### Description

Cardoso’s JADE algorithm as well as his functions for joint diagonalization are ported to R. Also several other blind source separation (BSS) methods, like AMUSE and SOBI, and some criteria for performance evaluation of BSS algorithms, are given.

### Details

- **Package**: JADE
- **Type**: Package
- **Version**: 1.9-93
- **Date**: 2015-08-14
- **License**: GPL (>= 2)

### Author(s)

Klaus Nordhausen, Jean-Francois Cardoso, Jari Miettinen, Hannu Oja, Esa Ollila, Sara Taskinen

Maintainer: Klaus Nordhausen <klaus.nordhausen@utu.fi>

### amari.error

**Amari Error**

Computes the Amari Error to evaluate the performance of an ICA algorithm.
Usage

amari.error(W.hat, A, standardize = F)

Arguments

W.hat          The estimated square unmixing matrix W.
A              The true square mixing matrix A.
standardize    Logical value if A and W.hat need to be standardized. Default is FALSE.

Details

The Amari Error can be used in simulation studies to evaluate the performance of an ICA algorithm. The Amari error is permutation invariant but not scale invariant. Therefore if different algorithms should be compared the matrices should be scaled in the same way. If standardize is TRUE, this will be done by the function by standardizing `W.hat` and the inverse of `A` in such a way, that every row has length 1, the largest absolute value of the row has a positive sign and the rows are ordered decreasingly according to their largest values.

Note that this function assumes the ICA model is $X = SA'$, as is assumed by JADE and ics. However fastICA and PearsonICA assume $X = SA$. Therefore matrices from those functions have to be transposed first.

The Amari Error is scaled in such a way, that it takes a value between 0 and 1. And 0 corresponds to an optimal separation.

Value

The value of the Amari Error.

Examples

S <- cbind(rt(1000, 4), rnorm(1000), runif(1000))
A <- matrix(rnorm(9), ncol = 3)
X <- S %*% t(A)
W.hat <- JADE(X, 3)$W
amari.error(W.hat, A)
amari.error(W.hat, A, TRUE)
AMUSE Method for Blind Source Separation

Description

AMUSE method for the second order blind source separation problem. The function estimates the unmixing matrix in a second order stationary source separation model by jointly diagonalizing the covariance matrix and an autocovariance matrix at lag k.

Usage

```r
AMUSE(x, ...)  
```

## Default S3 method:
```r
AMUSE(x, k = 1, ...)  
```

## S3 method for class 'ts'
```r
AMUSE(x, ...)  
```

Arguments

x a numeric matrix or a multivariate time series object of class `ts`. Missing values are not allowed.

k integer lag for the autocovariance matrix, must be larger than 0. Default is 1.

... further arguments to be passed to or from methods.

Details

The lag k has a huge effect on the performance and it should be chosen so that the eigenvalues of autocovariance matrix are distinct. The function assumes always as many sources as there are time series.

Value

A list with class 'bss' containing the following components:

w estimated unmixing matrix.

EV eigenvectors of autocovariance matrix.

k lag of the autocovariance matrix used.

S estimated sources as time series objected standardized to have mean 0 and unit variances.

Author(s)

Klaus Nordhausen
bss.components

Function to Extract Estimated Sources from an Object of Class bss

Description

Extracts the sources estimated by an bss method.

Usage

bss.components(object)

Arguments

object object of class bss
Author(s)
Klaus Nordhausen

Examples

```R
A <- matrix(rnorm(9),3,3)
s1 <- arima.sim(list(ar=c(0.3,0.6)),1000)
s2 <- arima.sim(list(ma=c(-0.3,0.3)),1000)
s3 <- arima.sim(list(ar=c(-0.8,0.1)),1000)
S <- cbind(s1,s2,s3)
X <- 5 %*% t(A)

res1 <- AMUSE(X)
head(bss.components(res1))
colMeans(bss.components(res1))
cov(bss.components(res1))
```

Description

This is an R version of Cardoso’s joint_diag matlab function for joint diagonalization of k complex-valued square matrices.

Usage

cjd(X, eps = 1e-06, maxiter = 100)

Arguments

- **X**: A matrix of k stacked p x p complex matrices with dimension c(kp,p) or an array with dimension c(p,p,k).
- **eps**: Convergence tolerance.
- **maxiter**: Maximum number of iterations.

Value

- **V**: An orthogonal matrix.
- **D**: A stacked matrix with the diagonal matrices or an array with the diagonal matrices. The form of the output depends on the form of the input.

Author(s)
Jean-Francois Cardoso. Ported to R by Klaus Nordhausen.

coef.bss

Coefficients of a bss Object

Description

Extracts the estimated unmixing matrix from an object of class bss.

Usage

## S3 method for class 'bss'
coef(object, ...)
ComonGAP

Arguments

- object: object of class bss.
- ... further arguments to be passed to or from methods.

Author(s)

Klaus Nordhausen

Examples

```r
A <- matrix(rnorm(9),3,3)
s1 <- arima.sim(list(ar=c(0.3,0.6)),1000)
s2 <- arima.sim(list(ma=c(-0.3,0.3)),1000)
s3 <- arima.sim(list(ar=c(-0.8,0.1)),1000)
S <- cbind(s1,s2,s3)
X <- S %*% t(A)
res1 <- AMUSE(X)
coef(res1)
coef(res1) # should be a matrix with one dominant element in each row and column
```

ComonGAP

Comon’s Gap

Description

Comon’s GAP criterion to evaluate the performance of an ICA algorithm.

Usage

ComonGAP(A, A.hat)

Arguments

- A: The true square mixing matrix.
- A.hat: The estimated square mixing matrix.

Details

Comon’s GAP criterion is permutation and scale invariant. It can take every positive value and 0 corresponds to an optimal separation. If A is however nearly singular the values of the criterion can be huge.

Note that this function assumes the ICA model is \( X = S \alpha \), as is assumed by JADE and ics. However fastICA and PearsonICA assume \( X = SA \). Therefore matrices from those functions have to be transposed first.
Value

The value of the Comon’s GAP.

ComonGAP(A, A.hat)

djd Function for Joint Diagonalization of k Square Matrices in a Deflation Based Manner

Description

This function jointly diagonalizes k real-valued square matrices by searching an orthogonal matrix in a deflation based manner.

Usage

djd(X, G = "max", r = 2, eps = 1e-06, maxiter = 500)

Arguments

X an array containing the k p times p real valued matrices of dimension c(p, p, k).
G criterion function used for the the algorithm. Options are max, pow and log. See details.
r power value used if G="pow" or G="max". 0 is not meaningful for this value. See details.
eps convergence tolerance.
maxiter maximum number of iterations.
Details

Denote the square matrices as $A_i$, $i = 1, \ldots, k$. This algorithm searches then an orthogonal matrix $W$ so that $D_i = W'A_iW$ is diagonal for all $i$. If the $A_i$ commute then there is an exact solution. If not, the function will perform an approximate joint diagonalization by maximizing $\sum G(w_j'A_iw_j)$ where $w_j$ are the orthogonal vectors in $W$.

The function $G$ can be choosen to be of the form $G(x) = |x|^r$ or $G(x) = \log(x)$. If $G="\max"$ is chosen, the function $G$ is of the form $G(x) = |x|^r$, and the diagonalization criterion will be maximized globally at each stage by choosing an appropriate initial value from a set of random vectors. If $G="\pow"$ or $G="\log"$ are chosen, the initial values are the eigenvectors of $A_1$ which plays hence a special role.

Value

The matrix $W$

Examples

```r
Z <- matrix(runif(9), ncol = 3)
U <- eigen(Z)$vectors
D1 <- diag(runif(3))
D2 <- diag(runif(3))
D3 <- diag(runif(3))
D4 <- diag(runif(3))

X.matrix <- array(0, dim=c(3, 3, 4))
X.matrix[,,1] <- t(U) %*% D1 %*% U
X.matrix[,,2] <- t(U) %*% D2 %*% U
X.matrix[,,3] <- t(U) %*% D3 %*% U
X.matrix[,,4] <- t(U) %*% D4 %*% U

W1 <- djd(X.matrix)
round(U %*% W1, 4) # should be a signed permutation matrix if W1 is correct.

W2 <- djd(X.matrix, r=1)
round(U %*% W2, 4) # should be a signed permutation matrix if W2 is correct.

W3 <- djd(X.matrix, G="\log")
```
round(U %*% W3, 4) # should be a signed permutation
  # matrix if W3 is correct.

---

**FG**  
*Joint Diagonalization of Real Positive-definite Matrices*

**Description**

This is a slightly modified version of Flury's FG algorithm for the joint diagonalization of k positive-definite matrices. The underlying function is written in C.

**Usage**

```r
FG(X, weight = NULL, init = NULL, maxiter = 100, eps = 1e-06, na.action = na.fail)
```

**Arguments**

- `X`: A matrix of k stacked pxp matrices with dimension c(kp,p) or an array with dimension c(p,p,k).
- `weight`: A vector of length k to give weight to the different matrices, if NULL, all matrices have equal weight.
- `init`: ???, if NULL, ???
- `maxiter`: Maximum number of iterations.
- `eps`: Convergence tolerance.
- `na.action`: A function which indicates what should happen when the data contain 'NA's. Default is to fail.

**Value**

A list with the components:

- `V`: An orthogonal matrix.
- `D`: A stacked matrix with the diagonal matrices or an array with the diagonal matrices. The form of the output depends on the form of the input.
- `iter`: The Fortran function returns also the number of iterations.

**Author(s)**

Jari Miettinen

**References**

**See Also**

`rjd`, `rjd.fortran`
Description

The FOBI method for independent component analysis (ICA). We assume that all components have different kurtosis values.

Usage

FOBI(X, na.action = na.fail)

Arguments

X a numeric matrix.
na.action A function which indicates what should happen when the data contain 'NA's. Default is to fail.

Value

A list with class 'bss' containing the following components:

W estimated unmixing matrix.
EV eigenvectors of autocovariance matrix.
Xmu the original mean of the data.
S estimated sources as time series objected standardized to have mean 0 and unit variances.

Note

More general is the function ics in the ICS package.

res<-FOBI(X)
MD(coef(res),A)

JADE Algorithm for ICA

Description

This is an R version of Cardoso’s JADE ICA algorithm (for real data) ported from matlab. The ported version is 1.5. Some minor changes compared to the matlab function are explained in the details section. The matlab code can be found for example on the ICA central homepage.

The function uses frjd for the joint diagonalization.

Usage

JADE(X, n.comp = NULL, eps = 1e-06, maxiter = 100, na.action = na.fail)

Arguments

X Numeric data matrix or dataframe.
n.comp Number of components to extract.
eps Convergence tolerance.
maxiter Maximum number of iterations.
na.action A function which indicates what should happen when the data contain 'NA's. Default is to fail.

Details

Some minor modifications were done when porting the function to R, and they are:

1 the model assumed here is \(X = SA' + \mu\). Therefore \(S\) and \(X\) have one row per observation. Note that this still differs from the model definition in R of FastICA and PearsonICA but agrees with ics.
2 The whitening covariance matrix is divided by \(n-1\) and not \(n\) (\(n = \text{number of observations}\)).
3 The initial value for the joint diagonalisation is always I.
4 The original eps would be \(\frac{1}{100\sqrt{n}}\).

It is also worth mentioning that the estimated independent components \(S\) are scaled to unit variance and are ordered in such a way, that their fourth moments are in the decreasing order. The signs of the unmixing matrix \(W\) are fixed so that the sum of the elements on each row is positive.

For further details see also the documentation of the original matlab code ("MatlabjadeR.m") on the ICA central homepage (http://www.tsi.enst.fr/icacentral/).
Value

A list with class 'bss' containing the following components:

- **A**: The estimated mixing matrix.
- **W**: The estimated unmixing matrix.
- **S**: Dataframe with the estimated independent components.
- **Xmu**: The location of the original data.

Author(s)

Jean-Francois Cardoso. Ported to R by Klaus Nordhausen

References

Examples

```r
# 3 source and 3 signals
S <- cbind(rt(1000, 4), rnorm(1000), runif(1000))
A <- matrix(rnorm(9), ncol = 3)
X <- S %*% t(A)
res <- JADE(X, 3)
res$A
res$W
res$[1:10,]
(sweep(X, 2, res$Xmu) %*% t(res$W))[1:10,]
round(res$W %*% A, 4)

# 2 sources and 3 signals
S2 <- cbind(rt(1000, 4), rnorm(1000))
A2 <- matrix(rnorm(6), ncol = 2)
X2 <- S2 %*% t(A2)
res2 <- JADE(X2, 2)
res2$A
res2$W
res2$[1:10,]
(sweep(X2, 2, res2$Xmu) %*% t(res2$W))[1:10,]
SIR(S2, res2$)
```
**Description**

This algorithm generalizes the JADE algorithm, as it provides JADE when k is set to the number of dimensions. Otherwise k can be considered as a way to reduce the number of cumulant matrices to be jointly diagonalized. Hence small values of k speed up the method considerably in high-dimensional cases. In general, k can be considered as maximum number of underlying identical sources.

The function uses Fobi as an initial estimate and frjd for the joint diagonalization.

**Usage**

```r
k_JADE(X, k = 1, eps = 1e-06, maxiter = 100, na.action = na.fail)
```

**Arguments**

- `X` Numeric data matrix or dataframe.
- `k` integer value between 1 and the number of columns of X. Default is 1.
- `eps` Convergence tolerance.
- `maxiter` Maximum number of iterations.
- `na.action` A function which indicates what should happen when the data contain 'NA's. Default is to fail.

**Details**

The order of the estimated components is fixed so that their fourth moments are in the decreasing order.

**Value**

A list with class ‘bss’ containing the following components:

- `A` The estimated mixing matrix.
- `W` The estimated unmixing matrix.
- `S` Matrix with the estimated independent components.
- `xmu` The location of the original data.

**Note**

The function uses Fobi as initial estimate and frjd for the joint diagonalization.

MD(coef(res_k1), A)

---

MD

Minimum Distance index MD

Description

Computes the Minimum Distance index MD to evaluate the performance of an ICA algorithm.

Usage

MD(W.hat, A)

Arguments

W.hat The estimated square unmixing matrix W.
A The true square mixing matrix A.

Details

$$MD(\hat{W}, A) = \frac{1}{\sqrt{P - 1}} \inf_{PD} \|PD\hat{W}A - I\|,$$

where $P$ is a permutation matrix and $D$ a diagonal matrix with nonzero diagonal entries.
The step that minimizes the index of the set over all permutation matrix can be expressed as a linear sum assignment problem (LSAP) for which we use as solver the Hungarian method implemented as solve_lasp in the clue package.

Note that this function assumes the ICA model is $X = SA'$, as is assumed by JADE and ics. However fastICA and PearsonICA assume $X = SA$. Therefore matrices from those functions have to be transposed first.

The MD index is scaled in such a way, that it takes a value between 0 and 1. And 0 corresponds to an optimal separation.

Value
The value of the MD index.

Author(s)
Klaus Nordhausen

X <- S %*% t(A)

W.hat <- JADE(X, 3)$W
MD(W.hat, A)
```

### multscatter

**Function to Compute Several Scatter Matrices for the Same Data**

**Description**

The function can be used to compute several scatter matrices for the same data.

**Usage**

```r
multscatter(scatterlist, X, toshape = TRUE)
```
Arguments

scatterlist a vector with the names of the scatter matrices to be computed. Note that each of these functions should only return a matrix of size p times p.

X the n times p data matrix for which the scatter should be computed.

toshape logical, whether scatter matrices should be converted to shape matrices. If TRUE, all matrices will have determinant 1.

Details

It is important that the functions do not need any additional input and that they return only the p times p scatter matrix. Hence it might be sometimes necessary to write wrappers for some of the functions. See examples.

Value

An array of dimension c(p,p,k) where k is the number of scatter matrices.

Author(s)

Klaus Nordhausen

Examples

# example requires the packages ICS and ICSNP
library(ICSNP)
X <- cbind(rexp(1000), rt(1000,6), runif(1000))

my.tm1 <- function(X,df=1) tM(X,)$V
my.tm2 <- function(X,df=2) tM(X,)$V

multscatter(c("cov","cov4","HP1.shape","my.tm1", "my.tm2"), X)
multscatter(c("cov","cov4","HP1.shape","my.tm1", "my.tm2"), X, toshape=FALSE)

NSS.JD Method for Nonstationary Blind Source Separation

Description

The NSS.JD method for nonstationary blind source separation. The method first whitens the complete data and then divides it into K time intervals. Then frjd is used to jointly diagonalize the covariance matrices computed for the individual time intervals to find the sources.
Usage

NSS.JD(X, 
## Default S3 method:
NSS.JD(X, K=12, Tau=0, n.cuts=NULL, eps = 1e-06, maxiter = 100, 
## S3 method for class 'ts'
NSS.JD(X, )

Arguments

X a numeric matrix or a multivariate time series object of class ts. Missing values are not allowed.

K number of intervals to be used.

Tau By default 0 which means covariance are computed of each time interval, if Tau is an integer > 0 then rather autocovariance matrices at lag Tau are used for the joint diagonalization.

n.cuts if NULL, then the time series is divided into K equally long intervals. To specify intervals n.cuts should be given in the form c(1,n.cut.1,...,n.cut.k, nrow(X)) to specify where to split the time series.

eps maximum number of iterations for frjd.

maxiter convergence tolerance for frjd.

... further arguments to be passed to or from methods.

Details

The model assumes that the mean of the p-variate time series is constant but the variances change over time.

Value

A list with class 'bss' containing the following components:

w estimated unmixing matrix.

k the lag used for the autocovariance matrix.

n.cut specifying the intervals where data is split

K the number of intervals used

S estimated sources as time series objected standardized to have mean 0 and that the variance of the sources are 1.

NSS2c <- NSS.JD(X, n.cuts=c(1,300,500,600,1000))
MD(coef(NSS2c),A)
```

NSS.SD Method for Nonstationary Blind Source Separation

Description

The NSS.SD method for nonstationary blind source separation. The function estimates the un-mixing matrix in a nonstationary source separation model by simultaneously diagonalizing two covariance matrices computed for different time intervals.
Usage

NSS.SD(X, ...)

## Default S3 method:
NSS.SD(X, n.cut=NULL, ...)
## S3 method for class 'ts'
NSS.SD(X, ...)

Arguments

X
   a numeric matrix or a multivariate time series object of class ts. Missing values
   are not allowed.

n.cut
   either an integer between 1 and nrow(X) or an vector of length 3 of the form
   c(1,n.cut,nrow(X)) to specify where to split the time series. If NULL, then
   c(1,floor(nrow(X)/2),nrow(X)) is used.

... 
   further arguments to be passed to or from methods.

Details

The model assumes that the mean of the p-variate time series is constant but the variances change
over time.

Value

A list with class 'bss' containing the following components:

\( \hat{W} \)
   estimated unmixing matrix.

\( EV \)
   eigenvalues from the eigenvalue-eigenvector decomposition.

\( n.cut \)
   specifying the intervals where data is split

\( S \)
   estimated sources as time series objected standardized to have mean 0 and that
   the sources in the first interval are 1.

NSS.TD.JD

NSS.TD.JD Method for Nonstationary Blind Source Separation

Description

The NSS.TD.JD method for nonstationary blind source separation. The method first whitens the complete data and then divides it into K time intervals. It is then assumed that within each interval the time series is approximately second order stationary and within each interval L autocovariance are computed. The underlying sources are then found by jointly diagonalizing the K*L autocovariance matrices using frjd.

Usage

NSS.TD.JD(X, ...)

## Default S3 method:
NSS.TD.JD(X, K=12, Tau=0:11, n.cuts=NA, eps = 1e-06, maxiter = 100, ...)
## S3 method for class 'ts'
NSS.TD.JD(X, ...)

MD(coef(NSS1b),A)

NSS1c <- NSS.SD(X, n.cut=c(1,600,1000))
MD(coef(NSS1c),A)
Arguments

- **X**: a numeric matrix or a multivariate time series object of class `ts`. Missing values are not allowed.
- **K**: number of intervals to be used.
- **Tau**: Lags for the autocovariance matrices to be computed within each interval.
- **n.cuts**: if NULL, then the time series is divided into K equally long intervals. To specify intervals n.cuts should be given in the form c(1,n.cut.1,...,n.cut.k, nrow(X)) to specify where to split the time series.
- **eps**: maximum number of iterations for `frjd`.
- **maxiter**: convergence tolerance for `frjd`.
- **...**: further arguments to be passed to or from methods.

Details

The model assumes that the mean of the p-variate time series is constant but the variances change over time.

Value

A list with class `bss` containing the following components:

- **W**: estimated unmixing matrix.
- **k**: the lags used for the autocovariance matrix used in each interval.
- **n.cut**: specifying the intervals where data is split
- **K**: the number of intervals used
- **S**: estimated sources as time series objected standardized to have mean 0 and that the sources 1.

```r
n <- 1000
s1 <- rnorm(n)
s2 <- 2*sin(pi/200*1:n)* rnorm(n)
s3 <- c(rnorm(n/2), rnorm(100,0,2), rnorm(n/2-100,0,1.5))
S <- cbind(s1,s2,s3)
plot.ts(S)
A<-matrix(rnorm(9),3,3)
X<- S%*%t(A)

NSS3 <- NSS.TD.JD(X)
NSS3
MD(coef(NSS3),A)
plot(NSS3)
cor(NSS3$S, S)

NSS3b <- NSS.TD.JD(X, Tau=c(0,3,7,12), K=6)
MD(coef(NSS3b),A)

NSS3c <- NSS.TD.JD(X, n.cuts=c(1,300,500,600,1000))
MD(coef(NSS3c),A)
```

Description

Plots the estimated sources resulting from a bss method. If the bss method is based on second order assumptions and returned the sources as a time series object it will plot the sources using `plot.ts`, otherwise it will plot a scatter plot matrix using `pairs`.

Usage

```r
## S3 method for class 'bss'
plot(x, ...)
```

Arguments

- `x` : object of class bss.
- `...` : further arguments to be passed to or from methods.

Author(s)

Klaus Nordhausen

`plot.ts, pairs`
Examples

```r
A <- matrix(rnorm(9),3,3)
s1 <- arima.sim(list(ar=c(0.3,0.6)),1000)
s2 <- arima.sim(list(ma=c(-0.3,0.3)),1000)
s3 <- arima.sim(list(ar=c(-0.8,0.1)),1000)

S <- cbind(s1,s2,s3)
X <- S %*% t(A)

res1 <- AMUSE(X)
plot(res1)
# not so useful:
plot(res1, plot.type = "single", col=1:3)

# not meaningful for this data
res2 <- JADE(X)
plot(res2)
```

print.bss  Printing an Object of Class bss

Description

Prints an object of class bss. It prints all elements of the list of class bss except the component S which is the source matrix.

Usage

```r
## S3 method for class 'bss'
print(x, ...)  
```

Arguments

- `x` object of class bss.
- `...` further arguments to be passed to or from methods.

Joint Diagonalization of Real Matrices

Description

This is an R version of Cardoso’s rjd matlab function for joint diagonalization of k real-valued square matrices. A version written in C is also available and preferrable.

Usage

rjd(X, eps = 1e-06, maxiter = 100, na.action = na.fail)
frjd(X, weight = NULL, maxiter = 100, eps = 1e-06, na.action = na.fail)
rjd.fortran(X, weight = NULL, maxiter = 100, eps = 1e-06, na.action = na.fail)

Arguments

x A matrix of k stacked pxp matrices with dimension c(kp,p) or an array with dimension c(p,p,k).
weight A vector of length k to give weight to the different matrices, if NULL, all matrices have equal weight.
eps Convergence tolerance.
maxiter Maximum number of iterations.
na.action A function which indicates what should happen when the data contain 'NA's. Default is to fail.

Details

Denote the square matrices as $A_i$, $i = 1, \ldots, k$. The algorithm searches an orthogonal matrix $V$ so that $D_i = V'A_iV$ is diagonal for all $i$. If the $A_i$ commute then there is an exact solution. Otherwise, the function will perform an approximate joint diagonalization by trying to make the $D_i$ as diagonal as possible.

Cardoso points out that notion of approximate joint diagonalization is ad hoc and very small values of eps make in that case not much sense since the diagonality criterion is ad hoc itself.

Value

A list with the components

V An orthogonal matrix.
D A stacked matrix with the diagonal matrices or an array with the diagonal matrices. The form of the output depends on the form of the input.
iter The frjd function returns also the number of iterations.

Examples

```r
Z <- matrix(rrunif(9), ncol = 3)
U <- eigen(Z)$vectors
d1 <- diag(runif(3))
d2 <- diag(runif(3))
d3 <- diag(runif(3))
d4 <- diag(runif(3))

X.matrix <- rbind(t(U) %*% d1 %*% t(U) %*% d2 %*% t(U) %*% d3 %*% t(U) %*% d4 %*% t(U))
res.matrix <- rjd(X.matrix)
res.matrix$V
round(U %*% res.matrix$V, 4) # should be a signed permutation
# matrix if V is correct.
round(res.matrix$V, 4)

# compare to C version
#res.matrix.C <- frjd(X.matrix)
#res.matrix.C$V
#round(U %*% res.matrix.C$V, 4)
#round(res.matrix.C$V, 4)

X.array <- aperm(array(t(X.matrix), dim = c(3,3,4)), c(2,1,3))
res.array <- rjd(X.array)
round(res.array$V, 4)
res.array.C <- frjd(X.array)
round(res.array.C$V, 4)
```

SIR

**Signal to Interference Ratio**

Description

Computes the signal to interference ratio between true and estimated signals

Usage

SIR(S, S.hat)
Arguments

S: Matrix or dataframe with the true numeric signals.
S.hat: Matrix or dataframe with the estimated numeric signals.

Details

The signal to interference ratio is measured in dB and values over 20 are thought to be good. It is scale and permutation invariant and can be seen as measuring the correlation between the matched true and estimated signals.

Value

The value of the signal to interference ratio.

Examples

```r
S <- cbind(rt(1000, 4), rnorm(1000), runif(1000))
A <- matrix(rnorm(9), ncol = 3)
X <- S %*% t(A)

S.hat <- JADE(X, 3)$S
SIR(S, S.hat)
```

Description

The SOBI method for the second order blind source separation problem. The function estimates the unmixing matrix in a second order stationary source separation model by jointly diagonalizing the covariance matrix and several autocovariance matrices at different lags.
Usage

SOBI(X, ...)

## Default S3 method:
SOBI(X, k=12, method="frjd", eps = 1e-06, maxiter = 100, ...)
## S3 method for class 'ts'
SOBI(X, ...)

Arguments

x
a numeric matrix or a multivariate time series object of class ts. Missing values
are not allowed.

k
if a single integer, then the lags 1:k are used, if an integer vector, then these are
used as the lags.

method
method to use for the joint diagonalization, options are djd, rjd and frjd.

eps
maximum number of iterations.

maxiter
convergence tolerance.

... further arguments to be passed to or from methods.

Details

The order of the estimated components is fixed so that the sums of squared autocovariances are in
the decreasing order.

Value

A list with class 'bss' containing the following components:

w
estimated unmixing matrix.

k
lags used.

method
method used for the joint diagonalization.

s
estimated sources as time series objected standardized to have mean 0 and unit
variances.
