'
llist(a, b)
llist(a, b, d=0)
llist(a, b, t)

w <- llist(a, b>5, d=101:103)
sapply(w, function(x){
  hist(as.numeric(x), xlab=label(x))
})
```
Lag

Lag a Numeric, Character, or Factor Vector

Description
Shifts a vector shift elements later. Character or factor variables are padded with ",", numerics with NA. The shift may be negative.

Usage
Lag(x, shift = 1)

Arguments
x
a vector
shift
integer specifying the number of observations to be shifted to the right. Negative values imply shifts to the left.

Details
Attributes of the original object are carried along to the new lagged one.

Value
a vector like x

Author(s)
Frank Harrell

lag

Examples
Lag(1:5,2)
Lag(letters[1:4],2)
Lag(factor(letters[1:4]),-2)
# Find which observations are the first for a given subject
id <- c('a','a','b','b','b','c')
id != Lag(id)
!duplicated(id)
**Description**

`latex` converts its argument to a `.tex` file appropriate for inclusion in a LaTeX2e document. `latex` is a generic function that calls one of `latex.default`, `latex.function`, `latex.list`. `latex.default` does appropriate rounding and decimal alignment and produces a file containing a LaTeX tabular environment to print the matrix or data.frame `x` as a table.

`latex.function` prepares an S function for printing by issuing `sed` commands that are similar to those in the S.to.latex procedure in the s.to.latex package (Chambers and Hastie, 1993). `latex.function` can also produce verbatim output or output that works with the Sweave LaTeX style at [http://biostat.mc.vanderbilt.edu/SweaveTemplate](http://biostat.mc.vanderbilt.edu/SweaveTemplate).

`latex.list` calls `latex` recursively for each element in the argument.

`latexTranslate` translates particular items in character strings to LaTeX format, e.g., makes `a^2 = a^2$` for superscript within variable labels. LaTeX names of greek letters (e.g., "alpha") will have backslashes added if `greek=true`. Math mode is inserted as needed. `latexTranslate` assumes that input text always has matches, e.g. `[]` `[]` `()`, and that surrounding by `$` is OK.

`htmlTranslate` is similar to `latexTranslate` but for html translation. It doesn’t need math mode and assumes dollar signs are just that.

`latexSN` converts a vector floating point numbers to character strings using LaTeX exponents. Dollar signs to enter math mode are not added. Similarly, `htmlSN` converts to scientific notation in html.

`latexverbatim` on an object executes the object’s print method, capturing the output for a file inside a LaTeX verbatim environment.

`dvi` uses the system latex command to compile LaTeX code produced by `latex`, including any needed styles. `dvi` will put a `\documentclass{report}` and `\end{document}` wrapper around a file produced by `latex`. By default, the ‘geometry’ LaTeX package is used to omit all margins and to set the paper size to a default of 5.5in wide by 7in tall. The result of `dvi` is a `.dvi` file. To both format and screen display a non-default size, use for example `print(dvi(latex(x), width=3, height=4),width=3,height=4)`. Note that you can use something like `xdvi -geometry 460x650 -margins 2.25in file' without changing LaTeX defaults to emulate this.

`dvips` will use the system `dvips` command to print the `.dvi` file to the default system printer, or create a postscript file if file is specified.

`dvigv` uses the system `dvips` command to convert the input object to a `.dvi` file, and uses the system `dvips` command to convert it to postscript. Then the postscript file is displayed using Ghostview (assumed to be the system command `gv`).

There are `show` methods for displaying typeset LaTeX on the screen without running it through `dvi` using `show.dvi(object)`. The `show` method will run it through `dvi` automatically. These `show` methods are not S Version 4 methods so you have to use full names such as `show.dvi` and `show.latex`. Use the print methods for more automatic display of typesetting, e.g. typing `latex(x)` will invoke `xdvi` to view the typeset document.
Usage

latex(object, ...)

## Default S3 method:
latex(object,
   title=first.word(deparse(substitute(object))),
   file=paste(title, ".tex", sep=""),

## S3 method for class 'dvi'
dvigv(object, ...)
Arguments

**object**
For `latex`, any S object. For `dvi` or `dvigr`, an object created by `latex`. For `latexTranslate` is a vector of character strings to translate. Any NAs are set to blank strings before conversion.

**x**
y any object to be printed verbatim for `latexverbatim`. For `latexSN` or `htmlSN`, `x` is a numeric vector.

**title**
name of file to create without the ".tex" extension. If this option is not set, value/string of x (see above) is printed in the top left corner of the table. Set `title=''` to suppress this output.

**file**
n name of the file to create. The default file name is `xNtex` where `x` is the first word in the name of the argument for `x`. Set `file=''` to have the generated LaTeX code just printed to standard output. This is especially useful when running under Sweave in R using its `results= tex` tag, to save having to manage many small external files. When `file=''`, latex keeps track of LaTeX styles that are called for by creating or modifying an object `latexStyles` (in `.GlobalTemp in R or in frame 0 in S-Plus). latexStyles is a vector containing the base names of all the unique LaTeX styles called for so far in the current session. See the end of the examples section for a way to use this object to good effect. For `dvips`, `file` is the name of an output postscript file.

**append**
defaults to `FALSE`. Set to `TRUE` to append output to an existing file.

**label**
a text string representing a symbolic label for the table for referencing in the LaTeX `\label` and `\xref` commands. `label` is only used if `caption` is given.

**rowlabel**
If `x` has row dimnames, `rowlabel` is a character string containing the column heading for the row dimnames. The default is the name of the argument for `x`.

**rowlabel.just**
If `x` has row dimnames, specifies the justification for printing them. Possible values are "l", "r", "c". The heading (`rowlabel`) itself is left justified if `rowlabel.just="l"`, otherwise it is centered.

**cgroup**
a vector of character strings defining major column headings. The default is to have none.

**n.cgroup**
a vector containing the number of columns for which each element in `cgroup` is a heading. For example, specify `cgroup=c("Major 1","Major 2"), n.cgroup=c(3,3)` if "Major 1" is to span columns 1-3 and "Major 2" is to span columns 4-6. `rowlabel` does not count in the column numbers. You can omit `n.cgroup` if all groups have the same number of columns.

**rgroup**
a vector of character strings containing headings for row groups. `n.rgroup` must be present when `rgroup` is given. The first `n.rgroup[1]` rows are sectioned off and `rgroup[1]` is used as a bold heading for them. The usual row dimnames (which must be present if `rgroup` is) are indented. The next `n.rgroup[2]` rows are treated likewise, etc.

**n.rgroup**
integer vector giving the number of rows in each grouping. If `rgroup` is not specified, `n.rgroup` is just used to divide off blocks of rows by horizontal lines. If `rgroup` is given but `n.rgroup` is omitted, `n.rgroup` will default so that each row group contains the same number of rows.
cgroupTexCmd
A character string specifying a LaTeX command to be used to format column
group labels. The default, "\bfseries", sets the current font to 'bold'. It is pos-
sible to supply a vector of strings so that each column group label is formatted
differently. Please note that the first item of the vector is used to format the
title (even if a title is not used). Currently the user needs to handle these issue.
Multiple effects can be achieved by creating custom LaTeX commands; for ex-
ample, "\providecommand{\redscshape}{\color{red}\scshape}" creates
a LaTeX command called '\redscshape' that formats the text in red small-caps.

rgroupTexCmd
A character string specifying a LaTeX command to be used to format row group
labels. The default, "\bfseries", sets the current font to 'bold'. A vector of
strings can be supplied to format each row group label differently. Normal re-
cycling applies if the vector is shorter than n.rgroups. See also cgroupTexCmd
above regarding multiple effects.

rownamesTexCmd
A character string specifying a LaTeX command to be used to format rownames.
The default, NULL, applies no command. A vector of different commands can
also be supplied. See also cgroupTexCmd above regarding multiple effects.

colnamesTexCmd
A character string specifying a LaTeX command to be used to format column
labels. The default, NULL, applies no command. It is possible to supply a vector
of strings to format each column label differently. If column groups are not used,
the first item in the vector will be used to format the title. Please note that if col-
umn groups are used the first item of cgroupTexCmd and not colnamesTexCmd
is used to format the title. The user needs to allow for these issues when sup-
plying a vector of commands. See also cgroupTexCmd above regarding multiple
effects.

cellTexCmds
A matrix of character strings which are LaTeX commands to be used to format
each element, or cell, of the object. The matrix must have the same NROW() and
NCOL() as the object. The default, NULL, applies no formats. Empty strings
also apply no formats, and one way to start might be to create a matrix of empty
strings with matrix(rep("", NROW(x) * NCOL(x)), nrow=NROW(x)) and
then selectively change appropriate elements of the matrix. Note that you might
need to set numeric.dollar=FALSE (to disable math mode) for some effects to
work. See also cgroupTexCmd above regarding multiple effects.

na.blank
Set to TRUE to use blanks rather than NA for missing values. This usually looks
better in latex.

insert.bottom
an optional character string to typeset at the bottom of the table. For "ctable"
style tables, this is placed in an unmarked footnote.

insert.bottom.width
character string; a tex width controlling the width of the insert.bottom text. Cur-
tently only does something with using longtable=TRUE.

insert.top
a character string to insert as a heading right before beginning tabular environ-
ment. Useful for multiple sub-tables.

first.hline.double
set to FALSE to use single horizontal rules for styles other than "bookmark" or
"ctable"

rownames
rownames for tabular environment. Default is rownames of matrix or data.frame.
Specify rowname=NULL to suppress the use of row names.
cgroup.just: justification for labels for column groups. Defaults to "c".

colheads: a character vector of column headings if you don't want to use dimnames(object)[[2]]. Specify colheads=FALSE to suppress column headings.

extracolheads: an optional vector of extra column headings that will appear under the main headings (e.g., sample sizes). This character vector does not need to include an empty space for any rowname in effect, as this will be added automatically. You can also form subheadings by splitting character strings defining the column headings using the usual backslash \ newline character.

extracolsize: size for extracolheads or for any second lines in column names; default is "scriptsize".

dcolumn: see format.df

numeric.dollar: logical, default !dcolumn. Set to TRUE to place dollar signs around numeric values when dcolumn=FALSE. This assures that latex will use minus signs rather than hyphens to indicate negative numbers. Set to FALSE when dcolumn=TRUE, as dcolumn.sty automatically uses minus signs.

math.row.names: logical, set true to place dollar signs around the row names.

already.math.row.names: set to TRUE to prevent any math mode changes to row names

math.col.names: logical, set true to place dollar signs around the column names.

already.math.col.names: set to TRUE to prevent any math mode changes to column names

hyperref: if table.env=TRUE is a character string used to generate a LaTeX hyperref enclosure

continued: a character string used to indicate pages after the first when making a long table

cdot: see format.df

longtable: Set to TRUE to use David Carlisle's LaTeX longtable style, allowing long tables to be split over multiple pages with headers repeated on each page. The "style" element is set to "longtable". The latex \usepackage must reference \{longtable\}. The file \longtable.sty will need to be in a directory in your TEXINPUTS path.

draft.longtable: I forgot what this does.

ctable: set to TRUE to use Wybo Dekker's ctable style from CTAN. Even though for historical reasons it is not the default, it is generally the preferred method. Thicker but not doubled \hline's are used to start a table when ctable is in effect.

booktabs: set booktabs=TRUE to use the booktabs style of horizontal rules for better tables. In this case, double \hline's are not used to start a table.

table.env: Set table.env=FALSE to suppress enclosing the table in a LaTeX \table environment. table.env only applies when longtable=FALSE. You may not specify a caption if table.env=FALSE.

here: Set to TRUE if you are using table.env=TRUE with longtable=FALSE and you have installed David Carlisle's \here.sty LaTeX style. This will cause the LaTeX \table environment to be set up with option 'H' to guarantee that the table
will appear exactly where you think it will in the text. The "style" element is set to "here". The latex `\usepackage` must reference `[here]`. The file `here.sty` will need to be in a directory in your TEXINPUTS path. `here` is largely obsolete with LaTeX2e.

lines.page Applies if longtable=TRUE. No more than lines.page lines in the body of a table will be placed on a single page. Page breaks will only occur at rgroup boundaries.

caption a text string to use as a caption to print at the top of the first page of the table. Default is no caption.

caption.lot a text string representing a short caption to be used in the “List of Tables”. By default, LaTeX will use caption. If you get inexplicable ‘latex’ errors, you may need to supply caption.lot to make the errors go away.

caption.loc set to "bottom" to position a caption below the table instead of the default of "top".

star apply the star option for ctables to allow a table to spread over two columns when in twocolumn mode.

double.slash set to TRUE to output ‘|’ as ‘||’ in LaTeX commands. Useful when you are reading the output file back into an S vector for later output.

vbar logical. When vbar==TRUE, columns in the tabular environment are separated with vertical bar characters. When vbar==FALSE, columns are separated with white space. The default, vbar==FALSE, produces tables consistent with the style sheet for the Journal of the American Statistical Association.

collabel.just justification for column labels.

assignment logical. When TRUE, the default, the name of the function and the assignment arrow are printed to the file.

where specifies placement of floats if a table environment is used. Default is "!htbp". To allow tables to appear in the middle of a page of text you might specify where="!htbp" to latex.default.

size size of table text if a size change is needed (default is no change). For example you might specify size="small" to use LaTeX font size “small”. For latex.function is a character string that will be appended to "Sinput" such as "small".

center default is "center" to enclose the table in a ‘center’ environment. Use center="centering" or "centerline" to instead use LaTeX ‘centering’ or centerline directives, or center="none" to use no centering. centerline can be useful when objects besides a tabular are enclosed in a single table environment. This option was implemented by Markus Jäntti <markus.jantti@iki.fi> of Abo Akademi University.

landscape set to TRUE to enclose the table in a ‘landscape’ environment. When ctable is TRUE, will use the rotate argument to ctable.

type The default uses the S alltt environment for latex.function, Set type="verbatim" to instead use the LaTeX ‘verbatim’ environment. Use type="Sinput" if using Sweave, especially if you have customized the Sinput environment, for example using the Sweave1 style which uses the listings LaTeX package.
width.cutoff  
other arguments are accepted and ignored except that latex passes arguments to format.df (e.g., col.just and other formatting options like dec, rdec, and cdec). For latexVerbatim these arguments are passed to the print function. Ignored for latexTranslate and htmlTranslate. For htmlSN, these arguments are passed to prettyNum or format.

inn, out  
specify additional input and translated strings over the usual defaults

pb  
If pb=TRUE, latexTranslate also translates '{[()]}' to math mode using '\left, \right'.

greek  
set to TRUE to have latexTranslate put names for greek letters in math mode and add backslashes. For htmlTranslate, translates greek letters to corresponding html characters, ignoring "modes".

na  
single character string to translate NA values to for latexTranslate and htmlTranslate

code  
set to 'unicode' to use HTML unicode characters or '&' to use the ampersand pound number format

pretty  
set to FALSE to have htmlSN use format instead of prettyNum

hspace  
horizontal space, e.g., extra left margin for verbatim text. Default is none. Use e.g. hspace="10ex" to add 10 extra spaces to the left of the text.

length  
for S-Plus only; is the length of the output page for printing and capturing verbatim text

width, height  
are the options( ) to have in effect only for when print is executed. Defaults are current options. For dvi these specify the paper width and height in inches if nomargins=TRUE, with defaults of 5.5 and 7, respectively.

prlog  
set to TRUE to have dvi print, to the S-Plus session, the LaTeX .log file.

multicol  
set to FALSE to not use 'multicolumn' in header of table

nomargins  
set to FALSE to use default LaTeX margins when making the .dvi file

Details

latex.default outputs a LaTeX comment containing the calling statement. To suppress outputting this comment, run options(omitlatexcom=TRUE) before running. This is helpful when running RMarkdown to produce pdf output using LaTeX, as this uses pandoc which is fooled into try to escape the percent comment symbol.

If running under Windows and using MikTeX, latex and yap must be in your system path, and yap is used to browse '.dvi' files created by latex. You should install the 'geometry.sty' and 'ctable.sty' styles in MikTeX to make optimum use of latex().

On Mac OS X, you may have to append the '/usr/texbin' directory to the system path. Thanks to Kevin Thorpe (<kevin.thorpe@utoronto.ca>) one way to set up Mac OS X is to install 'X11' and 'X11SDK' if not already installed, start 'X11' within the R GUI, and issue the command Sys.setenv( PATH=paste(Sys.getenv("PATH"),"/usr/texbin",sep=":") ) To avoid any complications of using 'X11' under MacOS, users can install the 'TeXShop' package, which will associate '.dvi' files with a viewer that displays a 'pdf' version of the file after a hidden conversion from '.dvi' to 'pdf'.

System options can be used to specify external commands to be used. Defaults are given by options(xdvicmd='xdvi') or options(xdvicmd='yap'), options(dvipscmd='dvips'), options(latexcmd='latex') For MacOS specify options(xdvicmd='MacdviX') or if TeXShop is installed, options(xdvicmd='open').
To use `pdflatex` rather than `latex`, set `options(latexcmd='pdflatex'), options(dviExtension='pdf'),` and `options('xdvicmd')` to your chosen PDF previewer.

If running S-Plus and your directory for temporary files is not `/tmp` (Unix/Linux) or `\windows\temp` (Windows), add your own `tempdir` function such as `tempdir <- function() "'/yourmaindirectory/yoursubdirectory'`.

To prevent the latex file from being displayed store the result of `latex` in an object, e.g. `w <- latex(object, file='foo.tex')`.

**Value**

`latex` and `dvi` return a list of class `latex` or `dvi` containing character string elements `file` and `style`. `file` contains the name of the generated file, and `style` is a vector (possibly empty) of styles to be included using the LaTeX2e `\usepackage` command.

`latexTranslate` returns a vector of character strings.

**Side Effects**

creates various system files and runs various Linux/UNIX system commands which are assumed to be in the system path.

x <- matrix(1:6, nrow=2, dimnames=list(c('a','b'),c('c','d','this that')))
## Not run:
latex(x)  # creates x.tex in working directory
# The result of the above command is an object of class "latex"
# which here is automatically printed by the latex print method.
# The latex print method prepends and appends latex headers and
# calls the latex program in the PATH. If the latex program is
# not in the PATH, you will get error messages from the operating
# system.
```
latexCheckOptions  

Check whether the options for latex functions have been specified.

**Description**

Check whether the options for latex functions have been specified. If any of `options()[[c("latexcmd","dviExtension","xdvicmd")]]` are NULL, an error message is displayed.
latexDotchart

Usage
latexCheckOptions(...)

Arguments
... Any arguments are ignored.

Value

If any NULL options are detected, the invisible text of the error message. If all three options have non-NULL values, NULL.

latexdotchart

Enhanced Dot Chart for LaTeX Picture Environment with epic

Description
latexDotchart is a translation of the dotchart3 function for producing a vector of character strings containing LaTeX picture environment markup that mimics dotchart3 output. The LaTeX epic and color packages are required. The add and horizontal=FALSE options are not available for latexDotchart, however.

Usage
latexDotchart(data, labels, groups=NULL, gdata=NA,
   xlab='', auxdata, auxgdata=NULL, auxtitle,
   w=4, h=4, margin,
   lines=TRUE, dotsize = .075, size='small', size.labels='small',
   size.group.labels='normalsize', ttllabels=FALSE, sort=TRUE,
   xaxis=TRUE, lcolor='gray', ...)}

Arguments
data a numeric vector whose values are shown on the x-axis
labels a vector of labels for each point, corresponding to x. If omitted, names(data) are used, and if there are no names, integers prefixed by "#" are used.
groups an optional categorical variable indicating how data values are grouped
gdata data values for groups, typically summaries such as group medians
xlab x-axis title

auxdata a vector of auxiliary data, of the same length as the first (data) argument. If present, this vector of values will be printed outside the right margin of the dot chart. Usually auxdata represents cell sizes.

auxgdata similar to auxdata but corresponding to the gdata argument. These usually represent overall sample sizes for each group of lines.

auxtitle if auxdata is given, auxtitle specifies a column heading for the extra printed data in the chart, e.g., "N"

w width of picture in inches

h height of picture in inches

margin a 4-vector representing, in inches, the margin to the left of the x-axis, below the y-axis, to the right of the x-axis, and above the y-axis. By default these are computed making educated cases about how to accommodate auxdata etc.

lines set to FALSE to suppress drawing of reference lines
dotsize diameter of filled circles, in inches, for drawing dots

size size of text in picture. This and the next two arguments are LaTeX font commands without the opening backslash, e.g., 'normalsize', 'small', 'large', smaller[2].

size.labels size of labels

size.group.labels size of labels corresponding to groups
ttlabels set to TRUE to use typewriter monospaced font for labels

sort set to FALSE to keep latexDotchart from sorting the input data, i.e., it will assume that the data are already properly arranged. This is especially useful when you are using gdata and groups and you want to control the order that groups appear on the chart (from top to bottom).

xaxis set to FALSE to suppress drawing x-axis

lcolor color for horizontal reference lines. Default is "gray"

... ignored

## End(Not run)
```

### Description

latexTabular creates a character vector representing a matrix or data frame in a simple ‘tabular’ environment.

### Usage

```r
latexTabular(x, headings=colnames(x),
             align =paste(rep('c',ncol(x)),collapse=''),
             halign=paste(rep('c',ncol(x)),collapse=''),
             helvetica=TRUE, translate=TRUE, hline=0, center=FALSE, ...)
```

### Arguments

- **x**: a matrix or data frame, or a vector that is automatically converted to a matrix.
- **headings**: a vector of character strings specifying column headings for ‘latexTabular’, defaulting to x’s colnames. To make multi-line headers use the newline character inside elements of headings.
- **align**: a character strings specifying column alignments for ‘latexTabular’, defaulting to paste(rep('c',ncol(x)),collapse='') to center. You may specify align='c|c' and other LaTeX tabular formatting.
latexTherm

Description

latexTherm creates a LaTeX picture environment for drawing a series of thermometers whose heights depict the values of a variable y assumed to be scaled from 0 to 1. This is useful for showing fractions of sample analyzed in any table or plot, intended for a legend. For example, four thermometers might be used to depict the fraction of enrolled patients included in the current analysis, the fraction randomized, the fraction of patients randomized to treatment A being analyzed, and the fraction randomized to B being analyzed. The picture is placed inside a LaTeX macro definition for macro variable named name, to be invoked by the user later in the LaTeX file using name preceeded by a backslash.

If y has an attribute "table", it is assumed to contain a character string with LaTeX code. This code is used as a tooltip popup for PDF using the LaTeX ocgtools package or using style tooltips.
Typically the code will contain a tabular environment. The user must define a LaTeX macro tooltipn that takes two arguments (original object and pop-up object) that does the pop-up.

latexNeedle is similar to latexTherm except that vertical needles are produced and each may have its own color. A grayscale box is placed around the needles and provides the 0-1 y-axis reference. Horizontal grayscale grid lines may be drawn.

pngNeedle is similar to latexNeedle but is for generating small png graphics. The full graphics file name is returned invisibly.

Usage

```latex
latexTherm(y, name, w = 0.075, h = 0.15, spacefactor = 1/2, extra = 0.07, file = "", append = TRUE)
latexNeedle(y, x=NULL, col='black', href=0.5, name, w=.05, h=.15, extra=0, file = "", append=TRUE)
pngNeedle(y, x=NULL, col='black', href=0.5, lwd=3.5, w=6, h=18, file=tempfile(fileext='.png'))
```

Arguments

- **y**: a vector of 0-1 scaled values. Boxes and their frames are omitted for NA elements.
- **x**: a vector corresponding to y giving x-coordinates. Scaled accordingly, or defaults to equally-spaced values.
- **name**: name of LaTeX macro variable to be defined.
- **w**: width of a single box (thermometer) in inches. For latexNeedle and pngNeedle is the spacing between needles, the latter being in pixels.
- **h**: height of a single box in inches. For latexNeedle and pngNeedle is the height of the frame, the latter in pixels.
- **spacefactor**: fraction of w added for extra space between boxes for latexTherm.
- **extra**: extra space in inches to set aside to the right of and above the series of boxes or frame.
- **file**: name of file to which to write LaTeX code. Default is the console. Also used as base file name for png graphic. Default for that is from tempfile.
- **append**: set to FALSE to write over file.
- **col**: a vector of colors corresponding to positions in y. col is repeated if too short.
- **href**: values of y (0-1) for which horizontal grayscale reference lines are drawn for latexNeedle and pngNeedle. Set to NULL to not draw any reference lines.
- **lwd**: line width of needles for pngNeedle.

**Pretty-print the Structure of a Data Object**

**Description**

This is a function to pretty-print the structure of any data object (usually a list). It is similar to the R function `str`. 
Usage

list.tree(struct, depth=-1, numbers=FALSE, maxlen=22, maxcomp=12,
        attr.print=TRUE, front="", fill=" ", name.of, size=TRUE)

Arguments

struct    The object to be displayed
depth     Maximum depth of recursion (of lists within lists ...) to be printed; negative
          value means no limit on depth.
numbers   If TRUE, use numbers in leader instead of dots to represent position in structure.
maxlen    Approximate maximum length (in characters) allowed on each line to give the
          first few values of a vector. maxlen=0 suppresses printing any values.
maxcomp   Maximum number of components of any list that will be described.
attr.print Logical flag, determining whether a description of attributes will be printed.
front     Front material of a line, for internal use.
fill      Fill character used for each level of indentation.
name.of   Name of object, for internal use (deparsed version of struct by default).
size      Logical flag, should the size of the object in bytes be printed?

A description of the structure of struct will be printed in outline form, with in-

dentation for each level of recursion, showing the internal storage mode, length,
class(es) if any, attributes, and first few elements of each data vector. By default
each level of list recursion is indicated by a "." and attributes by "A".

makeNstr(" ", 5)
```

---

**mApply**

Apply a Function to Rows of a Matrix or Vector

---

**Description**

`mApply` is like `tapply` except that the first argument can be a matrix or a vector, and the output is cleaned up if `simplify=TRUE`. It uses code adapted from Tony Plate (<tplate@blackmesacapital.com>) to operate on grouped submatrices.

As `mApply` can be much faster than using `by`, it is often worth the trouble of converting a data frame to a numeric matrix for processing by `mApply`. `asNumericMatrix` will do this, and `matrix2DataFrame` will convert a numeric matrix back into a data frame.
mApply

Usage

mApply(X, INDEX, FUN, ..., simplify=TRUE, keepmatrix=FALSE)

Arguments

X a vector or matrix capable of being operated on by the function specified as the FUN argument
INDEX list of factors, each of same number of rows as 'X' has.
FUN the function to be applied. In the case of functions like '+', '
... optional arguments to 'FUN'.
simplify set to 'FALSE' to suppress simplification of the result in to an array, matrix, etc.
keepmatrix set to TRUE to keep result as a matrix even if simplify is TRUE, in the case of only one stratum

Value

For mApply, the returned value is a vector, matrix, or list. If FUN returns more than one number, the result is an array if simplify=TRUE and is a list otherwise. If a matrix is returned, its rows correspond to unique combinations of INDEX. If INDEX is a list with more than one vector, FUN returns more than one number, and simplify=FALSE, the returned value is a list that is an array with the first dimension corresponding to the last vector in INDEX, the second dimension corresponding to the next to last vector in INDEX, etc., and the elements of the list-array correspond to the values computed by FUN. In this situation the returned value is a regular array if simplify=TRUE. The order of dimensions is as previously but the additional (last) dimension corresponds to values computed by FUN.

Methods for Storing and Analyzing Multiple Choice Variables

Description

`mChoice` is a function that is useful for grouping variables that represent individual choices on a multiple choice question. These choices are typically factor or character values but may be of any type. Levels of component factor variables need not be the same; all unique levels (or unique character values) are collected over all of the multiple variables. Then a new character vector is formed with integer choice numbers separated by semicolons. Optimally, a database system would have exported the semicolon-separated character strings with a `levels` attribute containing strings defining value labels corresponding to the integer choice numbers. `mChoice` is a function for creating a multiple-choice variable after the fact. `mChoice` variables are explicitly handed by the `describe` and `summary.formula` functions. NAs or blanks in input variables are ignored.

`format.mChoice` will convert the multiple choice representation to text form by substituting `levels` for integer codes. `as.double.mChoice` converts the `mChoice` object to a binary numeric matrix, one column per used level (or all levels of `drop=FALSE`). This is called by the user by invoking `as.numeric`. There is a print method and a summary method, and a print method for the `summary.mChoice` object. The summary method computes frequencies of all two-way choice combinations, the frequencies of the top 5 combinations, information about which other choices are present when each given choice is present, and the frequency distribution of the number of choices per observation. This summary output is used in the `describe` function.

`in.mChoice` creates a logical vector the same length as `x` whose elements are `TRUE` when the observation in `x` contains at least one of the codes or value labels in the second argument.

`match.mChoice` creates an integer vector of the indexes of all elements in `table` which contain any of the specified levels.

`is.mChoice` returns `TRUE` is the argument is a multiple choice variable.

Usage

```r
mChoice(..., label='',
       sort.levels=c('original','alphabetic'),
       add.none=FALSE, drop=TRUE)

# S3 method for class 'mChoice'
format(x, minlength=NULL, sep=";", ...)

# S3 method for class 'mChoice'
as.double(x, drop=FALSE, ...)

# S3 method for class 'mChoice'
print(x, quote=FALSE, max.levels=NULL,
      width=getOption("width"), ...)

# S3 method for class 'mChoice'
```
as.character(x, ...)

## S3 method for class 'mChoice'
summary(object, ncombos=5, minlength=NULL, drop=TRUE, ...)

## S3 method for class 'summary.mChoice'
print(x, prlabel=TRUE, ...)

## S3 method for class 'mChoice'
x[...], drop=FALSE]

match.mChoice(x, table, nomatch=NA, incomparables=FALSE)

inmChoice(x, values)

is.mChoice(x)

## S3 method for class 'mChoice'
Summary(..., na.rm)

Arguments

na.rm Logical: remove NA’s from data
table a vector (mChoice) of values to be matched against.
nomatch value to return if a value for x does not exist in table.
incomparables logical whether incomparable values should be compared.
... a series of vectors
sort. By default, choice codes are sorted in ascending numeric order. Set sort=FALSE to preserve the original left to right ordering from the input variables.
label a character string label attribute to attach to the matrix created by mChoice
sort.levels set sort.levels="alphabetic" to sort the columns of the matrix created by mChoice alphabetically by category rather than by the original order of levels in component factor variables (if there were any input variables that were factors)
add.none Set add.none to TRUE to make a new category 'none' if it doesn’t already exist and if there is an observations with no choices selected.
drop set drop=FALSE to keep unused factor levels as columns of the matrix produced by mChoice
x an object of class "mchoice" such as that created by mChoice. For is.mChoice is any object.
object an object of class "mchoice" such as that created by mChoice
ncombos maximum number of combos.
width With of a line of text to be formated
quote quote the output
max.levels max levels to be displayed
minlength

By default no abbreviation of levels is done in format and summary. Specify a positive integer to use abbreviation in those functions. See abbreviate.

sep

character to use to separate levels when formatting

prlabel

set to FALSE to keep print.summary.mChoice from printing the variable label and number of unique values

values

a scalar or vector. If values is integer, it is the choice codes, and if it is a character vector, it is assumed to be value labels.

Value

mChoice returns a character vector of class "mChoice" plus attributes "levels" and "label". summary.mChoice returns an object of class "summary.mChoice". inmChoice returns a logical vector. format.mChoice returns a character vector, and as.double.mChoice returns a binary numeric matrix.

options(digits=3)
set.seed(3)
n <- 20
sex <- factor(sample(c("m","f"), n, rep=TRUE))
age <- rnorm(n, 50, 5)
treatment <- factor(sample(c("Drug","Placebo"), n, rep=TRUE))

# Generate a 3-choice variable; each of 3 variables has 5 possible levels
symp <- c('Headache','Stomach Ache','Hangnail',
'Muscle Ache','Depressed')
symptom1 <- sample(symp, n, TRUE)
symptom2 <- sample(symp, n, TRUE)
symptom3 <- sample(symp, n, TRUE)
cbind(symptom1, symptom2, symptom3)[1:5,]
Symptoms <- mChoice(symptom1, symptom2, symptom3, label='Primary Symptoms')
Symptoms
print(Symptoms, long=TRUE)
format(Symptoms[1:5])
inmChoice(Symptoms,'Headache')
levels(Symptoms)
inmChoice(Symptoms, 3)
```r
inmChoice(Symptoms, c('Headache', 'Hangnail'))
# Note: In this example, some subjects have the same symptom checked # multiple times; in practice these redundant selections would be NAs # mChoice will ignore these redundant selections

meanage <- N <- numeric(5)
for(j in 1:5) {
  meanage[j] <- mean(age[inmChoice(Symptoms,j)])
  N[j] <- sum(inmChoice(Symptoms,j))
}
names(meanage) <- names(N) <- levels(Symptoms)
meanage

# Manually compute mean age for 2 symptoms
mean(age[symptom1=='Headache' | symptom2=='Headache' | symptom3=='Headache'])
mean(age[symptom1=='Hangnail' | symptom2=='Hangnail' | symptom3=='Hangnail'])

summary(Symptoms)

# Frequency table sex*treatment, sex*Symptoms
summary(sex ~ treatment + Symptoms, fun=table)

# Check:
ma <- inmChoice(Symptoms, 'Muscle Ache')
table(sex[ma])

# could also do:
# summary(sex ~ treatment + mChoice(symptom1,symptom2,symptom3), fun=table)

# Compute mean age, separately by 3 variables
summary(age ~ sex + treatment + Symptoms)

summary(age ~ sex + treatment + Symptoms, method="cross")

f <- summary(treatment ~ age + sex + Symptoms, method="reverse", test=TRUE)
f
# trio of numbers represent 25th, 50th, 75th percentile
print(f, long=TRUE)
```
Usage

```r
mdb.get(file, tables=NULL, lowernames=FALSE, allow=NULL,
    dateformat='%m/%d/%y', mdbexportArgs='-b strip', ...)
```

Arguments

- **file**: the file name containing the Access database
- **tables**: character vector specifying the names of tables to import. Default is to import all tables. Specify `tables=TRUE` to return the list of available tables.
- **lowernames**: set this to `TRUE` to change variable names to lower case
- **allow**: a vector of characters allowed by R that should not be converted to periods in variable names. By default, underscores in variable names are converted to periods as with R before version 1.9.
- **dateformat**: see `cleanup.import`. Default is the usual Access format used in the U.S.
- **mdbexportArgs**: command line arguments to issue to mdb-export. Set to '' to omit '-b strip'.
- **...**: arguments to pass to `csv.get`

Details

Uses the `mdbtools` package executables `mdb-tables`, `mdb-schema`, and `mdb-export` (with by default option `-b strip` to drop any binary output). In Debian/Ubuntu Linux run `apt-get install mdbtools`. `cleanup.import` is invoked by `csv.get` to transform variables and store them as efficiently as possible.

Value

a new data frame or a list of data frames

Author(s)

Frank Harrell, Vanderbilt University

See Also

data.frame, cleanup.import, csv.get, Date, chron

Examples

```r
## Not run:
# Read all tables in the Microsoft Access database Nwind.mdb
d <- mdb.get('Nwind.mdb')
contents(d)
for(z in d) print(contents(z))
# Just print the names of tables in the database
mdb.get('Nwind.mdb', tables=TRUE)
# Import one table
Orders <- mdb.get('Nwind.mdb', tables='Orders')

## End(Not run)
```
Merge

Merge Multiple Data Frames or Data Tables

Description
Merges an arbitrarily large series of data frames or data tables containing common id variables (keys for data tables). Information about number of observations and number of unique ids in individual and final merged datasets is printed. The first data frame has special meaning in that all of its observations are kept whether they match ids in other data frames or not. For all other data frames, by default non-matching observations are dropped. The first data frame is also the one against which counts of unique ids are compared. Sometimes merge drops variable attributes such as labels and units. These are restored by Merge. If all objects are of class data.table, faster merging will be done using the data.table package's join operation. This assumes that all objects have identical key variables and those of the variables on which to merge.

Usage

```
merge(..., id, all = TRUE, verbose = TRUE)
```

Arguments

- `...` two or more dataframes or data tables
- `id` a formula containing all the identification variables such that the combination of these variables uniquely identifies subjects or records of interest. May be omitted for data tables; in that case the key function retrieves the id variables.
- `all` set to FALSE to drop observations not found in second and later data frames (only applies if not using data.table)
- `verbose` set to FALSE to not print information about observations

Examples

```r
## Not run:
a <- data.frame(sid=1:3, age=c(20,30,40))
b <- data.frame(sid=c(1,2,2), bp=c(120,130,140))
d <- data.frame(sid=c(1,3,4), wt=c(170,180,190))
all <- merge(a, b, d, id = ~ sid)
# For data.table, first file must be the master file and must
# contain all ids that ever occur. ids not in the master will
# not be merged from other datasets.
a <- data.table(a); setkey(a, sid)
# data.table also does not allow duplicates without allow.cartesian=TRUE
b <- data.table(sid=1:2, bp=c(120,130)); setkey(b, sid)
d <- data.table(d); setkey(d, sid)
all <- merge(a, b, d)

## End(Not run)
```
mgp.axis

Draw Axes With Side-Specific mgp Parameters

Description

mgp.axis is a version of axis that uses the appropriate side-specific mgp parameter (see par) to account for different space requirements for axis labels vertical vs. horizontal tick marks. mgp.axis also fixes a bug in axis(2, ...) that causes it to assume las=1.

mgp.axis.labels is used so that different spacing between tick marks and axis tick mark labels may be specified for x- and y-axes. Use mgp.axis.labels('default') to set defaults. Users can set values manually using mgp.axis.labels(x,y) where x and y are 2nd value of par('mgp') to use. Use mgp.axis.labels(type=w) to retrieve values, where w='x', 'y', 'x' and 'y', 'xy', to get 3 mgp values (first 3 types) or 2 mgp.axis.labels.

Usage

mgp.axis(side, at = NULL, ..., mgp = mgp.axis.labels(type = if (side == 1 | side == 3) "x"
else "y"),
axistitle = NULL, cex.axis=par('cex.axis'), cex.lab=par('cex.lab'))

mgp.axis.labels(value,type=c('xy','x','y','x and y'))

Arguments

side, at see par
... arguments passed through to axis
mgp, cex.axis, cex.lab see par
axistitle if specified will cause axistitle to be drawn on the appropriate axis as a title
value vector of values to which to set system option mgp.axis.labels
type see above

Value

mgp.axis.labels returns the value of mgp (only the second element of mgp if type="xy" or a list with elements x and y if type="x or y", each list element being a 3-vector) for the appropriate axis if value is not specified, otherwise it returns nothing but the system option mgp.axis.labels is set.

mgp.axis returns nothing.

Side Effects

mgp.axis.labels stores the value in the system option mgp.axis.labels

par

Examples

```r
## Not run:
mgp.axis.labels(type='x')  # get default value for x-axis
mgp.axis.labels(type='y')  # get value for y-axis
mgp.axis.labels(type='xy')  # get 2nd element of both mgps
mgp.axis.labels(type='x and y')  # get a list with 2 elements
mgp.axis.labels(c(3,5,0), type='x')  # set
options('mgp.axis.labels')  # retrieve

plot(..., axes=FALSE)
mgp.axis(1, "X Label")
mgp.axis(2, "Y Label")

## End(Not run)
```

Description

The `mhgr` function computes the Cochran-Mantel-Haenszel stratified risk ratio and its confidence limits using the Greenland-Robins variance estimator.

The `lrcum` function takes the results of a series of 2x2 tables representing the relationship between test positivity and diagnosis and computes positive and negative likelihood ratios (with all their deficiencies) and the variance of their logarithms. Cumulative likelihood ratios and their confidence intervals (assuming independence of tests) are computed, assuming a string of all positive tests or a string of all negative tests. The method of Simel et al as described in Altman et al is used.

Usage

```r
mhgr(y, group, strata, conf.int = 0.95)
## S3 method for class 'mhgr'
print(x, ...)

lrcum(a, b, c, d, conf.int = 0.95)
## S3 method for class 'lrcum'
print(x, dec=3, ...
```
Arguments

- `y`: a binary response variable
- `group`: a variable with two unique values specifying comparison groups
- `strata`: the stratification variable
- `conf.int`: confidence level
- `x`: an object created by `mhgr` or `lrcum`
- `a`: frequency of true positive tests
- `b`: frequency of false positive tests
- `c`: frequency of false negative tests
- `d`: frequency of true negative tests
- `dec`: number of places to the right of the decimal to print for `lrcum`
- `...`: additional arguments to be passed to other print functions

Details

Uses equations 4 and 13 from Greenland and Robins.

Value

A list of class "mhgr" or of class "lrcum".

Description

Adds minor tick marks to an existing plot. All minor tick marks that will fit on the axes will be drawn.

Usage

minor.tick(nx=2, ny=2, tick.ratio=0.5, x.args = list(), y.args = list())

Arguments

nx            number of intervals in which to divide the area between major tick marks on the X-axis. Set to 1 to suppress minor tick marks.
ny            same as nx but for the Y-axis.
tick.ratio    ratio of lengths of minor tick marks to major tick marks. The length of major tick marks is retrieved from par("tck").
x.args        additional arguments (e.g. post, lwd) used by axis() function when rendering the X-axis.
y.args        same as x.args but for Y-axis.

Side Effects

Miscellaneous Functions

Description

This documents miscellaneous small functions in Hmisc that may be of interest to users.

clowess runs lowess but if the iter argument exceeds zero, sometimes wild values can result, in which case lowess is re-run with iter=0.

confbar draws multi-level confidence bars using small rectangles that may be of different colors.

getLatestSource fetches and sources the most recent source code for functions in packages in the Vanderbilt University CVS repository.

grType retrieves the system option grType, which is forced to be "base" if the plotly package is not installed.

prType retrieves the system option prType, which is set to "plain" if the option is not set. print methods that allow for markdown/html/latex can be automatically invoked by setting options(prType="html") or options(prType='latex').

htmlSpecialType retrieves the system option htmlSpecialType, which is set to "unicode" if the option is not set. htmlSpecialType='unicode' cause html-generating functions in Hmisc and rms to use unicode for special characters, and htmlSpecialType='&' uses the older ampersand 3-digit format.

inverseFunction generates a function to find all inverses of a monotonic or nonmonotonic function that is tabulated at vectors (x,y), typically 1000 points. If the original function is monotonic, simple linear interpolation is used and the result is a vector, otherwise linear interpolation is used within each interval in which the function is monotonic and the result is a matrix with number of columns equal to the number of monotonic intervals. If a requested y is not within any interval, the extreme x that pertains to the nearest extreme y is returned. Specifying what='sample' to the returned function will cause a vector to be returned instead of a matrix, with elements taken as a random choice of the possible inverses.

james.stein computes James-Stein shrunken estimates of cell means given a response variable (which may be binary) and a grouping indicator.

km.quick provides a fast way to invoke survfitKM in the survival package to get Kaplan-Meier estimates for a single stratum for a vector of time points (if times is given) or to get a vector of survival time quantiles (if q is given).

latexBuild takes pairs of character strings and produces a single character string containing concatenation of all of them, plus an attribute "close" which is a character string containing the LaTeX closure that will balance LaTeX code with respect to parentheses, braces, brackets, or begin vs. end. When an even-numbered element of the vector is not a left parenthesis, brace, or bracket, the

```r
points(runif(20), runif(20)) # plotting data
axis(1, pos = 0.5, lwd = 2) # showing X-axis at Y = 0.5 with formatting
axis(2, col = 2) # formatted Y-axis
minor.tick( nx = 4, ny = 4, tick.ratio = 0.3,
  x.args = list(pos = 0.5, lwd = 2), # X-minor tick format arguments
  y.args = list(col = 2)) # Y-minor tick format arguments
```
Misc

... element is taken as a word that was surrounded by `begin` and `end` for which the corresponding
end is constructed in the returned attribute.

`lm.fit.qr.bare` is a fast stripped-down function for computing regression coefficients, residuals,
$R^2$, and fitted values. It uses `lm.fit`.

`matxv` multiplies a matrix by a vector, handling automatic addition of intercepts if the matrix does
not have a column of ones. If the first argument is not a matrix, it will be converted to one. An optional
argument allows the second argument to be treated as a matrix, useful when its rows represent
bootstrap reps of coefficients. Then $ab'$ is computed. `matxv` respects the "intercepts" attribute if
it is stored on `b` by the `rms` package. This is used by `orm` fits that are bootstrap-repeated by `bootcov`
where only the intercept corresponding to the median is retained. If `kint` has nonzero length, it is
checked for consistency with the attribute.

`makeSteps` is a copy of the `dostep` function inside the `survival` package's `plot.survfit` function.
It expands a series of points to include all the segments needed to plot step functions. This is useful
for drawing polygons to shade confidence bands for step functions.

`nomiss` returns a data frame (if its argument is one) with rows corresponding to NAs removed, or it
returns a matrix with rows with any element missing removed.

`outerText` uses `axis()` to put right-justified text strings in the right margin. Placement depends on
`par[('mar')[4]]`

`plotlyParm` is a list of functions useful for specifying parameters to `plotly` graphics.

`plotp` is a generic to handle `plotp` methods to make `plotly` graphics.

`sepUnitsTrans` converts character vectors containing values such as $c(3 \text{\ days}, 3 \text{\ day}, 4 \text{\ month}, 2 \text{\ years}, 2 \text{\ weeks})$
to numeric vectors (here $c(3, 3, 122, 730, 14, 7)$) in a flexible fashion. The user can specify a vector
of units of measurements and conversion factors. The units with a conversion factor of 1 are
taken as the target units, and if those units are present in the character strings they are ignored. The
target units are added to the resulting vector as the "units" attribute.

`strgraphwrap` is like `strwrap` but is for the current graphics environment.

`tobase64image` is a function written by Dirk Eddelbuettel that uses the `base64enc` package to
convert a png graphic file to base64 encoding to include as an inline image in an html file.

`trap.rule` computes the area under a curve using the trapezoidal rule, assuming $x$ is sorted.

`trellis.strip.blank` sets up Trellis or Lattice graphs to have a clear background on the strips for
panel labels.

`unPaste` provides a version of the S-Plus `unpaste` that works for R and S-Plus.

`whichClosePW` is a very fast function using weighted multinomial sampling to determine which
element of a vector is "closest" to each element of another vector. `whichClosest` quickly finds the
closest element without any randomness.

`whichClosest` is a slow function that finds, after jittering the lookup table, the $k$ closest matchest
to each element of the other vector, and chooses from among these one at random.

`xless` is a function for Linux/Unix users to invoke the system `xless` command to pop up a window
to display the result of printing an object.

Usage

```r
confbar(at, est, se, width, q = c(0.7, 0.8, 0.9, 0.95, 0.99),
        col = gray(c(0, 0.25, 0.5, 0.75, 1)))
```
Misc

```r
type = c("v", "h"), labels = TRUE, ticks = FALSE,
cex = 0.5, side = "l", lwd = 5, clip = c(-1e+30, 1e+30),
fun = function(x) x,
qfun = function(x) ifelse(x == 0.5, qnorm(x),
  ifelse(x < 0.5, qnorm(x/2),
    qnorm((1 + x)/2))))
getLatestSource(x==NULL, package='Misc', recent=NULL, avail=FALSE,
type=c('svn','cvs'))
grType()
prType()
htmlSpecialType()
inverseFunction(x, y)
james.stein(y, group)
km.quick(S, times, q)
l_TEXBuild(..., insert, sep='')
lm.fit.qr.bare(x, y, tolerance, intercept=TRUE, xpi=FALSE, singzero=FALSE)
matxv(a, b, kint=1, bmat=FALSE)
nomiss(x)
outerText(string, y, cex=par('cex'), ...)
plotlyParm
plotp(data, ...)
sepUnitsTrans(x, conversion=c(day=1, month=365.25/12, year=365.25, week=7),
  round=FALSE, digits=0)
strgraphwrap(x, width = 0.9 * getOption("width"),
  indent = 0, exdent = 0,
  prefix = "", simplify = TRUE, units='user', cex=NULL)
tobase64image(file, Rd = FALSE, alt = "image")
trap.rule(x, y)
trellis.strip.blank()
unPaste(str, sep="/")
whichClosest(x, w)
whichClosePW(x, w, f=0.2)
whichClosek(x, w, k)
xless(x, ..., title)
```

**Arguments**

- `a` a numeric matrix or vector
- `alt,Rd` see base64::img
- `at` x-coordinate for vertical confidence intervals, y-coordinate for horizontal
- `avail` set to TRUE to have getLatestSource return a data frame of available files and latest versions instead of fetching any
- `b` a numeric vector
- `cex` character expansion factor
- `clip` interval to truncate limits
- `col` vector of colors
conversion is a named numeric vector.
data is an object having a plotp method.
digits is the number of digits used for round.
est is a vector of point estimates for confidence limits.
f is a scaling constant.
file is a file name.
fun is a function to transform scale.
group is a categorical grouping variable.
insert is a list of 3-element lists for latexBuild. The first of each 3-element list is a character string with an environment name. The second specifies the order: "before" or "after", the former indicating that when the environment is found, the third element of the list is inserted before or after it, according to the second element.
intercept is set to FALSE to not automatically add a column of ones to the x matrix.
k is used to get the k closest matches.
kint is which element of b to add to the result if a does not contain a column for intercepts.
bmat is set to TRUE to consider b a matrix of repeated coefficients, usually resampled estimates with rows corresponding to resamples.
labels is set to FALSE to omit drawing confidence coefficients.
lwd is line widths.
package is the name of package for getLatestSource, default is 'Hmisc'.
q is a vector of confidence coefficients or quantiles.
qfun is quantiles on transformed scale.
recent is an integer telling getLatestSource to get the recent most recently modified files from the package.
round is set to TRUE to round converted values.
S is a Surv object.
se is a vector of standard errors.
sep is a single character string specifying the delimiter. For latexBuild the default is "\".
side is for confbar is "b","l","t","r" for bottom, left, top, right.
str is a character string vector.
string is a character string vector.
ticks is set to TRUE to draw lines between rectangles.
times is a numeric vector of times.
title is a character string to title a window or plot.
tolerance is tolerance for judging singularity in matrix.
Misc 207

type  "v" for vertical, "h" for horizontal. For getLatestSource this specifies the type of source code repository, 'svn' (the default) or 'cvs', which is now outdated as Subversion has replaced CVS in the Vanderbilt Biostatistics server.

w      a numeric vector
width   width of confidence rectangles in user units, or see strwrap
x      a numeric vector (matrix for lm.fit.qr.bare) or data frame. For xless may be any object that is sensible to print. For sepUnitsTrans is a character or factor variable. For getLatestSource is a character string or vector of character strings containing base file names to retrieve from CVS. Set x='all' to retrieve all source files. For clowess, x may also be a list with x and y components. For InverseFunction, x and y contain evaluations of the function whose inverse is needed. x is typically an equally-spaced grid of 1000 points. For strgraphwrap is a character vector.

xp, xi set to TRUE to add an element to the result containing the inverse of $X'X$
singzero set to TRUE to set coefficients corresponding to singular variables to zero instead of NA.
y      a numeric vector. For inverseFunction y is the evaluated function values at x.
indent, exdent, prefix see strwrap
simplify see sapply
units see par
...

... arguments passed through to another function. For latexBuild represents pairs, with odd numbered elements being character strings containing LaTeX code or a zero-length object to ignore, and even-numbered elements representing LaTeX left parenthesis, left brace, or left bracket, or environment name.

**mtitle**

**Margin Titles**

**Description**

Writes overall titles and subtitles after a multiple image plot is drawn. If `par()$oma==c(0,0,0,0)`, `title` is used instead of `mtext`, to draw titles or subtitles that are inside the plotting region for a single plot.

**Usage**

```r
mtitle(main, ll, lc, lr=
1r=format(Sys.time(),'%d%b%y'),
cex.m=1.75, cex.l=.5, …)
```

none

**Arguments**

- `main` main title to be centered over entire figure, default is none
- `ll` subtitle for lower left of figure, default is none
- `lc` subtitle for lower center of figure, default is none
- `lr` subtitle for lower right of figure, default is today’s date in format 23Jan91 for UNIX or R (Thu May 30 09:08:13 1996 format for Windows). Set to "" to suppress lower right title.
- `cex.m` character size for main, default is 1.75
- `cex.l` character size for subtitles
- `…` other arguments passed to `mtext`

---
**multLines**

**Value**

nothing

**Side Effects**

plots

**Author(s)**

Frank Harrell  
Department of Biostatistics, Vanderbilt University  
<f.harrell@vanderbilt.edu>

**See Also**

par, mtext, title, unix, pstamp

**Examples**

```r
# Set up for 1 plot on figure, give a main title, 
# use date for lr
plot(runif(20),runif(20))
mltitle("Main Title")

# Set up for 2 x 2 matrix of plots with a lower left subtitle and overall title
par(mfrow=c(2,2), oma=c(3,0,3,0))
plot(runif(20),runif(20))
plot(rnorm(20),rnorm(20))
plot(exp(rnorm(20)),exp(rnorm(20)))
mltitle("Main Title",ll="n=20")
```

**Description**

Plots multiple lines based on a vector `x` and a matrix `y`, draws thin vertical lines connecting limits represented by columns of `y` beyond the first. It is assumed that either (1) the second and third columns of `y` represent lower and upper confidence limits, or that (2) there is an even number of columns beyond the first and these represent ascending quantiles that are symmetrically arranged around 0.5. If `options(grType='plotly')` is in effect, uses plotly graphics instead of grid or base graphics. For plotly you may want to set the list of possible colors, etc. using `pobj=plot_ly(colors=...)`. `lwd`, `lty`, `lwd.vert` are ignored under plotly.
Usage

```
mutLines(x, y, pos = c('left', 'right'), col='gray',
        lwd=1, lty=1, lwd.vert = .85, lty.vert = 1,
        alpha = 0.4, grid = FALSE,
        pobj=plotly::plot_ly(), xlim, name=colnames(y)[1], legendgroup=name,
        showlegend=TRUE, ...)
```

Arguments

- **x**: a numeric vector
- **y**: a numeric matrix with number of rows equal to the number of x elements
- **pos**: when pos='left' the vertical lines are drawn, right to left, to the left of the point (x, y[1,]). Otherwise lines are drawn left to right to the right of the point.
- **col**: a color used to connect (x, y[1,]) pairs. The same color but with transparency given by the alpha argument is used to draw the vertical lines
- **lwd**: line width for main lines
- **lty**: line types for main lines
- **lwd.vert**: line width for vertical lines
- **lty.vert**: line type for vertical lines
- **alpha**: transparency
- **grid**: set to TRUE when using grid/lattice
- **pobj**: an already started plotly object to add to
- **xlim**: global x-axis limits (required if using plotly)
- **name**: trace name if using plotly
- **legendgroup**: legend group name if using plotly
- **showlegend**: whether or not to show traces in legend, if using plotly
- **...**: passed to add_lines or add_segments if using plotly

Author(s)

Frank Harrell

Examples

```
x <- 1:4
y <- cbind(x, x-3, x-2, x-1, x+1, x+2, x+3)
plot(NA, NA, xlim=c(1,4), ylim=c(-2, 7))
multLines(x, y, col='blue')
multLines(x, y, col='red', pos='right')
```
**na.delete**

---

**Row-wise Deletion na.action**

---

**Description**

Does row-wise deletion as `na.omit`, but adds frequency of missing values for each predictor to the "na.action" attribute of the returned model frame. Optionally stores further details if `options(na.detail.response=TRUE)`.

**Usage**

```r
na.delete(frame)
```

**Arguments**

- `frame`  
a model frame

**Value**

a model frame with rows deleted and the "na.action" attribute added.

**Author(s)**

Frank Harrell  
Department of Biostatistics  
Vanderbilt University  
<f.harrell@vanderbilt.edu>

**See Also**

`na.omit`, `na.keep`, `na.detail.response`, `model.frame.default`, `naresid`, `naprint`

**Examples**

```r
# options(na.action="na.delete")
# ols(y ~ x)
```

---

**na.detail.response**

---

**Detailed Response Variable Information**

---

**Description**

This function is called by certain na.action functions if `options(na.detail.response=TRUE)` is set. By default, this function returns a matrix of counts of non-NA's and the mean of the response variable computed separately by whether or not each predictor is NA. The default action uses the last column of a Surv object, in effect computing the proportion of events. Other summary functions may be specified by using `options(na.fun.response="name of function")`. 

---
Usage

na.detail.response(mf)

Arguments

mf a model frame

Value

a matrix, with rows representing the different statistics that are computed for the response, and columns representing the different subsets for each predictor (NA and non-NA value subsets).

Author(s)

Frank Harrell
Department of Biostatistics
Vanderbilt University
<f.harrell@vanderbilt.edu>

# 10 8
# # Frequencies of Missing Values Due to Each Variable
# y age sex
# 0 2 0
# # Statistics on Response by Missing/Non-Missing Status of Predictors
# age=NA age!=NA sex!=NA Any NA No NA
**na.keep**

---

### Description

Does not delete rows containing NAs, but does add details concerning the distribution of the response variable if `options(na.detail.response=TRUE)`. This `na.action` is primarily for use with `describe.formula`.

### Usage

```r
na.keep(mf)
```

### Arguments

- **mf**: a model frame

### Value

The same model frame with the "na.action" attribute

### Author(s)

Frank Harrell  
Department of Biostatistics  
Vanderbilt University  
<f.harrell@vanderbilt.edu>
See Also

na.omit, na.delete, model.frame.default, na.detail.response, naresid, naprint, describe

Examples

```r
options(na.action="na.keep", na.detail.response=TRUE)

x2 <- runif(20)
x2[1:4] <- NA
y <- rnorm(20)
describe(y ~ x1*x2)
```

### nobsY

**Compute Number of Observations for Left Hand Side of Formula**

**Description**

After removing any artificial observations added by addMarginal, computes the number of non-missing observations for all left-hand-side variables in `formula`. If `formula` contains a term `id(variable)` variable is assumed to be a subject ID variable, and only unique subject IDs are counted. If group is given and its value is the name of a variable in the right-hand-side of the model, an additional object `nobs` is returned that is a matrix with as many columns as there are left-hand variables, and as many rows as there are levels to the group variable. This matrix has the further breakdown of unique non-missing observations by group. The concatenation of all ID variables, is returned in a list element `id`.

**Usage**

```r
nobsY(formula, group=NULL, data = NULL, subset = NULL,
na.action = naretain, matrixna=c('all', 'any'))
```

**Arguments**

- `formula` a formula object
- `group` character string containing optional name of a stratification variable for computing sample sizes
- `data` a data frame
- `subset` an optional subsetting criterion
- `na.action` an optional NA-handling function
- `matrixna` set to "all" if an observation is to be considered NA if all the columns of the variable are NA, otherwise use matrixna="any" to consider the row missing if any of the columns are missing

**Value**

an integer, with an attribute "formula" containing the original formula but with an id variable (if present) removed
Examples

d <- expand.grid(sex=c('female', 'male', NA),
    country=c('US', 'Romania'),
    reps=1:2)
d$subject.id <- c(0, 0, 3:12)
dm <- addMarginal(d, sex, country)
dim(dm)
nobsY(sex + country - 1, data=d)
nobsY(sex + country ~ id(subject.id), data=d)
nobsY(sex + country ~ id(subject.id) + reps, group='reps', data=d)
nobsY(sex - 1, data=d)
nobsY(sex ~ 1, data=dm)
nobsY(sex ~ id(subject.id), data=dm)

nstr

Creates a string of arbitrary length

Description

Creates a vector of strings which consists of the string segment given in each element of the string vector repeated times.

Usage

nstr(string, times)

Arguments

string character: vector of string segments to be repeated. Will be recycled if argument times is longer.
times integer: vector of number of times to repeat the corresponding segment. Will be recycled if argument string is longer.

Value

returns a character vector the same length as the longest of the two arguments.

Note

Will throw a warning if the length of the longer argument is not an even multiple of the shorter argument.

Author(s)

Charles Dupont

paste, rep
Examples

```r
cstr(c("a"), c(0, 3, 4))
cstr(c("a", "b", "c"), c(1, 2, 3))
cstr(c("a", "b", "c"), 4)
```

**Description**

Extract the number of intercepts from a model

**Usage**

```r
num.intercepts(fit, type=c('fit', 'var', 'coef'))
```

**Arguments**

- `fit` a model fit object
- `type` the default is to return the formal number of intercepts used when fitting the model. Set `type='var'` to return the actual number of intercepts stored in the `var` object, or `type='coef'` to return the actual number in the fitted coefficients. The former will be less than the number fitted for `orm` fits, and the latter for `orm` fits passed through `fit.mult.impute`

**Value**

`num.intercepts` returns an integer with the number of intercepts in the model.

**See Also**

`orm`, `fit.mult.impute`
panel.bpplot

Description

For all their good points, box plots have a high ink/information ratio in that they mainly display 3 quartiles. Many practitioners have found that the "outer values" are difficult to explain to non-statisticians and many feel that the notion of "outliers" is too dependent on (false) expectations that data distributions should be Gaussian.

panel.bpplot is a panel function for use with trellis, especially for bwplot. It draws box plots (without the whiskers) with any number of user-specified "corners" (corresponding to different quantiles), but it also draws box-percentile plots similar to those drawn by Jeffrey Banfield's (<umsfjban@bill.oscs.montana.edu>) bpplot function. To quote from Banfield, "box-percentile plots supply more information about the univariate distributions. At any height the width of the irregular 'box' is proportional to the percentile of that height, up to the 50th percentile, and above the 50th percentile the width is proportional to 100 minus the percentile. Thus, the width at any given height is proportional to the percent of observations that are more extreme in that direction. As in boxplots, the median, 25th and 75th percentiles are marked with line segments across the box."

panel.bpplot can also be used with base graphics to add extended box plots to an existing plot, by specifying nogrid=TRUE, height=....

panel.bpplot is a generalization of bpplot and panel.bwplot in that it works with trellis (making the plots horizontal so that category labels are more visible), it allows the user to specify the quantiles to connect and those for which to draw reference lines, and it displays means (by default using dots).

bpplt draws horizontal box-percentile plot much like those drawn by panel.bpplot but taking as the starting point a matrix containing quantiles summarizing the data. bpplt is primarily intended to be used internally by plot.summary.formula.reverse or plot.summaryM but when used with no arguments has a general purpose: to draw an annotated example box-percentile plot with the default quantiles used and with the mean drawn with a solid dot. This schematic plot is rendered nicely in postscript with an image height of 3.5 inches.

bppltm is like bpplt but for plotly graphics, and it does not draw an annotated extended box plot example.

bpplottm uses the lattice bwplot function to depict multiple numeric continuous variables with varying scales in a single lattice graph, after reshaping the dataset into a tall and thin format.

Usage

panel.bpplot(x, y, box.ratio=1, means=TRUE, qref=c(.5,.25,.75),
probs=c(.05,.125,.25,.375), nout=0,
nloc=c('right lower', 'right', 'left', 'none'), cex.n=.7,
datatdensity=FALSE, scat1d.opts=NULL,
violin=FALSE, violin.opts=NULL,
font=box.dot$font, pch=box.dot$pch,
cex.means =box.dot$cex, col=box.dot$col,
nogrid=TRUE, height=NULL, ...)

# E.g. bwplot(formula, panel=panel.bpplot, panel.bpplot.parameters)

bpplt(stats, xlim, xlab=' ', box.ratio = 1, means=TRUE, qref=c(.5,.25,.75), qomit=c(.025,.975), pch=16, cex.labels=par('cex'), cex.points=if(prototype)1 else 0.5, grid=FALSE)

bppltp(p=plotly::plot_ly(),
   stats, xlim, xlab=' ', box.ratio = 1, means=TRUE, qref=c(.5,.25,.75), qomit=c(.025,.975), teststat=NULL, showlegend=TRUE)

bpplotM(formula=NULL, groups=NULL, data=NULL, subset=NULL, na.action=NULL, qlim=0.01, xlim=NULL, nloc=c('right lower','right','left','none'), vnames=c('labels', 'names'), cex.n=0.7, cex.strip=1, outerlabels=TRUE, ...)

Arguments

x continuous variable whose distribution is to be examined

y grouping variable

box.ratio see panel.bwplot

means set to FALSE to suppress drawing a character at the mean value

qref vector of quantiles for which to draw reference lines. These do not need to be included in probs.

probs vector of quantiles to display in the box plot. These should all be less than 0.5; the mirror-image quantiles are added automatically. By default, probs is set to c(.05,.125,.25,.375) so that intervals contain 0.9, 0.75, 0.5, and 0.25 of the data. To draw all 99 percentiles, i.e., to draw a box-percentile plot, set probs=seq(.01,.99,by=.01). To make a more traditional box plot, use probs=.25.

nout tells the function to use scat1d to draw tick marks showing the nout smallest and nout largest values if nout >= 1, or to show all values less than the nout quantile or greater than the 1-nout quantile if 0 < nout <= 0.5. If nout is a whole number, only the first n/2 observations are shown on either side of the median, where n is the total number of observations.

nloc location to plot number of non-NA observations next to each box. Specify nloc='none' to suppress. For panel.bpplot, the default nloc is 'none' if nogrid=TRUE.

cex.n character size for nloc

datatdensity set to TRUE to invoke scat1d to draw a data density (one-dimensional scatter diagram or rug plot) inside each box plot.

scat1d.opts a list containing named arguments (without abbreviations) to pass to scat1d when datadensity=TRUE or nout > 0
**panel.bpplot**

violin set to TRUE to invoke panel.violin in addition to drawing box-percentile plots

violin.opts a list of options to pass to panel.violin

cex.means character size for dots representing means

font,pch,col see panel.bwplot

nogrid set to TRUE to use in base graphics

height if nogrid=TRUE, specifies the height of the box in user y units

... arguments passed to points or panel.bpplot or bwplot

stats,xlim,xlab,qomit,cex.labels,cex.points,grid

undocumented arguments to bpplt. For bpplotM, xlim is a list with elements named as the x-axis variables, to override the qlim calculations with user-specified x-axis limits for selected variables. Example: xlim=list(age=c(20,60)).

p an already-started plotly object

teststat an html expression containing a test statistic

showlegend set to TRUE to have plotly include a legend. Not recommended when plotting more than one variable.

formula a formula with continuous numeric analysis variables on the left hand side and stratification variables on the right. The first variable on the right is the one that will vary the fastest, forming the y-axis. formula may be omitted, in which case all numeric variables with more than 5 unique values in data will be analyzed. Or formula may be a vector of variable names in data to analyze. In the latter two cases (and only those cases), groups must be given, representing a character vector with names of stratification variables.

groups see above

data an optional data frame

subset an optional subsetting expression or logical vector

na.action specifies a function to possibly subset the data according to NAs (default is no such subsetting).

qlim the outer quantiles to use for scaling each panel in bpplotM

vnames default is to use variable label attributes when they exist, or use variable names otherwise. Specify vnames='names' to always use variable names for panel labels in bpplotM

cex.strip character size for panel strip labels

outerlabels if TRUE, pass the lattice graphics through the latticeExtra package’s useOuterStrips function if there are two conditioning (paneling) variables, to put panel labels in outer margins.

partition

Partitions an object into different sets

Description
Partitions an object into subsets of length defined in the sep argument.

Usage

```r
partition(x, sep, ...)
partition.matrix(x, rowsep, colsep, ...)
```

Arguments

- `x`: object to be partitioned.
- `sep`: determines how many elements should go into each set. The sum of sep should be equal to the length of x.
- `rowsep`: determines how many rows should go into each set. The sum of rowsep must equal the number of rows in x.
- `colsep`: determines how many columns should go into each set. The sum of colsep must equal the number of columns in x.
- `...`: arguments used in other methods of partition.

Value
A list of equal length as sep containing the partitioned objects.

Author(s)
Charles Dupont

Examples

```r
a <- 1:7
partition.vector(a, sep=c(1,3,2,1))
```
plotCorrPrecision

Plot Precision of Estimate of Pearson Correlation Coefficient

Description

This function plots the precision (margin of error) of the product-moment linear correlation coefficient $r$ vs. sample size, for a given vector of correlation coefficients $\rho$. Precision is defined as the larger of the upper confidence limit minus $\rho$ and $\rho$ minus the lower confidence limit. `labcurve` is used to automatically label the curves.

Usage

```
plotCorrPrecision(rho = c(0, 0.5), n = seq(10, 400, length = 100),
                  conf.int = 0.95, offset=0.025, ...)
```

Arguments

- `rho` single or vector of true correlations. A worst-case precision graph results from $\rho=0$
- `n` vector of sample sizes to use on the x-axis
- `conf.int` confidence coefficient; default uses 0.95 confidence limits
- `offset` see `labcurve`
- `...` other arguments to `labcurve`

plotlyM

plotly Multiple

Description
Generates multiple plotly graphics, driven by specs in a data frame

Usage
plotlyM(data, x = ~x, y = ~y, xhi = ~xhi, yhi = ~yhi,
htext = NULL, multplot = NULL, strata = NULL, fitter = NULL,
color = NULL, size = NULL, showpts = !length(fitter),
rotate = FALSE, xlab = NULL, ylab = NULL, ylabpos = c("top", 
"y"), xhim = NULL, ylim = NULL, shareX = TRUE, shareY = FALSE,
height = NULL, width = NULL, nrows = NULL, ncols = NULL,
colors = NULL, alphaSegments = 1, alphaCline = 0.3, digits = 4,
zeroline = TRUE)

Arguments

data input data frame
x formula specifying the x-axis variable
y formula for y-axis variable
xhi formula for upper x variable limits (x taken to be lower value)
yhi formula for upper y variable limit (y taken to be lower value)
htext formula for hovertext variable
multplot formula specifying a variable in data that when stratified on produces a separate plot
strata formula specifying an optional stratification variable
fitter a fitting such as loess
color plotly formula specifying a color variable or e.g. ~ I('black'). To keep colors constant over multiple plots you will need to specify an AsIs color when you don’t have a variable representing color groups.
size plotly formula specifying a symbol size variable or AsIs
showpts if fitter is given, set to TRUE to show raw data points in addition to smooth fits
rotate set to TRUE to reverse the roles of x and y, for example to get horizontal dot charts with error bars
xlab x-axis label. May contain html.
ylab a named vector of y-axis labels, possibly containing html (see example below). The names of the vector must correspond to levels of the multplot variable.
ylabpos position of y-axis labels. Default is on top left of plot. Specify ylabpos= ’y’ for usual y-axis placement.
xlim 2-vector of x-axis limits, optional
ylim 2-vector of y-axis limits, optional
shareX specifies whether x-axes should be shared when they align vertically over multiple plots
shareY specifies whether y-axes should be shared when they align horizontally over multiple plots
height height of the combined image in pixels
width width of the combined image in pixels
nrows the number of rows to produce using subplot
ncols the number of columns to produce using subplot (specify at most one of nrows, ncols)
colors the color palette. Leave unspecified to use the default plotly palette
alphaSegments alpha transparency for line segments (when xhi or yhi is not NA)
alphaCline alpha transparency for lines used to connect points
digits number of significant digits to use in constructing hovertext
zeroline set to FALSE to suppress vertical line at x=0

Details

Generates multiple plotly traces and combines them with plotly::subplot. The traces are controlled by specifications in data frame data plus various arguments. data must contain these variables: x, y, and tracename (if color is not an "AsIs" color such as ~ I('black')), and can contain these optional variables: xhi, yhi (rows containing NA for both xhi and yhi represent points, and those with non-NA xhi or yhi represent segments, connect (set to TRUE for rows for points, to connect the symbols), legendgroup (see plotly documentation), and htext (hovertext). If the color argument is given and it is not an "AsIs" color, the variable named in the color formula must also be in data. Likewise for size. If the multplot is given, the variable given in the formula must be in data. If strata is present, another level of separate plots is generated by levels of strata, within levels of multplot.

If fitter is specified, x,y coordinates for an individual plot are run through fitter, and a line plot is made instead of showing data points.

Value

plotly object produced by subplot

Author(s)

Frank Harrell

Examples

```r
## Not run:
set.seed(1)
pts <- expand.grid(x=c('y1', 'y2', 'y3'), x=1:4, g=c('a', 'b'), xhi=NA,
                  tracename='mean', legendgroup='mean',
                  connect=TRUE, size=4)
```
plsmo

Plot smoothed estimates

Description

Plot smoothed estimates of x vs. y, handling missing data for lowess or supsmu, and adding axis labels. Optionally suppresses plotting extrapolated estimates. An optional group variable can be specified to compute and plot the smooth curves by levels of group. When group is present, the datadensity option will draw tick marks showing the location of the raw x-values, separately for each curve. plsmo has an option to plot connected points for raw data, with no smoothing. The non-panel version of plsmo allows y to be a matrix, for which smoothing is done separately over its columns. If both group and multi-column y are used, the number of curves plotted is the product of the number of groups and the number of y columns.

method='intervals' is often used when y is binary, as it may be tricky to specify a reasonable smoothing parameter to lowess or supsmu in this case. The 'intervals' method uses the cut2 function to form intervals of x containing a target of mobs observations. For each interval the ifun function summarizes y, with the default being the mean (proportions for binary y). The results are plotted as step functions, with vertical discontinuities drawn with a saturation of 0.15 of the original color. A plus sign is drawn at the mean x within each interval. For this approach, the default x-range is the entire raw data range, and trim and evaluate are ignored. For panel.plsmo it is best to specify type='1' when using 'intervals'.

panel.plsmo is a panel function for trellis for the xyplot function that uses plsmo and its options to draw one or more nonparametric function estimates on each panel. This has advantages over using xyplot with panel.xyplot and panel.loess: (1) by default it will invoke
labcurve to label the curves where they are most separated, (2) the datadensity option will put rug plots on each curve (instead of a single rug plot at the bottom of the graph), and (3) when panel.plsmo invokes plsmo it can use the "super smoother" (supsmu function) instead of lowess, or pass method=‘intervals’. panel.plsmo senses when a group variable is specified to xyplot so that it can invoke panel.superpose instead of panel.xyplot. Using panel.plsmo through trellis has some advantages over calling plsmo directly in that conditioning variables are allowed and trellis uses nicer fonts etc.

When a group variable was used, panel.plsmo creates a function Key in the session frame that the user can invoke to draw a key for individual data point symbols used for the groups. By default, the key is positioned at the upper right corner of the graph. If Key(locator(1)) is specified, the key will appear so that its upper left corner is at the coordinates of the mouse click.

For ggplot2 graphics the counterparts are stat_plsmo and histSpike.

Usage

```
plsmo(x, y, method=c("lowess","supsmu","raw","intervals"), xlab, ylab,
      add=FALSE, lty=1 : l, col=par("col"), lwd=par("lwd"),
      iter=if(length(unique(y))>2) 3 else 0, bass=0, f=2/3, mobs=30, trim,
      fun, ifun=mean, group, prefix, xlim, ylim,
      label.curves=TRUE, datadensity=FALSE, scat1d.opts=NULL,
      lines=TRUE, subset=TRUE,
      grid=FALSE, evaluate=NULL, ...)
```

#To use panel function:
#xyplot(formula=y ~ x | conditioningvars, groups,
#   panel=panel.plsmo, type='b',
#   label.curves=TRUE,
#   lwd = superpose.line$lwd,
#   lty = superpose.line$lty,
#   pch = superpose.symbol$pch,
#   cex = superpose.symbol$cex,
#   font = superpose.symbol$font,
#   col = NULL, scat1d.opts=NULL, ...)

Arguments

- `x` vector of x-values, NAs allowed
- `y` vector or matrix of y-values, NAs allowed
- `method` "lowess" (the default), "supsmu", "raw" to not smooth at all, or "intervals" to use intervals (see above)
- `xlab` x-axis label iff add=F. Defaults of label(x) or argument name.
- `ylab` y-axis label, like xlab.
- `add` Set to T to call lines instead of plot. Assumes axes already labeled.
- `lty` line type, default=1,2,3,..., corresponding to columns of y and group combinations
col

vector of line widths for the curves, corresponding to group. Default is current par("lwd").

lwd

iter

iter parameter if method="lowess", default=0 if y is binary, and 3 otherwise.

bass

bass parameter if method="supsmu", default=0.

f

passed to the lowess function, for method="lowess"

mobs

for method='intervals', the target number of observations per interval

trim

only plots smoothed estimates between trim and 1-trim quantiles of x. Default is to use 10th smallest to 10th largest x in the group if the number of observations in the group exceeds 200 (0 otherwise). Specify trim=0 to plot over entire range.

fun

after computing the smoothed estimates, if fun is given the y-values are transformed by fun()

ifun

a summary statistic function to apply to the y-variable for method='intervals'. Default is mean.

group

a variable, either a factor vector or one that will be converted to factor by plsmo, that is used to stratify the data so that separate smooths may be computed

prefix

a character string to appear in group of group labels. The presence of prefix ensures that labcurve will be called even when add=TRUE.

xlim

a vector of 2 x-axis limits. Default is observed range.

ylim

a vector of 2 y-axis limits. Default is observed range.

label.curves

set to FALSE to prevent labcurve from being called to label multiple curves corresponding to groups. Set to a list to pass options to labcurve. lty and col are passed to labcurve automatically.

datadensity

set to TRUE to draw tick marks on each curve, using x-coordinates of the raw data x values. This is done using scat1d.

scat1d.opts

a list of options to hand to scat1d

lines.

set to FALSE to suppress smoothed curves from being drawn. This can make sense if datadensity=TRUE.

subset

a logical or integer vector specifying a subset to use for processing, with respect to all variables being analyzed

grid

set to TRUE if the R grid package drew the current plot

evaluate

number of points to keep from smoother. If specified, an equally-spaced grid of evaluate x values will be obtained from the smoother using linear interpolation. This will keep from plotting an enormous number of points if the dataset contains a very large number of unique x values.

...optional arguments that are passed to scat1d, or optional parameters to pass to plsmo from panel.plsmo. See optional arguments for plsmo above.

type

set to p to have panel.plsmo plot points (and not call plsmo), 1 to call plsmo and not plot points, or use the default b to plot both.

pch,cex,font

vectors of graphical parameters corresponding to the groups (scalars if group is absent). By default, the parameters set up by trellis will be used.
Value

plsmo returns a list of curves (x and y coordinates) that was passed to labcurve.

Side Effects

plots, and panel.plsmo creates the key function in the session frame.

# Try to duplicate this smooth by replicating 51st observation 100 times
lines(wtd.loess.noiter(c(x,rep(x[51],99)),c(y,rep(y[51],99))),
    type='ordered all'), col=3)
# Note: These two don't agree exactly

---

### popower

**Power and Sample Size for Ordinal Response**

**Description**

popower computes the power for a two-tailed two sample comparison of ordinal outcomes under the proportional odds ordinal logistic model. The power is the same as that of the Wilcoxon test but with ties handled properly. posamsize computes the total sample size needed to achieve a given power. Both functions compute the efficiency of the design compared with a design in which the response variable is continuous. print methods exist for both functions. Any of the input arguments may be vectors, in which case a vector of powers or sample sizes is returned. These functions use the methods of Whitehead (1993).

pomodm is a function that assists in translating odds ratios to differences in mean or median on the original scale.

**Usage**

```r
popower(p, odds.ratio, n, n1, n2, alpha=0.05)
## S3 method for class 'popower'
print(x, ...)
posamsize(p, odds.ratio, fraction=.5, alpha=0.05, power=0.8)
## S3 method for class 'posamsize'
print(x, ...)
pomodm(x=NULL, p, odds.ratio=1)
```
Arguments

- **p**: a vector of marginal cell probabilities which must add up to one. The \( i \)th element specifies the probability that a patient will be in response level \( i \), averaged over the two treatment groups.
- **odds.ratio**: the odds ratio to be able to detect. It doesn’t matter which group is in the numerator.
- **n**: total sample size for `popower`. You must specify either \( n \) or \( n1 \) and \( n2 \). If you specify \( n \), \( n1 \) and \( n2 \) are set to \( n/2 \).
- **n1**: for `popower`, the number of subjects in treatment group 1
- **n2**: for `popower`, the number of subjects in group 2
- **alpha**: type I error
- **x**: an object created by `popower` or `posamsize`, or a vector of data values given to `ponomd` that corresponds to the vector \( p \) of probabilities. If \( x \) is omitted for `ponomd`, the `odds.ratio` will be applied and the new vector of individual probabilities will be returned. Otherwise if \( x \) is given to `ponomd`, a 2-vector with the mean and median \( x \) after applying the odds ratio is returned.
- **fraction**: for `posamsize`, the fraction of subjects that will be allocated to group 1
- **power**: for `posamsize`, the desired power (default is 0.8)
  
  ... unused

Value

A list containing `power` and `eff` (relative efficiency) for `popower`, or containing `n` and `eff` for `posamsize`.

# Compute the mean and median x after shifting the probability
# distribution by an odds ratio under the proportional odds model
x <- 1:5
p <- c(0.05, .2, .2, .3, .25)
# For comparison make up a sample that looks like this
X <- rep(1:5, 20 * p)
c(mean=mean(X), median=median(X))
pomodm(x, p, odds.ratio=1)  # still have to figure out the right median
pomodm(x, p, odds.ratio=0.5)

print.char.list  
prints a list of lists in a visually readable format.

Description

Takes a list that is composed of other lists and matrixes and prints it in a visually readable format.

Usage

## S3 method for class 'char.list'
print(x, ..., hsep = c("|"), vsep = c("-"), csep = c("*")), print.it = TRUE,
rownames.halign = c("left", "centre", "right"),
rownames.valign = c("top", "centre", "bottom"),
colnames.halign = c("centre", "left", "right"),
colnames.valign = c("centre", "top", "bottom"),
text.halign = c("right", "centre", "left"),
text.valign = c("top", "centre", "bottom"),
rownames.width, rownames.height,
min.colwidth = .Options$digits, max.rowheight = NULL,
abbreviate.dimnames = TRUE, page.width = .Options$width,
colnames.width, colnames.height, prefix.width,
superprefix.width = prefix.width)

Arguments

x  list object to be printed
... place for extra arguments to reside.
hsep character used to separate horizontal fields
vsep character used to separate vertical fields
csep character used where horizontal and vertical separators meet.
print.it should the value be printed to the console or returned as a string.
rownames.halign horizontal justification of row names.
rownames.valign vertical justification of row names.
colnames.halign horizontal justification of column names.
colnames.valign vertical justification of column names.
text.halign horizontal justification of cell text.
text.valign vertical justification of cell text.
rownames.width minimum width of row name strings.
rownames.height minimum height of row name strings.
min.colwidth minimum column width.
max.rowheight maximum row height.
abbreviate.dimnames should the row and column names be abbreviated.
page.width width of the page being printed on.
colnames.width minimum width of the column names.
colnames.height minimum height of the column names
prefix.width maximum width of the rowname columns
superprefix.width maximum width of the super rowname columns

Value

String that formatted table of the list object.
print.char.matrix

Author(s)
Charles Dupont

Function to print a matrix with stacked cells

Description
Prints a dataframe or matrix in stacked cells. Line break characters in a matrix element will result in a line break in that cell, but tab characters are not supported.

Usage
```r
## S3 method for class 'char.matrix'
print(x, file = "", col.name.align = "cen", col.txt.align = "right",
cell.align = "cen", hsep = "|", vsep = "-", csep = "+", row.names = TRUE,
col.names = FALSE, append = FALSE,
top.border = TRUE, left.border = TRUE, ...)
```

Arguments
- `x`: a matrix or dataframe
- `file`: name of file if file output is desired. If left empty, output will be to the screen
- `col.name.align`: if column names are used, they can be aligned right, left or centre. Default "cen" results in names centred between the sides of the columns they name. If the width of the text in the columns is less than the width of the name, `col.name.align` will have no effect. Other options are "right" and "left".
- `col.txt.align`: how character columns are aligned. Options are the same as for `col.name.align` with no effect when the width of the column is greater than its name.
- `cell.align`: how numbers are displayed in columns
- `hsep`: character string to use as horizontal separator, i.e. what separates columns
- `vsep`: character string to use as vertical separator, i.e. what separates rows. Length cannot be more than one.
- `csep`: character string to use where vertical and horizontal separators cross. If `hsep` is more than one character, `csep` will need to be the same length. There is no provision for multiple vertical separators
- `row.names`: logical: are we printing the names of the rows?
- `col.names`: logical: are we printing the names of the columns?
- `append`: logical: if file is not "", are we appending to the file or overwriting?
- `top.border`: logical: do we want a border along the top above the columns?
- `left.border`: logical: do we want a border along the left of the first column?
- `...`: unused
Details

If any column of x is a mixture of character and numeric, the distinction between character and numeric columns will be lost. This is especially so if the matrix is of a form where you would not want to print the column names, the column information being in the rows at the beginning of the matrix.

Row names, if not specified in the making of the matrix will simply be numbers. To prevent printing them, set row.names = FALSE.

Value

No value is returned. The matrix or dataframe will be printed to file or to the screen.

print.char.matrix(z)

prnz

Print and Object with its Name

Description

Prints an object with its name and with an optional descriptive text string. This is useful for annotating analysis output files and for debugging.

Usage

prn(x, txt, file)
prselect

Selectively Print Lines of a Text Vector

Description

Given one or two regular expressions or exact text matches, removes elements of the input vector that match these specifications. Omitted lines are replaced by .... This is useful for selectively suppressing some of the printed output of R functions such as regression fitting functions, especially in the context of making statistical reports using Sweave or Odfweave.

Usage

prselect(x, start = NULL, stop = NULL, i = 0, j = 0, pr = TRUE)

Arguments

x input character vector
start text or regular expression to look for starting line to omit. If omitted, deletions start at the first line.
stop text or regular expression to look for ending line to omit. If omitted, deletions proceed until the last line.
i increment in number of first line to delete after match is found
j increment in number of last line to delete after match is found
pr set to FALSE to suppress printing

Side Effects

prints

Examples

```r
x <- c('the', 'cat', 'ran', 'past', 'the', 'dog')
prselect(x, 'big', 'bad')  # omit nothing - no match
prselect(x, 'the', 'past')  # omit first 4 lines
prselect(x, 'the', 'junk')  # omit nothing - no match for stop
prselect(x, 'ran', 'dog')  # omit last 4 lines
prselect(x, 'cat')  # omit lines 2-
prselect(x, 'cat', i=1)  # omit lines 3-
prselect(x, 'cat', 'past')  # omit lines 2-4
prselect(x, 'cat', 'past', j=1)  # omit lines 2-6
prselect(x, 'cat', 'past', j=-1)  # omit lines 2-3
prselect(x, 't$', 'dog')  # omit lines 2-6; t must be at end
```

# Example for Sweave: run a regression analysis with the rms package
# then selectively output only a portion of what print.ols prints.
# (Thanks to \email{romain.francois@dbmail.com})
```r
<<z, eval=FALSE, echo=T>>=
library(rms)
y <- rnorm(20); x1 <- rnorm(20); x2 <- rnorm(20)
ols(y ~ x1 + x2)
<<echo=F>>=
z <- capture.output(
  <<z2>>
  # ) )
prselect(z, 'Residuals:')  # keep only summary stats; or:
prselect(z, stop='Coefficients', j=-1)  # keep coefficients, rmse, R^2; or:
prselect(z, 'Coefficients', 'Residual standard error', j=-1)  # omit coef
@```

Description

Date-time stamp the current plot in the extreme lower right corner. Optionally add the current working directory and arbitrary other text to the stamp.
**Description**

`rcorr` Computes a matrix of Pearson’s *r* or Spearman’s *rho* rank correlation coefficients for all possible pairs of columns of a matrix. Missing values are deleted in pairs rather than deleting all rows of *x* having any missing variables. Ranks are computed using efficient algorithms (see reference 2), using midranks for ties.

**Usage**

```r
corr(x, y, type=c("pearson","spearman"))
```

# S3 method for class 'rcorr'
print(x, ...)

**Arguments**

- **x**: a numeric matrix with at least 5 rows and at least 2 columns (if `y` is absent). For print, `x` is an object produced by `rcorr`.
- **y**: a numeric vector or matrix which will be concatenated to `x`. If `y` is omitted for `rcorr`, `x` must be a matrix.
- **type**: specifies the type of correlations to compute. Spearman correlations are the Pearson linear correlations computed on the ranks of non-missing elements, using midranks for ties.
- **...**: argument for method compatibility.

**Details**

Uses midranks in case of ties, as described by Hollander and Wolfe. P-values are approximated by using the t or F distributions.

**Value**

`rcorr` returns a list with elements `r`, the matrix of correlations, `n` the matrix of number of observations used in analyzing each pair of variables, and `P`, the asymptotic P-values. Pairs with fewer than 2 non-missing values have the `r` values set to NA. The diagonals of `n` are the number of non-NAs for the single variable corresponding to that row and column.

**Author(s)**

Frank Harrell  
Department of Biostatistics  
Vanderbilt University  
<fr@biostat.vanderbilt.edu>

**References**

**See Also**

`hoeffd, cor, combine.levels, varclus, dotchart3, impute, chisq.test, cut2`

**Examples**

```r
x <- c(-2, -1, 0, 1, 2)  
y <- c(4, 1, 0, 1, 4)  
z <- c(1, 2, 3, 4, NA)  
v <- c(1, 2, 3, 4, 5)  
rcorr(cbind(x,y,z,v))
```
**Description**

Computes the c index and the corresponding generalization of Somers’ $D_{xy}$ rank correlation for a censored response variable. Also works for uncensored and binary responses, although its use of all possible pairings makes it slow for this purpose. $D_{xy}$ and c are related by $D_{xy} = 2(c - 0.5)$.

rcorr.cens handles one predictor variable. rcorrcens computes rank correlation measures separately by a series of predictors. In addition, rcorrcens has a rough way of handling categorical predictors. If a categorical (factor) predictor has two levels, it is coverted to a numeric having values 1 and 2. If it has more than 2 levels, an indicator variable is formed for the most frequently level vs. all others, and another indicator for the second most frequent level and all others. The correlation is taken as the maximum of the two (in absolute value).

**Usage**

```
rcorr.cens(x, S, outx=FALSE)
```

```
## S3 method for class 'formula'
rcorrcens(formula, data=NULL, subset=NULL,
           na.action=na.retain, exclude.imputed=TRUE, outx=FALSE,
           ...)
```

**Arguments**

- **x**: a numeric predictor variable
- **S**: an Surv object or a vector. If a vector, assumes that every observation is uncensored.
- **outx**: set to TRUE to not count pairs of observations tied on x as a relevant pair. This results in a Goodman–Kruskal gamma type rank correlation.
- **formula**: a formula with a Surv object or a numeric vector on the left-hand side
- **data, subset, na.action**: the usual options for models. Default for na.action is to retain all values, NA or not, so that NAs can be deleted in only a pairwise fashion.
- **exclude.imputed**: set to FALSE to include imputed values (created by impute) in the calculations.
- **...**: extra arguments passed to biVar.

**Value**

rcorr.cens returns a vector with the following named elements: C Index, Dxy, S, n, missing, uncensored, Relevant Pairs, Concordant, and Uncertain

- **n**: number of observations not missing on any input variables
missing number of observations missing on x or S
relevant number of pairs of non-missing observations for which S could be ordered
concordant number of relevant pairs for which x and S are concordant.
uncertain number of pairs of non-missing observations for which censoring prevents classification of concordance of x and S.

rcorr.cens.formula returns an object of class biVar which is documented with the biVar function.

rcorrp.cens  Rank Correlation for Paired Predictors with a Possibly Censored Response, and Integrated Discrimination Index

Description

Computes U-statistics to test for whether predictor X1 is more concordant than predictor X2, extending rcorr.cens. For method=1, estimates the fraction of pairs for which the x1 difference is more impressive than the x2 difference. For method=2, estimates the fraction of pairs for which x1 is concordant with S but x2 is not.

For binary responses the function improveProb provides several assessments of whether one set of predicted probabilities is better than another, using the methods described in Pencina et al (2007). This involves NRI and IDI to test for whether predictions from model x1 are significantly different from those obtained from predictions from model x2. This is a distinct improvement over comparing ROC areas, sensitivity, or specificity.

Usage

rcorrp.cens(x1, x2, S, outx=FALSE, method=1)

improveProb(x1, x2, y)

## S3 method for class 'improveProb'
print(x, digits=3, conf.int=.95, ...)

rcorrp.cens  Rank Correlation for Paired Predictors with a Possibly Censored Response, and Integrated Discrimination Index

Description

Computes U-statistics to test for whether predictor X1 is more concordant than predictor X2, extending rcorr.cens. For method=1, estimates the fraction of pairs for which the x1 difference is more impressive than the x2 difference. For method=2, estimates the fraction of pairs for which x1 is concordant with S but x2 is not.

For binary responses the function improveProb provides several assessments of whether one set of predicted probabilities is better than another, using the methods described in Pencina et al (2007). This involves NRI and IDI to test for whether predictions from model x1 are significantly different from those obtained from predictions from model x2. This is a distinct improvement over comparing ROC areas, sensitivity, or specificity.

Usage

rcorrp.cens(x1, x2, S, outx=FALSE, method=1)

improveProb(x1, x2, y)

## S3 method for class 'improveProb'
print(x, digits=3, conf.int=.95, ...)
Arguments

- **x1**: first predictor (a probability, for `improveProb`)
- **x2**: second predictor (a probability, for `improveProb`)
- **S**: a possibly right-censored `Surv` object. If `S` is a vector instead, it is converted to a `Surv` object and it is assumed that no observations are censored.
- **outx**: set to `TRUE` to exclude pairs tied on `x1` or `x2` from consideration
- **method**: see above
- **y**: a binary 0/1 outcome variable
- **x**: the result from `improveProb`
- **digits**: number of significant digits for use in printing the result of `improveProb`
- **conf.int**: level for confidence limits
- **...**: unused

Details

If `x1,x2` represent predictions from models, these functions assume either that you are using a separate sample from the one used to build the model, or that the amount of overfitting in `x1` equals the amount of overfitting in `x2`. An example of the latter is giving both models equal opportunity to be complex so that both models have the same number of effective degrees of freedom, whether a predictor was included in the model or was screened out by a variable selection scheme.

Note that in the first part of their paper, Pencina et al. presented measures that required binning the predicted probabilities. Those measures were then replaced with better continuous measures that are implemented here.

Value

A vector of statistics for `rcorrp.cens`, or a list with class `improveProb` of statistics for `improveProb`:

- **n**: number of cases
- **na**: number of events
- **nb**: number of non-events
- **pup.ev**: mean of pairwise differences in probabilities for those with events and a pairwise difference of probabilities $> 0$
- **pup.ne**: mean of pairwise differences in probabilities for those without events and a pairwise difference of probabilities $> 0$
- **pdown.ev**: mean of pairwise differences in probabilities for those with events and a pairwise difference of probabilities $> 0$
- **pdown.ne**: mean of pairwise differences in probabilities for those without events and a pairwise difference of probabilities $> 0$
- **nri**: Net Reclassification Index $= (\text{pup.ev} - \text{pdown.ev}) - (\text{pup.ne} - \text{pdown.ne})$
- **se.nri**: standard error of NRI
- **z.nri**: Z score for NRI
netrec = Net Reclassification Index = \( p_{up.ev} - p_{down.ev} \)

se_netrec = SE of NRI of events

z_netrec = Z score for NRI of events

netrec_ne = Net Reclassification Index = \( p_{up.ne} - p_{down.ne} \)

se_netrec_ne = SE of NRI of non-events

z_netrec_ne = Z score for NRI of non-events

improvesens = improvement in sensitivity

improvespec = improvement in specificity

idi = Integrated Discrimination Index

se_idi = SE of IDI

z_idi = Z score of IDI

rcspline.eval

Restricted Cubic Spline Design Matrix

Description

Computes matrix that expands a single variable into the terms needed to fit a restricted cubic spline (natural spline) function using the truncated power basis. Two normalization options are given for somewhat reducing problems of ill-conditioning. The antiderivative function can be optionally created. If knot locations are not given, they will be estimated from the marginal distribution of x.

Usage

rcspline.eval(x, knots, nk=5, inclx=FALSE, knots.only=FALSE, type="ordinary", norm=2, rpm=NULL, pc=FALSE, fractioned=0.05)

Arguments

x a vector representing a predictor variable
knots knot locations. If not given, knots will be estimated using default quantiles of x. For 3 knots, the outer quantiles used are 0.10 and 0.90. For 4-6 knots, the outer quantiles used are 0.05 and 0.95. For nk > 6, the outer quantiles are 0.025 and 0.975. The knots are equally spaced between these on the quantile scale. For fewer than 100 non-missing values of x, the outer knots are the 5th smallest and largest x.

nk number of knots. Default is 5. The minimum value is 3.
inclx set to TRUE to add x as the first column of the returned matrix
knots.only return the estimated knot locations but not the expanded matrix
type "ordinary" to fit the function, "integral" to fit its anti-derivative.
norm '0' to use the terms as originally given by Devlin and Weeks (1986), '1' to normalize non-linear terms by the cube of the spacing between the last two knots, '2' to normalize by the square of the spacing between the first and last knots (the default). norm=2 has the advantage of making all nonlinear terms be on the x-scale.
rpm

If given, any NAs in x will be replaced with the value rpm after estimating any knot locations.

pc

Set to TRUE to replace the design matrix with orthogonal (uncorrelated) principal components computed on the scaled, centered design matrix

fractied

If the fraction of observations tied at the lowest and/or highest values of x is greater than or equal to fractied, the algorithm attempts to use a different algorithm for knot finding based on quantiles of x after excluding the one or two values with excessive ties. And if the number of unique x values excluding these values is small, the unique values will be used as the knots. If the number of knots to use other than these exterior values is only one, that knot will be at the median of the non-extreme x. This algorithm is not used if any interior values of x also have a proportion of ties equal to or exceeding fractied.

Value

If knots.only=TRUE, returns a vector of knot locations. Otherwise returns a matrix with x (if inclx=TRUE) followed by nk-2 nonlinear terms. The matrix has an attribute knots which is the vector of knots used. When pc is TRUE, an additional attribute is stored: pcpars, which contains the center and scale vectors and the rotation matrix.

```
**rcspline.plot**  
*Plot Restricted Cubic Spline Function*

**Description**
Provides plots of the estimated restricted cubic spline function relating a single predictor to the response for a logistic or Cox model. The `rcspline.plot` function does not allow for interactions as do `lrm` and `cph`, but it can provide detailed output for checking spline fits. This function uses the `rcspline.eval`, `lrm.fit`, and Therneau’s `coxph.fit` functions and plots the estimated spline regression and confidence limits, placing summary statistics on the graph. If there are no adjustment variables, `rcspline.plot` can also plot two alternative estimates of the regression function when `model=“logistic”`: proportions or logit proportions on grouped data, and a nonparametric estimate. The nonparametric regression estimate is based on smoothing the binary responses and taking the logit transformation of the smoothed estimates, if desired. The smoothing uses `supsmu`.

**Usage**
```r
crcspline.plot(x, y, model=c(“logistic”, “cox”, “ols”), xrange, event, nk=5,  
knots=NULL, show=c(“xbeta”, “prob”), adj=NULL, xlab, ylab,  
ylim, plim=c(0,1), plotcl=TRUE, showknots=TRUE, add=FALSE,  
subset, lty=1, noprint=FALSE, m, smooth=FALSE, bass=1,  
main=”auto”, statloc)
```

**Arguments**
- **x**: a numeric predictor
- **y**: a numeric response. For binary logistic regression, y should be either 0 or 1.
- **model**: “logistic” or “cox”. For “cox”, uses the `coxph.fit` function with method=“efron” argument set.
- **xrange**: range for evaluating x, default is f and 1−f quantiles of x, where f = \(\frac{10}{\max(N,200)}\)
- **event**: event/censoring indicator if model=“cox”. If event is present, model is assumed to be “cox”
- **nk**: number of knots
- **knots**: knot locations, default based on quantiles of x (by `rcspline.eval`)
- **show**: “xbeta” or “prob” - what is plotted on y-axis
- **adj**: optional matrix of adjustment variables
- **xlab**: x-axis label, default is the “label” attribute of x
- **ylab**: y-axis label, default is the “label” attribute of y
- **ylim**: y-axis limits for logit or log hazard
- **plim**: y-axis limits for probability scale
- **plotcl**: plot confidence limits
- **showknots**: show knot locations with arrows
- **add**: add this plot to an already existing plot
subset subset of observations to process, e.g. sex == "male"

lty line type for plotting estimated spline function

noprint suppress printing regression coefficients and standard errors

m for model="logistic", plot grouped estimates with triangles. Each group contains m ordered observations on x.

smooth plot nonparametric estimate if model="logistic" and adj is not specified

bass smoothing parameter (see supsmu)

main main title, default is "Estimated Spline Transformation"

statloc location of summary statistics. Default positioning by clicking left mouse button where upper left corner of statistics should appear. Alternative is "11" to place below the graph on the lower left, or the actual x and y coordinates. Use "none" to suppress statistics.

Value

list with components (‘knots’, ‘x’, ‘xbeta’, ‘lower’, ‘upper’) which are respectively the knot locations, design matrix, linear predictor, and lower and upper confidence limits

#rcspline.plot(log10(cad.dur+1), tvdlm, m=150)
\end{verbatim}

\begin{verbatim}
rcspline.restate
Re-state Restricted Cubic Spline Function
\end{verbatim}

Description

This function re-states a restricted cubic spline function in the un-linearly-restricted form. Coefficients for that form are returned, along with an \texttt{R} functional representation of this function and a \LaTeX\ character representation of the function. \texttt{rcsplineFunction} is a fast function that creates a function to compute a restricted cubic spline function with given coefficients and knots, without reformatting the function to be pretty (i.e., into unrestricted form).
Usage

```r
rcspline.restate(knots, coef,  
  type=c("ordinary","integral"),  
  x="x", lx=nchar(x),  
  norm=2, columns=65, before="& &", after="\\",  
  begin="", nbegin=0, digits=max(8, .Options$digits))
```

```r
rcsplineFunction(knots, coef, norm=2, type=c('ordinary', 'integral'))
```

Arguments

- **knots**: vector of knots used in the regression fit
- **coef**: vector of coefficients from the fit. If the length of coef is \(k - 1\), where \(k\) is equal to the length(knots), the first coefficient must be for the linear term and remaining \(k - 2\) coefficients must be for the constructed terms (e.g., from `rcspline.eval`). If the length of coef is \(k\), an intercept is assumed to be in the first element (or a zero is prepended to coef for `rcsplineFunction`).
- **type**: The default is to represent the cubic spline function corresponding to the coefficients and knots. Set `type = "integral"` to instead represent its anti-derivative.
- **x**: a character string to use as the variable name in the LaTeX expression for the formula.
- **lx**: length of \(x\) to count with respect to `columns`. Default is length of character string contained by \(x\). You may want to set `lx` smaller than this if it includes non-printable LaTeX commands.
- **norm**: normalization that was used in deriving the original nonlinear terms used in the fit. See `rcspline.eval` for definitions.
- **columns**: maximum number of symbols in the LaTeX expression to allow before inserting a newline (``\\``) command. Set to a very large number to keep text all on one line.
- **before**: text to place before each line of LaTeX output. Use `"& &"` for an equation array environment in LaTeX where you want to have a left-hand prefix e.g. `"f(X) & = &"` or using `"\lefteqn"`.
- **after**: text to place at the end of each line of output.
- **begin**: text with which to start the first line of output. Useful when adding LaTeX output to part of an existing formula
- **nbegin**: number of columns of printable text in `begin`
- **digits**: number of significant digits to write for coefficients and knots

Value

`rcspline.restate` returns a vector of coefficients. The coefficients are un-normalized and two coefficients are added that are linearly dependent on the other coefficients and knots. The vector of coefficients has four attributes: `knots` is a vector of knots, `latex` is a vector of text strings with the LaTeX representation of the formula. `columns.used` is the number of columns used in the output string since the last newline command. `function` is an R function, which is also return in character
string format as the text attribute. \texttt{rcsplineFunction} returns an \texttt{R} function with arguments \texttt{x} (a user-supplied numeric vector at which to evaluate the function), and some automatically-supplied other arguments.

pred.value <- coef[1] + xx.simple * w
plot(x, pred.value, type='l')  # same as above
\end{verbatim}
**Description**

Uses flexible parametric additive models (see *areg* and its use of regression splines) to determine how well each variable can be predicted from the remaining variables. Variables are dropped in a stepwise fashion, removing the most predictable variable at each step. The remaining variables are used to predict. The process continues until no variable still in the list of predictors can be predicted with an $R^2$ or adjusted $R^2$ of at least $rR$ or until dropping the variable with the highest $R^2$ (adjusted or ordinary) would cause a variable that was dropped earlier to no longer be predicted at least at the $rR$ level from the now smaller list of predictors.

**Usage**

```r
redun(formula, data=NULL, subset=NULL, r2 = 0.9,
      type = c("ordinary", "adjusted"), nk = 3, tlinear = TRUE,
      allcat=FALSE, minfreq=0, iters=FALSE, pc=FALSE, pr = FALSE, ...)
```

## S3 method for class 'redun'

```r
print(x, digits=3, long=TRUE, ...)
```

**Arguments**

- `formula`: a formula. Enclose a variable in `I()` to force linearity.
- `data`: a data frame
- `subset`: usual subsetting expression
- `r2`: ordinary or adjusted $R^2$ cutoff for redundancy
- `type`: specify "adjusted" to use adjusted $R^2$
- `nk`: number of knots to use for continuous variables. Use `nk=0` to force linearity for all variables.
- `tlinear`: set to `FALSE` to allow a variable to be automatically nonlinearly transformed (see *areg*) while being predicted. By default, only continuous variables on the right hand side (i.e., while they are being predictors) are automatically transformed, using regression splines. Estimating transformations for target (dependent) variables causes more overfitting than doing so for predictors.
- `allcat`: set to `TRUE` to ensure that all categories of categorical variables having more than two categories are redundant (see details below)
- `minfreq`: For a binary or categorical variable, there must be at least two categories with at least `minfreq` observations or the variable will be dropped and not checked for redundancy against other variables. `minfreq` also specifies the minimum frequency of a category or its complement before that category is considered when `allcat=TRUE`.
- `iterms`: set to `TRUE` to consider derived terms (dummy variables and nonlinear spline components) as separate variables. This will perform a redundancy analysis on pieces of the variables.
if `terms` is `TRUE` you can set `pc` to `TRUE` to replace the submatrix of terms corresponding to each variable with the orthogonal principal components before doing the redundancy analysis. The components are based on the correlation matrix.

Set to `FALSE` to monitor progress of the stepwise algorithm.

Arguments to pass to `dataframeReduce` to remove "difficult" variables from `data` if `formula` is `~.` to use all variables in `data` (data must be specified when these arguments are used). Ignored for `print`.

An object created by `redun`.

Number of digits to which to round $R^2$ values when printing.

Set to `FALSE` to prevent the `print` method from printing the $R^2$ history and the original $R^2$ with which each variable can be predicted from ALL other variables.

Details

A categorical variable is deemed redundant if a linear combination of dummy variables representing it can be predicted from a linear combination of other variables. For example, if there were 4 cities in the data and each city's rainfall was also present as a variable, with virtually the same rainfall reported for all observations for a city, city would be redundant given rainfall (or vice-versa; the one declared redundant would be the first one in the formula). If two cities had the same rainfall, city might be declared redundant even though tied cities might be deemed non-redundant in another setting. To ensure that all categories may be predicted well from other variables, use the `allcat` option. To ignore categories that are too infrequent or too frequent, set `minfreq` to a nonzero integer. When the number of observations in the category is below this number or the number of observations not in the category is below this number, no attempt is made to predict observations being in that category individually for the purpose of redundancy detection.

Value

An object of class "redun".

Examples

```r
set.seed(1)
n <- 100
x1 <- runif(n)
x2 <- runif(n)
```
Description

If the first argument is a matrix, `reshape` strings out its values and creates row and column vectors specifying the row and column each element came from. This is useful for sending matrices to Trellis functions, for analyzing or plotting results of `table` or `crosstabs`, or for reformating serial data stored in a matrix (with rows representing multiple time points) into vectors. The number of observations in the new variables will be the product of the number of rows and number of columns in the input matrix. If the first argument is a vector, the `id` and `colvar` variables are used to restructure it into a matrix, with `NA`s for elements that corresponded to combinations of `id` and `colvar` values that did not exist in the data. When more than one vector is given, multiple matrices are created. This is useful for restructuring irregular serial data into regular matrices. It is also useful for converting data produced by `expand.grid` into a matrix (see the last example). The number of rows of the new matrices equals the number of unique values of `id`, and the number of columns equals the number of unique values of `colvar`.

When the first argument is a vector and the `id` is a data frame (even with only one variable), `reshape` will produce a data frame, and the unique groups are identified by combinations of the values of all variables in `id`. If a data frame constant is specified, the variables in this data frame are assumed to be constant within combinations of `id` variables (if not, an arbitrary observation in constant will be selected for each group). A row of constant corresponding to the target `id` combination is then carried along when creating the data frame result.

A different behavior of `reshape` is achieved when `base` and `reps` are specified. In that case `x` must be a list or data frame, and those data are assumed to contain one or more non-repeating measurements (e.g., baseline measurements) and one or more repeated measurements represented by variables named by pasting together the character strings in the vector `base` with the integers 1, 2, ..., `reps`. The input data are rearranged by repeating each value of the baseline variables `reps` times and by transposing each observation's values of one of the set of repeated measurements as `reps` observations under the variable whose name does not have an integer pasted to the end. If `x` has a `row.names` attribute, those observation identifiers are each repeated `reps` times in the output object. See the last example.

Usage

```r
reshape(x, ..., id, colvar, base, reps, times=1:reps,
        timevar='seqno', constant=NULL)
```

Arguments

- **x**: a matrix or vector, or, when `base` is specified, a list or data frame
- **...**: other optional vectors, if `x` is a vector
- **id**: A numeric, character, category, or factor variable containing subject identifiers, or a data frame of such variables that in combination form groups of interest. Required if `x` is a vector, ignored otherwise.
- **colvar**: A numeric, character, category, or factor variable containing column identifiers. `colvar` is using a "time of data collection" variable. Required if `x` is a vector, ignored otherwise.
- **base**: vector of character strings containing base names of repeated measurements
- **reps**: number of times variables named in `base` are repeated. This must be a constant.
- **times**: when `base` is given, `times` is the vector of times to create if you do not want to use consecutive integers beginning with 1.
- **timevar**: specifies the name of the time variable to create if `times` is given, if you do not want to use `seqno`
- **constant**: a data frame with the same number of rows in `id` and `x`, containing auxiliary information to be merged into the resulting data frame. Logically, the rows of `constant` within each group should have the same value of all of its variables.

Details

In converting dimnames to vectors, the resulting variables are numeric if all elements of the matrix dimnames can be converted to numeric, otherwise the corresponding row or column variable remains character. When the dimnames if `x` have a names attribute, those two names become the new variable names. If `x` is a vector and another vector is also given (in ...), the matrices in the resulting list are named the same as the input vector calling arguments. You can specify customized names for these on-the-fly by using e.g. `reshape(x=x, y=y, id=, colvar=)`. The new names will then be `X` and `Y` instead of `x` and `y`. A new variable named `seqno` is also added to the resulting object. `seqno` indicates the sequential repeated measurement number. When `base` and `times` are specified, this new variable is named the character value of `timevar` and the values are given by a table lookup into the vector `times`.

Value

If `x` is a matrix, returns a list containing the row variable, the column variable, and the `as.vector(x)` vector, named the same as the calling argument was called for `x`. If `x` is a vector and no other vectors were specified as ..., the result is a matrix. If at least one vector was given to ..., the result is a list containing k matrices, where k one plus the number of vectors in ... If `x` is a list or data frame, the same type of object is returned. If `x` is a vector and `id` is a data frame, a data frame will be the result.

rlegend

Special Version of legend for R

Description

rlegend is a version of legend for R that implements plot=FALSE, adds grid=TRUE, and defaults lty, lwd, pch to NULL and checks for length>0 rather than missing(), so it’s easier to deal with non-applicable parameters. But when grid is in effect, the preferred function to use is rlegendg, which calls the lattice draw.key function.

Usage

rlegend(x, y, legend, fill, col = "black", lty = NULL, lwd = NULL, pch = NULL, angle = NULL, density = NULL, bty = "o", bg = par("bg"), pt.bg = NA, cex = 1, xjust = 0, yjust = 1, x.intersp = 1, y.intersp = 1, adj = 0, text.width = NULL, merge = do.lines & has.pch, trace = FALSE, ncol = 1, horiz = FALSE, plot = TRUE, grid = FALSE, ...)

rlegendg(x, y, legend, col=pr$col[1], lty=NULL, lwd=NULL, pch=NULL, cex=pr$cex[1], other=NULL)

Arguments

x, y, legend, fill, col, lty, lwd, pch, angle, density, bty, bg, pt.bg, cex, xjust, yjust, x.intersp, y.intersp, adj

plot

set to FALSE to suppress drawing the legend. This is used the compute the size needed for when the legend is drawn with a later call to rlegend.

grid

set to TRUE if the grid package is in effect

other

a list containing other arguments to pass to draw.key. See the help file for xyplot.
Value

a list with elements rect and text. rect has elements w, h, left, top with size/position information.

rm.boot  

*Bootstrap Repeated Measurements Model*

Description

For a dataset containing a time variable, a scalar response variable, and an optional subject identification variable, obtains least squares estimates of the coefficients of a restricted cubic spline function or a linear regression in time after adjusting for subject effects through the use of subject dummy variables. Then the fit is bootstrapped B times, either by treating time and subject ID as fixed (i.e., conditioning the analysis on them) or as random variables. For the former, the residuals from the original model fit are used as the basis of the bootstrap distribution. For the latter, samples are taken jointly from the time, subject ID, and response vectors to obtain unconditional distributions. If a subject id variable is given, the bootstrap sampling will be based on samples with replacement from subjects rather than from individual data points. In other words, either none or all of a given subject’s data will appear in a bootstrap sample. This cluster sampling takes into account any correlation structure that might exist within subjects, so that confidence limits are corrected for within-subject correlation. Assuming that ordinary least squares estimates, which ignore the correlation structure, are consistent (which is almost always true) and efficient (which would not be true for certain correlation structures or for datasets in which the number of observation times vary greatly from subject to subject), the resulting analysis will be a robust, efficient repeated measures analysis for the one-sample problem.

Predicted values of the fitted models are evaluated by default at a grid of 100 equally spaced time points ranging from the minimum to maximum observed time points. Predictions are for the average subject effect. Pointwise confidence intervals are optionally computed separately for each of the points on the time grid. However, simultaneous confidence regions that control the level of confidence for the entire regression curve lying within a band are often more appropriate, as they allow the analyst to draw conclusions about nuances in the mean time response profile that were not stated apriori. The method of Tibshirani (1997) is used to easily obtain simultaneous confidence sets for the set of coefficients of the spline or linear regression function as well as the average intercept parameter (over subjects). Here one computes the objective criterion (here both the -2 log likelihood evaluated at the bootstrap estimate of beta but with respect to the original design matrix and response vector, and the sum of squared errors in predicting the original response vector) for the original fit as well as for all of the bootstrap fits. The confidence set of the regression coefficients is the set of all coefficients that are associated with objective function values that are less than or
equal to say the 0.95 quantile of the vector of B + 1 objective function values. For the coefficients satisfying this condition, predicted curves are computed at the time grid, and minima and maxima of these curves are computed separately at each time point to derive the final simultaneous confidence band.

By default, the log likelihoods that are computed for obtaining the simultaneous confidence band assume independence within subject. This will cause problems unless such log likelihoods have very high rank correlation with the log likelihood allowing for dependence. To allow for correlation or to estimate the correlation function, see the cor.pattern argument below.

Usage

```r
rm.boot(time, y, id=seq(along=time), subset,
  plot.individual=FALSE,
  bootstrap.type=c('x fixed', 'x random'),
  nk=6, knots, B=500, smoother=supsmu,
  xlab, xlim, ylim=range(y),
  times=seq(min(time), max(time), length=100),
  absorb.subject.effects=FALSE,
  rho=0, cor.pattern=c('independent', 'estimate'), ncor=10000,
  ...
)
```

```r
## S3 method for class 'rm.boot'
plot(x, obj2, conf.int=.95,
  xlab=x$xlab, ylab=x$ylab,
  xlim, ylim=x$ylim,
  individual.boot=FALSE,
  pointwise.band=FALSE,
  curves.in.simultaneous.band=FALSE,
  col.pointwise.band=2,
  objective=c('2 log L', 'sse', 'dep -2 log L'), add=FALSE, ncurves,
  multi=FALSE, multi.method=c('color', 'density'),
  multi.conf =c(.05, 1, 2, 3, 4, 5, 6, 7, 8, 9, .95, .99),
  multi.density=c(-1, 90, 80, 70, 60, 50, 40, 30, 20, 10, 7, 4),
  multi.col =c(1, 8, 20, 5, 2, 7, 15, 13, 10, 11, 9, 14),
  subtitles=TRUE, ...)
```

Arguments

- `time` numeric time vector
- `y` continuous numeric response vector of length the same as `time`. Subjects having multiple measurements have the measurements strung out.
- `x` an object returned from `rm.boot`
- `id` subject ID variable. If omitted, it is assumed that each time-response pair is measured on a different subject.
- `subset` subset of observations to process if not all the data
plot.individual

set to TRUE to plot nonparametrically smoothed time-response curves for each subject

bootstrap.type

specifies whether to treat the time and subject ID variables as fixed or random

nk

number of knots in the restricted cubic spline function fit. The number of knots may be 0 (denoting linear regression) or an integer greater than 2 in which \(k\) knots results in \(k - 1\) regression coefficients excluding the intercept. The default is 6 knots.

knots

vector of knot locations. May be specified if nk is omitted.

B

number of bootstrap repetitions. Default is 500.

smoother

a smoothing function that is used if plot.individual=TRUE. Default is supsmu.

xlab

label for x-axis. Default is "units" attribute of the original time variable, or "time" if no such attribute was defined using the units function.

xlim

specifies x-axis plotting limits. Default is to use range of times specified to rm.boot.

ylim

for rm.boot this is a vector of y-axis limits used if plot.individual=TRUE. It is also passed along for later use by plot.rm.boot. For plot.rm.boot, ylim can be specified, to override the value stored in the object stored by rm.boot. The default is the actual range of y in the input data.

times

a sequence of times at which to evaluated fitted values and confidence limits. Default is 100 equally spaced points in the observed range of time.

absorb.subject.effects

If TRUE, adjusts the response vector y before re-sampling so that the subject-specific effects in the initial model fit are all zero. Then in re-sampling, subject effects are not used in the models. This will downplay one of the sources of variation. This option is used mainly for checking for consistency of results, as the re-sampling analyses are simpler when absorb.subject.effects=TRUE.

rho

The log-likelihood function that is used as the basis of simultaneous confidence bands assumes normality with independence within subject. To check the robustness of this assumption, if rho is not zero, the log-likelihood under multivariate normality within subject, with constant correlation \(\rho\) between any two time points, is also computed. If the two log-likelihoods have the same ranks across re-samples, allowing the correlation structure does not matter. The agreement in ranks is quantified using the Spearman rank correlation coefficient. The plot method allows the non-zero intra-subject correlation log-likelihood to be used in deriving the simultaneous confidence band. Note that this approach does assume homoscedasticity.

cor.pattern

More generally than using an equal-correlation structure, you can specify a function of two time vectors that generates as many correlations as the length of these vectors. For example, cor.pattern=function(time1, time2) \(0.2^\sqrt{(abs(time1-time2)/10)}\) would specify a dampening serial correlation pattern. cor.pattern can also be a list containing vectors x (a vector of absolute time differences) and y (a corresponding vector of correlations). To estimate the correlation function as a function of absolute time differences within subjects, specify cor.pattern="estimate". The products of all possible pairs of residuals (or at least up to ncor of them)
within subjects will be related to the absolute time difference. The correlation function is estimated by computing the sample mean of the products of standardized residuals, stratified by absolute time difference. The correlation for a zero time difference is set to 1 regardless of the lowess estimate. NOTE: This approach fails in the presence of large subject effects; correcting for such effects removes too much of the correlation structure in the residuals.

ncor
the maximum number of pairs of time values used in estimating the correlation function if cor.pattern="estimate"

... other arguments to pass to smoother if plot.individual=TRUE

obj2
a second object created by rm.boot that can also be passed to plot.rm.boot. This is used for two-sample problems for which the time profiles are allowed to differ between the two groups. The bootstrapped predicted y values for the second fit are subtracted from the fitted values for the first fit so that the predicted mean response for group 1 minus the predicted mean response for group 2 is what is plotted. The confidence bands that are plotted are also for this difference. For the simultaneous confidence band, the objective criterion is taken to be the sum of the objective criteria (-2 log L or sum of squared errors) for the separate fits for the two groups. The times vectors must have been identical for both calls to rm.boot, although NAs can be inserted by the user of one or both of the time vectors in the rm.boot objects so as to suppress certain sections of the difference curve from being plotted.

conf.int
the confidence level to use in constructing simultaneous, and optionally pointwise, bands. Default is 0.95.

ylab
label for y-axis. Default is the "label" attribute of the original y variable, or "y" if no label was assigned to y (using the label function, for example).

individual.boot
set to TRUE to plot the first 100 bootstrap regression fits

pointwise.band
set to TRUE to draw a pointwise confidence band in addition to the simultaneous band

curves.in.simultaneous.band
set to TRUE to draw all bootstrap regression fits that had a sum of squared errors (obtained by predicting the original y vector from the original time vector and id vector) that was less than or equal to the conf.int quantile of all bootstrapped models (plus the original model). This will show how the point by point max and min were computed to form the simultaneous confidence band.

col.pointwise.band
color for the pointwise confidence band. Default is ‘2’, which defaults to red for default Windows S-PLUS setups.

objective
the default is to use the -2 times log of the Gaussian likelihood for computing the simultaneous confidence region. If neither cor.pattern nor rho was specified to rm.boot, the independent homoscedastic Gaussian likelihood is used. Otherwise the dependent homoscedastic likelihood is used according to the specified or estimated correlation pattern. Specify objective="sse" to instead use the sum of squared errors.

add
set to TRUE to add curves to an existing plot. If you do this, titles and subtitles are omitted.
ncurves when using individual.boot=TRUE or curves.in.simultaneous.band=TRUE, you can plot a random sample of ncurves of the fitted curves instead of plotting up to B of them.

multi set to TRUE to draw multiple simultaneous confidence bands shaded with different colors. Confidence levels vary over the values in the multi.conf vector.

multi.method specifies the method of shading when multi=TRUE. Default is to use colors, with the default colors chosen so that when the graph is printed under S-Plus for Windows 4.0 to an HP LaserJet printer, the confidence regions are naturally ordered by darkness of gray-scale. Regions closer to the point estimates (i.e., the center) are darker. Specify multi.method="density" to instead use densities of lines drawn per inch in the confidence regions, with all regions drawn with the default color. The polygon function is used to shade the regions.

multi.conf vector of confidence levels, in ascending order. Default is to use 12 confidence levels ranging from 0.05 to 0.99.

multi.density vector of densities in lines per inch corresponding to multi.conf. As is the convention in the polygon function, a density of -1 indicates a solid region.

multi.col vector of colors corresponding to multi.conf. See multi.method for rationale.

subtitles set to FALSE to suppress drawing subtitles for the plot

Details

Observations having missing time or y are excluded from the analysis.

As most repeated measurement studies consider the times as design points, the fixed covariable case is the default. Bootstrapping the residuals from the initial fit assumes that the model is correctly specified. Even if the covariables are fixed, doing an unconditional bootstrap is still appropriate, and for large sample sizes unconditional confidence intervals are only slightly wider than conditional ones. For moderate to small sample sizes, the bootstrap.type="x random" method can be fairly conservative.

If not all subjects have the same number of observations (after deleting observations containing missing values) and if bootstrap.type="x fixed", bootstrapped residual vectors may have a length m that is different from the number of original observations n. If m > n for a bootstrap repetition, the first n elements of the randomly drawn residuals are used. If m < n, the residual vector is appended with a random sample with replacement of length n − m from itself. A warning message is issued if this happens. If the number of time points per subject varies, the bootstrap results for bootstrap.type="x fixed" can still be invalid, as this method assumes that a vector (over subjects) of all residuals can be added to the original yhats, and varying number of points will cause mis-alignment.

For bootstrap.type="x random" in the presence of significant subject effects, the analysis is approximate as the subjects used in any one bootstrap fit will not be the entire list of subjects. The average (over subjects used in the bootstrap sample) intercept is used from that bootstrap sample as a predictor of average subject effects in the overall sample.

Once the bootstrap coefficient matrix is stored by rm.boot, plot.rm.boot can be run multiple times with different options (e.g., different confidence levels).

See bootcov in the rms library for a general approach to handling repeated measurement data for ordinary linear models, binary and ordinal models, and survival models, using the unconditional bootstrap. bootcov does not handle bootstrapping residuals.
an object of class `rm.boot` is returned by `rm.boot`. The principal object stored in the returned object
is a matrix of regression coefficients for the original fit and all of the bootstrap repetitions (object `Coef`), along with vectors of the corresponding -2 log likelihoods are sums of squared errors. The
original fit object from `lm.fit.qr` is stored in `fit`. For this fit, a cell means model is used for the
id effects.
plot.rm.boot returns a list containing the vector of times used for plotting along with the overall
fitted values, lower and upper simultaneous confidence limits, and optionally the pointwise confi-
dence limits.

rMultinom  Generate Multinomial Random Variables with Varying Probabilities

Description

Given a matrix of multinomial probabilities where rows correspond to observations and columns
to categories (and each row sums to 1), generates a matrix with the same number of rows as has
probs and with m columns. The columns represent multinomial cell numbers, and within a row the
columns are all samples from the same multinomial distribution. The code is a modification of that
in the impute.polyreg function in the MICE package.

Usage

rMultinom(probs, m)

Arguments

probs  matrix of probabilities
m  number of samples for each row of probs

Value

an integer matrix having m columns

See Also

rbinom
Example

```r
set.seed(1)
w <- rMultinom(rbind(c(.1,.2,.3,.4),c(.4,.3,.2,.1)), 200)
t(apply(w, 1, table)/200)
```

---

**sampleSize.bin**

**Sample Size for 2-sample Binomial**

**Description**

Computes sample size(s) for 2-sample binomial problem given vector or scalar probabilities in the two groups.

**Usage**

```r
sampleSize.bin(alpha, beta, pit, pic, rho=0.5)
```

**Arguments**

- `alpha` scalar ONE-SIDED test size, or two-sided size/2
- `beta` scalar or vector of powers
- `pit` hypothesized treatment probability of success
- `pic` hypothesized control probability of success
- `rho` proportion of the sample devoted to treated group (0 < rho < 1)

**Value**

TOTAL sample size(s)

**AUTHOR**

Rick Chappell
Dept. of Statistics and Human Oncology
University of Wisconsin at Madison
<chappell@stat.wisc.edu>

**Examples**

```r
alpha <- .05
beta <- c(.70,.80,.90,.95)

# N1 is a matrix of total sample sizes whose
# rows vary by hypothesized treatment success probability and
# columns vary by power
# See Meinert's book for formulae.
```

`samplesize.bin` 267
sas.get

Convert a SAS Dataset to an S Data Frame

Description

Converts a SAS dataset into an S data frame. You may choose to extract only a subset of variables or a subset of observations in the SAS dataset. You may have the function automatically convert PROC FORMAT

- coded variables to factor objects. The original SAS codes are stored in an attribute called sas.codes and these may be added back to the levels of a factor variable using the code.levels function. Information about special missing values may be captured in an attribute of each variable having special missing values. This attribute is called special.miss, and such variables are given class special.miss. There are print, [], format, and is.special.miss methods for such variables. The chron function is used to set up date, time, and date-time variables. If using S-Plus 5 or 6 or later, the timedate function is used instead. Under R, Dates is used for dates and chron for date-times. For times without dates, these still need to be stored in date-time format in POSIX. Such SAS time variables are given a major class of POSIXt and a format.POSIXt function so that the date portion (which will always be 1/1/1970) will not print by default. If a date variable represents a partial date (0.5 added if month missing, 0.25 added if day missing, 0.75 if both), an attribute partial.date is added to the variable, and the variable also becomes a class imputed variable. The describe function uses information about partial dates and special missing values. There is an option to automatically uncompress (or gunzip) compressed SAS datasets.

Usage

sas.get(libraryName, member, variables=character(0), ifs=character(0), format.library=libraryName, id, dates=c("sas","ymmd","yearfrac","yearfrac2"), keep.log=TRUE, log.file="_temp_.log", macro=sas.get.macro, data.frame.out=existsFunction("data.frame"), clean.up=FALSE, quiet=FALSE, temp=tempfile("SaS"), formats=TRUE, recode=formats, special.miss=FALSE, sasprog="sas", as.is=.5, check.unique.id=TRUE, force.single=FALSE, pos, uncompress=FALSE, defaultencoding="latin1")
is.special.miss(x, code)

## S3 method for class 'special.miss'
x[...], drop=FALSE]

## S3 method for class 'special.miss'
print(x, ...)

## S3 method for class 'special.miss'
format(x, ...)

sas.codes(object)

code.levels(object)

### Arguments

**libraryName** character string naming the directory in which the dataset is kept.

**drop** logical. If TRUE the result is coerced to the lowest possible dimension.

**member** character string giving the second part of the two part SAS dataset name. (The first part is irrelevant here - it is mapped to the UNIX directory name.)

**x** a variable that may have been created by sas.get with special.miss=T or with recode in effect.

**variables** vector of character strings naming the variables in the SAS dataset. The S dataset will contain only those variables from the SAS dataset. To get all of the variables (the default), an empty string may be given. It is a fatal error if any one of the variables is not in the SAS dataset. You can use sas.contents to get the variables in the SAS dataset. If you have retrieved a subset of the variables in the SAS dataset and which to retrieve the same list of variables from another dataset, you can program the value of variables - see one of the last examples.

**ifs** a vector of character strings, each containing one SAS “subsetting if” statement. These will be used to extract a subset of the observations in the SAS dataset.

**format.library** The UNIX directory containing the file ‘formats.sct’, which contains the definitions of the user defined formats used in this dataset. By default, we look for the formats in the same directory as the data. The user defined formats must be available (so SAS can read the data).

**formats** Set formats to FALSE to keep sas.get from telling the SAS macro to retrieve value label formats from format.library. When you do not specify formats or recode, sas.get will set format to TRUE if a SAS format catalog (‘.sct’ or ‘.sc2’) file exists in format.library. Value label formats if present are stored as the formats attribute of the returned object (see below). A format is used if it is referred to by one or more variables in the dataset, if it contains no ranges of values (i.e., it identifies value labels for single values), and if it is a character format or a numeric format that is not used just to label missing values. If you set recode to TRUE, 1, or 2, formats defaults to TRUE. To fetch the values and labels for variable x in the dataset d you could type:
f <- attr(d$x, "format")
formats <- attr(d, "formats")
formats$f$values; formats$f$labels

recode

This parameter defaults to TRUE if formats is TRUE. If it is TRUE, variables that
have an appropriate format (see above) are recoded as factor objects, which
map the values to the value labels for the format. Alternatively, set recode
to 1 to use labels of the form value:label, e.g. 1:good 2:better 3:best. Set
recode to 2 to use labels such as good(1) better(2) best(3). Since sas.codes
and code.levels add flexibility, the usual choice for recode is TRUE.

special.miss

For numeric variables, any missing values are stored as NA in S. You can re-
cover special missing values by setting special.miss to TRUE. This will cause
the special.miss attribute and the special.miss class to be added to each
variable that has at least one special missing value. Suppose that variable y was
.\E in observation 3 and .G in observation 544. The special.miss attribute for
y then has the value
list(codes=c("E","G"),obs=c(3,544))
To fetch this information for variable y you would say for example
s <- attr(y, "special.miss")
s$codes; s$obs
or use is.special.miss(x) or the print.special.miss method, which will
replace NA values for the variable with ‘E’ or ‘G’ if they correspond to special
missing values. The describe function uses this information in printing a data
summary.

id

The name of the variable to be used as the row names of the S dataset. The id
variable becomes the row.names attribute of a data frame, but the id variable
is still retained as a variable in the data frame. (if data.frame.out is FALSE,
this will be the attribute 'id' of the R dataset.) You can also specify a vector of
variable names as the id parameter. After fetching the data from SAS, all these
variables will be converted to character format and concatenated (with a space
as a separator) to form a (hopefully) unique identification variable.

dates.
as.is

IF data.frame.out = TRUE, SAS character variables are converted to S factor
objects if as.is = FALSE or if as.is is a number between 0 and 1 inclusive
and the number of unique values of the variable is less than the number of obser-
vations (n) times as.is. The default if as.is is 0.5, so character variables are
converted to factors only if they have fewer than n/2 unique values. The primary
purpose of this is to keep unique identification variables as character values in
the data frame instead of using more space to store both the integer factor codes
and the factor labels.

check.unique.id

If id is specified, the row names are checked for uniqueness if check.unique.id = TRUE.
If any are duplicated, a warning is printed. Note that if a data frame is being cre-
ated with duplicate row names, statements such as my.data.frame["B23",]
will retrieve only the first row with a row name of
B23

.
force.single  By default, SAS numeric variables having $LENGTH > 4$ are stored as S double precision numerics, which allow for the same precision as a SAS LENGTH $8$ variable. Set force.single = TRUE to store every numeric variable in single precision (7 digits of precision). This option is useful when the creator of the SAS dataset has failed to use a LENGTH statement. R does not have single precision, so no attempt is made to convert to single if running R.

dates  One of the character strings "sas", "yearfrac", "yearfrac2", "yymmdd". If a SAS variable has a date format (one of "DATE", "MMDDYY", "YYMMDD", "DDMMYY", "YYQ", "MONYY", "JULIAN"), it will be converted to the format specified by dates before being given to S. "sas" gives days from 1/1/1960 (from 1/1/1970 if using chron), "yearfrac" gives days from 1/1/1900 divided by 365.25, "yearfrac2" gives year plus fraction of current year, and "yymmdd" gives a 6 digit number YYMMD

keep.log  logical flag: if FALSE, delete the SAS log file upon completion.

log.file  the name of the SAS log file.

macro  the name of an S object in the current search path that contains the text of the SAS macro called by R. The R object is a character vector that can be edited using for example sas.get.macro <- editor(sas.get.macro).

data.frame.out  logical flag: if TRUE, the return value will be an S data frame, otherwise it will be a list.

clean.up  logical flag: if TRUE, remove all temporary files when finished. You may want to keep these while debugging the SAS macro. Not needed for R.

quiet  logical flag: if FALSE, print the contents of the SAS log file if there has been an error.

temp  the prefix to use for the temporary files. Two characters will be added to this, the resulting name must fit on your file system.

sasprog  the name of the system command to invoke SAS

uncompress  set to TRUE to automatically invoke the UNIX gunzip command (if ‘member.ssd01.gz’ exists) or the uncompress command (if ‘member.ssd01.Z’ exists) to uncompress the SAS dataset before proceeding. This assumes you have the file permissions to allow uncompressing in place. If the file is already uncompressed, this option is ignored.
pos by default, a list or data frame which contains all the variables is returned. If you specify pos, each individual variable is placed into a separate object (whose name is the name of the variable) using the assign function with the pos argument. For example, you can put each variable in its own file in a directory, which in some cases may save memory over attaching a data frame.

code a special missing value code (‘A’ through ‘Z’ or ‘_’) to check against. If code is omitted, is.special.miss will return a TRUE for each observation that has any special missing value.

defaultencoding encoding to assume if the SAS dataset does not specify one. Defaults to "latin1".

object a variable in a data frame created by sas.get

... ignored

Details
If you specify special.miss = TRUE and there are no special missing values in the data SAS dataset, the SAS step will bomb.

For variables having a

PROC FORMAT VALUE

format with some of the levels undefined, sas.get will interpret those values as NA if you are using recode.

The SAS macro ‘sas\_get’ uses record lengths of up to 4096 in two places. If you are exporting records that are very long (because of a large number of variables and/or long character variables), you may want to edit these

LRECL

s to quadruple them, for example.

Value
if data.frame.out is TRUE, the output will be a data frame resembling the SAS dataset. If id was specified, that column of the data frame will be used as the row names of the data frame. Each variable in the data frame or vector in the list will have the attributes label and format containing SAS labels and formats. Underscores in formats are converted to periods. Formats for character variables have $ placed in front of their names. If formats is TRUE and there are any appropriate format definitions in format.library, the returned object will have attribute formats containing lists named the same as the format names (with periods substituted for underscores and character formats prefixed by $). Each of these lists has a vector called values and one called labels with the

PROC FORMAT; VALUE ...

definitions.

If data.frame.out is FALSE, the output will be a list of vectors, each containing a variable from the SAS dataset. If id was specified, that element of the list will be used as the id attribute of the entire list.
Side Effects

if a SAS error occurs and quiet is FALSE, then the SAS log file will be printed under the control of the less pager.

BACKGROUND

The references cited below explain the structure of SAS datasets and how they are stored under UNIX. See SAS Language for a discussion of the "subsetting if" statement.

Note

You must be able to run SAS (by typing sas) on your system. If the S command !sas does not start SAS, then this function cannot work.

If you are reading time or date-time variables, you will need to execute the command library(chron) to print those variables or the data frame if the timedate function is not available.

## End(Not run)
Enhanced Importing of SAS Transport Files using `read.xport`

### Description

Uses the `read.xport` and `lookup.xport` functions in the `foreign` library to import SAS datasets. SAS date, time, and date/time variables are converted respectively to `Date`, `POSIX`, or `POSIXct` objects in R, variable names are converted to lower case, SAS labels are associated with variables, and (by default) integer-valued variables are converted from storage mode double to integer. If the user ran `PROC FORMAT CNTLOUT=` in SAS and included the resulting dataset in the SAS version 5 transport file, variables having customized formats that do not include any ranges (i.e., variables having standard `PROC FORMAT; VALUE label formats`) will have their format labels looked up, and these variables are converted to `S factor`.

For those users having access to SAS, `method='csv'` is preferred when importing several SAS datasets. Run SAS macro `exportlib.sas` available from [http://biostat.mc.vanderbilt.edu/twiki/pub/Main/Hmisc/exportlib.sas](http://biostat.mc.vanderbilt.edu/twiki/pub/Main/Hmisc/exportlib.sas) to convert all SAS datasets in a SAS data library (from any engine supported by your system) into CSV files. If any customized formats are used, it is assumed that the `PROC FORMAT CNTLOUT=` dataset is in the data library as a regular SAS dataset, as above.

`SASdsLabels` reads a file containing `PROC CONTENTS` printed output to parse dataset labels, assuming that `PROC CONTENTS` was run on an entire library.

### Usage

```r
sasxport.get(file, lowernames=TRUE, force.single = TRUE,
             method=c('read.xport','dataload','csv'), formats=NULL, allow=NULL,
             out=NULL, keep=NULL, drop=NULL, as.is=0.5, FUN=NULL)
```

```r
sasdslabels(file)
```

### Arguments

- **file**: name of a file containing the SAS transport file. `file` may be a URL beginning with `http://`. For `sasdslabels`, `file` is the name of a file containing a `PROC CONTENTS` output listing. For `method='csv'`, `file` is the name of the directory containing all the CSV files created by running the `exportlib` SAS macro.

- **lowernames**: set to `FALSE` to keep from converting SAS variable names to lower case.

- **force.single**: set to `FALSE` to keep integer-valued variables not exceeding $2^{31} - 1$ in value from being converted to integer storage mode.

- **method**: set to "dataload" if you have the `dataload` executable installed and want to use it instead of `read.xport`. This seems to correct some errors in which rarely some factor variables are always missing when read by `read.xport` when in fact they have some non-missing values.

- **formats**: a data frame or list (like that created by `read.xport`) containing `PROC FORMAT` output, if such output is not stored in the main transport file.
allow
a vector of characters allowed by \( R \) that should not be converted to periods in variable names. By default, underscores in variable names are converted to periods as with \( R \) before version 1.9.

out
a character string specifying a directory in which to write separate \( R \) save files (.rda files) for each regular dataset. Each file and the data frame inside it is named with the SAS dataset name translated to lower case and with underscores changed to periods. The default NULL value of out results in a data frame or a list of data frames being returned. When out is given, sasxport.get returns only metadata (see below), invisibly. out only works with methods='csv'. out should not have a trailing slash.

keep
a vector of names of SAS datasets to process (original SAS upper case names). Must include PROC FORMAT dataset if it exists, and if the kept datasets use any of its value label formats.

drop
a vector of names of SAS datasets to ignore (original SAS upper case names)

as.is
SAS character variables are converted to S factor objects if as.is=FALSE or if as.is is a number between 0 and 1 inclusive and the number of unique values of the variable is less than the number of observations \( n \) times as.is. The default if as.is is .5, so character variables are converted to factors only if they have fewer than \( n/2 \) unique values. The primary purpose of this is to keep unique identification variables as character values in the data frame instead of using more space to store both the integer factor codes and the factor labels.

FUN
an optional function that will be run on each data frame created, when method='csv' and out are specified. The result of all the FUN calls is made into a list corresponding to the SAS datasets that are read. This list is the FUN attribute of the result returned by sasxport.get.

Details
See contents.list for a way to print the directory of SAS datasets when more than one was imported.

Value
If there is more than one dataset in the transport file other than the PROC FORMAT file, the result is a list of data frames containing all the non-PROC FORMAT datasets. Otherwise the result is the single data frame. There is an exception if out is specified; that causes separate \( R \) save files to be written and the returned value to be a list corresponding to the SAS datasets, with key PROC CONTENTS information in a data frame making up each part of the list. sasdsLabels returns a named vector of dataset labels, with names equal to the dataset names.

Facilitate Use of save and load to Remote Directories

Description

These functions are slightly enhanced versions of save and load that allow a target directory to be specified using options(LoadPath="pathname"). If the LoadPath option is not set, the current working directory is used.

Usage

```r
# options(LoadPath='mypath')
Save(object, name=deparse(substitute(object)), compress=TRUE)
Load(object)
```

Arguments

- **object**: the name of an object, usually a data frame. It must not be quoted.
- **name**: an optional name to assign to the object and file name prefix, if the argument name is not used
- **compress**: see `save`. Default is TRUE which corresponds to gzip.

Details

Save creates a temporary version of the object under the name given by the user, so that `save` will internalize this name. Then subsequent `Load` or `load` will cause an object of the original name to be created in the global environment. The name of the R data file is assumed to be the name of the object (or the value of `name`) appended with ".rda".

- `save`, `load`

Examples

```r
## Not run:
d <- data.frame(x=1:3, y=11:13)
options(LoadPath='..//data/rda')
Save(d)  # creates ../data/rda/d.rda
Load(d)  # reads ../data/rda/d.rda
Save(d, 'D')  # creates object D and saves it in ../D.rda

## End(Not run)
```
Description

`scat1d` adds tick marks (bar codes, rug plot) on any of the four sides of an existing plot, corresponding with non-missing values of a vector `x`. This is used to show the data density. Can also place the tick marks along a curve by specifying y-coordinates to go along with the `x` values.

If any two values of `x` are within `eps * w` of each other, where `eps` defaults to .001 and `w` is the span of the intended axis, values of `x` are jittered by adding a value uniformly distributed in `[-jitfrac*w, jitfrac*w]`, where `jitfrac` defaults to .008. Specifying `preserve=TRUE` invokes `jitter2` with a different logic of jittering. Allows plotting random sub-segments to handle very large `x` vectors (see `tfrac`).

`jitter2` is a generic method for jittering, which does not add random noise. It retains unique values and ranks, and randomly spreads duplicate values at equidistant positions within limits of enclosing values. `jitter2` is especially useful for numeric variables with discrete values, like rating scales. Missing values are allowed and are returned. Currently implemented methods are `jitter2.default` for vectors and `jitter2.data.frame` which returns a `data.frame` with each numeric column jittered.

datatdensity is a generic method used to show data densities in more complex situations. Here, another `datatdensity` method is defined for `data.frame`. Depending on the `which` argument, some or all of the variables in a `data.frame` will be displayed, with `scat1d` used to display continuous variables and, by default, bars used to display frequencies of categorical, character, or discrete numeric variables. For such variables, when the total length of value labels exceeds 200, only the first few characters from each level are used. By default, `datatdensity.data.frame` will construct one axis (i.e., one strip) per variable in the `data.frame`. Variable names appear to the left of the axes, and the number of missing values (if greater than zero) appear to the right of the axes. An optional `group` variable can be used for stratification, where the different strata are depicted using different colors. If the `q` vector is specified, the desired quantiles (over all groups) are displayed with solid triangles below each axis.

When the sample size exceeds 2000 (this value may be modified using the `nhistspike` argument, `datatdensity` calls `histspike` instead of `scat1d` to show the data density for numeric variables. This results in a histogram-like display that makes the resulting graphics file much smaller. In this case, `datatdensity` uses the `minf` argument (see below) so that very infrequent data values will not be lost on the variable’s axis, although this will slightly distort the histogram.

`histspike` is another method for showing a high-resolution data distribution that is particularly good for very large datasets (say `n > 1000`). By default, `histspike` bins the continuous `x` variable into 100 equal-width bins and then computes the frequency counts within bins (if `n` does not exceed 10, no binning is done). If `add=FALSE` (the default), the function displays either proportions or frequencies as in a vertical histogram. Instead of bars, spikes are used to depict the frequencies. If `add=FALSE`, the function assumes you are adding small density displays that are intended to take up a small amount of space in the margins of the overall plot. The `frac` argument is used as with `scat1d` to determine the relative length of the whole plot that is used to represent the maximum frequency. No jittering is done by `histspike`. 
histSpike can also graph a kernel density estimate for \(x\), or add a small density curve to any of 4 sides of an existing plot. When \(y\) or curve is specified, the density or spikes are drawn with respect to the curve rather than the \(x\)-axis.

histSpikeg is similar to histSpike but is for adding layers to a ggplot2 graphics object or traces to a plotly object. histSpikeg can also add lowess curves to the plot.

**Usage**

```r
scat1d(x, side=3, frac=0.02, jitfrac=0.008, tfrac,
    eps=ifelse(preserve,0,.001),
    lwd=0.1, col=par("col"),
    y=NULL, curve=NULL,
    bottom.align=FALSE,
    preserve=FALSE, fill=1/3, limit=TRUE, nhistSpike=2000, nint=100,
    type=c("proportion","count","density"), grid=FALSE, ...)

jitter2(x, ...)
## Default S3 method:
jitter2(x, fill=1/3, limit=TRUE, eps=0,
    presorted=FALSE, ...)

## S3 method for class 'data.frame'
jitter2(x, ...)

datatdensity(object, ...)
## S3 method for class 'data.frame'
datatdensity(object, group,
    which=c("all","continuous","categorical"),
    method.cat=c("bar","freq"),
    col.group=1:10,
    n.unique=10, show.na=TRUE, nint=1, naxes,
    q, bottom.align=nint>1,
    cex.axis=sc(.5,.3), cex.var=sc(.8,.3),
    lmgp=NULL, tck=sc(-.009,-.002),
    ranges=NULL, labels=NULL, ...)
## sc(a,b) means default to a if number of axes <= 3, b if >=50, use
## linear interpolation within 3-50

histSpike(x, side=1, nint=100, frac=.05, minf=NULL, mult.width=1,
    type=c("proportion","count","density"),
    xlim=range(x), ylim=c(0,max(f)), xlab=deparse(substitute(x)),
    ylab=switch(type,proportion='Proportion',
                count  ='Frequency',
                density = 'Density'),
    y=NULL, curve=NULL, add=FALSE,
    bottom.align=type="density", col=par("col"), lwd=par("lwd"),
    ...)
```

---

The code above provides usage examples for various functions related to plotting and data visualization. The `scat1d` function allows for the addition of a small density curve to existing plots, with options for different display styles and parameters. The `jitter2` function offers a default S3 method for adding layers to ggplot2 graphics objects, and `datatdensity` is designed for data frames, offering options for different methods and parameters to control the display of density estimates. The `histSpike` function is used for adding spikes to a plot, and `histSpikeg` is for adding layers to ggplot2 or plotly objects, including lowess curves.
Arguments

|x| a vector of numeric data, or a data frame (for jitter2)
|object| a data frame or list (even with unequal number of observations per variable, as long as group is not specified)
|side| axis side to use (1=bottom (default for histSpike), 2=left, 3=top (default for scatld), 4=right)
|frac| fraction of smaller of vertical and horizontal axes for tick mark lengths. Can be negative to move tick marks outside of plot. For histSpike, this is the relative y-direction length to be used for the largest frequency. When scatld calls histSpike, it multiplies its frac argument by 2.5. For histSpikeg, frac is a function of f, the vector of all frequencies. The default function scales tick marks so that they are between 0.01 and 0.03 of the y range, linearly scaled in the square root of the frequency less one.
|jitfrac| fraction of axis for jittering. If jitfrac ≤ 0, no jittering is done. If preserve=TRUE, the amount of jittering is independent of jitfrac.
|tfrac| Fraction of tick mark to actually draw. If tfrac < 1, will draw a random fraction tfrac of the line segment at each point. This is useful for very large samples or ones with some very dense points. The default value is 1 if the number of non-missing observations n is less than 125, and max(.1, 125/n) otherwise.
|eps| fraction of axis for determining overlapping points in x. For preserve=TRUE the default is 0 and original unique values are retained, bigger values of eps tends to bias observations from dense to sparse regions, but ranks are still preserved.
|lwd| line width for tick marks, passed to segments
|col| color for tick marks, passed to segments
|y| specify a vector the same length as x to draw tick marks along a curve instead of by one of the axes. The y values are often predicted values from a model. The side argument is ignored when y is given. If the curve is already represented as a table look-up, you may specify it using the curve argument instead. y may be a scalar to use a constant vertical placement.
|curve| a list containing elements x and y for which linear interpolation is used to derive y values corresponding to values of x. This results in tick marks being drawn along the curve. For histSpike, interpolated y values are derived for binmidpoints.
|bottom.align| set to TRUE to have the bottoms of tick marks (for side=1 or side=3) aligned at the y-coordinate. The default behavior is to center the tick marks. For
scat1d

data density, data frame, bottom align defaults to TRUE if nint > 1. In other words, if you are only labeling the first and last axis tick mark, the scat1d tick marks are centered on the variable’s axis.

preserve
set to TRUE to invoke jitter2

fill
maximum fraction of the axis filled by jittered values. If d are duplicated values between a lower value l and upper value u, then d will be spread within ±fill * \min(u - d, d - l)/2.

limit
specifies a limit for maximum shift in jittered values. Duplicate values will be spread within ±fill * \min(u - d, d - l)/2. The default TRUE restricts jittering to the smallest \min(u - d, d - l)/2 observed and results in equal amount of jittering for all d. Setting to FALSE allows for locally different amount of jittering, using maximum space available.

nhistSpike
If the number of observations exceeds or equals nhistSpike, scat1d will automatically call histSpike to draw the data density, to prevent the graphics file from being too large.

type
used by or passed to histSpike. Set to "count" to display frequency counts rather than relative frequencies, or "density" to display a kernel density estimate computed using the density function.

grid
set to TRUE if the R grid package is in effect for the current plot

nint
number of intervals to divide each continuous variable’s axis for datadensity. For histSpike, is the number of equal-width intervals for which to bin x, and if instead nint is a character string (e.g., nint="all"), the frequency tabulation is done with no binning. In other words, frequencies for all unique values of x are derived and plotted. For histSpikeg, if x has no more than nint unique values, all observed values are used, otherwise the data are rounded before tabulation so that there are no more than nint intervals.

... optional arguments passed to scat1d from datadensity or to histSpike from scat1d. For histSpikep are passed to the lines list to add_trace.

presorted
set to TRUE to prevent from sorting for determining the order l < d < u. This is useful if an existing meaningful local order would be destroyed by sorting, as in sin(\pi * sort(round(runif(1000, 0, 10), 1))).

group
an optional stratification variable, which is converted to a factor vector if it is not one already

which
set which="continuous" to only plot continuous variables, or which="categorical" to only plot categorical, character, or discrete numeric ones. By default, all types of variables are depicted.

method.cat
set method.cat="freq" to depict frequencies of categorical variables with digits representing the cell frequencies, with size proportional to the square root of the frequency. By default, vertical bars are used.

col.group
colors representing the group strata. The vector of colors is recycled to be the same length as the levels of group.

n.unique
number of unique values a numeric variable must have before it is considered to be a continuous variable

show.na
set to FALSE to suppress drawing the number of NAs to the right of each axis
**naxes**
number of axes to draw on each page before starting a new plot. You can set naxes larger than the number of variables in the data frame if you want to compress the plot vertically.

**q**
a vector of quantiles to display. By default, quantiles are not shown.

**cex.axis**
character size for draw labels for axis tick marks

**cex.var**
character size for variable names and frequency of NAs

**lmgp**
spacing between numeric axis labels and axis (see par for mgp)

**tck**
see tck under par

**ranges**
a list containing ranges for some or all of the numeric variables. If ranges is not given or if a certain variable is not found in the list, the empirical range, modified by pretty, is used. Example: ranges=list(age=c(10,100), pressure=c(50,150)).

**labels**
a vector of labels to use in labeling the axes for datadensity.data.frame. Default is to use the names of the variable in the input data frame. Note: margin widths computed for setting aside names of variables use the names, and not these labels.

**minf**
For histSpike, if minf is specified low bin frequencies are set to a minimum value of minf times the maximum bin frequency, so that rare data points will remain visible. A good choice of minf is 0.075. datadensity.data.frame passes minf=0.075 to scatld to pass to histSpike. Note that specifying minf will cause the shape of the histogram to be distorted somewhat.

**mult.width**
multiplier for the smoothing window width computed by histSpike when type="density"

**xlim**
a 2-vector specifying the outer limits of x for binning (and plotting, if add=FALSE and nint is a number). For histSpikeg, observations outside the xlim range are ignored.

**ylim**
y-axis range for plotting (if add=FALSE). Often needed for histSpikeg to help scale the tick mark line segments.

**xlab**
x-axis label (add=FALSE); default is name of input argument x

**ylab**
y-axis label (add=FALSE)

**add**
set to TRUE to add the spike-histogram to an existing plot, to show marginal data densities

**formula**
a formula of the form y ~ x1 or y ~ x1 + ... where y is the name of the y-axis variable being plotted with ggplot, x1 is the name of the x-axis variable, and optional ... are variables used by ggplot to produce multiple curves on a panel and/or facets.

**predictions**
the data frame being plotted by ggplot, containing x and y coordinates of curves. If omitted, spike histograms are drawn at the bottom (default) or top of the plot according to side.

**data**
for histSpikeg is a mandatory data frame containing raw data whose frequency distribution is to be summarized, using variables in formula.

**plotly**
an existing plotly object. If not NULL, histSpikeg uses plotly instead of ggplot.
lowess set to TRUE to have `histspikeg` add a `geom_line` layer to the `ggplot2` graphic, containing `lowess()` nonparametric smoothers. This causes the returned value of `histspikeg` to be a list with two components: "hist" and "lowess" each containing a layer. Fortunately, `ggplot2` plots both layers automatically. If the dependent variable is binary, `iter=0` is passed to `lowess` so that outlier detection is turned off; otherwise `iter=3` is passed.

span passed to `lowess` as the `f` argument

histcol color of line segments (tick marks) for `histspikeg`. Default is black. Set to any color or to "default" to use the prevailing colors for the graphic.

showlegend set to FALSE too have the added `plotly` traces not have entries in the plot legend

Details

For `scat1d` the length of line segments used is `frac*min(par()$pin)/par()$uin[opp]` data units, where `opp` is the index of the opposite axis and `frac` defaults to .02. Assumes that `plot` has already been called. Current `par("usr")` is used to determine the range of data for the axis of the current plot. This range is used in jittering and in constructing line segments.

Value

`histspike` returns the actual range of `x` used in its binning

Side Effects

`schat1d` adds line segments to plot. `datadensity.data.frame` draws a complete plot. `histspike` draws a complete plot or adds to an existing plot.

pairs(jitter2(dfram))     # pairs for jittered data.frame
# This gets reasonable pairwise scatter plots for all combinations of
# variables where
#
# - continuous variables (with unique values) are not jittered at all, thus
# all relations between continuous variables are shown as they are,
# extreme values have exact positions.
#
# - discrete variables get a reasonable amount of jittering, whether they
# have 2, 3, 5, 10, 20 ... levels
```
score.binary

Score a Series of Binary Variables

Description

Creates a new variable from a series of logical conditions. The new variable can be a hierarchical category or score derived from considering the rightmost TRUE value among the input variables, an additive point score, a union, or any of several others by specifying a function using the fun argument.
Usage

score.binary(..., fun=max, points=1:p,
    na.rm=funtext == "max", retfactor=TRUE)

Arguments

...                      a list of variables or expressions which are considered to be binary or logical
fun                      a function to compute on each row of the matrix represented by a specific observation of all the variables in ...
points                   points to assign to successive elements of ... . The default is 1, 2, ..., p, where p is the number of elements. If you specify one number for points, that number will be duplicated (i.e., equal weights are assumed).
na.rm                    set to TRUE to remove NAs from consideration when processing each row of the matrix of variables in ... . For fun=max, na.rm=TRUE is the default since score.binary assumes that a hierarchical scale is based on available information. Otherwise, na.rm=FALSE is assumed. For fun=mean you may want to specify na.rm=TRUE.
retfactor                applies if fun=max, in which case retfactor=TRUE makes score.binary return a factor object since a hierarchical scale implies a unique choice.

Value

a factor object if retfactor=TRUE and fun=max or a numeric vector otherwise. Will not contain NAs if na.rm=TRUE unless every variable in a row is NA. If a factor object is returned, it has levels "none" followed by character string versions of the arguments given in ...

See Also

any, sum, max, factor

Examples

set.seed(1)
age <- rnorm(25, 70, 15)
previous.disease <- sample(0:1, 25, TRUE)
#Hierarchical scale, highest of 1:age>70 2:previous.disease
score.binary(age>70, previous.disease, retfactor=FALSE)
#Same as above but return factor variable with levels "none" "age>70"
# "previous.disease"
score.binary(age>70, previous.disease)

#Additive scale with weights 1:age>70 2:previous.disease
score.binary(age>70, previous.disease, fun=sum)
#Additive scale, equal weights
score.binary(age>70, previous.disease, fun=sum, points=c(1,1))
#Same as saying points=1
#Union of variables, to create a new binary variable
score.binary(age>70, previous.disease, fun=any)

### sedit

**Character String Editing and Miscellaneous Character Handling Functions**

**Description**

This suite of functions was written to implement many of the features of the UNIX sed program entirely within S (function sedit). The substring.location function returns the first and last position numbers that a sub-string occupies in a larger string. The substring2<- function does the opposite of the builtin function substring. It is named substring2 because for S-Plus there is a built-in function substring, but it does not handle multiple replacements in a single string.

replace.substring.wild edits character strings in the fashion of "change xxxANYTHINGyyyy to aaaaANYTHINGbbbb", if the "ANYTHING" passes an optional user-specified test function. Here, the "yyyy" string is searched for from right to left to handle balancing parentheses, etc.

numeric.string and all.digits are two examples of test functions, to check, respectively if each of a vector of strings is a legal numeric or if it contains only the digits 0-9. For the case where old="*" or "**", or for replace.substring.wild with the same values of old or with front=TRUE or back=TRUE, sedit (if wild.literal=FALSE) and replace.substring.wild will edit the largest substring satisfying test.

substring2 is just a copy of substring so that substring2<- will work.

**Usage**

```r
sedit(text, from, to, test, wild.literal=FALSE)
substring.location(text, string, restrict)
# substring(text, first, last) <- setto  # S-Plus only
replace.substring.wild(text, old, new, test, front=FALSE, back=FALSE)
numeric.string(string)
alldigits(string)
substring2(text, first, last)
substring2(text, first, last) <- value
```

**Arguments**

- **text**: a vector of character strings for sedit, substring2, substring2<- or a single character string for substring.location, replace.substring.wild.
- **from**: a vector of character strings to translate from, for sedit. A single asterisk wild card, meaning allow any sequence of characters (subject to the test function, if any) in place of the "*". An element of from may begin with "^" to force the match to begin at the beginning of text, and an element of from can end with "$" to force the match to end at the end of text.
- **to**: a vector of character strings to translate to, for sedit. If a corresponding element in from had an "*", the element in to may also have an "*". Only single asterisks are allowed. If to is not the same length as from, the rep function is used to make it the same length.
string  a single character string, for substring.location, numeric.string, all.digits

first  a vector of integers specifying the first position to replace for substring2<-. first may also be a vector of character strings that are passed to sedit to use as patterns for replacing substrings with setto. See one of the last examples below.

last  a vector of integers specifying the ending positions of the character substrings to be replaced. The default is to go to the end of the string. When first is character, last must be omitted.

setto  a character string or vector of character strings used as replacements, in substring2<-

old  a character string to translate from for replace.string.wild. May be "*$" or "^*$" or any string containing a single "*" but not beginning with "^" or ending with "$".

new  a character string to translate to for replace.string.wild

test  a function of a vector of character strings returning a logical vector whose elements are TRUE or FALSE according to whether that string element qualifies as the wild card string for sedit, replace.string.wild

wild.literal  set to TRUE to not treat asterisks as wild cards and to not look for "^" or "$" in old

restrict  a vector of two integers for substring.location which specifies a range to which the search for matches should be restricted

front  specifying front = TRUE and old = "*" is the same as specifying old = "^*

back  specifying back = TRUE and old = "*" is the same as specifying old = "*$"

value  a character vector

Value  

sedit returns a vector of character strings the same length as text. substring.location returns a list with components named first and last, each specifying a vector of character positions corresponding to matches. replace.string.wild returns a single character string. numeric.string and all.digits return a single logical value.

Side Effects  

substring2<- modifies its first argument

Examples

```r
x <- 'this string'
substring2(x, 3, 4) <- 'IS'
x
substring2(x, 7) <- '

substring.location('abcdefgabc', 'ab')
substring.location('abcdefgabc', 'ab', restrict=c(3,999))

replace.substring.wild('this is a cat','this*cat','that*dog')
replace.substring.wild('there is a cat','is a*','is not a*')
replace.substring.wild('this is a cat','is a*','Z')

qualify <- function(x) x=='1.5' | x=='2.5'
replace.substring.wild('He won 1.5 million $','won million',
  'lost million', test=qualify)
replace.substring.wild('He won 1 million $','won million',
  'lost million', test=qualify)
replace.substring.wild('He won 1.2 million $','won million',
  'lost million', test=numeric.string)

x <- c('a = b','c < d','hello')
sedit(x, c('=','he*o'),c('=', 'hex'))

dsedit('x23', '*$','[*]', test=numeric.string)
dsedit('23xx', '**','Y*(x) ', test=all.digits)

replace.substring.wild("abcdefabcdef", "d*f", "xy")

x <- "abcd"
substring2(x, "bc") <- "BCX"
x
substring2(x, "B*d") <- "B*D"
x
```

Description

`show.pch` plots the definitions of the pch parameters. `show.col` plots definitions of integer-valued colors. `character.table` draws numeric equivalents of all latin characters; the character on line

xy and column z of the table has numeric code "xyz", which you would surround in quotes and proceed by a backslash.

Usage

show.pch(object = par("font"))
show.col(object=NULL)
character.table(font=1)

Arguments

object font for show.pch, ignored for show.col.
font

## End(Not run)

---

showPsfrag  

Display image from psfrag LaTeX strings

Description

showPsfrag is used to display (using ghostview) a postscript image that contained psfrag LaTeX strings, by building a small LaTeX script and running latex and dvips.

Usage

showPsfrag(filename)

Arguments

filename name or character string or character vector specifying file prefix.
simplifyDims

Description
Takes a list where each element is a group of rows that have been spanned by a multirow row and combines it into one large matrix.

Usage
simplifyDims(x)

Arguments
x list of spanned rows

Details
All rows must have the same number of columns. This is used to format the list for printing.

Value
a matrix that contains all of the spanned rows.

Author(s)
Charles Dupont

See Also
rbind
Examples

```r
a <- list(a = matrix(1:25, ncol=5), b = matrix(1:10, ncol=5), c = 1:5)
simplifyDims(a)
```

---

**Description**

This function simulates the power of a two-sample test from a proportional odds ordinal logistic model for a continuous response variable- a generalization of the Wilcoxon test. The continuous data model is normal with equal variance. Nonlinear covariate adjustment is allowed, and the user can optionally specify discrete ordinal level overrides to the continuous response. For example, if the main response is systolic blood pressure, one can add two ordinal categories higher than the highest observed blood pressure to capture heart attack or death.

**Usage**

```r
simRegOrd(n, nsim=1000, delta=0, odds.ratio=1, sigma, p=NULL, x=NULL, X=x, Eyx, alpha=0.05, pr=FALSE)
```

**Arguments**

- `n`: combined sample size (both groups combined)
- `nsim`: number of simulations to run
- `delta`: difference in means to detect, for continuous portion of response variable
- `odds.ratio`: odds ratio to detect for ordinal overrides of continuous portion
- `sigma`: standard deviation for continuous portion of response
- `p`: a vector of marginal cell probabilities which must add up to one. The i-th element specifies the probability that a patient will be in response level i for the control arm for the discrete ordinal overrides.
- `x`: optional covariate to adjust for - a vector of length n
- `X`: a design matrix for the adjustment covariate x if present. This could represent for example x and x^2 or cubic spline components.
- `Eyx`: a function of x that provides the mean response for the control arm treatment
- `alpha`: type I error
- `pr`: set to TRUE to see iteration progress

**Value**

A list containing `n`, `delta`, `sigma`, `power`, `betas`, `se`, `pvals` where `power` is the estimated power (scalar), and `betas`, `se`, `pvals` are `nsim`-vectors containing, respectively, the ordinal model treatment effect estimate, standard errors, and 2-tailed p-values. When a model fit failed, the corresponding entries in `betas`, `se`, `pvals` are NA and power is the proportion of non-failed iterations for which the treatment p-value is significant at the `alpha` level.

power.t.test(n = n/2, delta = delta, sd = sd, type = 'two.sample') # 0.70
set.seed(1)
w <- simRegOrd(n, delta = delta, sigma = sd, pr = TRUE) # 0.686

## Now do ANCOVA with a quadratic effect of a covariate
n <- 100
x <- rnorm(n)
w <- simRegOrd(n, nsim = 400, delta = delta, sigma = sd, x = x,
               
               X = cbind(x, x^2),
               Eyx = function(x) x + x^2, pr = TRUE)
w$pwr # 0.68

## Fit a cubic spline to some simulated pilot data and use the fitted
## function as the true equation in the power simulation
require(rms)
N <- 1000
set.seed(2)
x <- rnorm(N)
y <- x + x^2 + rnorm(N, 0, sd = sd)
f <- ols(y ~ rcs(x, 4), x = TRUE)

n <- 100
j <- sample(1: N, n, replace = n > N)
x <- x[j]
X <- f$x[j,]
w <- simRegOrd(n, nsim = 400, delta = delta, sigma = sd, x = x,
               
               X = X,
               Eyx = function(f), pr = TRUE)
w$pwr # 0.70

## Finally, add discrete ordinal category overrides and high end of y
## Start with no effect of treatment on these ordinal event levels (OR=1.0)
## smean.sd

### Compute Summary Statistics on a Vector

**Description**

A number of statistical summary functions is provided for use with `summary.formula` and `summarize` (as well as `tapply` and by themselves). `smean.cl.normal` computes 3 summary variables: the sample mean and lower and upper Gaussian confidence limits based on the t-distribution. `smean.sd` computes the mean and standard deviation. `smean.sdl` computes the mean plus or minus a constant times the standard deviation. `smean.cl.boot` is a very fast implementation of the basic nonparametric bootstrap for obtaining confidence limits for the population mean without assuming normality. These functions all delete NAs automatically. `smedian.hilow` computes the sample median and a selected pair of outer quantiles having equal tail areas.

**Usage**

```r
smean.cl.normal(x, mult=qt((1+conf.int)/2,n-1), conf.int=.95, na.rm=TRUE)
smean.sd(x, na.rm=TRUE)
smean.sdl(x, mult=2, na.rm=TRUE)
smean.cl.boot(x, conf.int=.95, B=1000, na.rm=TRUE, reps=FALSE)
```

```r
w <- simRegOrd(n, nsim=400, delta=delta, odds.ratio=1, sigma=sd,
               x=X, X=X, Ey=Function(f),
               p=c(.38, .01, .01),
               pr=TRUE)
w$power ## 0.61 (0.3 if p=.8 .1 , 0.37 for .9 .05 .05, 0.50 for .95 .025 .025)

## Now assume that odds ratio for treatment is 2.5
## First compute power for clinical endpoint portion of Y alone
or <- 2.5
p <- c(.9, .05, .05)
popower(p, odds.ratio=or, n=100) # 0.275

## Compute power of t-test on continuous part of Y alone
power.t.test(n = 100 / 2, delta=delta, sd=sd, type='two.sample') # 0.70

## Note this is the same as the p.o. model power from simulation above
## Solve for OR that gives the same power estimate from popower
popower(rep(.01, 100), odds.ratio=2.4, n=100) # 0.706

## Compute power for continuous Y with ordinal override
w <- simRegOrd(n, nsim=400, delta=delta, odds.ratio=or, sigma=sd,
               x=x, X=X, Ey=Function(f),
               p=c(.9, .05, .05),
               pr=TRUE)
w$power ## 0.72

## End(Not run)
```
smedian.hilow(x, conf.int=.95, na.rm=TRUE)

Arguments

x for summary functions `smean.*`, `smedian.hilow`, a numeric vector from which NAs will be removed automatically

na.rm defaults to TRUE unlike built-in functions, so that by default NAs are automatically removed

mult for `smean.cl.normal` is the multiplier of the standard error of the mean to use in obtaining confidence limits of the population mean (default is appropriate quantile of the t distribution). For `smean.sdl`, `mult` is the multiplier of the standard deviation used in obtaining a coverage interval about the sample mean. The default is `mult=2` to use plus or minus 2 standard deviations.

conf.int for `smean.cl.normal` and `smean.cl.boot` specifies the confidence level (0-1) for interval estimation of the population mean. For `smedian.hilow`, `conf.int` is the coverage probability the outer quantiles should target. When the default, 0.95, is used, the lower and upper quantiles computed are 0.025 and 0.975.

B number of bootstrap resamples for `smean.cl.boot`

reps set to TRUE to have `smean.cl.boot` return the vector of bootstrapped means as the `reps` attribute of the returned object

Value

a vector of summary statistics

Author(s)

Frank Harrell
Department of Biostatistics
Vanderbilt University
<frank.harrell@vanderbilt.edu>

See Also

`summarize`, `summary.formula`

Examples

```r
set.seed(1)
x <- rnorm(100)
smean.sd(x)
smean.sdl(x)
smean.cl.normal(x)
smean.cl.boot(x)
smedian.hilow(x, conf.int=.5)  # 25th and 75th percentiles

# Function to compute 0.95 confidence interval for the difference in two means
# g is grouping variable
```
bootdif <- function(y, g) {
  g <- as.factor(g)
  a <- attr(smean.cl.boot(y[g==levels(g)[1]], B=2000, reps=TRUE), 'reps')
  b <- attr(smean.cl.boot(y[g==levels(g)[2]], B=2000, reps=TRUE), 'reps')
  meandif <- diff(tapply(y, g, mean, na.rm=TRUE))
  a.b <- quantile(b-a, c(.025,.975))
  res <- c(mean(diff), a.b)
  names(res) <- c('Mean Difference', '.025', '.975')
  res
}

solvet <- function(a, b, tol=1e-09) {
  qr.solve(a, b, tol=tol)
}

somers2 <- function(x, y, weights=NULL, normwt=FALSE, na.rm=TRUE) {
  # Computes Somers' Dxy rank correlation...
}
Arguments

x  typically a predictor variable. NAs are allowed.
y  a numeric outcome variable coded 0-1. NAs are allowed.
weights  a numeric vector of observation weights (usually frequencies). Omit or specify a zero-length vector to do an unweighted analysis.
normwt  set to TRUE to make weights sum to the actual number of non-missing observations.
na.rm  set to FALSE to suppress checking for NAs.

Details

The rcorr.cens function, which although slower than somers2 for large sample sizes, can also be used to obtain Dxy for non-censored binary y, and it has the advantage of computing the standard deviation of the correlation index.

Value

a vector with the named elements C, Dxy, n (number of non-missing pairs), and Missing. Uses the formula \( C = \frac{\text{mean}(\text{rank}(x[y == 1])) - (n1 + 1)/2}{(n - n1)/(n1)} \), where \( n1 \) is the frequency of \( y=1 \).

# Check weights
x <- 1:6
y <- c(0,0,1,0,1,1)
f <- c(3,2,2,3,2,1)
somers2(x, y)
somers2(rep(x, f), rep(y, f))
somers2(x, y, f)
```
spower

Simulate Power of 2-Sample Test for Survival under Complex Conditions

Description

Given functions to generate random variables for survival times and censoring times, spower simulates the power of a user-given 2-sample test for censored data. By default, the logrank (Cox 2-sample) test is used, and a logrank function for comparing 2 groups is provided. Optionally a Cox model is fitted for each each simulated dataset and the log hazard ratios are saved (this requires the survival package). A print method prints various measures from these. For composing R functions to generate random survival times under complex conditions, the Quantile2 function allows the user to specify the intervention:control hazard ratio as a function of time, the probability of a control subject actually receiving the intervention (dropin) as a function of time, and the probability that an intervention subject receives only the control agent as a function of time (non-compliance, dropout). Quantile2 returns a function that generates either control or intervention uncensored survival times subject to non-constant treatment effect, dropin, and dropout. There is a plot method for plotting the results of Quantile2, which will aid in understanding the effects of the two types of non-compliance and non-constant treatment effects. Quantile2 assumes that the hazard function for either treatment group is a mixture of the control and intervention hazard functions, with mixing proportions defined by the dropin and dropout probabilities. It computes hazards and survival distributions by numerical differentiation and integration using a grid of (by default) 7500 equally-spaced time points.

The logrank function is intended to be used with spower but it can be used by itself. It returns the 1 degree of freedom chi-square statistic, with the hazard ratio estimate as an attribute.

The Weibull2 function accepts as input two vectors, one containing two times and one containing two survival probabilities, and it solves for the scale and shape parameters of the Weibull distribution \((S(t) = e^{-\alpha t^\gamma})\) which will yield those estimates. It creates an R function to evaluate survival probabilities from this Weibull distribution. Weibull2 is useful in creating functions to pass as the first argument to Quantile2.

The Lognorm2 and Gompertz2 functions are similar to Weibull2 except that they produce survival functions for the log-normal and Gompertz distributions.

When cox=TRUE is specified to spower, the analyst may wish to extract the two margins of error by using the print method for spower objects (see example below) and take the maximum of the two.

Usage

```
spower(rcontrol, rinterv, rcens, nc, ni, 
  test=logrank, cox=FALSE, nsim=500, alpha=0.05, pr=TRUE)

## S3 method for class 'spower'
print(x, conf.int=.95, ...)

Quantile2(scontrol, hratio, 
  dropin=function(times)0, dropout=function(times)0, 
  m=7500, tmax, qtmax=.001, mplot=200, pr=TRUE, ...)
```
## S3 method for class 'Quantile2'
print(x, ...)

## S3 method for class 'Quantile2'
plot(x,
     what=c("survival", "hazard", "both", "drop", "hratio", "all"),
     dropsep=FALSE, lty=1:4, col=1, xlim, ylim=NULL,
     label.curves=NULL, ...)

logrank(S, group)
Gompertz2(times, surv)
Lognorm2(times, surv)
Weibull2(times, surv)

### Arguments

- **rcontrol**: a function of \( n \) which returns \( n \) random uncensored failure times for the control group. `spower` assumes that non-compliance (dropin) has been taken into account by this function.

- **rinterv**: similar to `rcontrol` but for the intervention group

- **rcens**: a function of \( n \) which returns \( n \) random censoring times. It is assumed that both treatment groups have the same censoring distribution.

- **nc**: number of subjects in the control group

- **ni**: number in the intervention group

- **scontrol**: a function of a time vector which returns the survival probabilities for the control group at those times assuming that all patients are compliant.

- **hratio**: a function of time which specifies the intervention:control hazard ratio (treatment effect)

- **x**: an object of class “Quantile2” created by `Quantile2`, or of class “spower” created by `spower`

- **conf.int**: confidence level for determining fold-change margins of error in estimating the hazard ratio

- **S**: a `Surv` object or other two-column matrix for right-censored survival times

- **group**: group indicators have length equal to the number of rows in `S` argument.

- **times**: a vector of two times

- **surv**: a vector of two survival probabilities

- **test**: any function of a `Surv` object and a grouping variable which computes a chi-square for a two-sample censored data test. The default is `logrank`.

- **cox**: If true, the two margins of error are available by using the `print` method for `spower` objects (see example below) and taking the maximum of the two.

- **nsim**: number of simulations to perform (default=500)

- **alpha**: type I error (default=.05)
If `FALSE` prevents `spower` from printing progress notes for simulations. If `FALSE` prevents `Quantile2` from printing `tmax` when it calculates `tmax`.

A function of time specifying the probability that a control subject actually is treated with the new intervention at the corresponding time.

A function of time specifying the probability of an intervention subject dropping out to control conditions. As a function of time, `dropout` specifies the probability that a patient is treated with the control therapy at time `t`. `dropin` and `dropout` form mixing proportions for control and intervention hazard functions.

Number of time points used for approximating functions (default is 7500)

Maximum time point to use in the grid of `m` times. Default is the time such that `scontrol(time)` is `qtmax`.

Survival probability corresponding to the last time point used for approximating survival and hazard functions. Default is 0.001. For `tmax` of the time for which a simulated time is needed which corresponds to a survival probability of less than `qtmax`, the simulated value will be `tmax`.

Number of points used for approximating functions for use in plotting (default is 200 equally spaced points)

Optional arguments passed to the `scontrol` function when it's evaluated by `Quantile2`. Unused for `print.spower`.

A single character constant (may be abbreviated) specifying which functions to plot. The default is "both" meaning both survival and hazard functions. Specify what="drop" to just plot the `dropin` and `dropout` functions, what="hratio" to plot the hazard ratio functions, or "all" to make 4 separate plots showing all functions (6 plots if `dropsep=TRUE`).

If `TRUE` makes `plot.Quantile2` separate pure and contaminated functions onto separate plots

Vector of line types

Vector of colors

Optional x-axis limits

Optional y-axis limits

Optional list which is passed as the `opts` argument to `labcurve`.

Returns the power estimate (fraction of simulated chi-squares greater than the alpha-critical value). If `cox=TRUE`, `spower` returns an object of class "spower" containing the power and various other quantities.

`Quantile2` returns an R function of class "Quantile2" with attributes that drive the `plot` method. The major attribute is a list containing several lists. Each of these sub-lists contains a `Time` vector along with one of the following: survival probabilities for either treatment group and with or without contamination caused by non-compliance, hazard rates in a similar way, intervention:control hazard ratio function with and without contamination, and `dropin` and `dropout` functions.

`logrank` returns a single chi-square statistic.

`Weibull2`, `Lognorm2` and `Gompertz2` return an R function with three arguments, only the first of which (the vector of times) is intended to be specified by the user.
Side Effects

spower prints the iteration number every 10 iterations if pr=TRUE.

```
spss.get invokes the read.spss function in the foreign package to read an SPSS file, with a default output format of "data.frame". The label function is used to attach labels to individual variables instead of to the data frame as done by read.spss. By default, integer-valued variables are converted to a storage mode of integer unless force.single=FALSE. Date variables are converted to R date variables. By default, underscores in names are converted to periods.
Usage

spss.get(file, lowernames=FALSE, datevars = NULL,
          use.value.labels = TRUE, to.data.frame = TRUE,
          max.value.labels = Inf, force.single=TRUE,
          allow=NULL, charfactor=FALSE, reencode = NA)

Arguments

file       input SPSS save file. May be a file on the WWW, indicated by file starting
           with 'http://' or 'https://'.
lowernames set to TRUE to convert variable names to lower case
datevars   vector of variable names containing dates to be converted to R internal format
use.value.labels
           see `read.spss`
to.data.frame see `read.spss`; default is TRUE for spss.get
max.value.labels
           see `read.spss`
force.single set to FALSE to prevent integer-valued variables from being converted from storage mode double to integer
allow      a vector of characters allowed by R that should not be converted to periods in variable names. By default, underscores in variable names are converted to periods as with R before version 1.9.
charfactor set to TRUE to change character variables to factors if they have fewer than n/2 unique values. Blanks and null strings are converted to NAs.
reencode   see `read.spss`

Value

a data frame or list

Author(s)

stata.get  

Enhanced Importing of STATA Files

Description

Reads a file in Stata version 5-11 binary format format into a data frame.

Usage

stata.get(file, lowernames = FALSE, convert.dates = TRUE,
convert.factors = TRUE, missing.type = FALSE,
convert.underscore = TRUE, warn.missing.labels = TRUE,
force.single = TRUE, allow=NULL, charfactor=FALSE, ...)

Arguments

file  input SPSS save file. May be a file on the WWW, indicated by file starting with "http://":
lowernames set to TRUE to convert variable names to lower case
convert.dates see read.dta
convert.factors see read.dta
missing.type see read.dta
convert.underscore see read.dta
warn.missing.labels see read.dta
force.single set to FALSE to prevent integer-valued variables from being converted from storage mode double to integer
allow a vector of characters allowed by R that should not be converted to periods in variable names. By default, underscores in variable names are converted to periods as with R before version 1.9.
charfactor set to TRUE to change character variables to factors if they have fewer than n/2 unique values. Blanks and null strings are converted to NAs.
... arguments passed to read.dta.

Details

stata.get invokes the read.dta function in the foreign package to read an STATA file, with a default output format of data.frame. The label function is used to attach labels to individual variables instead of to the data frame as done by read.dta. By default, integer-valued variables are converted to a storage mode of integer unless force.single=FALSE. Date variables are converted to R Date variables. By default, underscores in names are converted to periods.
stat_plsmo

Value

A data frame

Author(s)

Charles Dupont

See Also

read.dta,cleanup.import,label,data.frame,Date

Examples

## Not run:
w <- stata.get('/tmp/my.dta')
## End(Not run)

stat_plsmo

Add a lowess smoother without confidence bands.

Description

Automatically selects iter=0 for lowess if y is binary, otherwise uses iter=3.

Usage

stat_plsmo(mapping = NULL, data = NULL, geom = "smooth",
position = "identity", n = 80, fullrange = FALSE, span = 2/3,
fun = function(x) x, na.rm = FALSE, show.legend = NA,
inherit.aes = TRUE, ...)

Arguments

mapping, data, geom, position, show.legend, inherit.aes
see ggplot2 documentation

n
number of points to evaluate smoother at

fullrange
should the fit span the full range of the plot, or just the data

span
see f argument to lowess

fun
a function to transform smoothed y

na.rm
If FALSE (the default), removes missing values with a warning. If TRUE silently removes missing values.

... other arguments are passed to smoothing function
string.bounding.box

Determine Dimensions of Strings

Description
This determines the number of rows and maximum number of columns of each string in a vector.

Usage
string.bounding.box(string, type = c("chars", "width"))

Arguments

string  vector of strings

type  character: whether to count characters or screen columns

Value
a data.frame with additional columns

y  predicted value

See Also
lowess for loess smoother.

Examples

c <- ggplot(mtcars, aes(qsec, wt))
c + stat_plsmo()
c + stat_plsmo() + geom_point()
c + stat_plsmo(span = 0.1) + geom_point()

# Smoothers for subsets
c <- ggplot(mtcars, aes(y=wt, x=mpg)) + facet_grid(. ~ cyl)
c + stat_plsmo() + geom_point()
c + stat_plsmo(fullrange = TRUE) + geom_point()

# Geoms and stats are automatically split by aesthetics that are factors

c <- ggplot(mtcars, aes(y=wt, x=mpg, colour=factor(cyl)))
c + stat_plsmo() + geom_point()
c + stat_plsmo(aes(fill = factor(cyl))) + geom_point()
c + stat_plsmo(fullrange=TRUE) + geom_point()

# Example with logistic regression
data("kyphosis", package="rpart")
qplot(Age, as.numeric(Kyphosis) - 1, data = kyphosis) + stat_plsmo()
### string.break.line

**Value**

- **rows**: vector containing the number of character rows in each string
- **columns**: vector containing the maximum number of character columns in each string

**Author(s)**

Charles Dupont

**See Also**

nchar, stringDims

**Examples**

```r
a <- c("this is a single line string", "This is a\nmulti-line string")
stringDims(a)
```

---

### string.break.line

**Break a String into Many Lines at Newlines**

**Description**

Takes a string and breaks it into separate substrings where there are newline characters.

**Usage**

```r
string.break.line(string)
```

**Arguments**

- **string**: character vector to be separated into many lines.

**Value**

Returns a list that is the same length of as the string argument.

Each list element is a character vector.

Each character vectors elements are the split lines of the corresponding element in the string argument vector.

**Author(s)**

Charles Dupont

**See Also**

strsplit
Examples

a <- c('', 'this is a single line string',
       'This is a\nmulti-line string."

b <- string.break.line(a)

stringDims  String Dimentions

Description

Finds the height and width of all the string in a character vector.

Usage

stringDims(string)

Arguments

string        vector of strings

Details

stringDims finds the number of characters in width and number of lines in height for each string in the string argument.

Value

height        a vector of the number of lines in each string.
width         a vector with the number of character columns in the longest line.

Author(s)

Charles Dupont

See Also

string.bounding.box, nchar

Examples

a <- c("this is a single line string", "This is a\n\n\n\nmulti line string")
stringDims(a)
Description

Subplot will embed a new plot within an existing plot at the coordinates specified (in user units of the existing plot).

Usage

```
subplot(fun, x, y, size=c(1,1), vadj=0.5, hadj=0.5, pars=NULL)
```

Arguments

- **fun**: an expression or function defining the new plot to be embedded.
- **x**: x-coordinate(s) of the new plot (in user coordinates of the existing plot).
- **y**: y-coordinate(s) of the new plot, x and y can be specified in any of the ways understood by `xy.coords`.
- **size**: The size of the embedded plot in inches if x and y have length 1.
- **vadj**: vertical adjustment of the plot when y is a scalar, the default is to center vertically, 0 means place the bottom of the plot at y, 1 places the top of the plot at y.
- **hadj**: horizontal adjustment of the plot when x is a scalar, the default is to center horizontally, 0 means place the left edge of the plot at x, and 1 means place the right edge of the plot at x.
- **pars**: a list of parameters to be passed to `par` before running `fun`.

Details

The coordinates x and y can be scalars or vectors of length 2. If vectors of length 2 then they determine the opposite corners of the rectangle for the embedded plot (and the parameters size, vadj, and hadj are all ignored.

If x and y are given as scalars then the plot position relative to the point and the size of the plot will be determined by the arguments size, vadj, and hadj. The default is to center a 1 inch by 1 inch plot at x, y. Setting vadj and hadj to (0, 0) will position the lower left corner of the plot at (x, y).

The rectangle defined by x, y, size, vadj, and hadj will be used as the plotting area of the new plot. Any tick marks, axis labels, main and sub titles will be outside of this rectangle.

Any graphical parameter settings that you would like to be in place before `fun` is evaluated can be specified in the `pars` argument (warning: specifying layout parameters here (`plt`, `mfrow`, etc.) may cause unexpected results).

After the function completes the graphical parameters will have been reset to what they were before calling the function (so you can continue to augment the original plot).
Value

An invisible list with the graphical parameters that were in effect when the subplot was created. Passing this list to \texttt{par} will enable you to augment the embedded plot.

par(tmp2)
abline(v=0, col='green')
par(op)
\end{verbatim}

\textbf{summarize} 

\textit{Summarize Scalars or Matrices by Cross-Classification}

Description

\texttt{summarize} is a fast version of \texttt{summary.formula(formula,method="cross",overall=FALSE)} for producing stratified summary statistics and storing them in a data frame for plotting (especially with \texttt{trellis xyplot} and \texttt{dotplot} and \texttt{Hmisc xyplot}). Unlike \texttt{aggregate}, \texttt{summarize} accepts a matrix as its first argument and a multi-valued \texttt{FUN} argument and \texttt{summarize} also labels the variables in the new data frame using their original names. Unlike methods based on \texttt{tapply}, \texttt{summarize}
stores the values of the stratification variables using their original types, e.g., a numeric by variable will remain a numeric variable in the collapsed data frame. summarize also retains "label" attributes for variables. summarize works especially well with the Hmisc xyplot function for displaying multiple summaries of a single variable on each panel, such as means and upper and lower confidence limits.

asNumericMatrix converts a data frame into a numeric matrix, saving attributes to reverse the process by matrix2dataframe. It saves attributes that are commonly preserved across row subsetting (i.e., it does not save dim, dimnames, or names attributes).

matrix2dataframe converts a numeric matrix back into a data frame if it was created by asNumericMatrix.

Usage

```r
summarize(x, by, FUN, ..., 
  stat.name=deparse(substitute(x)),
  type=c('variables','matrix'), subset=TRUE,
  keepcolnames=FALSE)

asNumericMatrix(x)

matrix2dataframe(x, at=attr(x, 'origAttributes'), restoreAll=TRUE)
```

Arguments

- `x` a vector or matrix capable of being operated on by the function specified as the FUN argument
- `by` one or more stratification variables. If a single variable, by may be a vector, otherwise it should be a list. Using the Hmisc llist function instead of list will result in individual variable names being accessible to summarize. For example, you can specify llist(age,group,sex) or llist(Age=age,group,sex). The latter gives age.group a new temporary name, Age.
- `FUN` a function of a single vector argument, used to create the statistical summaries for summarize. FUN may compute any number of statistics.
- `...` extra arguments are passed to FUN
- `stat.name` the name to use when creating the main summary variable. By default, the name of the X argument is used. Set stat.name to NULL to suppress this name replacement.
- `type` Specify type="matrix" to store the summary variables (if there are more than one) in a matrix.
- `subset` a logical vector or integer vector of subscripts used to specify the subset of data to use in the analysis. The default is to use all observations in the data frame.
- `keepcolnames` by default when type="matrix", the first column of the computed matrix is the name of the first argument to summarize. Set keepcolnames=TRUE to retain the name of the first column created by FUN
- `x` a data frame (for asNumericMatrix) or a numeric matrix (for matrix2dataframe).
at List containing attributes of original data frame that survive subsetting. Defaults to attribute "origAttributes" of the object x, created by the call to asNumericMatrix

restoreAll set to FALSE to only restore attributes label, units, and levels instead of all attributes

Value

For summarize, a data frame containing the by variables and the statistical summaries (the first of which is named the same as the X variable unless stat.name is given). If type="matrix", the summaries are stored in a single variable in the data frame, and this variable is a matrix.

asNumericMatrix returns a numeric matrix and stores an object origAttributes as an attribute of the returned object, with original attributes of component variables, the storage.mode.

matrix2DataFrame returns a data frame.

**summary.formula**

**Summarize Data for Making Tables and Plots**

**Description**

`summary.formula` summarizes the variables listed in an S formula, computing descriptive statistics (including ones in a user-specified function). The summary statistics may be passed to `print` methods, `plot` methods for making annotated dot charts, and `latex` methods for typesetting tables using LaTeX. `summary.formula` has three methods for computing descriptive statistics on univariate or multivariate responses, subsetted by categories of other variables. The method of summarization is specified in the parameter `method` (see details below). For the response and cross methods, the statistics used to summarize the data may be specified in a very flexible way (e.g., the geometric mean, 33rd percentile, Kaplan-Meier 2-year survival estimate, mixtures of several statistics). The default summary statistic for these methods is the mean (the proportion of positive responses for a binary response variable). The cross method is useful for creating data frames which contain summary statistics that are passed to `trellis` as raw data (to make multi-panel dot charts, for example). The `print` methods use the `print.char.matrix` function to print boxed tables.

The right hand side of formula may contain `mChoice` ("multiple choice") variables. When `test=TRUE` each choice is tested separately as a binary categorical response.

The `plot` method for `method="reverse"` creates a temporary function `Key` in frame 0 as is done by the `xyplot` and `Ecdf.formula` functions. After `plot` runs, you can type `Key()` to put a legend in a default location, or e.g. `Key(locator(1))` to draw a legend where you click the left mouse button. This key is for categorical variables, so to have the opportunity to put the key on the graph you will probably want to use the command `plot(object, which="categorical")`. A second function `Key2` is created if continuous variables are being plotted. It is used the same as `Key`. If the `which` argument is not specified to `plot`, two pages of plots will be produced. If you don't define `par(mfrow=)` yourself, `plot.summary.formula.reverse` will try to lay out a multi-panel graph to best fit all the individual dot charts for continuous variables.

There is a subscripting method for objects created with `method="response"`. This can be used to print or plot selected variables or summary statistics where there would otherwise be too many on one page.

`cumcategory` is a utility function useful when summarizing an ordinal response variable. It converts such a variable having `k` levels to a matrix with `k-1` columns, where column `i` is a vector of zeros and ones indicating that the categorical response is in level `i+1` or greater. When the left hand side of formula is `cumcategory(y)`, the default function will summarize it by computing all of the relevant cumulative proportions.

Functions `conTestkw`, `catTestchisq`, `ordTestpo` are the default statistical test functions for `summary.formula`. These defaults are: Wilcoxon-Kruskal-Wallis test for continuous variables, Pearson chi-square test
for categorical variables, and the likelihood ratio chi-square test from the proportional odds model for ordinal variables. These three functions serve also as templates for the user to create her own testing functions that are self-defining in terms of how the results are printed or rendered in LaTeX, or plotted.

Usage

```r
## S3 method for class 'formula'
summary(formula, data=NULL, subset=NULL, 
n.action=NULL, fun = NULL, 
method = c("response", "reverse", "cross"), 
overall = method == "response" | method == "cross", 
continuous = TRUE, na.rm = TRUE, na.include = method != "reverse", 
g = 4, quant = c(0.025, 0.05, 0.125, 0.25, 0.375, 0.5, 0.625, 
                 0.75, 0.875, 0.95, 0.975), 
nmin = if (method == "reverse") 100 
          else 0, 
test = FALSE, conTest = conTestkw, catTest = catTestchisq, 
ordTest = ordTestpo, ...)
```

```r
## S3 method for class 'summary.formula.response'
x[i, j, drop=FALSE]
```

```r
## S3 method for class 'summary.formula.response'
print(x, vnames=c('labels','names'), prUnits=TRUE, 
      abbreviate.dimnames=FALSE, 
      prefix.width, min.colwidth, formatArgs=NULL, ...)
```

```r
## S3 method for class 'summary.formula.response'
plot(x, which = 1, vnames = c('labels','names'), xlim, xlab, 
      pch = c(16, 1, 2, 17, 15, 3, 4, 5, 0), superposeStrata = TRUE, 
      dotfont = 1, add = FALSE, reset.par = TRUE, main, subtitles = TRUE, 
      ...)
```

```r
## S3 method for class 'summary.formula.response'
l latex(object, title = first.word(deparse(substitute(object))), caption, 
      trios, vnames = c('labels', 'names'), prn = TRUE, prUnits = TRUE, 
      rowlabel = '', cdec = 2, ncaption = TRUE, ...)
```

```r
## S3 method for class 'summary.formula.reverse'
print(x, digits, prn = any(n != N), pctdig = 0, 
      what=c('%', 'proportion'), 
      npct = c('numerator', 'both', 'denominator', 'none'), 
      exclude = TRUE, vnames = c('labels', 'names'), prUnits = TRUE, 
      sep = '/', abbreviate.dimnames = FALSE, 
      prefix.width = max(nchar(lab)), min.colwidth, formatArgs=NULL, round=NULL, 
      ptest = c('P', 'stat', 'df', 'name'), prmsd = FALSE, long = FALSE, 
      pdig = 3, eps = 0.001, ...)
```
## S3 method for class 'summary.formula.reverse'

```r
plot(x, vnames = c('labels', 'names'), what = c('proportion', '%'),
     which = c('both', 'categorical', 'continuous'),
     xlim = ifelse(is.categorical(what), c(0, 1),
                   c(0, 100)),
     xlab = ifelse(is.categorical(what), 'Proportion',
                   'Percentage'),
     pch = c(16, 1, 2, 17, 15, 3, 4, 5, 0), exclude = TRUE,
     dotfont = 1, main,
     prtest = c('P', 'stat', 'df', 'name'), pdig = 3, eps = 0.001,
     conType = c('dot', 'bp', 'raw'), cex.means = 0.5, ...)
```

## S3 method for class 'summary.formula.reverse'

```r
latex(object, title = first.word(deparse(substitute(object))), digits,
      prn = any(n != N), pctdig = 0, what = c('%', 'proportion'),
      npct = c('numerator', 'both', 'denominator', 'slash', 'none'),
      npct.size = 'scriptsizes', Nsize = "scriptsizes", exclude = TRUE,
      vnames = c('labels', "names"), prUnits = TRUE, middle.bold = FALSE,
      outer.size = "scriptsizes", caption, rowlabel = "",
      insert.bottom = TRUE, dcolumn = FALSE, formatArgs = NULL, round = NULL,
      prtest = c('P', 'stat', 'df', 'name'), prmsd = FALSE,

      rowlabel = "", ...
```

stratify(..., na.group = FALSE, shortlabel = TRUE)

## S3 method for class 'summary.formula.cross'

```r
formula(x, ...)
```

cumcategory(y)

conTestkw(group, x)
catTestchisq(tab)
ordTestpo(group, x)
Arguments

**formula**

An R formula with additive effects. For method="response" or "cross", the dependent variable has the usual connotation. For method="reverse", the dependent variable is what is usually thought of as an independent variable, and it is one that is used to stratify all of the right hand side variables. For method="response" (only), the formula may contain one or more invocations of the stratify function whose arguments are defined below. This causes the entire analysis to be stratified by cross-classifications of the combined list of stratification factors. This stratification will be reflected as major column groupings in the resulting table, or as more response columns for plotting. If formula has no dependent variable method="reverse" is the only legal value and so method defaults to "reverse" in this case.

**x**

an object created by `summary.formula`. For `contTest kw` a numeric vector, and for `ordTest po`, a numeric or factor variable that can be considered ordered.

**y**

a numeric, character, category, or factor vector for `cumcategory`. Is converted to a categorical variable is needed.

**drop**

logical. If TRUE the result is coerced to the lowest possible dimension.

**data**

name or number of a data frame. Default is the current frame.

**subset**

a logical vector or integer vector of subscripts used to specify the subset of data to use in the analysis. The default is to use all observations in the data frame.

**na.action**

function for handling missing data in the input data. The default is a function defined here called `naretain`, which keeps all observations for processing, with missing variables or not.

**fun**

function for summarizing data in each cell. Default is to take the mean of each column of the possibly multivariate response variable. You can specify `fun="%"` to compute percentages (100 times the mean of a series of logical or binary variables). User-specified functions can also return a matrix. For example, you might compute quartiles on a bivariate response. Does not apply to method="reverse".

**method**

The default is "response", in which case the response variable may be multivariate and any number of statistics may be used to summarize them. Here the responses are summarized separately for each of any number of independent variables. Continuous independent variables (see the `continuous` parameter below) are automatically stratified into g (see below) quantile groups (if you want to control the discretization for selected variables, use the `cut2` function on them). Otherwise, the data are subsetted by all levels of discrete right hand side variables. For multivariate responses, subjects are considered to be missing if any of the columns is missing.

The method="reverse" option is typically used to make baseline characteristic tables, for example. The single left hand side variable must be categorical (e.g., treatment), and the right hand side variables are broken down one at a time by the "dependent" variable. Continuous variables are described by three quantiles (quartiles by default) along with outer quantiles (used only for scaling x-axes when plotting quartiles; all are used when plotting box-percentile plots), and categorical ones are described by counts and percentages. If there is no left
hand side variable, summary assumes that there is only one group in the data, so
that only one column of summaries will appear. If there is no dependent variable
in formula, method defaults to "reverse" automatically.

The method="cross" option allows for a multivariate dependent variable and
for up to three independents. Continuous independent variables (those with
at least continuous unique values) are automatically divided into g quantile
groups. The independents are cross-classified, and marginal statistics may op-
tionally be computed. The output of summary.formula in this case is a data
frame containing the independent variable combinations (with levels of "All"
corresponding to marginals) and the corresponding summary statistics in the
matrix S. The output data frame is suitable for direct use in trellis. The print
and latex typesetting methods for this method allows for a special two-way
format if there are two right hand variables.

overall For method="reverse", setting overall=TRUE makes a new column with over-
all statistics for the whole sample. For method="cross", overall=TRUE (the
default) results in all marginal statistics being computed. For trellis displays
(usually multi-panel dot plots), these marginals just form other categories. For
"response", the default is overall=TRUE, causing a final row of global sum-
mary statistics to appear in tables and dot charts. If test=TRUE these marginal
statistics are ignored in doing statistical tests.

continuous specifies the threshold for when a variable is considered to be continuous (when
there are at least continuous unique values). factor variables are always con-
sidered to be categorical no matter how many levels they have.

na.rm TRUE (the default) to exclude NAs before passing data to fun to compute statistics, FALSE otherwise. na.rm=FALSE is useful if the response variable is a ma-
natrix and you do not wish to exclude a row of the matrix if any of the columns
in that row are NA. na.rm also applies to summary statistic functions such as
smean.cl.normal. For these na.rm defaults to TRUE unlike built-in functions.

na.include for method="response", set na.include=FALSE to exclude missing values from
being counted as their own category when subsetting the response(s) by levels
of a categorical variable. For method="reverse" set na.include=TRUE to keep
missing values of categorical variables from being excluded from the table.

g number of quantile groups to use when variables are automatically categorized
with method="response" or "cross" using cut2

rmin if fewer than rmin observations exist in a category for "response" (over all
strata combined), that category will be ignored. For "reverse", for categories
of the response variable in which there are less than or equal to rmin non-
missing observations, the raw data are retained for later plotting in place of box
plots.

test applies if method="reverse". Set to TRUE to compute test statistics using tests
specified in conTest and catTest.

conTest a function of two arguments (grouping variable and a continuous variable) that
returns a list with components P (the computed P-value), stat (the test statistic,
either chi-square or F), df (degrees of freedom), testname (test name),
statname (statistic name), namefun ("chisq", "fstat"), an optional compo-
nent latexstat (LaTeX representation of statname), an optional component
plotmathstat (for R - the plotmath representation of statname, as a character string), and an optional component note that contains a character string note about the test (e.g., "test not done because n < 5"). conTest is applied to continuous variables on the right-hand-side of the formula when method = "reverse". The default uses the spearman2 function to run the Wilcoxon or Kruskal-Wallis test using the F distribution.

catTest a function of a frequency table (an integer matrix) that returns a list with the same components as created by conTest. By default, the Pearson chi-square test is done, without continuity correction (the continuity correction would make the test conservative like the Fisher exact test).

ordTest a function of a frequency table (an integer matrix) that returns a list with the same components as created by conTest. By default, the Proportional odds likelihood ratio test is done.

... for summary.formula these are optional arguments for cut2 when variables are automatically categorized. For plot methods these arguments are passed to dotchart2. For Key and Key2 these arguments are passed to key, text, or mtitle. For print methods these are optional arguments to print. char. matrix. For latex methods these are passed to latex.default. One of the most important of these is file. Specifying file = "" will cause LaTeX code to just be printed to standard output rather than be stored in a permanent file.

object an object created by summary.formula

quant vector of quantiles to use for summarizing data with method = "reverse". This must be numbers between 0 and 1 inclusive and must include the numbers 0.5, 0.25, and 0.75 which are used for printing and for plotting quantile intervals. The outer quantiles are used for scaling the x-axes for such plots. Specify outer quantiles as P and Q to scale the x-axes using the whole observed data ranges instead of the default (a 0.95 quantile interval). Box-percentile plots are drawn using all but the outer quantiles.

vnames By default, tables and plots are usually labeled with variable labels (see the label and sas.get functions). To use the shorter variable names, specify vnames = "name".

pch vector of plotting characters to represent different groups, in order of group levels. For method = "response" the characters correspond to levels of the stratify variable if superposeStrata = TRUE, and if no strata are used or if superposeStrata = FALSE, the pch vector corresponds to the which argument for method = "response".

superposeStrata If stratify was used, set superposeStrata = FALSE to make separate dot charts for each level of the stratification variable, for method = 'response'. The default is to superposition all strata on one dot chart.

dotfont font for plotting points

reset.par set to FALSE to suppress the restoring of the old par values in plot.summary.formula.response

abbreviate.dinnames see print.char.matrix

prefix.width see print.char.matrix
**min.colwidth**  
Minimum column width to use for boxes printed with `print.char.matrix`. The default is the maximum of the minimum column label length and the minimum length of entries in the data cells.

**formatArgs**  
A list containing other arguments to pass to `format.default` such as `scientific`, e.g., `formatArgs=list(scientific=c(-5,5))`. For `print.summary.formula.reverse` and `format.summary.formula.reverse`, `formatArgs` applies only to statistics computed on continuous variables, not to percents, numerators, and denominators. The `round` argument may be preferred.

**digits**  
Number of significant digits to print. Default is to use the current value of the `digits` system option.

**prn**  
Set to TRUE to print the number of non-missing observations on the current (row) variable. The default is to print these only if any of the counts of non-missing values differs from the total number of non-missing values of the left-hand-side variable. For `method="cross"` the default is to always print N.

**prnmiss**  
Set to FALSE to suppress printing counts of missing values for "cross".

**what**  
For `method="reverse"` specifies whether proportions or percentages are to be plotted.

**pctdig**  
Number of digits to the right of the decimal place for printing percentages. The default is zero, so percents will be rounded to the nearest percent.

**npct**  
Specifies which counts are to be printed to the right of percentages. The default is to print the frequency (numerator of the percent) in parentheses. You can specify "both" to print both numerator and denominator, "denominator", "slash" to typeset horizontally using a forward slash, or "none".

**npct.size**  
The size for typesetting `npct` information which appears after percents. The default is "scriptsize".

**Nsize**  
When a second row of column headings is added showing sample sizes, `Nsize` specifies the LaTeX size for these subheadings. Default is "scriptsize".

**exclude**  
By default, method="reverse" objects will be printed, plotted, or typeset by removing redundant entries from percentage tables for categorical variables. For example, if you print the percent of females, you don’t need to print the percent of males. To override this, set `exclude=FALSE`.

**prUnits**  
Set to FALSE to suppress printing or latexing units attributes of variables, when method='reverse' or 'response'.

**sep**  
Character to use to separate quantiles when printing method="reverse" tables.

**prtest**  
A vector of test statistic components to print if `test=TRUE` was in effect when `summary.formula` was called. Defaults to printing all components. Specify `prtest=FALSE` or `prtest="none"` to not print any tests. This applies to `print`, `latex`, and `plot` methods for `method='reverse'`.

**round**  
For `print.summary.formula.reverse` and `latex.summary.formula.reverse` specify `round` to round the quantiles and optional mean and standard deviation to `round` digits after the decimal point.

**prmsd**  
Set to TRUE to print mean and SD after the three quantiles, for continuous variables with method="reverse".
msdsize defaults to NULL to use the current font size for the mean and standard deviation if \texttt{prmsd} is \texttt{TRUE}. Set to a character string to specify an alternate LaTeX font size.

long set to \texttt{TRUE} to print the results for the first category on its own line, not on the same line with the variable label (for \texttt{method="reverse"} with \texttt{print} and \texttt{latex} methods)

pdig number of digits to the right of the decimal place for printing P-values. Default is 3. This is passed to \texttt{format.pval}.

eps P-values less than \texttt{eps} will be printed as $<$ \texttt{eps}. See \texttt{format.pval}.

auxCol an optional auxiliary column of information, right justified, to add in front of statistics typeset by \texttt{latex.summary.formula.reverse}. This argument is a list with a single element that has a name specifying the column heading. If this name includes a newline character, the portions of the string before and after the newline form respectively the main heading and the subheading (typically set in smaller font), respectively. See the \texttt{extracolheads} argument to \texttt{latex.default}. \texttt{auxCol} is filled with blanks when a variable being summarized takes up more than one row in the output. This happens with categorical variables.

twoway for \texttt{method="cross"} with two right hand side variables, \texttt{twoway} controls whether the resulting table will be printed in enumeration format or as a two-way table (the default)

which For \texttt{method="response"} specifies the sequential number or a vector of subscripts of statistics to plot. If you had any \texttt{stratify} variables, these are counted as if more statistics were computed. For \texttt{method="reverse"} specifies whether to plot results for categorical variables, continuous variables, or both (the default).

contype For plotting \texttt{method="reverse"} plots for continuous variables, dot plots showing quartiles are drawn by default. Specify \texttt{contype=bp} to draw box-percentile plots using all the quantiles in \texttt{quant} except the outermost ones. Means are drawn with a solid dot and vertical reference lines are placed at the three quartiles. Specify \texttt{contype=raw} to make a strip chart showing the raw data. This can only be used if the sample size for each left-hand-side group is less than or equal to \texttt{nmin}.

cex.means character size for means in box-percentile plots; default is .5

xlim vector of length two specifying x-axis limits. For \texttt{method="reverse"}, this is only used for plotting categorical variables. Limits for continuous variables are determined by the outer quantiles specified in \texttt{quant}.

xlab x-axis label

add set to \texttt{TRUE} to add to an existing plot

main a main title. For \texttt{method="reverse"} this applies only to the plot for categorical variables.

subtitles set to \texttt{FALSE} to suppress automatic subtitles

caption character string containing LaTeX table captions.
**summary.formula**

- **title**: name of resulting LaTeX file omitting the .tex suffix. Default is the name of the summary object. If caption is specified, title is also used for the table's symbolic reference label.

- **trios**: If for method="response" you summarized the response(s) by using three quantiles, specify trios=TRUE or trios=v to group each set of three statistics into one column for LaTeX output, using the format a B c, where the outer quantiles are in smaller font (scriptsize). For trios=TRUE, the overall column names are taken from the column names of the original data matrix. To give new column names, specify trios=v, where v is a vector of column names, of length m/3, where m is the original number of columns of summary statistics.

- **rowlabel**: see latex.default (under the help file latex)

- **cdec**: number of decimal places to the right of the decimal point for LaTeX. This value should be a scalar (which will be properly replicated), or a vector with length equal to the number of columns in the table. For "response" tables, this length does not count the column for N.

- **ncaption**: set to FALSE to not have latex.summary.formula.response put sample sizes in captions

- **i**: a vector of integers, or character strings containing variable names to subset on. Note that each row subsetted on in an summary.formula.reverse object subsets on all the levels that make up the corresponding variable (automatically).

- **j**: a vector of integers representing column numbers

- **middle.bold**: set to TRUE to have LaTeX use bold face for the middle quantile for method="reverse"

- **outer.size**: the font size for outer quantiles for "reverse" tables

- **insert.bottom**: set to FALSE to suppress inclusion of definitions placed at the bottom of LaTeX tables for method="reverse"

- **dcolumn**: see latex

- **na.group**: set to TRUE to have missing stratification variables given their own category (NA)

- **shortlabel**: set to FALSE to include stratification variable names and equal signs in labels for strata levels

- **dotchart**: set to TRUE to output a dotchart in the LaTeX table being generated.

- **group**: for contTest and ordTest, a numeric or factor variable with length the same as x

- **tab**: for catTest, a frequency table such as that created by table()

**Value**

summary.formula returns a data frame or list depending on method. plot.summary.formula.reverse returns the number of pages of plots that were made.

**Side Effects**

plot.summary.formula.reverse creates a function Key and Key2 in frame 0 that will draw legends.

## End(Not run)
Description

`summaryM` summarizes the variables listed in an S formula, computing descriptive statistics and optionally statistical tests for group differences. This function is typically used when there are multiple left-hand-side variables that are independently against by groups marked by a single right-hand-side variable. The summary statistics may be passed to `print` methods, `plot` methods for making annotated dot charts and extended box plots, and `latex` methods for typesetting tables using LaTeX. The `html` method uses `htmlTable::htmlTable` to typeset the table in html, by passing information to the `latex` method with `html=TRUE`. This is for use with RMarkdown under RStudio. The print methods use the `print.char.matrix` function to print boxed tables.

The `plot` method creates `plotly` graphics if `options(grType='plotly')`, otherwise base graphics are used. `plotly` graphics provide extra information such as which quantile is being displayed when hovering the mouse. Test statistics are displayed by hovering over the mean.

Continuous variables are described by three quantiles (quartiles by default) when printing, or by the following quantiles when plotting expended box plots using the `bpplt` function: 0.05, 0.125, 0.25, 0.375, 0.5, 0.625, 0.75, 0.875, 0.95. The box plots are scaled to the 0.025 and 0.975 quantiles of each continuous left-hand-side variable. Categorical variables are described by counts and percentages.

The left hand side of formula may contain `mChoice` ("multiple choice") variables. When `test=TRUE` each choice is tested separately as a binary categorical response.

The `plot` method for method="reverse" creates a temporary function `Key` as is done by the `xyplot` and `Ecdf.formula` functions. After plot runs, you can type `Key()` to put a legend in a default location, or e.g. `Key(locator(1))` to draw a legend where you click the left mouse button. This key is for categorical variables, so to have the opportunity to put the key on the graph you will probably want to use the command `plot(object, which="categorical")`. A second function `Key2` is created if continuous variables are being plotted. It is used the same as Key. If the which argument is not specified to `plot`, two pages of plots will be produced. If you don’t define `par(mfrow=)` yourself, `plot.summaryM` will try to lay out a multi-panel graph to best fit all the individual charts for continuous variables.

Usage

```r
summaryM(formula, groups=NULL, data=NULL, subset, na.action=na.retain, overall=FALSE, continuous=10, na.include=FALSE, quant=c(0.025, 0.05, 0.125, 0.25, 0.375, 0.5, 0.625, 0.75, 0.875, 0.95), nmin=100, test=FALSE, conTest=conTestkw, catTest=catTestchisq, ordTest=ordTestpo)
```

## S3 method for class 'summaryM'

```r
print(x, digits, prn = any(n != N), what=c('proportion', '%'), pctdig = if(what == 'p') 0 else 2, npct = c('numerator', 'both', 'denominator', 'none'), exclude=TRUE, vnames = c('labels', 'names'), pUnits = TRUE, sep = '/ ', abbreviate.dimnames = FALSE, prefix.width = max(nchar(lab)), min.colwidth, formatArgs=NULL, round=NULL, prtest = c('P', 'stat', 'df', 'name'), prmsd = FALSE, long = FALSE, pdig = 3, eps = 0.001, prob = c(0.25, 0.5, 0.75), prN = FALSE, ...)
```
## Arguments

**formula**
An S formula with additive effects. There may be several variables on the right hand side separated by "+", or the numeral 1, indicating that there is no grouping variable so that only margin summaries are produced. The right hand side variable, if present, must be a discrete variable producing a limited number of groups. On the left hand side there may be any number of variables, separated by "+", and these may be of mixed types. These variables are analyzed separately by the grouping variable.

**groups**
if there is more than one right-hand variable, specify groups as a character string containing the name of the variable used to produce columns of the table. The remaining right hand variables are combined to produce levels that cause sepa-
rate tables or plots to be produced.

\texttt{x}

an object created by \texttt{summaryM}. For \texttt{conTestkw} a numeric vector, and for \texttt{ordTestpo}, a numeric or factor variable that can be considered ordered.

\texttt{data}

name or number of a data frame. Default is the current frame.

\texttt{subset}

a logical vector or integer vector of subscripts used to specify the subset of data to use in the analysis. The default is to use all observations in the data frame.

\texttt{na.action}

function for handling missing data in the input data. The default is a function defined here called \texttt{na.retain}, which keeps all observations for processing, with missing variables or not.

\texttt{overall}

Setting \texttt{overall=TRUE} makes a new column with overall statistics for the whole sample. If \texttt{test=TRUE} these marginal statistics are ignored in doing statistical tests.

\texttt{continuous}

specifies the threshold for when a variable is considered to be continuous (when there are at least \texttt{continuous} unique values). factor variables are always considered to be categorical no matter how many levels they have.

\texttt{na.include}

Set \texttt{na.include=TRUE} to keep missing values of categorical variables from being excluded from the table.

\texttt{nmin}

For categories of the response variable in which there are less than or equal to \texttt{nmin} non-missing observations, the raw data are retained for later plotting in place of box plots.

\texttt{test}

Set to \texttt{TRUE} to compute test statistics using tests specified in \texttt{conTest} and \texttt{catTest}.

\texttt{conTest}

a function of two arguments (grouping variable and a continuous variable) that returns a list with components \texttt{P} (the computed \texttt{P}-value), \texttt{stat} (the test statistic, either chi-square or \texttt{F}), \texttt{df} (degrees of freedom), \texttt{testname} (test name), \texttt{namefun} ("\texttt{chisq}", "\texttt{fstat}"), \texttt{statname} (statistic name), an optional component \texttt{latexstat} (LaTeX representation of \texttt{statname}), an optional component \texttt{plotmathstat} (for R - the \texttt{plotmath} representation of \texttt{statname}, as a character string), and an optional component \texttt{note} that contains a character string note about the test (e.g., "\texttt{test not done because n < 5}"). \texttt{conTest} is applied to continuous variables on the right-hand-side of the formula when \texttt{method=reverse}. The default uses the \texttt{spearmann2} function to run the Wilcoxon or Kruskal-Wallis test using the \texttt{F} distribution.

\texttt{catTest}

a function of a frequency table (an integer matrix) that returns a list with the same components as created by \texttt{conTest}. By default, the Pearson chi-square test is done, without continuity correction (the continuity correction would make the test conservative like the Fisher exact test).

\texttt{ordTest}

a function of a frequency table (an integer matrix) that returns a list with the same components as created by \texttt{conTest}. By default, the Proportional odds likelihood ratio test is done.

\texttt{...}

For \texttt{Key} and \texttt{Key2} these arguments are passed to \texttt{key}, \texttt{text}, or \texttt{mtitle}. For \texttt{print} methods these are optional arguments to \texttt{print.char.matrix}. For \texttt{latex} methods these are passed to \texttt{latex.default}. For \texttt{html} the arguments are passed the \texttt{latex.summaryM}, and the arguments may not include \texttt{file}.

\texttt{object}

an object created by \texttt{summaryM}
`quant` vector of quantiles to use for summarizing continuous variables. These must be numbers between 0 and 1 inclusive and must include the numbers 0.5, 0.25, and 0.75 which are used for printing and for plotting quantile intervals. The outer quantiles are used for scaling the x-axes for such plots. Specify outer quantiles as 0 and 1 to scale the x-axes using the whole observed data ranges instead of the default (a 0.95 quantile interval). Box-percentile plots are drawn using all but the outer quantiles.

`prob` vector of quantiles to use for summarizing continuous variables. These must be numbers between 0 and 1 inclusive and have previously been included in the `quant` argument of `summaryM`. The vector must be of length three. By default it contains 0.25, 0.5, and 0.75.

Warning: specifying 0 and 1 as two of the quantiles will result in computing the minimum and maximum of the variable. As for many random variables the minimum will continue to become smaller as the sample size grows, and the maximum will continue to get larger. Thus the min and max are not recommended as summary statistics.

`vnames` By default, tables and plots are usually labeled with variable labels (see the `label` and `sas.get` functions). To use the shorter variable names, specify `vnames="name"`.

`pch` vector of plotting characters to represent different groups, in order of group levels.

`abbreviate.dimnames` see `print.char.matrix`

`prefix.width` see `print.char.matrix`

`min.colwidth` minimum column width to use for boxes printed with `print.char.matrix`. The default is the maximum of the minimum column label length and the minimum length of entries in the data cells.

`formatArgs` a list containing other arguments to pass to `format.default` such as `scientific`, e.g., `formatArgs=list(scientific=c(-5,5))`. For `print.summary.formula.reverse` and `format.summary.formula.reverse`, `formatArgs` applies only to statistics computed on continuous variables, not to percents, numerators, and denominators. The round argument may be preferred.

`digits` number of significant digits to print. Default is to use the current value of the `digits` system option.

`what` specifies whether proportions or percentages are to be printed or LaTeX’d

`pctdig` number of digits to the right of the decimal place for printing percentages or proportions. The default is zero if `what='%'`, so percents will be rounded to the nearest percent. The default is 2 for proportions.

`prn` set to TRUE to print the number of non-missing observations on the current (row) variable. The default is to print these only if any of the counts of non-missing values differs from the total number of non-missing values of the left-hand-side variable.

`prN` set to TRUE to print the number of non-missing observations on rows that contain continuous variables.
npct specifies which counts are to be printed to the right of percentages. The default is to print the frequency (numerator of the percent) in parentheses. You can specify "both" to print both numerator and denominator as a fraction, "denominator", "slash" to typeset horizontally using a forward slash, or "none".

npct.size the size for typesetting npct information which appears after percents. The default is "scriptsize".

Nsize When a second row of column headings is added showing sample sizes, Nsize specifies the LaTeX size for these subheadings. Default is "scriptsize".

exclude1 By default, summaryM objects will be printed, plotted, or typeset by removing redundant entries from percentage tables for categorical variables. For example, if you print the percent of females, you don't need to print the percent of males. To override this, set exclude1=FALSE.

prUnits set to FALSE to suppress printing or latexing units attributes of variables, when method='reverse' or 'response'

sep character to use to separate quantiles when printing tables

prtest a vector of test statistic components to print if test=TRUE was in effect when summaryM was called. Defaults to printing all components. Specify prtest=FALSE or prtest="none" to not print any tests. This applies to print, latex, and plot methods.

round Specify round to round the quantiles and optional mean and standard deviation to round digits after the decimal point. Set round='auto' to try an automatic choice.

prmsd set to TRUE to print mean and SD after the three quantiles, for continuous variables

msdsize defaults to NULL to use the current font size for the mean and standard deviation if prmsd is TRUE. Set to a character string or function to specify an alternate LaTeX font size.

brmsd set to TRUE to put the mean and standard deviation on a separate line, for html

long set to TRUE to print the results for the first category on its own line, not on the same line with the variable label

pdig number of digits to the right of the decimal place for printing P-values. Default is 3. This is passed to format.pval.

eps P-values less than eps will be printed as < eps. See format.pval.

auxCol an optional auxiliary column of information, right justified, to add in front of statistics typeset by latex.summaryM. This argument is a list with a single element that has a name specifying the column heading. If this name includes a newline character, the portions of the string before and after the newline form respectively the main heading and the subheading (typically set in smaller font), respectively. See the extracolheads argument to latex.default. auxCol is filled with blanks when a variable being summarized takes up more than one row in the output. This happens with categorical variables.

table.env set to FALSE to use tabular environment with no caption

tabenv1 set to TRUE in the case of stratification when you want only the first stratum's table to be in a table environment. This is useful when using hyperref.
which specifies whether to plot results for categorical variables, continuous variables, or both (the default).

vars Subscripts (indexes) of variables to plot for plotly graphics. Default is to plot all variables of each type (categorical or continuous).

conType For drawing plots for continuous variables, extended box plots (box-percentile-type plots) are drawn by default, using all quantiles in quant except for the outermost ones which are using for scaling the overall plot based on the non-stratified marginal distribution of the current response variable. Specify conType='dot' to draw dot plots showing the three quartiles instead. For extended box plots, means are drawn with a solid dot and vertical reference lines are placed at the three quartiles. Specify conType='raw' to make a strip chart showing the raw data. This can only be used if the sample size for each right-hand-side group is less than or equal to nmin.

cex.means character size for means in box-percentile plots; default is .5

cex character size for other plotted items

height, width dimensions in pixels for the plotly subplot object containing all the extended box plots. If height="auto", plot.summaryM will set height based on the number of continuous variables and ncols or for dot charts it will use hmisc::plotlyHeightDotchart. At present height is ignored for extended box plots due to vertical spacing problem with plotly graphics.

xlim vector of length two specifying x-axis limits. This is only used for plotting categorical variables. Limits for continuous variables are determined by the outer quantiles specified in quant.

xlab x-axis label

main a main title. This applies only to the plot for categorical variables.

ncols number of columns for plotly graphics for extended box plots. Defaults to 2. Recommendation is for 1-2.

caption character string containing LaTeX table captions.

title name of resulting LaTeX file omitting the .tex suffix. Default is the name of the summary object. If caption is specified, title is also used for the table’s symbolic reference label.

file name of file to write LaTeX code to. Specifying file="" will cause LaTeX code to just be printed to standard output rather than be stored in a permanent file.

append specify TRUE to add code to an existing file

rowlabel see latex.default (under the help file latex)

rowsep if html is TRUE, instructs the function to use a horizontal line to separate variables from one another. Recommended if brmsd is TRUE. Ignored for LaTeX.

middle.bold set to TRUE to have LaTeX use bold face for the middle quantile

outer.size the font size for outer quantiles

insert.bottom set to FALSE to suppress inclusion of definitions placed at the bottom of LaTeX tables. You can also specify a character string containing other text that overrides the automatic text. At present such text always appears in the main caption for LaTeX.
legend.bottom  set to TRUE to separate the table caption and legend. This will place table legends at the bottom of LaTeX tables.
html  set to TRUE to typeset with html
mspecs  list defining markup syntax for various languages, defaults to Hmisc markupspecs which the user can use as a starting point for editing
dcolumn  see latex

Value

a list. plot.summaryM returns the number of pages of plots that were made if using base graphics, or plotly objects created by plotly::subplot otherwise. If both categorical and continuous variables were plotted, the returned object is a list with two named elements Categorical and Continuous each containing plotly objects. Otherwise a plotly object is returned. The latex method returns attributes legend and nstrata.

Side Effects

plot.summaryM creates a function Key and Key2 in frame 0 that will draw legends, if base graphics are being used.

#### summaryP  

**Multi-way Summary of Proportions**

**Description**

`summaryP` produces a tall and thin data frame containing numerators (`freq`) and denominators (`denom`) after stratifying the data by a series of variables. A special capability to group a series of related yes/no variables is included through the use of the `ynbind` function, for which the user specifies a final argument `label` used to label the panel created for that group of related variables.

If `options(grType='plotly')` is not in effect, the plot method for `summaryP` displays proportions as a multi-panel dot chart using the `lattice` package's `dotplot` function with a special panel function. Numerators and denominators of proportions are also included as text, in the same colors as used by an optional groups variable. The formula argument used in the `dotplot` call is constructed, but the user can easily reorder the variables by specifying `formula`, with elements named `val` (category levels), `var` (classification variable name), `freq` (calculated result) plus the overall cross-classification variables excluding groups. If `options(grType='plotly')` is in effect, the plot method makes an entirely different display using `Hmisc::dotchartpl` with `codeplotly` if `marginVal` is specified, whereby a stratification variable causes more finely stratified estimates to be shown slightly below the lines, with smaller and translucent symbols if data has been run through `addmarginal`. The marginal summaries are shown as the main estimates and the user can turn off display of the stratified estimates, or view their details with hover text.

The `ggplot` method for `summaryP` does not draw numerators and denominators but the chart is more compact than using the plot method with base graphics because `ggplot2` does not repeat category names the same way as `lattice` does. Variable names that are too long to fit in panel strips are renamed (1), (2), etc. and an attribute “fnvar” is added to the result; this attribute is a character string defining the abbreviations, useful in a figure caption. The `ggplot2` object has labels for points plotted, used by `plotly::ggplotly` as hover text (see example).

The `latex` method produces one or more LaTeX tables containing a table representation of the result, with optional side-by-side display if `groups` is specified. Multiple `tabulars` result from the presence of non-group stratification factors.

**Usage**

```r
summaryP(formula, data = NULL, subset = NULL,  
na.action = na.retain, sort=TRUE,  
asna = c("unknown", "unspecified"), ...)  
## S3 method for class 'summaryP'
plot(x, formula=NULL, groups=NULL,  
marginVal=NULL, marginLabel=marginVal,  
refgroup=NULL, exclude1=TRUE, xlim = c(-0.05, 1.05),  
text.at=NULL, cex.values = 0.5,  
key = list(columns = length(groupslevels), x = 0.75,  
y = -0.04, cex = 0.9,  
...)
```
Arguments

* formula a formula with the variables for whose levels proportions are computed on the left hand side, and major classification variables on the right. The formula need to include any variable later used as groups, as the data summarization does not distinguish between superpositioning and paneling. For the plot method, formula can provide an overall to the default formula for dotplot().

* data an optional data frame. For ggplot.summaryP data is the result of summaryP.

* subset an optional subsetting expression or vector

* na.action function specifying how to handle NAs. The default is to keep all NAs in the analysis frame.

* sort set to FALSE to not sort category levels in descending order of global proportions

* asna character vector specifying level names to consider the same as NA. Set asna=NULL to not consider any.

* x an object produced by summaryP

* groups a character string containing the name of a superpositioning variable for obtaining further stratification within a horizontal line in the dot chart.

* marginVal if options(grType='plotly') is in effect and the data given to summaryP were run through addMarginal, specifies the category name that represents marginal summaries (usually "All").

* marginLabel specifies a different character string to use than the value of marginVal. For example, if marginal proportions were computed over all regions, one may specify marginVal="All", marginLabel="All Regions". marginLabel is only used for formatting graphical output.

* refgroup used when doing a plotly chart and a two-level group variable was used, resulting in the half-width confidence interval for the difference in two proportions to be shown, and the actual confidence limits and the difference added to hover text. See dotchartpl for more details.

* exclude1 By default, ggplot, plot, and latex methods for summaryP remove redundant entries from tables for variables with only two levels. For example, if you print the proportion of females, you don’t need to print the proportion of males. To override this, set exclude1=FALSE.
xlim  
x-axis limits. Default is c(0,1).

text.at  
specify to leave unused space to the right of each panel to prevent numerators and denominators from touching data points. text.at is the upper limit for scaling panels' x-axes but tick marks are only labeled up to max(xlim).

cex.values  
character size to use for plotting numerators and denominators

dotplot. To place a key above the entire chart use auto.key=list(columns=2) for example.

outerlabels  
by default if there are two conditioning variables besides groups, the latticeExtra package's useOuterStripes function is used to put strip labels in the margins, usually resulting in a much prettier chart. Set to FALSE to prevent usage of useOuterStripes.

autoarrange  
If TRUE, the formula is re-arranged so that if there are two conditioning (paneling) variables, the variable with the most levels is taken as the vertical condition.

col  
a vector of colors to use to override defaults in ggplot. When options(grType='plotly'), see dotchartpl.

shape  
a vector of plotting symbols to override ggplot defaults

mapping, environment  
not used; needed because of rules for generics

size  
for ggplot, a function that transforms denominators into metrics used for the size aesthetic. Default is the fourth root function so that the area of symbols is proportional to the square root of sample size. Specify NULL to not vary point sizes. size=sqrt is a reasonable alternative. Set size to an integer to categorize the denominators into size quantile groups using cut2. Unless size is an integer, the legend for sizes uses the minimum and maximum denominators and 6-tiles using quantile(...) so that actually occurring sample sizes are used as labels. size is overridden to NULL if the range in denominators is less than 10 or the ratio of the maximum to the minimum is less than 1.2. For latex, size is an optional font size such as "small"

sizerange  
a 2-vector specifying the range argument to the ggplot2 scale_size... function, which is the range of sizes allowed for the points according to the denominator. The default is sizerange=c(.7, 3.25) but the lower limit is increased according to the ratio of maximum to minimum sample sizes.

abblen  
lables of variables having only one level and having their name longer than abblen characters are abbreviated and documented in fnvar (described elsewhere here). The default abblen=5 is good for labels plotted vertically. If labels are rotated using theme a better value would be 12.

...  
used only for plotly graphics and these arguments are passed to dotchartpl

object  
an object produced by summaryP

file  
file name, defaults to writing to console

append  
set to FALSE to start output over

addlayer  
a ggplot layer to add to the plot object
Value

`summaryP` produces a data frame of class "summaryP". The plot method produces a lattice object of class "trellis". The `latex` method produces an object of class "latex" with an additional attribute `ngrouplevels` specifying the number of levels of any `groups` variable and an attribute `nstrata` specifying the number of strata.

colorfacet(ggplot(s))

plot(summaryP(race + sex ~ region, data=d), exclude=FALSE, col='green')

# Make your own plot using data frame created by summaryP
useOuterStrips(dotplot(val ~ freq | region * var, groups=treat, data=s, 
    xlim=c(0,1), scales=list(y='free', rot=0), xlab='Fraction', 
    panel=function(x, y, subscripts, ...) {
    denom <- s$denom[subscripts] 
    x <- x / denom 
    panel.dotplot(x=x, y=y, subscripts=subscripts, ...) })))

# Show marginal summary for all regions combined
s <- summaryP(race + sex ~ region, data=addMarginal(d, region))
plot(s, groups='region', key=list(space='top'), layout=c(1,2))

# Show marginal summaries for both race and sex
s <- summaryP(ybind(x1, x2, x3, x4, label='Exclusions', sort=FALSE) ~ 
    race + sex, data=addMarginal(d, race, sex))
plot(s, val ~ freq | sex*race)

## End(Not run)
**Graphical Summarization of Continuous Variables Against a Response**

**Description**

`summaryRc` is a continuous version of `summary.formula` with method='response'. It uses the `plsmo` function to compute the possibly stratified lowess nonparametric regression estimates, and plots them along with the data density, with selected quantiles of the overall distribution (over strata) of each x shown as arrows on top of the graph. All the x variables must be numeric and continuous or nearly continuous.

**Usage**

```
summaryRc(formula, data=NULL, subset=NULL,
            na.action=NULL, fun = function(x) x,
            na.rm = TRUE, ylab=NULL, ylim=NULL, xlim=NULL,
            nloc=NULL, datadensity=NULL,
            quant = c(0.05, 0.1, 0.25, 0.5, 0.75,
                     0.90, 0.95), quantloc=c('top', 'bottom'),
            cex.quant=1, srt.quantity=0,
            bpplot = c('none', 'top', 'top outside', 'top inside', 'bottom'),
            height.bpplot=0.08,
            trim=NULL, test = FALSE, vnames = c('labels', 'names'), ...)
```

**Arguments**

- **formula**: An `R` formula with additive effects. The formula may contain one or more invocations of the `stratify` function whose arguments are defined below. This causes the entire analysis to be stratified by cross-classifications of the combined list of stratification factors. This stratification will be reflected as separate lowess curves.
- **data**: name or number of a data frame. Default is the current frame.
- **subset**: a logical vector or integer vector of subscripts used to specify the subset of data to use in the analysis. The default is to use all observations in the data frame.
- **na.action**: function for handling missing data in the input data. The default is a function defined here called `na.retain`, which keeps all observations for processing, with missing variables or not.
- **fun**: function for transforming lowess estimates. Default is the identity function.
- **na.rm**: TRUE (the default) to exclude NAs before passing data to `fun` to compute statistics, FALSE otherwise.
- **ylab**: y-axis label. Default is label attribute of y variable, or its name.
- **ylim**: y-axis limits. By default each graph is scaled on its own.
- **xlim**: a list with elements named as the variable names appearing on the x-axis, with each element being a 2-vector specifying lower and upper limits. Any variable not appearing in the list will have its limits computed and possibly trimmed.
**nloc** location for sample size. Specify nloc=FALSE to suppress, or nloc=list(x, y) where x, y are relative coordinates in the data window. Default position is in the largest empty space.

**datadensity** see plsmo. Defaults to TRUE if there is a stratify variable, FALSE otherwise.

**quant** vector of quantiles to use for summarizing the marginal distribution of each x. This must be numbers between 0 and 1 inclusive. Use NULL to omit quantiles.

**quantloc** specify quantloc='bottom' to place at the bottom of each plot rather than the default.

**cex.quant** character size for writing which quantiles are represented. Set to 0 to suppress quantile labels.

**srt.quant** angle for text for quantile labels

**bpplot** if not 'none' will draw extended box plot at location given by bpplot, and quantiles discussed above will be suppressed. Specifying bpplot='top' is the same as specifying bpplot='top inside'.

**height.bpplot** height in inches of the horizontal extended box plot

**trim** The default is to plot from the 10th smallest to the 10th largest x if the number of non-NA exceeds 200, otherwise to use the entire range of x. Specify another quantile to use other limits, e.g., trim=0.01 will use the first and last percentiles

**test** Set to TRUE to plot test statistics (not yet implemented).

**vnames** By default, plots are usually labeled with variable labels (see the label and sas.get functions). To use the shorter variable names, specify vnames="names".

... arguments passed to plsmo

**Value**

no value is returned

**Examples**

```r
options(digits=3)
set.seed(177)
sex <- factor(sample(c("m","f"), 500, rep=TRUE))
age <- rnorm(500, 50, 5)
bp <- rnorm(500, 120, 7)
units(age) <- 'Years'; units(bp) <- 'mmHg'
label(bp) <- 'Systolic Blood Pressure'
```
Multiple left-hand formula variables along with right-hand side conditioning variables are reshaped into a "tall and thin" data frame if fun is not specified. The resulting raw data can be plotted with the plot method using user-specified panel functions for lattice graphics, typically to make a scatterplot or loess smooths, or both. The hmisc panel.psmo function is handy in this context. Instead, if fun is specified, this function takes individual response variables (which may be matrices, as in Surv objects) and creates one or more summary statistics that will be computed while the resulting data frame is being collapsed to one row per condition. The plot method in this case plots a multi-panel dot chart using the lattice dotplot function if panel is not specified to plot. There is an option to print selected statistics as text on the panels. summaryS pays special attention to hmisc variable annotations: label, units. When panel is specified in addition to fun, a special x-y plot is made that assumes that the x-axis variable (typically time) is discrete. This is used for example to plot multiple quantile intervals as vertical lines next to the main point. A special panel function mbarclPanel is provided for this purpose.

The plotp method produces corresponding plotly graphics.

When fun is given and panel is omitted, and the result of fun is a vector of more than one statistic, the first statistic is taken as the main one. Any columns with names not in textonly will figure into the calculation of axis limits. Those in textonly will be printed right under the dot lines in the dot chart. Statistics with names in textplot will figure into limits, be plotted, and printed. pch.stats can be used to specify symbols for statistics after the first column. When fun computed three columns that are plotted, columns two and three are taken as confidence limits for which horizontal "error bars" are drawn. Two levels with different thicknesses are drawn if there are four plotted summary statistics beyond the first.

mbarclPanel is used to draw multiple vertical lines around the main points, such as a series of quantile intervals stratified by x and paneling variables. If mbarclPanel finds a column of an argument yother that is named "se", and if there are exactly two levels to a superpositioning variable, the half-height of the approximate 0.95 confidence interval for the difference between two point estimates is shown, positioned at the midpoint of the two point estimates at an x value. This assumes normality of point estimates, and the standard error of the difference is the square root of the sum of
squares of the two standard errors. By positioning the intervals in this fashion, a failure of the two point estimates to touch the half-confidence interval is consistent with rejecting the null hypothesis of no difference at the 0.05 level.

mbarclpl is the sfun function corresponding to mbarclPanel for plotp, and medvpl is the sfun replacement for medvPanel.

medvPanel takes raw data and plots median y vs. x, along with confidence intervals and half-interval for the difference in medians as with mbarclPanel. Quantile intervals are optional. Very transparent vertical violin plots are added by default. Unlike panel.violin, only half of the violin is plotted, and when there are two superpose groups they are side-by-side in different colors.

For plotp, the function corresponding to medvPanel is medvpl, which draws back-to-back spike histograms, optional Gini mean difference, optional SD, quantiles (thin line version of box plot with 0.05 0.25 0.5 0.75 0.95 quantiles), and half-width confidence interval for differences in medians. For quantiles, the Harrell-Davis estimator is used.

Usage

summaryS(formula, fun = NULL, data = NULL, subset = NULL,
na.action = na.retain, continuous=10, ...)

## S3 method for class 'summaryS'
plot(x, formula=NULL, groups=NULL, panel=NULL,

  xlim=NULL, ylim=NULL, cex.strip=1, cex.values=0.5, pch.stats=NULL,
  key=list(columns=length(groupslevels)),
  x=0.75, y=-.04, cex=.9,
  col=trellis.par.get('superpose.symbol')$col, corner=c(0,1)),
  outerlabels=TRUE, autoarrange=TRUE, scatdNopts=NULL, ...)

## S3 method for class 'summaryS'
plotp(data, formula=NULL, groups=NULL, sfun=NULL,
  fitter=NULL, showpts=! length(fitter), funlabel=NULL,
  digits=5, xlim=NULL, ylim=NULL,
  shareX=TRUE, shareY=FALSE, autoarrange=TRUE, ...)

mbarclPanel(x, y, subscripts, groups=NULL, yother, ...)

medvPanel(x, y, subscripts, groups=NULL, violin=TRUE, quantiles=FALSE, ...)

mbarclpl(x, y, groups=NULL, yother, yvar=NULL, maintracename='y',
  xlim=NULL, ylim=NULL, xname='x', alphaSegments=0.45, ...)

medvpl(x, y, groups=NULL, yvar=NULL, maintracename='y',
  xlim=NULL, ylim=NULL, xlab=xname, ylab=NULL, xname='x',
  zeroline=FALSE, yother=NULL, alphaSegments=0.45,
  dhistboxp.opts=NULL, ...)
Arguments

formula  a formula with possibly multiple left and right-side variables separated by +. Analysis (response) variables are on the left and are typically numeric. For plot, formula is optional and overrides the default formula inferred for the reshaped data frame.

fun  an optional summarization function, e.g., `smean.sd`

data  optional input data frame. For plotp is the object produced by `summaryS`.

subset  optional subsetting criteria

na.action  function for dealing with NAs when constructing the model data frame

continuous  minimum number of unique values for a numeric variable to have to be considered continuous

...  ignored for `summaryS` and `mbarclPanel`, passed to strip and panel for plot. Passed to the `density` function by `medvPanel`. For plotp, are passed to `plotlyM` and `sfun`. For `mbarclpl`, passed to `plotlyM`.

x  an object created by `summaryS`. For `mbarclPanel` is an x-axis argument provided by `lattice`

groups  a character string or factor specifying that one of the conditioning variables is used for superpositioning and not paneling

panel  optional `lattice` panel function

paneldoesgroups  set to TRUE if, like `panel.plsmo`, the paneling function internally handles superpositioning for groups

datadensity  set to TRUE to add rug plots etc. using `scat1d`

ylab  optional y-axis label

funlabel  optional axis label for when fun is given

textonly  names of statistics to print and not plot. By default, any statistic named "n" is only printed.

textplot  names of statistics to print and plot

digits  used if any statistics are printed as text (including `plotly` hovertext), to specify the number of significant digits to render

custom  a function that customizes formatting of statistics that are printed as text. This is useful for generating `plotmath` notation. See the example in the tests directory.

xlim  optional x-axis limits

ylim  optional y-axis limits

cex.strip  size of strip labels

cex.values  size of statistics printed as text

pch.stats  symbols to use for statistics (not included the one one in column one) that are plotted. This is a named vectors, with names exactly matching those created by fun. When a column does not have an entry in `pch.stats`, no point is drawn for that column.

key  `lattice` key specification
outerlabels set to FALSE to not pass two-way charts through `useOuterStrips`
autoarrange set to FALSE to prevent plot from trying to optimize which conditioning variable is vertical
scat1d.opts a list of options to specify to `scat1d`
y, subscriptsp provided by lattice
yother passed to the panel function from the plot method based on multiple statistics computed
violin controls whether violin plots are included
quantiles controls whether quantile intervals are included
sfun a function called by `plotp.summaryS` to compute and plot user-specified summary measures. Two functions for doing this are provided here: `mbarclpl`, `medvpl`.
fitter a fitting function such as `loess` to smooth points. The smoothed values over a systematic grid will be evaluated and plotted as curves.
showpts set to TRUE to show raw data points in addition to smoothed curves
shareX TRUE to cause `plotly` to share a single x-axis when graphs are aligned vertically
shareY TRUE to cause `plotly` to share a single y-axis when graphs are aligned horizontally
yvar a character or factor variable used to stratify the analysis into multiple y-variables
maintracename a default trace name when it can’t be inferred
xname x-axis variable name for hover text when it can’t be inferred
xlab x-axis label when it can’t be inferred
alphaSegments alpha saturation to draw line segments for `plotly`
dhistboxp.opts list of options to pass to `dhistboxp`
zeroline set to FALSE to suppress `plotly` zero line at x=0

Value

a data frame with added attributes for `summaryS` or a lattice object ready to render for plot

```
symbol.freq

Description

This function can be used to represent contingency tables graphically. Frequency counts are represented as the heights of "thermometers" by default; you can also specify symbol='circle' to the function. There is an option to include marginal frequencies, which are plotted on a halved scale so as to not overwhelm the plot. If you do not ask for marginal frequencies to be plotted using marginals=T, symbol.freq will ask you to click the mouse where a reference symbol is to be drawn to assist in reading the scale of the frequencies.

Label attributes, if present, are used for x- and y-axis labels. Otherwise, names of calling arguments are used.

Usage

symbol.freq(x, y, symbol = c("thermometer", "circle"),
             marginals = FALSE, orig.scale = FALSE,
             inches = 0.25, width = 0.15, subset, srtx = 0, ...)

Arguments

x first variable to cross-classify
y second variable
symbol specify "thermometer" (the default) or "circle"
marginals set to TRUE to add marginal frequencies (scaled by half) to the plot
orig.scale set to TRUE when the first two arguments are numeric variables; this uses their original values for x and y coordinates)
inches see symbols
width see thermometers option in symbols
subset the usual subsetting vector
srtx rotation angle for x-axis labels
... other arguments to pass to symbols

**sys**  
*Run Unix or Dos Depending on System*

**Description**

Runs unix or dos depending on the current operating system. For R, just runs `system` with optional concatenation of first two arguments which are assumed named `command` and `text`.

**Usage**

```r
sys(command, text=NULL, output=TRUE)
# S-Plus: sys(..., minimized=FALSE)
```

**Arguments**

- `command`: system command to execute
- `text`: text to concatenate to system command, if any (typically options or file names or both)
- `output`: set to FALSE to not return output of command as a character vector

**Value**

see unix or dos

**Side Effects**

executes system commands

**See Also**

**t.test.cluster**  
*t-test for Clustered Data*

**Description**

Does a 2-sample t-test for clustered data.

**Usage**

```r
t.test.cluster(y, cluster, group, conf.int = 0.95)
## S3 method for class 't.test.cluster'
print(x, digits, ...)```
t.test.cluster

Arguments

- **y**: normally distributed response variable to test
- **cluster**: cluster identifiers, e.g. subject ID
- **group**: grouping variable with two values
- **conf.int**: confidence coefficient to use for confidence limits
- **x**: an object created by `t.test.cluster`
- **digits**: number of significant digits to print
- **...**: unused

Value

A matrix of statistics of class `t.test.cluster`

Examples

```r
set.seed(1)
y <- rnorm(800)
group <- sample(1:2, 800, TRUE)
cluster <- sample(1:40, 800, TRUE)
table(cluster, group)
t.test(y ~ group)  # R only
t.test.cluster(y, cluster, group)
# Note: negate estimates of differences from t.test to
# compare with t.test.cluster
```
Interface to Tabular Function

Description

*tabulr* is a front-end to the *tables* package’s *tabular* function so that the user can take advantage of variable annotations used by the *Hmisc* package, particular those created by the *label*, *units*, and *upData* functions. When a variable appears in a *tabular* function, the variable x is found in the data argument or in the parent environment, and the *labelLatex* function is used to create a LaTeX label. By default any units of measurement are right justified in the current LaTeX tabular field using *hfill*; use *nofill* to list variables for which units are not right-justified with *hfill*. Once the label is constructed, the variable name is preceeded by *headingHBlatex labelBIJx* in the formula before it is passed to *tabular*. *nolabel* can be used to specify variables for which labels are ignored.

*tabulr* also replaces *trio* with *table_trio*, *n* with *table_n*, and *freq* with *table_freq* in the formula.

*table_trio* is a function that takes a numeric vector and computes the three quartiles and optionally the mean and standard deviation, and outputs a LaTeX-formatted character string representing the results. By default, calculated statistics are formatted with 3 digits to the left and 1 digit to the right of the decimal point. Running *table_optionsHleft=1, right=r*I will use 1 and r digits instead. Other options that can be given to *table_options* are *prmsd=TRUE* to add mean +/- standard deviation to the result, *pn=TRUE* to add the sample size, *bold=TRUE* to set the median in bold face, *showfreq='all', 'low', 'high' used by the table_freq function, *pctdec*, specifying the number of places to the right of the decimal point for percentages (default is zero), and *npct='both', 'numerator', 'denominator', 'none' used by table_formatpct to control what appears after the percent. *Option pnformat* may be specified to control the formatting for *pn*. The default is "(n=...)". Specify *pnformat="non"* to suppress "n=". *pnwhen* specifies when to print the number of observations. The default is "always". Specify *pnwhen="ifna"* to include *n* only if there are missing values in the vector being processed.

*tabulr* substitutes *table_N* for *N* in the formula. This is used to create column headings for the number of observations, without a row label.

*table_freq* analyzes a character variable to compute, for a single output cell, the percents, numerator, and denominator for each category, or optimally just the maximum or minimum, as specified by *table_optionsHshowfreqI*.

*table_formatpct* is a function that formats percents depending on settings of options in *table_options*.

*nFmt* is a function that calls *sprintf* to format numeric values to have a specific number of digits to the left and to the right of the point.

*table_latexdefs* writes (by default) to the console a set of LaTeX definitions that can be invoked at any point thereafter in a *knitr* or *sweave* document by naming the macro, preceeded by a single slash. The *blfootnote* macro is called with a single LaTeX argument which will appear as a footnote without a number. *keytrio* invokes *blfootnote* to define the output of *table_trio* if mean and SD are not included. If mean and SD are included, use *keytriosd*. 

**tabulr**

**Usage**

```r
tabulr(formula, data = NULL, nolabel=NULL, nofill=NULL, ...) 
table_trio(x) 
table_freq(x) 
table_formatpct(num, den) 
nFm(x, left, right, neg=FALSE, pad=FALSE, html=FALSE) 
table_latexdefs(file='')
```

**Arguments**

*formula* a formula suitable for `tabular` except for the addition of `.variable name).n().trio.

*data* a data frame or list. If omitted, the parent environment is assumed to contain the variables.

*nolabel* a formula such as `~ x1 + x2` containing the list of variables for which labels are to be ignored, forcing use of the variable name

*nofill* a formula such as `~ x1 + x2` containing the list of variables for which units of measurement are not to be right-justified in the field using the LaTeX `hfill` directive

*...* other arguments to `tabular`

*x* a numeric vector

*num* a single numerator or vector of numerators

*den* a single denominator

*left, right* number of places to the left and right of the decimal point, respectively

*neg* set to `TRUE` if negative `x` values are allowed, to add one more space to the left of the decimal place

*pad* set to `TRUE` to replace blanks with the LaTeX tilde placeholder

*html* set to `TRUE` to make `pad` use an HTML space character instead of a LaTeX tilde space

*file* location of output of `table_latexdefs`

**Value**

`tabulr` returns an object of class "tabular"

   Heading()) + trio +
   (sex + stage + spiders)*Heading() + freq = drug, data=pbc)
latex(tab)
```

## End(Not run)
Description

tex is a little function to save typing when including TeX commands in graphs that are used with the psfrag package in LaTeX to typeset any LaTeX text inside a postscript graphic. tex surrounds the input character string with ‘\text{}’. This is especially useful for getting Greek letters and math symbols in postscript graphs. By default tex returns a string with psfrag commands specifying that the string be centered, not rotated, and not specially enlarged or shrunk.

Usage

tex(string, lref='c', psref='c', scale=1, srt=0)

Arguments

string a character string to be processed by psfrag in LaTeX.
lref LaTeX reference point for string. See the psfrag documentation referenced below. Default is "c" for centered (this is also the default for psref).
psref PostScript reference point.
scale scalar factor, default is 1
srt rotation for string in degrees (default is zero)

Value

tex returns a modified character string.

transace  Additive Regression and Transformations using ace or avas

Description

transace is ace packaged for easily automatically transforming all variables in a matrix. transace is a fast one-iteration version of transcan without imputation of NAs.

areg.boot uses areg or avas to fit additive regression models allowing all variables in the model (including the left-hand-side) to be transformed, with transformations chosen so as to optimize certain criteria. The default method uses areg whose goal it is to maximize $R^2$. method="avas" explicity tries to transform the response variable so as to stabilize the variance of the residuals. All-variables-transformed models tend to inflate $R^2$ and it can be difficult to get confidence limits for each transformation. areg.boot solves both of these problems using the bootstrap. As with the validate function in the rms library, the Efron bootstrap is used to estimate the optimism in the apparent $R^2$, and this optimism is subtracted from the apparent $R^2$ to obtain a bias-corrected $R^2$. This is done however on the transformed response variable scale.

Tests with 3 predictors show that the avas and ace estimates are unstable unless the sample size exceeds 350. Apparent $R^2$ with low sample sizes can be very inflated, and bootstrap estimates of $R^2$ can be even more unstable in such cases, resulting in optimism-corrected $R^2$ that are much lower than the actual $R^2$. The situation can be improved a little by restricting predictor transformations to be monotonic. On the other hand, the areg approach allows one to control overfitting by specifying the number of knots to use for each continuous variable in a restricted cubic spline function.

For method="avas" the response transformation is restricted to be monotonic. You can specify restrictions for transformations of predictors (and linearity for the response). When the first argument is a formula, the function automatically determines which variables are categorical (i.e., factor, category, or character vectors). Specify linear transformations by enclosing variables by
the identify function (I()), and specify monotonicity by using monotone(variable). Monotonicity restrictions are not allowed with method="areg".

The summary method for areg.boot computes bootstrap estimates of standard errors of differences in predicted responses (usually on the original scale) for selected levels of each predictor against the lowest level of the predictor. The smearing estimator (see below) can be used here to estimate differences in predicted means, medians, or many other statistics. By default, quartiles are used for continuous predictors and all levels are used for categorical ones. See Details below. There is also a plot method for plotting transformation estimates, transformations for individual bootstrap re-samples, and pointwise confidence limits for transformations. Unless you already have a par(mfrow=) in effect with more than one row or column, plot will try to fit the plots on one page. A predict method computes predicted values on the original or transformed response scale, or a matrix of transformed predictors. There is a Function method for producing a list of R functions that perform the final fitted transformations. There is also a print method for areg.boot objects.

When estimated means (or medians or other statistical parameters) are requested for models fitted with areg.boot (by summary.areg.boot or predict.areg.boot), the "smearing" estimator of Duan (1983) is used. Here we estimate the mean of the untransformed response by computing the arithmetic mean of ginverse(lp + residuals), where ginverse is the inverse of the nonparametric transformation of the response (obtained by reverse linear interpolation), lp is the linear predictor for an individual observation on the transformed scale, and residuals is the entire vector of residuals estimated from the fitted model, on the transformed scales (n residuals for n original observations). The smearingEst function computes the general smearing estimate. For efficiency smearingEst recognizes that quantiles are transformation-preserving, i.e., when one wishes to estimate a quantile of the untransformed distribution one just needs to compute the inverse transformation of the transformed estimate after the chosen quantile of the vector of residuals is added to it. When the median is desired, the estimate is ginverse(lp + median(residuals)). See the last example for how smearingEst can be used outside of areg.boot.

Mean is a generic function that returns an R function to compute the estimate of the mean of a variable. Its input is typically some kind of model fit object. Likewise, Quantile is a generic quantile function-producing function. Mean areg.boot and Quantile areg.boot create functions of a vector of linear predictors that transform them into the smearing estimates of the mean or quantile of the response variable, respectively. Quantile areg.boot produces exactly the same value as predict.areg.boot or smearingEst. Mean approximates the mapping of linear predictors to means over an evenly spaced grid of by default 200 points. Linear interpolation is used between these points. This approximate method is much faster than the full smearing estimator once Mean creates the function. These functions are especially useful in nomogram (see the example on hypothetical data).

Usage

transace(x, monotonic=NULL, categorical=NULL, binary=NULL, pl=TRUE)

areg.boot(x, data, weights, subset, na.action=na.delete,
        B=100, method=c("areg","avas"), nk=4, evaluation=100, valrsq=TRUE,
        probs=c(.25,.5,.75), tolerance=NULL)

## S3 method for class 'areg.boot'
print(x, ...)
## Arguments

**x**

for *transace* a numeric matrix. For *areg.boot* *x* is a formula. For *print* or *plot*, an object created by *areg.boot*. For *print.summary.areg.boot* and *object* created by *summary.areg.boot*.

**object**

an object created by *areg.boot*, or a model fit object suitable for *Mean* or *Quantile*.

**transEst**

a vector of transformed values. In log-normal regression these could be predicted log(Y) for example.

**inverseTrans**

a function specifying the inverse transformation needed to change *transEst* to the original untransformed scale. *inverseTrans* may also be a 2-element list.
transace

defining a mapping from the transformed values to untransformed values. Linear interpolation is used in this case to obtain untransform values.

binary, categorical, monotonic

These are vectors of variable names specifying what to assume about each column of x for transace. Binary variables are not transformed, of course.

pl

set pl=FALSE to prevent transace from plotting each fitted transformation

data

data frame to use if x is a formula and variables are not already in the search list

weights

a numeric vector of observation weights. By default, all observations are weighted equally.

subset

an expression to subset data if x is a formula

na.action

a function specifying how to handle NAs. Default is na.delete.

B

number of bootstrap samples (default=100)

method

"areg" (the default) or "avas"

nk

number of knots for continuous variables not restricted to be linear. Default is 4. One or two is not allowed. nk=0 forces linearity for all continuous variables.

evaluation

number of equally-spaced points at which to evaluate (and save) the nonparametric transformations derived by avas or ace. Default is 100. For Mean. areg.boot, evaluation is the number of points at which to evaluate exact smearing estimates, to approximate them using linear interpolation (default is 200).

valrsq

set to TRUE to more quickly do bootstrapping without validating $R^2$

probs

vector probabilities denoting the quantiles of continuous predictors to use in estimating effects of those predictors

tolerance

singularity criterion; list source code for the lm.fitqr.bare function.

res

a vector of residuals from the transformed model. Not required when statistic="lp" or statistic="fitted".

statistic

statistic to estimate with the smearing estimator. For smearingEst, the default results in computation of the sample median of the model residuals, then smearingEst adds the median residual and back-transforms to get estimated median responses on the original scale. statistic="lp" causes predicted transformed responses to be computed. For smearingEst, the result (for statistic="lp") is the input argument transEst. statistic="fitted" gives predicted untransformed responses, i.e., ginverse(lp), where ginverse is the inverse of the estimated response transformation, estimated by reverse linear interpolation on the tabulated nonparametric response transformation or by using an explicit analytic function. statistic="quantile" generalizes "median" to any single quantile q which must be specified. "mean" causes the population mean response to be estimated. For predict. areg.boot, statistic="terms" returns a matrix of transformed predictors. statistic can also be any R function that computes a single value on a vector of values, such as statistic=var. Note that in this case the function name is not quoted.

q

a single quantile of the original response scale to estimate, when statistic="quantile", or for Quantile. areg.boot.

ylim

2-vector of y-axis limits
boot

set to FALSE to not plot any bootstrapped transformations. Set it to an integer $k$
to plot the first $k$ bootstrap estimates.

col.boot

color for bootstrapped transformations

lwd.boot

line width for bootstrapped transformations

conf.int

confidence level (0-1) for pointwise bootstrap confidence limits and for esti-
mated effects of predictors in summary. areg.boot. The latter assumes normal-
ity of the estimated effects.

values

a list of vectors of settings of the predictors, for predictors for which you want to
override settings determined from probs. The list must have named components,
with names corresponding to the predictors. Example: values=list(x1=c(2,4,6,8),
x2=c(-1,0,1)) specifies that summary is to estimate the effect on $y$ of changing $x1$ from 2 to 4,
2 to 6, 2 to 8, and separately, of changing $x2$ from -1 to 0 and -1 to 1.

adj.to

a named vector of adjustment constants, for setting all other predictors when
examining the effect of a single predictor in summary. The more nonlinear is the
transformation of $y$ the more the adjustment settings will matter. Default values
are the medians of the values defined by values or probs. You only need to
name the predictors for which you are overriding the default settings. Example:
adj.to=c(x2=0, x5=10) will set $x2$ to 0 and $x5$ to 10 when assessing the impact
of variation in the other predictors.

newdata

a data frame or list containing the same number of values of all of the predictors
used in the fit. For factor predictors the ‘levels’ attribute do not need to be
in the same order as those used in the original fit, and not all levels need to be
represented. If newdata is omitted, you can still obtain linear predictors (on the
transformed response scale) and fitted values (on the original response scale),
but not "terms".

type

specifies how Function is to return the series of functions that define the trans-
formations of all variables. By default a list is created, with the names of the list
elements being the names of the variables. Specify type="individual" to have
separate functions created in the current environment (pos=-1, the default) or in
location defined by pos if where is specified. For the latter method, the names
of the objects created are the names of the corresponding variables, prefixed by
prefix and with suffix appended to the end. If any of pos, prefix, or suffix
is specified, type is automatically set to "individual".

ytype

By default the first function created by Function is the y-transformation. Spec-
ify ytype="inverse" to instead create the inverse of the transformation, to be
able to obtain originally scaled $y$-values.

prefix

character string defining the prefix for function names created when type="individual".
By default, the function specifying the transformation for variable $x$ will be
named .x.

suffix

character string defining the suffix for the function names

pos

See assign.

... arguments passed to other functions
transace

Details

As transace only does one iteration over the predictors, it may not find optimal transformations and it will be dependent on the order of the predictors in x.

ace and avas standardize transformed variables to have mean zero and variance one for each bootstrap sample, so if a predictor is not important it will still consistently have a positive regression coefficient. Therefore using the bootstrap to estimate standard errors of the additive least squares regression coefficients would not help in drawing inferences about the importance of the predictors. To do this, summary.areg.boot computes estimates of, e.g., the inter-quartile range effects of predictors in predicting the response variable (after untransforming it). As an example, at each bootstrap repetition the estimated transformed value of one of the predictors is computed at the lower quartile, median, and upper quartile of the raw value of the predictor. These transformed x values are then multiplied by the least squares estimate of the partial regression coefficient for that transformed predictor in predicting transformed y. Then these weighted transformed x values have the weighted transformed x value corresponding to the lower quartile subtracted from them, to estimate an x effect accounting for nonlinearity. The last difference computed is then the standardized effect of raising x from its lowest to its highest quartile. Before computing differences, predicted values are back-transformed to be on the original y scale in a way depending on statistic and q. The sample standard deviation of these effects (differences) is taken over the bootstrap samples, and this is used to compute approximate confidence intervals for effects and approximate P-values, both assuming normality.

predict does not re-insert NAs corresponding to observations that were dropped before the fit, when newdata is omitted.

statistic="fitted" estimates the same quantity as statistic="median" if the residuals on the transformed response have a symmetric distribution. The two provide identical estimates when the sample median of the residuals is exactly zero. The sample mean of the residuals is constrained to be exactly zero although this does not simplify anything.

Value

transace returns a matrix like x but containing transformed values. This matrix has attributes rsq (vector of $R^2$ with which each variable can be predicted from the others) and omitted (row numbers of x that were deleted due to NAs).

areg.boot returns a list of class 'areg.boot' containing many elements, including (if valrsq is TRUE) rsquare.app and rsquare.val. summary.areg.boot returns a list of class 'summary.areg.boot' containing a matrix of results for each predictor and a vector of adjust-to settings. It also contains the call and a 'label' for the statistic that was computed. A print method for these objects handles the printing. predict.areg.boot returns a vector unless statistic="terms", in which case it returns a matrix. Function. areg.boot returns by default a list of functions whose argument is one of the variables (on the original scale) and whose returned values are the corresponding transformed values. The names of the list of functions correspond to the names of the original variables. When type="individual", Function. areg.boot invisibly returns the vector of names of the created function objects. Mean. areg.boot and Quantile. areg.boot also return functions.

smearingEst returns a vector of estimates of distribution parameters of class 'labelled' so that print.labelled will print a label documenting the estimate that was used (see label). This label can be retrieved for other purposes by using e.g. label(obj), where obj was the vector returned by smearingEst.

Examples

# xtrans <- transace(cbind(age,sex,blood.pressure,race.code),
#   binary='sex', monotonic='age',
#   categorical='race.code')

# Generate random data from the model y = exp(x1 + epsilon/3) where
# x1 and epsilon are Gaussian(0,1)
set.seed(171)  # to be able to reproduce example
x1 <- rnorm(200)
x2 <- runif(200)  # a variable that is really unrelated to y]
x3 <- factor(sample(c('cat','dog','cow'), 200,TRUE))  # also unrelated to y
y <- exp(x1 + rnorm(200))/3
f <- areg.boot(y ~ x1 + x2 + x3, B=40)
f
plot(f)
# Note that the fitted transformation of y is very nearly log(y)
# (the appropriate one), the transformation of x1 is nearly linear,
# and the transformations of x2 and x3 are essentially flat
# (specifying monotone(x2) if method='avas' would have resulted
# in a smaller confidence band for x2)

summary(f)

# use summary(f, values=list(x2=c(.2,.5,.8))) for example if you
# want to use nice round values for judging effects

# Plot Y hat vs. Y (this doesn't work if there were NAs)
plot(fitted(f), y)  # or: plot(predict(f, statistic='fitted'), y)

# Show fit of model by varying x1 on the x-axis and creating separate
# panels for x2 and x3. For x2 using only a few discrete values
newdat <- expand.grid(x1=seq(-2,2,length=100), x2=c(.25,.75),
                        x3=c('cat','dog','cow'))
yhat <- predict(f, newdat, statistic='fitted')
# statistic='mean' to get estimated mean rather than simple inverse trans.
xYplot(yhat ~ x1 | x2, groups=x3, type='l', data=newdat)

## Not run:
# Another example, on hypothetical data
f <- areg.boot(response ~ I(age) + monotone(blood.pressure) + race)
# use I(response) to not transform the response variable
plot(f, conf.int=.9)
# Check distribution of residuals
plot(fitted(f), resid(f))
qqnorm(resid(f))
# Refit this model using ols so that we can draw a nomogram of it.
# The nomogram will show the linear predictor, median, mean.
# The last two are smearing estimators.
Function(f, type='individual')  # create transformation functions
f.ols <- ols(.response(response) ~ age +
             .blood.pressure(blood.pressure) + .race(race))
# Note: This model is almost exactly the same as f but there
# will be very small differences due to interpolation of
# transformations
meanr <- mean(f)  # create function of lp computing mean response
medr <- quantile(f)  # default quantile is .5
nomogram(f.ols, fun=list(Mean=meanr,Median=medr))

# Create S functions that will do the transformations
# This is a table look-up with linear interpolation
g <- Function(f)
plot(blood.pressure, g*blood.pressure(blood.pressure))
# produces the central curve in the last plot done by plot(f)

## End(Not run)

# Another simulated example, where y has a log-normal distribution
# with mean x and variance 1. Untransformed y thus has median
# exp(x) and mean exp(x + .5*sigma^2) = exp(x + .5)
# First generate data from the model y = exp(x + epsilon),
# epsilon ~ Gaussian(0, 1)

set.seed(139)
n <- 1000
x <- rnorm(n)
\begin{verbatim}
y <- exp(x + rnorm(n))
f <- areg.boot(y - x, B=20)
plot(f)  # note log shape for y, linear for x. Good!

# Last argument can be any statistical function operating
# on a vector that returns a single value
\end{verbatim}

\begin{description}
\item[transcan] \textit{Transformations/Imputations using Canonical Variates}

\item[Description] transcan is a nonlinear additive transformation and imputation function, and there are several functions for using and operating on its results. transcan automatically transforms continuous and categorical variables to have maximum correlation with the best linear combination of the other variables. There is also an option to use a substitute criterion - maximum correlation with the first principal component of the other variables. Continuous variables are expanded as restricted cubic splines and categorical variables are expanded as contrasts (e.g., dummy variables). By default, the first canonical variate is used to find optimum linear combinations of component columns. This function is similar to ace except that transformations for continuous variables are fitted using restricted cubic splines, monotonicity restrictions are not allowed, and NAs are allowed. When a variable has any NAs, transformed scores for that variable are imputed using least squares multiple regression incorporating optimum transformations, or NAs are optionally set to constants. Shrinkage can be used to safeguard against overfitting when imputing. Optionally, imputed values on the original scale are also computed and returned. For this purpose, recursive partitioning or multinomial
logistic models can optionally be used to impute categorical variables, using what is predicted to be the most probable category.

By default, transcan imputes NAs with “best guess” expected values of transformed variables, back transformed to the original scale. Values thus imputed are most like conditional medians assuming the transformations make variables’ distributions symmetric (imputed values are similar to conditional modes for categorical variables). By instead specifying n.impute, transcan does approximate multiple imputation from the distribution of each variable conditional on all other variables. This is done by sampling n.impute residuals from the transformed variable, with replacement (a la bootstrapping), or by default, using Rubin’s approximate Bayesian bootstrap, where a sample of size n with replacement is selected from the residuals on n non-missing values of the target variable, and then a sample of size m with replacement is chosen from this sample, where m is the number of missing values needing imputation for the current multiple imputation repetition. Neither of these bootstrap procedures assume normality or even symmetry of residuals. For sometimes-missing categorical variables, optimal scores are computed by adding the “best guess” predicted mean score to random residuals off this score. Then categories having scores closest to these predicted scores are taken as the random multiple imputations (impcat = "rpart" is not currently allowed with n.impute). The literature recommends using n.impute = 5 or greater. transcan provides only an approximation to multiple imputation, especially since it “freezes” the imputation model before drawing the multiple imputations rather than using different estimates of regression coefficients for each imputation. For multiple imputation, the aregImpute function provides a much better approximation to the full Bayesian approach while still not requiring linearity assumptions.

When you specify n.impute to transcan you can use fit.mult.impute to re-fit any model n.impute times based on n.impute completed datasets (if there are any sometimes missing variables not specified to transcan, some observations will still be dropped from these fits). After fitting n.impute models, fit.mult.impute will return the fit object from the last imputation, with coefficients replaced by the average of the n.impute coefficient vectors and with a component var equal to the imputation-corrected variance-covariance matrix. fit.mult.impute can also use the object created by the mice function in the mice library to draw the multiple imputations, as well as objects created by aregImpute. The following components of fit objects are also replaced with averages over the n.impute model fits: linear.predictors, fitted.values, stats, means, icoef, scale, center, y.imputed.

The summary method for transcan prints the function call, $R^2$ achieved in transforming each variable, and for each variable the coefficients of all other transformed variables that are used to estimate the transformation of the initial variable. If imputed=TRUE was used in the call to transcan, also uses the describe function to print a summary of imputed values. If long = TRUE, also prints all imputed values with observation identifiers. There is also a simple function print.transcan which merely prints the transformation matrix and the function call. It has an optional argument long, which if set to TRUE causes detailed parameters to be printed. Instead of plotting while transcan is running, you can plot the final transformations after the fact using plot.transcan or ggpplot.transcan, if the option trantab = TRUE was specified to transcan. If in addition the option imputed = TRUE was specified to transcan, plot and ggplot will show the location of imputed values (including multiples) along the axes. For ggplot, imputed values are shown as red plus signs.

impute method for transcan does imputations for a selected original data variable, on the original scale (if imputed=TRUE was given to transcan). If you do not specify a variable to impute, it will do imputations for all variables given to transcan which had at least one missing value. This assumes that the original variables are accessible (i.e., they have been attached) and that you want
the imputed variables to have the same names as the original variables. If \texttt{n.impute} was specified to \texttt{transcan} you must tell \texttt{impute} which imputation to use. Results are stored in \texttt{.GlobalEnv} when \texttt{list.out} is not specified (it is recommended to use \texttt{list.out=TRUE}).

The \texttt{predict} method for \texttt{transcan} computes predicted variables and imputed values from a matrix of new data. This matrix should have the same column variables as the original matrix used with \texttt{transcan}, and in the same order (unless a formula was used with \texttt{transcan}).

The \texttt{Function} function is a generic function generator. \texttt{Function\_transcan} creates \texttt{R} functions to transform variables using transformations created by \texttt{transcan}. These functions are useful for getting predicted values with predictors set to values on the original scale.

The \texttt{vcov} methods are defined here so that imputation-corrected variance-covariance matrices are readily extracted from \texttt{fit\_mult\_impute} objects, and so that \texttt{fit\_mult\_impute} can easily compute traditional covariance matrices for individual completed datasets.

The subscript method for \texttt{transcan} preserves attributes.

The \texttt{invertTabulated} function does either inverse linear interpolation or uses sampling to sample qualifying x-values having y-values near the desired values. The latter is used to get inverse values having a reasonable distribution (e.g., no floor or ceiling effects) when the transformation has a flat or nearly flat segment, resulting in a many-to-one transformation in that region. Sampling weights are a combination of the frequency of occurrence of x-values that are within \texttt{tol\_inverse} times the range of y and the squared distance between the associated y-values and the target y-value (\texttt{aty}).

\textbf{Usage}

\begin{verbatim}
transcan(x, method=c("canonical","pc"),
categorical=NULL, asis=NULL, nk, imputed=FALSE, n.impute,
boot.method=c('approximate bayesian', 'simple'),
trantab=FALSE, transformed=FALSE,
impcat=c("score", "multinom", "rpart"),
mincut=40,
inverse=c('linearInterp','sample'), tol\_inverse=.05,
pr=TRUE, pl=TRUE, allpl=FALSE, show.na=TRUE,
imputed.actual=c('none','datadensity','hist','qq','ecdf'),
iter.max=50, eps=.1, curtail=TRUE,
imp.con=FALSE, shrink=FALSE, init.cat="mode",
ires=if(is.null(boot.method)='simple')200 else 400,
data, subset, na.action, treeinfo=FALSE,
rhsimp=c('mean','random'), details.impcat=' ', ...)  

## S3 method for class 'transcan'
summary(object, long=FALSE, digits=6, ...)

## S3 method for class 'transcan'
print(x, long=FALSE, ...)

## S3 method for class 'transcan'
plot(x, ...)

## S3 method for class 'transcan'

\end{verbatim}
Arguments

x  a matrix containing continuous variable values and codes for categorical variables. The matrix must have column names (dimnames). If row names are present, they are used in forming the names attribute of imputed values if imputed = TRUE. x may also be a formula, in which case the model matrix is created automatically, using data in the calling frame. Advantages of using a formula are that categorical variables can be determined automatically by a variable being a factor variable, and variables with two unique levels are modeled as is. Variables with 3 unique values are considered to be categorical if a formula is specified. For a formula you may also specify that a variable is to remain untransformed by enclosing its name with the identify function, e.g. I(x3). The user may add other variable names to the asis and categorical vectors. For invertTabulated, x is a vector or a list with three components: the x vector, the corresponding vector of transformed values, and the corresponding vector of frequencies of the pair of original and transformed variables. For print, plot, ggplot, impute, and predict, x is an object created by transcan.
formula  any R model formula
fitter    any R, rms, modeling function (not in quotes) that computes a vector of coefficients and for which vcov will return a variance-covariance matrix. E.g., fitter = lm, glm, ols. At present models involving non-regression parameters (e.g., scale parameters in parametric survival models) are not handled fully.
xtrans   an object created by transcan, aregImpute, or mice
method   use method="canonical" or any abbreviation thereof, to use canonical variates (the default). method="pc" transforms a variable instead so as to maximize the correlation with the first principal component of the other variables.
categorical a character vector of names of variables in x which are categorical, for which the ordering of re-scored values is not necessarily preserved. If categorical is omitted, it is assumed that all variables are continuous (or binary). Set categorical="*" to treat all variables as categorical.
asis      a character vector of names of variables that are not to be transformed. For these variables, the guts of lm.fit method="qr" is used to impute missing values. You may want to treat binary variables asis (this is automatic if using a formula). If imputed = TRUE, you may want to use "categorical" for binary variables if you want to force imputed values to be one of the original data values. Set asis="*" to treat all variables asis.
nk        number of knots to use in expanding each continuous variable (not listed in asis) in a restricted cubic spline function. Default is 3 (yielding 2 parameters for a variable) if n < 30, 4 if 30 <= n < 100, and 5 if n >= 100 (4 parameters).
imputed   Set to TRUE to return a list containing imputed values on the original scale. If the transformation for a variable is non-monotonic, imputed values are not unique. transcan uses the approx function, which returns the highest value of the variable with the transformed score equalling the imputed score. imputed=TRUE also causes original-scale imputed values to be shown as tick marks on the top margin of each graph when show.na=TRUE (for the final iteration only). For categorical predictors, these imputed values are passed through the jitter function so that their frequencies can be visualized. When n.impute is used, each NA will have n.impute tick marks.
n.impute  number of multiple imputations. If omitted, single predicted expected value imputation is used. n.impute=5 is frequently recommended.
boot.method default is to use the approximate Bayesian bootstrap (sample with replacement from sample with replacement of the vector of residuals). You can also specify boot.method="simple" to use the usual bootstrap one-stage sampling with replacement.
trantab   Set to TRUE to add an attribute trantab to the returned matrix. This contains a vector of lists each with components x and y containing the unique values and corresponding transformed values for the columns of x. This is set up to be used easily with the approx function. You must specify trantab=TRUE if you want to later use the predict.transcan function with type = "original".
transformed set to TRUE to cause transcan to return an object transformed containing the matrix of transformed variables
impcat
This argument tells how to impute categorical variables on the original scale.
The default is `impcat="score"` to impute the category whose canonical variate
score is closest to the predicted score. Use `impcat="rpart"` to impute categorical
variables using the values of all other transformed predictors in conjunction with the `rpart` function. A better but somewhat slower approach is to use `impcat="multinom"` to fit a multinomial logistic model to the categorical variable, at the last iteration of the transcan algorithm. This uses the `multinom` function in the `nnet` library of the MASS package (which is assumed to have been installed by the user) to fit a polytomous logistic model to the current working transformations of all the other variables (using conditional mean imputation for missing predictors). Multiple imputations are made by drawing multinomial values from the vector of predicted probabilities of category membership for the missing categorical values.

mincut
If `imputed=TRUE`, there are categorical variables, and `impcat = "rpart"`,
mincut specifies the lowest node size that will be allowed to be split. The default is 40.

inverse
By default, imputed values are back-solved on the original scale using inverse
linear interpolation on the fitted tabulated transformed values. This will cause
distorted distributions of imputed values (e.g., floor and ceiling effects) when
the estimated transformation has a flat or nearly flat section. To instead use the `invertTabulated` function (see above) with the "sample" option, specify `inverse="sample"`.

tolInverse
the multiplier of the range of transformed values, weighted by freq and by the
distance measure, for determining the set of x values having y values within
a tolerance of the value of aty in `invertTabulated`. For `predict.transcan`,
inverse and tolInverse are obtained from options that were specified to transcan
by default. Otherwise, if not specified by the user, these default to the defaults
used to `invertTabulated`.

pr
For transcan, set to FALSE to suppress printing $R^2$ and shrinkage factors. Set
impute.transcan=FALSE to suppress messages concerning the number of NA
values imputed. Set `fit.mult.impute=FALSE` to suppress printing variance inflation factors accounting for imputation, rate of missing information, and degrees of freedom.

pl
Set to FALSE to suppress plotting the final transformations with distribution of
scores for imputed values. If `show.na=TRUE`.

allpl
Set to TRUE to plot transformations for intermediate iterations.

show.na
Set to FALSE to suppress the distribution of scores assigned to missing values (as
tick marks on the right margin of each graph). See also `imputed`.

imputed.actual
The default is "none" to suppress plotting of actual vs. imputed values for
all variables having any NA values. Other choices are "datadensity" to use
datatadensity to make a single plot, "hist" to make a series of back-to-back histograms, "qq" to make a series of q-q plots, or "ecdf" to make a series of empirical cdfs. For `imputed.actual="datadensity"` for example you get a rug plot of the non-missing values for the variable with beneath it a rug plot of the imputed values. When `imputed.actual` is not "none", `imputed` is automatically set to TRUE.
iter.max  maximum number of iterations to perform for transcan or predict. For predict, only one iteration is used if there are no NA values in the data or if imp.con was used.

eps  convergence criterion for transcan and predict. eps is the maximum change in transformed values from one iteration to the next. If for a given iteration all new transformations of variables differ by less than eps (with or without negating the transformation to allow for “flipping”) from the transformations in the previous iteration, one more iteration is done for transcan. During this last iteration, individual transformations are not updated but coefficients of transformations are. This improves stability of coefficients of canonical variates on the right-hand-side. eps is ignored when rhsImp=“random”.

curtail  for transcan, causes imputed values on the transformed scale to be truncated so that their ranges are within the ranges of non-imputed transformed values. For predict, curtail defaults to TRUE to truncate predicted transformed values to their ranges in the original fit (xt).

imp.con  for transcan, set to TRUE to impute NA values on the original scales with constants (medians or most frequent category codes). Set to a vector of constants to instead always use these constants for imputation. These imputed values are ignored when fitting the current working transformation for asingle variable.

shrink  default is FALSE to use ordinary least squares or canonical variate estimates. For the purposes of imputing NAs, you may want to set shrink=TRUE to avoid overfitting when developing a prediction equation to predict each variables from all the others (see details below).

init.cat  method for initializing scorings of categorical variables. Default is “mode” to use a dummy variable set to 1 if the value is the most frequent value (this is the default). Use “random” to use a random 0-1 variable. Set to “asis” to use the original integer codes as starting scores.

nres  number of residuals to store if n.impute is specified. If the dataset has fewer than nres observations, all residuals are saved. Otherwise a random sample of the residuals of length nres without replacement is saved. The default for nres is higher if boot.method=“approximate bayesian”.

data  Data frame used to fill the formula. For ggplot is the result of transcan with trantab=TRUE.

subset  an integer or logical vector specifying the subset of observations to fit

na.action  These may be used if x is a formula. The default na.action is na.retain (defined by transcan) which keeps all observations with any NA values. For impute.transcan, data is a data frame to use as the source of variables to be imputed, rather than using pos.in. For fit.mult.impute, data is mandatory and is a data frame containing the data to be used in fitting the model but before imputations are applied. Variables omitted from data are assumed to be available from frame1 and do not need to be imputed.

treeinfo  Set to TRUE to get additional information printed when impcat=“rpart”, such as the predicted probabilities of category membership.

rhsImp  Set to “random” to use random draw imputation when a sometimes missing variable is moved to be a predictor of other sometimes missing variables. De-
fault is rhsImp="mean", which uses conditional mean imputation on the transformed scale. Residuals used are residuals from the transformed scale. When "random" is used, transcan runs 5 iterations and ignores eps.

details.impcat set to a character scalar that is the name of a category variable to include in the resulting transcan object an element details.impcat containing details of how the categorical variable was multiply imputed.

... arguments passed to scatld or to the fitter function (for fit.mult.impute). For ggplot.transcan, these arguments are passed to facet_wrap, e.g. ncol=2.

long for summary, set to TRUE to print all imputed values. For print, set to TRUE to print details of transformations/imputations.

digits number of significant digits for printing values by summary

scale for ggplot.transcan set scale=TRUE to scale transformed values to [0,1] before plotting.

mapping,environment not used; needed because of rules about generics

var For impute, is a variable that was originally a column in x, for which imputed values are to be filled in. imputed=TRUE must have been used in transcan. Omit var to impute all variables, creating new variables in position pos (see assign).

imputation specifies which of the multiple imputations to use for filling in NA values

name name of variable to impute, for impute function. Default is character string version of the second argument (var) in the call to impute. For invertTabulated, is the name of variable being transformed (used only for warning messages).

pos.in location as defined by assign to find variables that need to be imputed, when all variables are to be imputed automatically by impute.transcan (i.e., when no input variable name is specified). Default is position that contains the first variable to be imputed.

list.out If var is not specified, you can set list.out=TRUE to have impute.transcan return a list containing variables with needed values imputed. This list will contain a single imputation. Variables not needing imputation are copied to the list as-is. You can use this list for analysis just like a data frame.

check set to FALSE to suppress certain warning messages

newdata a new data matrix for which to compute transformed variables. Categorical variables must use the same integer codes as were used in the call to transcan. If a formula was originally specified to transcan (instead of a data matrix), newdata is optional and if given must be a data frame; a model frame is generated automatically from the previous formula. The na.action is handled automatically, and the levels for factor variables must be the same and in the same order as were used in the original variables specified in the formula given to transcan.

fit.reps set to TRUE to save all fit objects from the fit for each imputation in fit.mult.impute. Then the object returned will have a component fits which is a list whose ith element is the ith fit object.
provides an approach to creating derived variables from a single filled-in dataset. The function specified as `dtrans` can even reshape the imputed dataset. An example of such usage is fitting time-dependent covariates in a Cox model that are created by "start, stop" intervals. Imputations may be done on a one record per subject data frame that is converted by `dtrans` to multiple records per subject. The imputation can enforce consistency of certain variables across records so that for example a missing value of sex will not be imputed as 'male' for one of the subject's records and 'female' as another. An example of how `dtrans` might be specified is `dtrans=function(w) {w$age <- w$years + w$months/12; w}` where months might have been imputed but years was never missing. An outline for using `dtrans` to impute missing baseline variables in a longitudinal analysis appears in Details below.

an expression containing R expressions for computing derived variables that are used in the model formula. This is useful when multiple imputations are done for component variables but the actual model uses combinations of these (e.g., ratios or other derivations). For a single derived variable you can specified for example `derived=expression(ratio <- weight/height)`. For multiple derived variables use the form `derived=expression(list(ratio <- weight/height; product <- weight*height))` or put the expression on separate input lines. To monitor the multiply-imputed derived variables you can add to the expression a command such as `print(describe(ratio))`. See the example below. Note that derived is not yet implemented.

a list of named additional arguments to pass to the `vcov` method for `fitter`. Useful for `orm` models for retaining all intercepts (`vcovOpts=list(intercepts='all')`) instead of just the middle one.

By default, the matrix of transformed variables is returned, with imputed values on the transformed scale. If you had specified `trantab=TRUE` to `transcan`, specifying `type="original"` does the table look-ups with linear interpolation to return the input matrix `x` but with imputed values on the original scale inserted for `NA` values. For categorical variables, the method used here is to select the category code having a corresponding scaled value closest to the predicted transformed value. This corresponds to the default `impcat`. Note: imputed values thus returned when type="original" are single expected value imputations even in `n.impute` is given.

an object created by `transcan`, or an object to be converted to R function code, typically a model fit object of some sort

When creating separate R functions for each variable in `x`, the name of the new function will be `prefix` placed in front of the variable name, and `suffix` placed in back of the name. The default is to use names of the form `.varname`, where `varname` is the variable name.

`assign` at which to store new functions (for `Function`). Default is `pos=-1`.

a vector corresponding to `x` for `invertTabulated`, if its first argument `x` is not a list

a vector of frequencies corresponding to cross-classified `x` and `y` if `x` is not a list. Default is a vector of ones.

vector of transformed values at which inverses are desired
transcan

rule see approx. transcan assumes rule is always 2.
regcoef.only set to TRUE to make vcov.default delete positions in the covariance matrix for any non-regression coefficients (e.g., log scale parameter from psm or survreg)
intercepts this is primarily for orm objects. Set to "none" to discard all intercepts from the covariance matrix, or to "all" or "mid" to keep all elements generated by orm (orm only outputs the covariance matrix for the intercept corresponding to the median). You can also set intercepts to a vector of subscripts for selecting particular intercepts in a multi-intercept model.

Details

The starting approximation to the transformation for each variable is taken to be the original coding of the variable. The initial approximation for each missing value is taken to be the median of the non-missing values for the variable (for continuous ones) or the most frequent category (for categorical ones). Instead, if imp.con is a vector, its values are used for imputing NA values. When using each variable as a dependent variable, NA values on that variable cause all observations to be temporarily deleted. Once a new working transformation is found for the variable, along with a model to predict that transformation from all the other variables, that latter model is used to impute NA values in the selected dependent variable if imp.con is not specified.

When that variable is used to predict a new dependent variable, the current working imputed values are inserted. Transformations are updated after each variable becomes a dependent variable, so the order of variables on x could conceivably make a difference in the final estimates. For obtaining out-of-sample predictions/transformations, predict uses the same iterative procedure as transcan for imputation, with the same starting values for fill-ins as were used by transcan. It also (by default) uses a conservative approach of curtailing transformed variables to be within the range of the original ones. Even when method = "pc" is specified, canonical variables are used for imputing missing values.

Note that fitted transformations, when evaluated at imputed variable values (on the original scale), will not precisely match the transformed imputed values returned in xt. This is because transcan uses an approximate method based on linear interpolation to back-solve for imputed values on the original scale.

Shrinkage uses the method of Van Houwelingen and Le Cessie (1990) (similar to Copas, 1983). The shrinkage factor is

$$1 - \frac{(1-R^2)(n-1)}{n-k-1}$$

where $R^2$ is the apparent $R^2$ for predicting the variable, $n$ is the number of non-missing values, and $k$ is the effective number of degrees of freedom (aside from intercepts). A heuristic estimate is used for $k$: $A = 1 + \sum(\max(0, Bi - 1))/m + m$, where $A$ is the number of d.f. required to represent the variable being predicted, the $Bi$ are the number of columns required to represent all the other variables, and $m$ is the number of all other variables. Division by $m$ is done because the transformations for the other variables are fixed at their current transformations the last time they were being predicted. The $+m$ term comes from the number of coefficients estimated on the right hand side, whether by least squares or canonical variates. If a shrinkage factor is negative, it is set to 0. The shrinkage factor is the ratio of the adjusted $R^2$ to the ordinary $R^2$. The adjusted $R^2$ is

$$1 - \frac{(1-R^2)(n-1)}{n-k-1}$$
which is also set to zero if it is negative. If \texttt{shrink=FALSE} and the adjusted $R^2$s are much smaller than the ordinary $R^2$s, you may want to run \texttt{transcan} with \texttt{shrink=TRUE}.

Canonical variates are scaled to have variance of 1.0, by multiplying canonical coefficients from \texttt{cancor} by $\sqrt{n-1}$.

When specifying a non-\texttt{rms} library fitting function to \texttt{fit.mult.impute} (e.g., \texttt{lm}, \texttt{glm}), running the result of \texttt{fit.mult.impute} through that fit’s \texttt{summary} method will not use the imputation-adjusted variances. You may obtain the new variances using \texttt{fit$var} or \texttt{vcov(fit)}.

When you specify a \texttt{rms} function to \texttt{fit.mult.impute} (e.g. \texttt{lrm}, \texttt{ols}, \texttt{cph}, \texttt{psm}, \texttt{bj}, \texttt{Rq}, \texttt{Gls}, \texttt{Glml}), automatically computed transformation parameters (e.g., knot locations for \texttt{rcs}) that are estimated for the first imputation are used for all other imputations. This ensures that knot locations will not vary, which would change the meaning of the regression coefficients.

Warning: even though \texttt{fit.mult.impute} takes imputation into account when estimating variances of regression coefficient, it does not take into account the variation that results from estimation of the shapes and regression coefficients of the customized imputation equations. Specifying \texttt{shrink=TRUE} solves a small part of this problem. To fully account for all sources of variation you should consider putting the \texttt{transcan} invocation inside a bootstrap or loop, if execution time allows. Better still, use \texttt{aregImpute} or a package such as \texttt{mice} that uses real Bayesian posterior realizations to multiply impute missing values correctly.

It is strongly recommended that you use the \texttt{Hmisc naclus} function to determine is there is a good basis for imputation. \texttt{naclus} will tell you, for example, if systolic blood pressure is missing whenever diastolic blood pressure is missing. If the only variable that is well correlated with diastolic bp is systolic bp, there is no basis for imputing diastolic bp in this case.

At present, \texttt{predict} does not work with multiple imputation.

When calling \texttt{fit.mult.impute} with \texttt{glm} as the fitter argument, if you need to pass a \texttt{family} argument to \texttt{glm} do it by quoting the family, e.g., \texttt{family="binomial"}.

\texttt{fit.mult.impute} will not work with proportional odds models when regression imputation was used (as opposed to predictive mean matching). That’s because regression imputation will create values of the response variable that did not exist in the dataset, altering the intercept terms in the model.

You should be able to use a variable in the formula given to \texttt{fit.mult.impute} as a numeric variable in the regression model even though it was a factor variable in the invocation of \texttt{transcan}. Use for example \texttt{fit.mult.impute(y ~ codes(x), lrm, trans)} (thanks to Trevor Thompson <trevor@hp5.eushc.org>).

Here is an outline of the steps necessary to impute baseline variables using the \texttt{dtrans} argument, when the analysis to be repeated by \texttt{fit.mult.impute} is a longitudinal analysis (using e.g. \texttt{Glml}).

1. Create a one row per subject data frame containing baseline variables plus follow-up variables that are assigned to windows. For example, you may have dozens of repeated measurements over years but you capture the measurements at the times measured closest to 1, 2, and 3 years after study entry

2. Make sure the dataset contains the subject ID

3. This dataset becomes the one passed to \texttt{aregImpute} as \texttt{data=}. You will be imputing missing baseline variables from follow-up measurements defined at fixed times.

4. Have another dataset with all the non-missing follow-up values on it, one record per measurement time per subject. This dataset should not have the baseline variables on it, and the
follow-up measurements should not be named the same as the baseline variable(s); the subject ID must also appear.

5. Add the dtrans argument to `fit.mult.impute` to define a function with one argument representing the one record per subject dataset with missing values filled from the current imputation. This function merges the above 2 datasets; the returned value of this function is the merged data frame.

6. This merged-on-the-fly dataset is the one handed by `fit.mult.impute` to your fitting function, so variable names in the formula given to `fit.mult.impute` must matched the names created by the merge.

Value

For `transcan`, a list of class `‘transcan’` with elements

- `call` (with the function call)
- `iter` (number of iterations done)
- `rsq`, `rsq.adj` containing the $R^2$'s and adjusted $R^2$'s achieved in predicting each variable from all the others
- `categorical` the values supplied for categorical
- `asis` the values supplied for asis
- `coef` the within-variable coefficients used to compute the first canonical variate
- `xcoef` the (possibly shrunk) across-variables coefficients of the first canonical variate that predicts each variable in-turn.
- `parms` the parameters of the transformation (knots for splines, contrast matrix for categorical variables)
- `fillin` the initial estimates for missing values (NA if variable never missing)
- `ranges` the matrix of ranges of the transformed variables (min and max in first and secondrow)
- `scale` a vector of scales used to determine convergence for a transformation.
- `formula` the formula (if x was a formula)

and optionally a vector of shrinkage factors used for predicting each variable from the others. For asis variables, the scale is the average absolute difference about the median. For other variables it is unity, since canonical variables are standardized. For xcoef, row i has the coefficients to predict transformed variable i, with the column for the coefficient of variable i set to NA. If `imputed=TRUE` was given, an optional element imputed also appears. This is a list with the vector of imputed values (on the original scale) for each variable containing NAs. Matrices rather than vectors are returned if n.impute is given. If `trantab=TRUE`, the trantab element also appears, as described above. If `n.impute > 0`, transcan also returns a list residuals that can be used for future multiple imputation.

impute returns a vector (the same length as var) of class ‘impute’ with NA values imputed.

predict returns a matrix with the same number of columns or variables as were in x.

`fit.mult.impute` returns a fit object that is a modification of the fit object created by fitting the completed dataset for the final imputation. The var matrix in the fit object has the imputation-corrected variance-covariance matrix. coefficients is the average (over imputations) of the coefficient vectors, variance.inflation.impute is a vector containing the ratios of the diagonals of the
between-imputation variance matrix to the diagonals of the average apparent (within-imputation) variance matrix. missingInfo is Rubin’s rate of missing information and dfmi is Rubin’s degrees of freedom for a t-statistic for testing a single parameter. The last two objects are vectors corresponding to the diagonal of the variance matrix. The class "fit.mult.impute" is prepended to the other classes produced by the fitting function.

fit.mult.impute stores intercepts attributes in the coefficient matrix and in var for orm fits.

**Side Effects**

prints, plots, and impute.transcan creates new variables.

translate  
_Translate Vector or Matrix of Text Strings_

**Description**

Uses the UNIX tr command to translate any character in `old` in `text` to the corresponding character in `new`. If `multichar=TRUE` or `old` and `new` have more than one element, or each have one element but they have different numbers of characters, uses the UNIX sed command to translate the series of characters in `old` to the series in `new` when these characters occur in `text`. If `old` or `new` contain a backslash, you sometimes have to quadruple it to make the UNIX command work. If they contain a forward slash, precede it by two backslashes. Invokes the builtin `chartr` function if `multichar=FALSE`.

**Usage**

`translate(text, old, new, multichar=FALSE)`

**Arguments**

- `text` scalar, vector, or matrix of character strings to translate.
- `old` vector old characters
- `new` corresponding vector of new characters
- `multichar` See above.

**Value**

an object like `text` but with characters translated

**See Also**

grep

**Examples**

```r
translate(c("ABC","DEF"),"ABCDTEFG", "abcdefg")
translate("23.12","\[\],"\\cdot") # change . to \cdot
translate(c("dog","cat","tiger"),c("dog","cat"),c("DOG","CAT"))
# S-Plus gives [1] "DOG" "CAT" "tiger" - check discrepancy
translate(c("dog","cat2","snake"),c("dog","cat"),"animal")
# S-Plus gives [1] "animal" "animal2" "snake"
```
trunc.POSIXt

| trunc.POSIXt | Return the floor, ceiling, or rounded value of date or time to specified unit. |

Description

trunc.POSIXt returns the date truncated to the specified unit. ceil.POSIXt returns next ceiling of the date at the unit selected in units. round.POSIXt returns the date or time value rounded to nearest specified unit selected in digits.

trunc.POSIXt and round.POSIXt have been extended from the base package functions trunc.POSIXt and round.POSIXt which in the future will add the other time units we need.

Usage

```r
ceil(x, units, ...) 
## Default S3 method:
ceil(x, units, ...)
trunc.POSIXt(x, units = c("secs", "mins", "hours", "days", "months", "years"), ...)
## S3 method for class 'POSIXt'
ceil(x, units = c("secs", "mins", "hours", "days", "months", "years"), ...)
round.POSIXt(x, digits = c("secs", "mins", "hours", "days", "months", "years"))
```

Arguments

- `x` date to be ceilinged, truncated, or rounded
- `units` unit to that is is rounded up or down to.
- `digits` same as `units` but different name to be compatible with `round` generic.
- `...` further arguments to be passed to or from other methods.

Value

An object of class POSIXlt.

Author(s)

Charles Dupont

Examples

date <- ISOdate(1932, 7, 12)
ceil(date, units='months')  # '1932-8-1'
truncPOSIXt(date, units='years')  # '1932-1-1'
roundPOSIXt(date, digits='months')  # '1932-7-1'

units  

Units Attribute of a Vector

Description

Sets or retrieves the "units" attribute of an object. For units.default replaces the builtin version, which only works for time series objects. If the variable is also given a label, subsetting (using [.labelled]) will retain the "units" attribute. For a Surv object, units first looks for an overall "units" attribute, then it looks for units for the time2 variable then for time1.

Usage

units(x, ...)
## Default S3 method:
units(x, none='', ...)
## S3 method for class 'Surv'
units(x, none='', ...)
## Default S3 replacement method:
units(x) <- value

Arguments

x  any object
...
ignored
value  the units of the object, or ""
none  value to which to set result if no appropriate attribute is found

Value

the units attribute of x, if any; otherwise, the units attribute of the tspar attribute of x if any; otherwise the value none. Handling for Surv objects is different (see above).

See Also

label
**Examples**

```r
fail.time <- c(10, 20)
units(fail.time) <- "Day"
describe(fail.time)
S <- Surv(fail.time)
units(S)

label(fail.time) <- 'Failure Time'
fail.time
```

---

**Description**

cleanup.import will correct errors and shrink the size of data frames. By default, double precision numeric variables are changed to integer when they contain no fractional components. Infinite values or values greater than 1e20 in absolute value are set to NA. This solves problems of importing Excel spreadsheets that contain occasional character values for numeric columns, as S converts these to Inf without warning. There is also an option to convert variable names to lower case and to add labels to variables. The latter can be made easier by importing a CNTLOUT dataset created by SAS PROC FORMAT and using the sasdict option as shown in the example below. cleanup.import can also transform character or factor variables to dates.

upData is a function facilitating the updating of a data frame without attaching it in search position one. New variables can be added, old variables can be modified, variables can be removed or renamed, and "labels" and "units" attributes can be provided. Various checks are made for errors and inconsistencies, with warnings issued to help the user. Levels of factor variables can be replaced, especially using the list notation of the standard merge.levels function. Unless force.single is set to FALSE, upData also converts double precision vectors to integer if no fractional values are present in a vector. upData is also used to process R workspace objects created by StatTransfer, which puts variable and value labels as attributes on the data frame rather than on each variable. If such attributes are present, they are used to define all the labels and value labels (through conversion to factor variables) before any label changes take place, and force.single is set to a default of FALSE, as StatTransfer already does conversion to integer.

Variables having labels but not classed "labelled" (e.g., data imported using the haven package) have that class added to them by upData.

The dataframesreduce function removes variables from a data frame that are problematic for certain analyses. Variables can be removed because the fraction of missing values exceeds a threshold, because they are character or categorical variables having too many levels, or because they are binary and have too small a prevalence in one of the two values. Categorical variables can also have their levels combined when a level is of low prevalence.

**Usage**

```r
cleanup.import(obj, labels, lowernames=FALSE, force.single=TRUE, force.numeric=TRUE, rmnames=TRUE,
```

---

**Update a Data Frame or Cleanup a Data Frame after Importing**

**Description**

cleanup.import will correct errors and shrink the size of data frames. By default, double precision numeric variables are changed to integer when they contain no fractional components. Infinite values or values greater than 1e20 in absolute value are set to NA. This solves problems of importing Excel spreadsheets that contain occasional character values for numeric columns, as S converts these to Inf without warning. There is also an option to convert variable names to lower case and to add labels to variables. The latter can be made easier by importing a CNTLOUT dataset created by SAS PROC FORMAT and using the sasdict option as shown in the example below. cleanup.import can also transform character or factor variables to dates.

upData is a function facilitating the updating of a data frame without attaching it in search position one. New variables can be added, old variables can be modified, variables can be removed or renamed, and "labels" and "units" attributes can be provided. Various checks are made for errors and inconsistencies, with warnings issued to help the user. Levels of factor variables can be replaced, especially using the list notation of the standard merge.levels function. Unless force.single is set to FALSE, upData also converts double precision vectors to integer if no fractional values are present in a vector. upData is also used to process R workspace objects created by StatTransfer, which puts variable and value labels as attributes on the data frame rather than on each variable. If such attributes are present, they are used to define all the labels and value labels (through conversion to factor variables) before any label changes take place, and force.single is set to a default of FALSE, as StatTransfer already does conversion to integer.

Variables having labels but not classed "labelled" (e.g., data imported using the haven package) have that class added to them by upData.

The dataframesreduce function removes variables from a data frame that are problematic for certain analyses. Variables can be removed because the fraction of missing values exceeds a threshold, because they are character or categorical variables having too many levels, or because they are binary and have too small a prevalence in one of the two values. Categorical variables can also have their levels combined when a level is of low prevalence.

**Usage**

```r
cleanup.import(obj, labels, lowernames=FALSE, force.single=TRUE, force.numeric=TRUE, rmnames=TRUE,
```
upData(object, ...,
   subset, rename, drop, keep, labels, units, levels, force.single=TRUE,
   lowernames=FALSE, caplabels=FALSE, moveUnits=FALSE,
   charfactor=FALSE, print=TRUE, html=FALSE)

dataframeReduce(data, fracmiss=1, maxlevels=NULL, minprev=0, print=TRUE)

Arguments

obj a data frame or list
object a data frame or list
data a data frame
force.single By default, double precision variables are converted to single precision (in S-Plus only) unless force.single=FALSE. force.single=TRUE will also convert vectors having only integer values to have a storage mode of integer, in R or S-Plus.
force.numeric Sometimes importing will cause a numeric variable to be changed to a factor vector. By default, cleanup.import will check each factor variable to see if the levels contain only numeric values and "". In that case, the variable will be converted to numeric, with "" converted to NA. Set force.numeric=FALSE to prevent this behavior.
rmnames set to ‘F’ to not have ‘cleanup.import’ remove ‘names’ or ‘.Names’ attributes from variables
labels a character vector the same length as the number of variables in obj. These character values are taken to be variable labels in the same order of variables in obj. For upData, labels is a named list or named vector with variables in no specific order.
lowernames set this to TRUE to change variable names to lower case. upData does this before applying any other changes, so variable names given inside arguments to upData need to be lower case if lowernames==TRUE.
big a value such that values larger than this in absolute value are set to missing by cleanup.import
sasdict the name of a data frame containing a raw imported SAS PROC CONTENTS CNTLOUT= dataset. This is used to define variable names and to add attributes to the new data frame specifying the original SAS dataset name and label.
print set to TRUE or FALSE to force or prevent printing of the current variable number being processed. By default, such messages are printed if the product of the number of variables and number of observations in obj exceeds 500,000. For dataframeReduce set print to FALSE to suppress printing information about dropped or modified variables. Similar for upData.
**datevars** character vector of names (after `lowernames` is applied) of variables to consider as a factor or character vector containing dates in a format matching `dateformat`. The default is "%F" which uses the yyyy-mm-dd format.

**datetimevars** character vector of names (after `lowernames` is applied) of variables to consider to be date-time variables, with date formats as described under `datevars` followed by a space followed by time in hh:mm:ss format. `chron` is used to store date-time variables. If all times in the variable are 00:00:00 the variable will be converted to an ordinary date variable.

**dateformat** for `cleanup.import` is the input format (see `strptime`)

**fixdates** for any of the variables listed in `datevars` that have a `dateformat` that `cleanup.import` understands, specifying `fixdates` allows corrections of certain formatting inconsistencies before the fields are attempted to be converted to dates (the default is to assume that the `dateformat` is followed for all observation for `datevars`). Currently `fixdates='year'` is implemented, which will cause 2-digit or 4-digit years to be shifted to the alternate number of digits when `dateform` is the default "%Y" or is "%y-%m-%d", "%m/%d/%y", or "%M/%D/%Y". Two-digits years are padded with 0 on the left. Set `dateformat` to the desired format, not the exceptional format.

**charfactor** set to TRUE to change character variables to factors if they have fewer than `n/2` unique values. Null strings and blanks are converted to NAs.

... for `upData`, one or more expressions of the form `variable=expression`, to derive new variables or change old ones.

**subset** an expression that evaluates to a logical vector specifying which rows of `object` should be retained. The expressions should use the original variable names, i.e., before any variables are renamed but after `lowernames` takes effect.

**rename** list or named vector specifying old and new names for variables. Variables are renamed before any other operations are done. For example, to rename variables `age` and `sex` to respectively `age` and `gender`, specify `rename=list(age="Age", sex="gender")` or `rename=c(age=...)`.

**drop** a vector of variable names to remove from the data frame

**keep** a vector of variable names to keep, with all other variables dropped

**units** a named vector or list defining "units" attributes of variables, in no specific order

**levels** a named list defining "levels" attributes for factor variables, in no specific order. The values in this list may be character vectors redefining `levels` (in order) or another list (see `merge.levels` if using S-Plus).

**caplabels** set to TRUE to capitalize the first letter of each word in each variable label

**moveUnits** set to TRUE to look for units of measurements in variable labels and move them to a "units" attribute. If an expression in a label is enclosed in parentheses or brackets it is assumed to be units if `moveUnits=TRUE`.

**html** set to TRUE to print conversion information as html vertabim at 0.6 size. The user will need to put `results='asis'` in a knitr chunk header to properly render this output.

**fracmiss** the maximum permissable proportion of NAs for a variable to be kept. Default is to keep all variables no matter how many NAs are present.
maxlevels  the maximum number of levels of a character or categorical or factor variable before the variable is dropped

minprev  the minimum proportion of non-missing observations in a category for a binary variable to be retained, and the minimum relative frequency of a category before it will be combined with other small categories

Value

a new data frame

upFirst

Change First Letters to Upper Case

Description

Changes the first letter of each word in a string to upper case, keeping selected words in lower case. Words containing at least 2 capital letters are kept as-is.

Usage

upFirst(txt, lower = FALSE, alllower = FALSE)

Arguments

txt a character vector
lower set to TRUE to make only the very first letter of the string upper case, and to keep words with at least 2 capital letters in their original form
alllower set to TRUE to make every word start with lower case unless it has at least 2 caps

References

http://en.wikipedia.org/wiki/Letter_case#Headings_and_publication_titles

Examples

upFirst(c('this and that','that is Beyond question'))

valueTags

Store Descriptive Information About an Object

Description

Functions get or set useful information about the contents of the object for later use.

Usage

valueTags(x)
valueTags(x) <- value

valueLabel(x)
valueLabel(x) <- value

valueName(x)
valueName(x) <- value

valueUnit(x)
valueUnit(x) <- value
Arguments

x an object
value for valueTags<- a named list of value tags. a character vector of length 1, or NULL.

Details

These functions store the a short name of for the contents, a longer label that is useful for display, and the units of the contents that is useful for display.

valueTag is an accessor, and valueTag<- is a replacement function for all of the value’s information.

valueName is an accessor, and valueName<- is a replacement function for the value’s name. This name is used when a plot or a latex table needs a short name and the variable name is not useful.

valueLabel is an accessor, and valueLabel<- is a replacement function for the value’s label. The label is used in a plots or latex tables when they need a descriptive name.

valueUnit is an accessor, and valueUnit<- is a replacement function for the value’s unit. The unit is used to add unit information to the R output.

Value

valueTag returns NULL or a named list with each of the named values name, label, unit set if they exists in the object.
For valueTag<- returns list
For valueName, valueLabel, and valueUnit returns NULL or character vector of length 1.
For valueName<-, valueLabel<-, and valueUnit returns value

x1 <- 1:10
x2 <- 10:1
valueLabel(x2) <- 'Label for x2'
valueUnit(x2) <- 'mmHg'
x2
### Description

Does a hierarchical cluster analysis on variables, using the Hoeffding D statistic, squared Pearson or Spearman correlations, or proportion of observations for which two variables are both positive as similarity measures. Variable clustering is used for assessing collinearity, redundancy, and for separating variables into clusters that can be scored as a single variable, thus resulting in data reduction. For computing any of the three similarity measures, pairwise deletion of NAs is done. The clustering is done by `hclust()`. A small function `naclus` is also provided which depicts similarities in which observations are missing for variables in a data frame. The similarity measure is the fraction of NAs in common between any two variables. The diagonals of this `sim` matrix are the fraction of NAs in each variable by itself. `naclus` also computes `na_per_obs`, the number of missing variables in each observation, and `mean_na`, a vector whose ith element is the mean number of missing variables other than variable i, for observations in which variable i is missing. The `naplot` function makes several plots (see the `which` argument).

So as to not generate too many dummy variables for multi-valued character or categorical predictors, `varclus` will automatically combine infrequent cells of such variables using an auxiliary function `combine.levels` that is defined here. If all values of x are NA, `combine.levels` returns a numeric vector is returned that is all NA.

`plotMultSim` plots multiple similarity matrices, with the similarity measure being on the x-axis of each subplot.

`na_pattern` prints a frequency table of all combinations of missingness for multiple variables. If there are 3 variables, a frequency table entry labeled 110 corresponds to the number of observations for which the first and second variables were missing but the third variable was not missing.

### Usage

```r
varclus(x, similarity=c("spearman","pearson","hoeffding","bothpos","ccbothpos"),
type=c("data.matrix","similarity.matrix"),
method="complete",
data=NULL, subset=NULL, na.action=na.retain,
trans=c("square", "abs", "none"), ...)
```

## S3 method for class 'varclus'

```r
print(x, abbrev=FALSE, ...)
```
## S3 method for class 'varclus'

```r
gclus(df, method)
naplot(obj, which=c('all','na per var','na per obs','mean na',
                      'na per var vs mean na'), ...)

combine.levels(x, minlev=.05)

plotMultSim(s, x=1:dim(s)[3],
            slim=range(pretty(c(0,max(s,na.rm=TRUE)))),
            slimds=FALSE,
            add=FALSE, lty=par('lty'), col=par('col'),
            lwd=par('lwd'), vname=NULL, h=.5, w=.75, u=.05,
            labelx=TRUE, xspace=.35)

na.pattern(x)
```

### Arguments

#### x

- a formula, a numeric matrix of predictors, or a similarity matrix. If `x` is a formula, `model.matrix` is used to convert it to a design matrix. If the formula excludes an intercept (e.g., `~ a + b -1`), the first categorical (factor) variable in the formula will have dummy variables generated for all levels instead of omitting one for the first level. For `combine.levels`, `x` is a character, category, or factor vector (or other vector that is converted to factor). For `plot` and `print`, `x` is an object created by `varclus`. For `na.pattern`, `x` is a list, data frame, or numeric matrix.

For `plotMultSim`, is a numeric vector specifying the ordered unique values on the x-axis, corresponding to the third dimension of `s`.

#### df

- a data frame

#### s

- an array of similarity matrices. The third dimension of this array corresponds to different computations of similarities. The first two dimensions come from a single similarity matrix. This is useful for displaying similarity matrices computed by `varclus`, for example. A use for this might be to show pairwise similarities of variables across time in a longitudinal study (see the example below). If `vname` is not given, `s` must have dimnames.

#### similarity

- the default is to use squared Spearman correlation coefficients, which will detect monotonic but nonlinear relationships. You can also specify linear correlation or Hoeffding’s (1948) D statistic, which has the advantage of being sensitive to many types of dependence, including highly non-monotonic relationships. For binary data, or data to be made binary, `similarity="bothpos"` uses as a similarity measure the proportion of observations for which two variables are both positive. `similarity="ccbothpos"` uses a chance-corrected measure which is the proportion of observations for which both variables are positive minus the product of the two marginal proportions. This difference is expected to be zero under independence. For diagonals, `"ccbothpos"` still uses the proportion of positives for the single variable. So "ccbothpos" is not really a similarity...
measure, and clustering is not done. This measure is useful for plotting with plotMultSim (see the last example).

**type**

If x is not a formula, it may be a data matrix or a similarity matrix. By default, it is assumed to be a data matrix.

**method**

See hclust. The default, for both varclus and naclus, is "compact" (for R it is "complete").

**data**

These may be specified if x is a formula. The default na.action is na.retain, defined by varclus. This causes all observations to be kept in the model frame, with later pairwise deletion of NAs.

**subset**

By default, when the similarity measure is based on Pearson’s or Spearman’s correlation coefficients, the coefficients are squared. Specify trans="abs" to take absolute values or trans="none" to use the coefficients as they stand.

... for varclus these are optional arguments to pass to the dataframeReduce function. Otherwise, passed to plclust (or to dotchart or dotchart2 for naplot).

**ylab**

Y-axis label. Default is constructed on the basis of similarity.

**legend**

Set to TRUE to plot a legend defining the abbreviations

**loc**

A list with elements x and y defining coordinates of the upper left corner of the legend. Default is locator(1).

**maxlen**

If a legend is plotted describing abbreviations, original labels longer than maxlen characters are truncated at maxlen.

**labels**

A vector of character strings containing labels corresponding to columns in the similar matrix, if the column names of that matrix are not to be used

**obj**

An object created by naclus

**which**

Defaults to "all" meaning to have naplot make 4 separate plots. To make only one of the plots, use which="na_per_var" (dot chart of fraction of NAs for each variable), "na_per_obs" (dot chart showing frequency distribution of number of variables having NAs in an observation), "mean_na" (dot chart showing mean number of other variables missing when the indicated variable is missing), or "na_per_var vs mean na", a scatterplot showing on the x-axis the fraction of NAs in the variable and on the y-axis the mean number of other variables that are NA when the indicated variable is NA.

**minlev**

The minimum proportion of observations in a cell before that cell is combined with one or more cells. If more than one cell has fewer than minlev*n observations, all such cells are combined into a new cell labeled "OTHER". Otherwise, the lowest frequency cell is combined with the next lowest frequency cell, and the level name is the combination of the two old level levels.

**abbrev**

Set to TRUE to abbreviate variable names for plotting or printing. Is set to TRUE automatically if legend=TRUE.

**slim**

2-vector specifying the range of similarity values for scaling the y-axes. By default this is the observed range over all of s.

**slimds**

Set to slimds to TRUE to scale diagonals and off-diagonals separately
add

set to TRUE to add similarities to an existing plot (usually specifying lty or col)

lty
col

lwd

line type, color, or line thickness for plotMultSim

vname

optional vector of variable names, in order, used in s

h

relative height for subplot

w

relative width for subplot

u

relative extra height and width to leave unused inside the subplot. Also used as the space between y-axis tick mark labels and graph border.

labelx

set to FALSE to suppress drawing of labels in the x direction

xspace

amount of space, on a scale of 1:n where n is the number of variables, to set aside for y-axis labels

Details

options(contrasts= c("contr.treatment", "contr.poly")) is issued temporarily by varclus to make sure that ordinary dummy variables are generated for factor variables. Pass arguments to the dataframeReduce function to remove problematic variables (especially if analyzing all variables in a data frame).

Value

for varclus or naclus, a list of class varclus with elements call (containing the calling statement), sim (similarity matrix), n (sample size used if x was not a correlation matrix already - n is a matrix), hclust, the object created by hclust, similarity, and method. naclus also returns the two vectors listed under description, and naplot returns an invisible vector that is the frequency table of the number of missing variables per observation. plotMultSim invisibly returns the limits of similarities used in constructing the y-axes of each subplot. For similarity="ccbothpos" the hclust object is NULL.

na.pattern creates an integer vector of frequencies.

Side Effects

plots

**wtd.stats**

*Weighted Statistical Estimates*

**Description**

These functions compute various weighted versions of standard estimators. In most cases the weights vector is a vector the same length of x, containing frequency counts that in effect expand x by these counts. weights can also be sampling weights, in which setting normwt to TRUE will often be appropriate. This results in making weights sum to the length of the non-missing elements in x. normwt=TRUE thus reflects the fact that the true sample size is the length of the x vector and not the sum of the original values of weights (which would be appropriate had normwt=FALSE). When weights is all ones, the estimates are all identical to unweighted estimates (unless one of the non-default quantile estimation options is specified to wtd.quantile). When missing data have already been deleted for, x, weights, and (in the case of wtd.loess.noiter) y, specifying na.rm=FALSE will save computation time. Omitting the weights argument or specifying NULL or a zero-length vector will result in the usual unweighted estimates.

wtd.mean, wtd.var, and wtd.quantile compute weighted means, variances, and quantiles, respectively. wtd.Ecdf computes a weighted empirical distribution function. wtd.table computes a weighted frequency table (although only one stratification variable is supported at present). wtd.rank computes weighted ranks, using mid–ranks for ties. This can be used to obtain Wilcoxon tests and rank correlation coefficients. wtd.loess.noiter is a weighted version of loess.smooth when no iterations for outlier rejection are desired. This results in especially good smoothing when y is binary. wtd.quantile removes any observations with zero weight at the beginning. Previously, these were changing the quantile estimates.

num.denom.setup is a utility function that allows one to deal with observations containing numbers of events and numbers of trials, by outputting two observations when the number of events and
non-events (trials - events) exceed zero. A vector of subscripts is generated that will do the proper
duplications of observations, and a new binary variable \( y \) is created along with usual cell frequencies
(weights) for each of the \( y=0, y=1 \) cells per observation.

Usage

\[
\begin{align*}
\text{wtd.mean}(x, \text{weights=NULL, normwt=}$\text{"ignored", na.rm=TRUE}) \\
\text{wtd.var}(x, \text{weights=NULL, normwt=}$\text{FALSE, na.rm=TRUE, } \\
\text{method=c('unbiased', 'ML'))} \\
\text{wtd.quantile}(x, \text{weights=NULL, probs=c(0, .25, .5, .75, 1), } \\
\text{type=c('quantile','(i-1)/(n-1)', 'i/(n+1)', 'i/n'), } \\
\text{normwt=FALSE, na.rm=TRUE}) \\
\text{wtd.Ecdf}(x, \text{weights=NULL, } \\
\text{type=c('i/n', '(i-1)/(n-1)', 'i/(n+1)'), } \\
\text{normwt=FALSE, na.rm=TRUE}) \\
\text{wtd.table}(x, \text{weights=NULL, type=c('list', 'table'), } \\
\text{normwt=FALSE, na.rm=TRUE}) \\
\text{wtd.rank}(x, \text{weights=NULL, normwt=FALSE, na.rm=TRUE}) \\
\text{wtd.loess.noiter}(x, y, \text{weights=rep(1,n), } \\
\text{span=2/3, degree=1, cell=.1333, } \\
\text{type=c('all', 'ordered all', 'evaluate'), } \\
\text{evaluation=100, na.rm=TRUE}) \\
\text{num.denom.set}\text{up}(\text{num, denom})
\end{align*}
\]

Arguments

\( x \) a numeric vector (may be a character or category or factor vector for \text{wtd.table})
\( \text{num} \) vector of numerator frequencies
\( \text{denom} \) vector of denominators (numbers of trials)
\( \text{weights} \) a numeric vector of weights
\( \text{normwt} \) specify \( \text{normwt=TRUE} \) to make weights sum to \( \text{length}(x) \) after deletion of NAs.
If \( \text{weights} \) are frequency weights, then \( \text{normwt} \) should be \( \text{FALSE} \), and if \( \text{weights} \) are normalization (aka reliability) weights, then \( \text{normwt} \) should be \( \text{TRUE} \). In the case of the former, no check is made that weights are valid frequencies.
\( \text{na.rm} \) set to \( \text{FALSE} \) to suppress checking for NAs
\( \text{method} \) determines the estimator type; if 'unbiased' (the default) then the usual unbiased estimate (using Bessel’s correction) is returned, if 'ML' then it is the maximum likelihood estimate for a Gaussian distribution. In the case of the latter, the \( \text{normwt} \) argument has no effect. Uses \text{stats}::\text{cov.wt} for both methods.
\( \text{probs} \) a vector of quantiles to compute. Default is 0 (min), .25, .5, .75, 1 (max).
\( \text{type} \) For \text{wtd.quantile}, type defaults to quantile to use the same interpolated order statistic method as quantile. Set type to "(i-1)/(n-1)","i/(n+1)" or "i/n" to use the inverse of the empirical distribution function, using, respectively, \( (wt - 1)/T, wt/(T+1) \), or \( wt/T \), where \( wt \) is the cumulative weight and \( T \) is the total weight (usually total sample size). These three values of type are the possibilities for \text{wtd.Ecdf}. For \text{wtd.table} the default type is "list", meaning that the function is to return a list containing two vectors: \( x \) is the sorted
unique values of \( x \) and \( \text{sum.of.weights} \) is the sum of weights for that \( x \). This is
the default so that you don't have to convert the \text{names} attribute of the result that can be obtained with \text{type}="table" to a numeric variable when \( x \) was
originally numeric. \text{type}="table" for \text{wtd.table} results in an object that is
the same structure as those returned from \text{table}. For \text{wtd.loess.noiter} the
default type is "all", indicating that the function is to return a list containing all
the original values of \( x \) (including duplicates and without sorting) and the
smoothed \( y \) values corresponding to them. Set \text{type}="ordered all" to sort by
\( x \), and \text{type}="evaluate" to evaluate the smooth only at evaluation equally
spaced points between the observed limits of \( x \).

\( y \)
a numeric vector the same length as \( x \)
\( \text{span}, \text{degree}, \text{cell}, \text{evaluation} \)
see \text{loess.smooth}. The default is linear (\text{degree}=1) and 100 points to evalua-
tion (if \text{type}="evaluate").

Details
The functions correctly combine weights of observations having duplicate values of \( x \) before com-
puting estimates.

When \text{normwt}=\text{FALSE} the weighted variance will not equal the unweighted variance even if the
weights are identical. That is because of the subtraction of 1 from the sum of the weights in the
denominator of the variance formula. If you want the weighted variance to equal the unweighted
variance when weights do not vary, use \text{normwt}=\text{TRUE}. The articles by Gatz and Smith discuss
alternative approaches, to arrive at estimators of the standard error of a weighted mean.

\text{wtd.rank} does not handle NAs as elegantly as \text{rank} if \text{weights} is specified.

Value
\text{wtd.mean} and \text{wtd.var} return scalars. \text{wtd.quantile} returns a vector the same length as \text{probs}.
\text{wtd.ecdf} returns a list whose elements \( x \) and \text{ecdf} correspond to unique sorted values of \( x \). If the
first CDF estimate is greater than zero, a point (\text{min}(x),0) is placed at the beginning of the estimates.
See above for \text{wtd.table}. \text{wtd.rank} returns a vector the same length as \( x \) (after removal of NAs,
depending on \text{na.rm}). See above for \text{wtd.loess.noiter}.

xtfrm.labelled

Auxiliary Function Method for Sorting and Ranking

Description

An auxiliary function method that is a workaround for bug in the implementation of xtfrm handles inheritance.

Usage

## S3 method for class 'labelled'
xtfrm(x)

Arguments

x any object of class labelled.

See Also

xtfrm

xy.group

Mean x vs. function of y in groups of x

Description

Compute mean x vs. a function of y (e.g. median) by quantile groups of x or by x grouped to have a given average number of observations. Deletes NAs in x and y before doing computations.

Usage

xy.group(x, y, m=150, g, fun=mean, result="list")
Arguments

- **x**: a vector, may contain NAs
- **y**: a vector of same length as x, may contain NAs
- **m**: number of observations per group
- **g**: number of quantile groups
- **fun**: function of y such as median or mean (the default)
- **result**: "list" (the default), or "matrix"

Value

If result="list", a list with components x and y suitable for plotting. If result="matrix", matrix with rows corresponding to x-groups and columns named n, x, and y.

See Also

cut2, tapply

Examples

```r
# plot(xy.group(x, y, g=10)) #Plot mean y by deciles of x
# xy.group(x, y, m=100, result="matrix") #Print table, 100 obs/group
```

Description

A utility function `cbind` returns the first argument as a vector and combines all other arguments into a matrix stored as an attribute called "other". The arguments can be named (e.g., `cbind(pressure=y, ylow, yhigh)`) or a label attribute may be pre-attached to the first argument. In either case, the name or label of the first argument is stored as an attribute "label" of the object returned by `cbind`. Storing other vectors as a matrix attribute facilitates plotting error bars, etc., as `trellis` really wants the x- and y-variables to be vectors, not matrices. If a single argument is given to `cbind` and that argument is a matrix with column names, the first column is taken as the main vector and remaining columns are taken as "other". A subscript method for `cbind` objects subscripts the other matrix along with the main y vector.

The `xyplot` function is a substitute for `xyplot` that allows for simulated multi-column y. It uses by default the panel.xyplot and `prepanel.xyplot` functions to do the actual work. The method argument passed to `panel.xyplot` from `xyplot` allows you to make error bars, the upper-only or lower-only portions of error bars, alternating lower-only and upper-only bars, bands, or filled bands. `panel.xyplot` decides how to alternate upper and lower bars according to whether the median y value of the current main data line is above the median y for all groups of lines or not. If the median is above the overall median, only the upper bar is drawn. For bands (but not 'filled bands'), any number of other columns of y will be drawn as lines having the same thickness, color, and type as the main data line. If plotting bars, bands, or filled bands and only one additional column is
specified for the response variable, that column is taken as the half width of a precision interval for $y$, and the lower and upper values are computed automatically as $y$ plus or minus the value of the additional column variable.

When a groups variable is present, panel.xYplot will create a function in frame 0 (.GlobalEnv in R) called Key that when invoked will draw a key describing the groups labels, point symbols, and colors. By default, the key is outside the graph. For S-Plus, if Key(locator(1)) is specified, the key will appear so that its upper left corner is at the coordinates of the mouse click. For R/Lattice the first two arguments of Key (x and y) are fractions of the page, measured from the lower left corner, and the default placement is at $x=0.05$, $y=0.95$. For R, an optional argument to sKey, other, may contain a list of arguments to pass to draw.key (see xYplot for a list of possible arguments, under the key option).

When method="quantile" is specified, xYplot automatically groups the x variable into intervals containing a target of nx observations each, and within each x group computes three quantiles of y and plots these as three lines. The mean $x$ within each $x$ group is taken as the $x$-coordinate. This will make a useful empirical display for large datasets in which scatterdiagrams are too busy to see patterns of central tendency and variability. You can also specify a general function of a data vector that returns a matrix of statistics for the method argument. Arguments can be passed to that function via a list methodArgs. The statistic in the first column should be the measure of central tendency. Examples of useful method functions are those listed under the help file for summary.formula such as smean.cl.normal.

xYplot can also produce bubble plots. This is done when size is specified to xYplot. When size is used, a function sKey is generated for drawing a key to the character sizes. See the bubble plot example. size can also specify a vector where the first character of each observation is used as the plotting symbol, if rangeCex is set to a single cex value. An optional argument to sKey, other, may contain a list of arguments to pass to draw.key (see xYplot for a list of possible arguments, under the key option). See the bubble plot example.

Dotplot is a substitute for dotplot allowing for a matrix x-variable, automatic superpositioning when groups is present, and creation of a Key function. When the x-variable (created by Cbind to simulate a matrix) contains a total of 3 columns, the first column specifies where the dot is positioned, and the last 2 columns specify starting and ending points for intervals. The intervals are shown using line type, width, and color from the trellis plot.line list. By default, you will usually see a darker line segment for the low and high values, with the dotted reference line elsewhere. A good choice of the pch argument for such plots is 3 (plus sign) if you want to emphasize the interval more than the point estimate. When the x-variable contains a total of 5 columns, the 2nd and 5th columns are treated as the 2nd and 3rd are treated above, and the 3rd and 4th columns define an inner line segment that will have twice the thickness of the outer segments. In addition, tick marks separate the outer and inner segments. This type of display (an example of which appeared in The Elements of Graphing Data by Cleveland) is very suitable for displaying two confidence levels (e.g., 0.9 and 0.99) or the 0.05, 0.25, 0.75, 0.95 sample quantiles, for example. For this display, the central point displays well with a default circle symbol.

setTrellis sets nice defaults for Trellis graphics, assuming that the graphics device has already been opened if using postscript, etc. By default, it sets panel strips to blank and reference dot lines to thickness 1 instead of the Trellis default of 2.

numericScale is a utility function that facilitates using xYplot to plot variables that are not considered to be numeric but which can readily be converted to numeric using as.numeric(). numericScale by default will keep the name of the input variable as a label attribute for the new numeric variable.
Usage

Cbind(...)

xyplot(formula, data = sys.frame(sys.parent()), groups,
       subset, xlab=NULL, ylab=NULL, ylim=NULL,
       panel=panel.xyplot, prepanel=prepanel.xyplot, scales=NULL,
       minor.ticks=NULL, sub=NULL, ...)

panel.xyplot(x, y, subscripts, groups=NULL,
              type=if(is.function(method) || method=='quantiles')
                  'b' else 'p',
              method=c("bars", "bands", "upper bars", "lower bars",
                       "alt bars", "quantiles", "filled bands"),
              methodArgs=NULL, label.curves=TRUE, abline,
              probs=c(.5,.25,.75), nx=NULL,
              cap=0.015, lty.bar=1,
              lwd=plot.line$lwd, lty=plot.line$lty, pch=plot.symbol$pch,
              cex=plot.symbol$cex, font=plot.symbol$font, col=NULL,
              lwd.bands=NULL, lty.bands=NULL, col.bands=NULL,
              minor.ticks=NULL, col.fill=NULL,
              size=NULL, rangeCex=c(.5,3), ...)

prepanel.xyplot(x, y, ...)

dotplot(formula, data = sys.frame(sys.parent()), groups, subset,
        xlab = NULL, ylab = NULL, ylim = NULL,
        panel=panel.Dotplot, prepanel=prepanel.Dotplot,
        scales=NULL, xscale=NULL, ...)

prepanel.Dotplot(x, y, ...)

panel.Dotplot(x, y, groups = NULL,
              pch = dot.symbol$pch,
              col = dot.symbol$col, cex = dot.symbol$cex,
              font = dot.symbol$font, abline, ...)

setTrellis(strip.blank=TRUE, lty.dot.line=2, lwd.dot.line=1)

numericScale(x, label=NULL, ...)

Arguments

... for Cbind ... is any number of additional numeric vectors. Unless you are
using Dotplot (which allows for either 2 or 4 "other" variables) or xyplot with
method="bands", vectors after the first two are ignored. If drawing bars and
only one extra variable is given in ..., upper and lower values are computed
as described above. If the second argument to Cbind is a matrix, that matrix is
stored in the "other" attribute and arguments after the second are ignored. For
bubble plots, name an argument cex.
Also can be other arguments to pass to labcurve.

formula
a trellis formula consistent with xyplot or dotplot

x
x-axis variable. For numericScale x is any vector such as as.numeric(x) returns a numeric vector suitable for x- or y-coordinates.

y
a vector, or an object created by Cbind for xyplot. y represents the main variable to plot, i.e., the variable used to draw the main lines. For Dotplot the first argument to Cbind will be the main x-axis variable.

data, subset, ylim, subscripts, groups, type, scales, panel, prepanel, xlab, ylab
see trellis.args. xlab and ylab get default values from "label" attributes.

xscale
allows one to use the default scales but specify only the x component of it for Dotplot

method
defaults to "bars" to draw error-bar type plots. See meaning of other values above. method can be a function. Specifying method=quantile, methodArgs=list(probs=c(.5,.25,.75)) is the same as specifying method="quantile" without specifying probs.

methodArgs
a list containing optional arguments to be passed to the function specified in method

label.curves
set to FALSE to suppress invocation of labcurve to label primary curves where they are most separated or to draw a legend in an empty spot on the panel. You can also set label.curves to a list of options to pass to labcurve. These options can also be passed as ... to xyplot. See the examples below.

abline
a list of arguments to pass to panel.abline for each panel, e.g. list(a=0, b=1, col=3) to draw the line of identity using color 3. To make multiple calls to panel.abline, pass a list of unnamed lists as abline, e.g., abline=list(list(h=0),list(v=1)).

probs
a vector of three quantiles with the quantile corresponding to the central line listed first. By default probs=c(.5,.25,.75). You can also specify probs through methodArgs=list(probs=...).

nx
number of target observations for each x group (see cut2 m argument). nx defaults to the minimum of 40 and the number of points in the current stratum divided by 4. Set nx=FALSE or nx=0 if x is already discrete and requires no grouping.

cap
the half-width of horizontal end pieces for error bars, as a fraction of the length of the x-axis

lty.bar
line type for bars

lwd, lty, pch, cex, font, col
see trellis.args. These are vectors when groups is present, and the order of their elements corresponds to the different groups, regardless of how many bands or bars are drawn. If you don't specify lty.bands, for example, all band lines within each group will have the same lty.

lty.bands, lwd.bands, col.bands
used to allow lty, lwd, col to vary across the different band lines for different groups. These parameters are vectors or lists whose elements correspond to the added band lines (i.e., they ignore the central line, whose line characteristics are
defined by lty, lwd, col). For example, suppose that 4 lines are drawn in addition to the central line. Specifying lwd.bands=1:4 will cause line widths of 1:4 to be used for every group, regardless of the value of lwd. To vary characteristics over the groups use e.g. lwd.bands=list(rep(1,4), rep(2,4)) or list(c(1,2,1,2), c(3,4,3,4)).

minor.ticks a list with elements at and labels specifying positions and labels for minor tick marks to be used on the x-axis of each panel, if any.

sub an optional subtitle

col.fill used to override default colors used for the bands in method='filled bands'. This is a vector when groups is present, and the order of the elements corresponds to the different groups, regardless of how many bands are drawn. The default colors for 'filled bands' are pastel colors matching the default colors superpose.line$col (plot.line$col)

size a vector the same length as x giving a variable whose values are a linear function of the size of the symbol drawn. This is used for example for bubble plots.

rangeCex a vector of two values specifying the range in character sizes to use for the size variable (lowest first, highest second). size values are linearly translated to this range, based on the observed range of size when x and y coordinates are not missing. Specify a single numeric cex value for rangeCex to use the first character of each observations’s size as the plotting symbol.

strip.blank set to FALSE to not make the panel strip backgrounds blank

lty.dot.line line type for dot plot reference lines (default = 1 for dotted; use 2 for dotted)

lwd.dot.line line thickness for reference lines for dot plots (default = 1)

label a scalar character string to be used as a variable label after numericScale converts the variable to numeric form

Details

Unlike xyplot, xyplot senses the presence of a groups variable and automatically invokes panel.superpose instead of panel.xyplot. The same is true for Dotplot vs. dotplot.

Value

Cbind returns a matrix with attributes. Other functions return standard trellis results.

Side Effects

plots, and panel.xyplot may create temporary Key and sKey functions in the session frame.

# A good way to check for stable variance of residuals from ols
# xyplot(resid(fit) ~ fitted(fit), method=smean.sdl)
# smean.sdl is defined with summary.formula in Hmisc

# Plot y vs. a special variable x
# xyplot(y ~ numericScale(x, label='Label for X') | country)
# For this example could omit label= and specify
# y ~ numericScale(x) | country, xlab='Label for X'

# Here is an example of using xyplot with several options
# to change various Trellis parameters,
# xyplot(y ~ x | z, groups=v, pch=c('1','2','3'),
s <- summarize(y, llist(month, year), smedian.hilow, conf.int=.5)

setTrellis()  # blank conditioning panel backgrounds
Dotplot(month ~ Cbind(y, Lower, Upper) | year, data=s)
  # or Cbind(...), groups=year, data=s

# Display a 5-number (5-quantile) summary (2 intervals, dot=median)
# Note that summarize produces a matrix for y, and Cbind(y) trusts the
# first column to be the point estimate (here the median)
 s <- summarize(y, llist(month, year), quantile,
                 probs=c(.5,.05,.25,.75,.95), type='matrix')
Dotplot(month ~ Cbind(y) | year, data=s)
  # Use factor(year) to make actual years appear in conditioning title strips

# Plot proportions and their Wilson confidence limits
set.seed(3)
d <- expand.grid(continent=c('USA','Europe'),
                 year=1999:2001,
                 reps=1:100)
  # Generate binary events from a population probability of 0.2
  # of the event, same for all years and continents
  d$y <- ifelse(runif(6*100) <= .2, 1, 0)
s <- with(d,
           summarize(y, llist(continent, year),
                      function(y) {
                         n <- sum(!is.na(y))
                         s <- sum(y, na.rm=TRUE)
                         binconf(s, n)
                      }, type='matrix')
)
Dotplot(year ~ Cbind(y) | continent, data=s, ylab='Year',
         xlab='Probability')

# Dotplot(z ~ x | g1*g2)
# 2-way conditioning
# Dotplot(z ~ x | g1, groups=g2); Key()
# Key defines symbols for g2
If the data are organized so that the mean, lower, and upper confidence limits are in separate records, the Hmisc reShape function is useful for assembling these 3 values as 3 variables a single observation, e.g., assuming type has values such as c('Mean','Lower','Upper'):

```
a <- reShape(y, id=month, colvar=type)
```

This will make a matrix with 3 columns named Mean Lower Upper and with 1/3 as many rows as the original data.

---

### yearDays

**Get Number of Days in Year or Month**

#### Description

Returns the number of days in a specific year or month.

#### Usage

```
yearDays(time)
monthDays(time)
```

#### Arguments

- `time`: A POSIXt or Date object describing the month or year in question.

#### Author(s)

Charles Dupont

#### See Also

- `POSIXt`, `Date`

---

### ybind

**Combine Variables in a Matrix**
ynbind

Description

ynbind column binds a series of related yes/no variables, allowing for a final argument label used to label the panel created for the group. labels for individual variables are collected into a vector attribute "labels" for the result; original variable names are used in place of labels for those variables without labels. A positive response is taken to be y, yes, present (ignoring case) or a logical TRUE value. By default, the columns are sorted be ascending order or the overall proportion of positives. A subsetting method is provided for objects of class "ynbind".

pBlock creates a matrix similarly labeled, from a general set of variables (without special handling of binaries), and sets to NA any observation not in subset so that when that block of variables is analyzed it will be only for that subset.

Usage

ynbind(..., label = deparse(substitute(...)),
       asna = c("unknown", "unspecified"), sort = TRUE)

pBlock(..., subset=NULL, label = deparse(substitute(...)))

Arguments

... a series of vectors
label a label for the group, to be attached to the resulting matrix as a "label" attribute, used by summaryP.

asna a vector of character strings specifying levels that are to be treated the same as NA if present

sort set to FALSE to not sort the columns by their proportions

subset subset criteria - either a vector of logicals or subscripts

Value

a matrix of class "ynbind" or "pBlock" with "label" and "labels" attributes. For "pBlock", factor input vectors will have values converted to character.

Author(s)

Frank Harrell

See Also

summaryP

Examples

x1 <- c('yEs', 'no', 'UNKNOWN', NA)
x2 <- c('y', 'n', 'no', 'present')
label(x2) <- 'X2'
X <- ynbind(x1, x2, label='x1-2')
X[1:3,]
%nin%

Find Matching (or Non-Matching) Elements

Description

%nin% is a binary operator, which returns a logical vector indicating if there is a match or not for its left operand. A true vector element indicates no match in left operand, false indicates a match.

Usage

`x %nin% table`

Arguments

- `x`: a vector (numeric, character, factor)
- `table`: a vector (numeric, character, factor), matching the mode of `x`

Value

vector of logical values with length equal to length of `x`.

See Also

`match %in%`

Examples

```r
c('a','b','c') %nin% c('a','b')
```
