

# Package ‘IPEC’

May 14, 2017

**Type** Package

**Title** Root Mean Square Curvature Calculation

**Version** 0.0.9

**Date** 2017-05-14

**Author** Peijian Shi, Peter Ridland, David A. Ratkowsky

**Maintainer** Peijian Shi <peijianshi@gmail.com>

**Imports** numDeriv (>= 2016.8-1), MASS

**Description**

Calculates the RMS intrinsic and parameter-effects curvatures of a nonlinear regression model.

**License** GPL-2

**NeedsCompilation** no

**Repository** CRAN

**Date/Publication** 2017-05-14 17:29:10 UTC

biasIPEC

*Bias Calculation Function***Description**

Calculates the bias in the estimates of the parameters of a given nonlinear regression model.

**Usage**

```
biasIPEC(expr, theta, x, y, tol = .Machine$double.eps, method = "Richardson",
         method.args = list(eps = 1e-04, d = 0.11,
                             zero.tol = sqrt(.Machine$double.eps/7e-07), r = 6, v = 2,
                             show.details = FALSE), side = NULL)
```

**Arguments**

expr	A given nonlinear regression model
theta	Vector of parameters of the model
x	Vector or matrix of observations of independent variable(s)
y	Vector of observations of response variable
tol	The tolerance for detecting linear dependencies in the columns of a matrix for calculating its inverse. See the input argument of tol of the <a href="#">solve</a> function in package <b>base</b>
method	It is the same as the input argument of method of the <a href="#">hessian</a> function in package <b>numDeriv</b>
method.args	It is the same as the input argument of method.args of the <a href="#">hessian</a> function in package <b>numDeriv</b>
side	It is the same as the input argument of side of the <a href="#">jacobian</a> function in package <b>numDeriv</b>

**Details**

The defined model should have two input arguments: a parameter vector and an independent variable vector or matrix, e.g. `myfun <- function(P, x){...}`, where P represents the parameter vector and x represents the independent variable vector or matrix.

An absolute value of `percent.bias` (see below) in excess of **1%** appears to be a good rule of thumb for indicating nonlinear behavior (Ratkowsky 1983).

**Value**

bias	Calculated bias
percent.bias	Calculated percentage bias that is equal to <code>bias/estimate * 100%</code>

**Note**

The current function can be applicable to nonlinear models with multiple independent variables.

**Author(s)**

bootIPEC

*Bootstrap Function for Nonlinear Regression*

---

### Description

Generates the density distributions, standard deviations, confidence intervals, covariance matrices and correlation matrices of parameters based on bootstrap replications.

### Usage

```

bootIPEC( expr, x, y, ini.val, target.fun = "RSS", control = list(),
          nboot = 200, alpha = 0.05, fig.opt = TRUE, fold = 3.5,
          seed = NULL, unique.num = 2, prog.opt = TRUE )

```

### Arguments

expr	A given parametric model
x	Vector or matrix of observations of independent variable(s)
y	Vector of observations of response variable
ini.val	A vector or list of initial values of model parameters
target.fun	Objective function, "RSS" and "chi.sq", for the optimization
control	A list of control parameters for using the <code>optim</code> function in package <b>stats</b>
nboot	The number of bootstrap replications
alpha	The significance level for calculating the $(1-\alpha)*100\%$ confidence intervals of parameters
fig.opt	Option of drawing figures of the distributions of bootstrap values of parameters and figures of pairwise comparisons of bootstrap values
fold	Parameter reducing the extreme bootstrap values of parameters

seed	The number to specify a seed for generating a set of random numbers
unique.num	The least number of sampled non-overlapping data points for carrying out a bootstrap nonlinear regression
prog.opt	Option of showing the running progress of bootstrap

### Details

`ini.val` can be a vector or a list that has saved initial values for model parameters,

e.g.  $y = \text{beta0} + \text{beta1} * x + \text{beta2} * x^2$ ,

`ini.val = list(beta0=seq(5, 15, len=2), beta1=seq(0.1, 1, len=9), beta2=seq(0.01, 0.05, len=5))`, which is similar to the usage of the input argument of `start` of `nls` in package `stats`.

`alpha` determines the confidence intervals of parameters, each  $(1-\text{alpha}) * 100\%$ .

`fold` is used to delete the data whose differences from the median exceed a certain fold of the difference between 3/4 and 1/4 quantiles of the bootstrap values of a model parameter.

`seed` is used in the `set.seed` function in package `base`. If `seed` is assigned to be a specific integer, the users can obtain the same bootstrap values (standard deviation, median, mean, confidence interval) for repeating this function.

The default of `unique.num` is 2. That is, at least two non-overlapping data points randomly sampled from  $(x, y)$  are needed for carrying out a bootstrap nonlinear regression.

### Value

<code>M</code>	The matrix saving the fitted results of all <code>nboot</code> bootstrap values of model parameters and goodness of fit
<code>perc.ci.mat</code>	The matrix saving the estimate, standard deviation, median, mean, and the calculated lower and upper limits of confidence interval based on the bootstrap percentile method
<code>bca.ci.mat</code>	The matrix saving the estimate, standard deviation, median, mean, and the calculated lower and upper limits of confidence interval based on the bootstrap $BC_a$ method
<code>covar.mat</code>	The covariance matrix of parameters based on the bootstrap values when <code>nboot &gt; 1</code>
<code>cor.mat</code>	The correlation matrix of parameters based on the bootstrap values when <code>nboot &gt; 1</code>

### Note

To obtain reliable confidence intervals of model parameters, more than **2000** bootstrap replications are recommended; whereas to obtain a reliable standard deviation of the estimate of a parameter, more than **30** bootstrap replications are sufficient (Efron and Tibshirani 1993). `bca.ci.mat` is recommended to show better confidence intervals of parameters than those in `perc.ci.mat`.

The outputs of model parameters will all be represented by  $\theta_i$ ,  $i$  from 1 to  $p$ , where  $p$  represents the number of model parameters. The letters of model parameters defined by users such as  $\beta_i$  will be automatically replaced by  $\theta_i$ .

curvIPEC

*RMS Curvature Calculation Function*

---

### Description

Calculates the root mean square curvatures (intrinsic and parameter-effects curvatures) of a nonlinear regression model.

### Usage

```

curvIPEC(expr, theta, x, y, tol = 1e-16, alpha = 0.05, method = "Richardson",
         method.args = list(eps = 1e-04, d = 0.11,
                             zero.tol = sqrt(.Machine$double.eps/7e-07),
                             r = 6, v = 2, show.details = FALSE), side = NULL)

```

### Arguments

expr	A given parametric model
theta	Vector of parameters of the model
x	Vector or matrix of observations of independent variable(s)
y	Vector of observations of response variable
tol	The tolerance for detecting linear dependencies in the columns of a matrix in the QR decomposition. See the input argument of <code>tol</code> of the <code>qr</code> function in package <b>base</b>
alpha	Parameter controlling the significance level for testing the significance of a curvature
method	It is the same as the input argument of <code>method</code> of the <code>hessian</code> function in package <b>numDeriv</b>
method.args	It is the same as the input argument of <code>method.args</code> of the <code>hessian</code> function in package <b>numDeriv</b>
side	It is the same as the input argument of <code>side</code> of the <code>jacobian</code> function in package <b>numDeriv</b>

**Details**

This function was built based on the [hessian](#) and [jacobian](#) functions in package **numDeriv**, with reference to the [rms.curv](#) function in package **MASS**. However, it is more general without being limited by the [deriv3](#) function in package **stats** and **nls** class like the [rms.curv](#) function in package **MASS**. It mainly relies on package **numDeriv**. The users only need provide the defined model, the fitted parameter vector, and the observations of independent and response variables, they will obtain the curvatures. The input argument `theta` can be obtained using the [fitIPEC](#) function in the current package, and it also can be obtained using the other nonlinear regression functions.

**Value**

<code>rms.ic</code>	The root mean square intrinsic curvature
<code>rms.pec</code>	The root mean square parameter-effects curvature
<code>critical.c</code>	Critical curvature value

**Note**

The calculation precision of curvature mainly depends on the setting of `method.args`. The two important default values in the list of `method.args` are `d = 0.11`, and `r = 6`.

This function cannot be used to calculate the maximum intrinsic and parameter-effects curvatures.

derivIPEC

*Derivative Calculation Function***Description**

Calculates the Jacobian and Hessian matrices of model parameters at a vector  $z$ .

**Usage**

```
derivIPEC(expr, theta, z, method = "Richardson",
          method.args = list(eps = 1e-04, d = 0.11,
                             zero.tol = sqrt(.Machine$double.eps/7e-07), r = 6, v = 2,
                             show.details = FALSE), side = NULL)
```

**Arguments**

expr	A given parametric model
theta	Vector of parameters of the model
z	Vector where the derivatives are calculated
method	It is the same as the input argument of method of the <a href="#">hessian</a> function in package <b>numDeriv</b>
method.args	It is the same as the input argument of method.args of the <a href="#">hessian</a> function in package <b>numDeriv</b>
side	It is the same as the input argument of side of the <a href="#">jacobian</a> function in package <b>numDeriv</b>

**Details**

The Hessian and Jacobian matrices are calculated at a vector  $z$ , which represents a value of a single independent variable or a combination of different values of multiple independent variables.

**Value**

Jacobian	The Jacobian matrix of parameters at $z$
Hessian	The Hessian matrix of parameters at $z$

fitIPEC

*Nonlinear Fitting Function*

---

## Description

Estimates the parameters of a given parametric model using the `optim` function in package `stats`.

## Usage

```

fitIPEC( expr, x, y, ini.val, target.fun = "RSS", control = list(),
         fig.opt = TRUE, xlim = NULL, ylim = NULL, xlab = NULL, ylab = NULL )

```

## Arguments

<code>expr</code>	A given parametric model
<code>x</code>	Vector or matrix of observations of independent variable(s)

<code>y</code>	Vector of observations of response variable
<code>ini.val</code>	A vector or list of initial values of model parameters
<code>target.fun</code>	Objective function, “RSS” and “chi.sq”, for the optimization
<code>control</code>	A list of control parameters for using the <code>optim</code> function in package <code>stats</code>
<code>fig.opt</code>	An option to determine whether to draw the fitted curve
<code>xlim</code>	The shown range of the $x$ -axis
<code>ylim</code>	The shown range of the $y$ -axis
<code>xlab</code>	The label of the $x$ -axis
<code>ylab</code>	The label of the $y$ -axis

### Details

The Nelder-Mead algorithm is the default in the `optim` function in package `stats`. The user can accurately estimate the model parameters by setting smaller relative convergence tolerance and larger maximum number of iterations in the input argument of `control`,

```
e.g. control=list(trace=FALSE, reltol=1e-20, maxit=50000),
```

at the expense of the running speed.

`ini.val` can be a vector or a list that has saved initial values for model parameters,

```
e.g. y = beta0 + beta1 * x + beta2 * x^2,
```

```
ini.val = list(beta0=seq(5, 15, len=2), beta1=seq(0.1, 1, len=9), beta2=seq(0.01, 0.05, len=5)),
```

which is similar to the usage of the input argument of `start` of `nls` in package `stats`.

### Value

<code>expr</code>	The formula used
<code>par</code>	Vector of estimates of parameters
<code>RSS</code>	Calculated residual sum of squares
<code>chi.sq</code>	Calculated $\chi^2$
<code>R.sq</code>	Calculated $R^2$

### Note

This function can be applicable to a nonlinear parametric model with a single independent variable or with multiple independent variables.

`R.sq` is only used to help users intuitively judge whether the fitted curve seriously deviates from the actual observations. However, it should NOT be used to decide which of several competing models is the most appropriate (Pages 44-45 in Ratkowsky 1990). RSS and curvatures are among the suitable candidates to answer such a question.

IPEC

*Root Mean Square Curvature Calculation*

---

### Description

Calculates the RMS intrinsic and parameter-effects curvatures of a nonlinear regression model.

### Details

The DESCRIPTION file:

```

Package:      IPEC
Type:         Package
Title:        Root Mean Square Curvature Calculation
Version:      0.0.9
Date:         2017-05-14
Author:       Peijian Shi, Peter Ridland, David A. Ratkowsky
Maintainer:   Peijian Shi <pejjianshi@gmail.com>
Imports:      numDeriv (>= 2016.8-1), MASS
Description:  Calculates the RMS intrinsic and parameter-effects curvatures of a nonlinear regression model.
License:      GPL-2
NeedsCompilation: no

```

Index of help topics:

```

isom

*Data on biochemical oxygen demand*

---

### Description

Data on the reaction rate of the catalytic isomerization of *n*-pentane to isopentane versus the partial pressures of hydrogen, *n*-pentane, and isopentane.

### Usage

```
data(isom)
```

### Details

There are four columns in the data set:

'y' is the vector of experimental reaction rate (in 1/hr);

'x1' is the vector of partial pressure of hydrogen;

'x2' is the vector of partial pressure of *n*-pentane;

'x3' is the vector of partial pressure of isopentane.

### Note

There were errors about the definitions of 'x2' and 'x3' in page 272 in Bates and Watts (1988). Here, we redefined them according to the paper of Carr (1960).

### References

shoots

*Height Growth Data of Bamboo Shoots*

---

## Description

The height growth data of four species of bamboos in the Nanjing Forestry University campus in 2016.

## Usage

```
data(shoots)
```

## Details

In the data set, there are four variables: code, species, time and height. code is used to save the number codes of different bamboo species; species is used to save the Latin names of different bamboo species; time is used to save the observation times (d) from a specific starting time of growth, and every bamboo has a different starting time of growth; height is used to save the measured aboveground height values (cm).

code = 1 represents *Phyllostachys iridescens*, and the starting time (namely time = 0) was defined as 12:00, 3rd April, 2016;

code = 2 represents *Phyllostachys mannii*, and the starting time (namely time = 0) was defined as 12:00, 4th April, 2016;

code = 3 represents *Sinobambusa tootsik*, and the starting time (namely time = 0) was defined as 12:00, 18th April, 2016;

code = 4 represents *Pleioblastus maculatus*, and the starting time (namely time = 0) was defined as 12:00, 29th April, 2016.

**Examples**

```

data(shoots)
attach(shoots)
# Choose a species
# 1: Phyllostachys iridescens; 2: Phyllostachys mannii;
# 3: Sinobambusa tootsik; 4: Pleioblastus maculatus
ind <- 1
x3 <- time[code == ind]
y3 <- height[code == ind]
dev.new()
par(mar=c(5,5,2,2))
plot(x3, y3, cex=1.5, cex.lab=1.5, cex.axis=1.5, xlab="Time (d)", ylab="Height (cm)")

```

skewIPEC

*Skewness Calculation Function***Description**

Calculates the skewness in the estimates of the parameters of a given model.

**Usage**

```

skewIPEC( expr, theta, x, y, tol = .Machine$double.eps, method = "Richardson",
          method.args = list(eps = 1e-04, d = 0.11,
                              zero.tol = sqrt(.Machine$double.eps/7e-07), r = 6, v = 2,
                              show.details = FALSE), side = NULL )

```

**Arguments**

<code>expr</code>	A given parametric model
<code>theta</code>	Vector of parameters of the model
<code>x</code>	Vector or matrix of observations of independent variable(s)
<code>y</code>	Vector of observations of response variable
<code>tol</code>	The tolerance for detecting linear dependencies in the columns of a matrix for calculating its inverse. See the input argument of <code>tol</code> of the <a href="#">solve</a> function in package <b>base</b>
<code>method</code>	It is the same as the input argument of <code>method</code> of the <a href="#">hessian</a> function in package <b>numDeriv</b>
<code>method.args</code>	It is the same as the input argument of <code>method.args</code> of the <a href="#">hessian</a> function in package <b>numDeriv</b>
<code>side</code>	It is the same as the input argument of <code>side</code> of the <a href="#">jacobian</a> function in package <b>numDeriv</b>

**Details**

The defined model should have two input arguments: a parameter vector and an independent variable vector or matrix, e.g. `myfun <- function(P, x){...}`, where `P` represents the parameter vector and `x` represents the independent variable vector or matrix.

Let  $|g_{1i}|$  be a measure of the skewness of the estimate of the  $i$ -th parameter. If  $|g_{1i}| < \mathbf{0.1}$ , the estimator  $\hat{\theta}_i$  of parameter  $\theta_i$  is very close-to-linear in behavior; if  $\mathbf{0.1} \leq |g_{1i}| < \mathbf{0.25}$ , the estimator is reasonably close-to-linear; if  $|g_{1i}| \geq \mathbf{0.25}$ , the skewness is very apparent; if  $|g_{1i}| > \mathbf{1}$ , the estimator is considerably nonlinear in behavior (Pages 27-28 in Ratkowsky 1990).

**Value**

skewness            Calculated skewness

**Note**

The current function can be applicable to nonlinear models with multiple independent variables.
