Package ‘LSRS’

October 12, 2022

Type Package
Title Land Surface Remote Sensing
Version 0.2.0
Author Mehdi Sarparast
Maintainer Mehdi Sarparast <mehdisarparast@gmail.com>
Description Rapid satellite data streams in operational applications have clear benefits for monitoring land cover, especially when information can be delivered as fast as changing surface conditions. Over the past decade, remote sensing has become a key tool for monitoring and predicting environmental variables by using satellite data. This package presents the main applications in remote sensing for land surface monitoring and land cover mapping (soil, vegetation, water...).
Suggests raster, sp, rasterVis, lattice, latticeExtra, RColorBrewer

Description

cover management factor in RUSLE model (C factor): Many people in the erosion control industry use the Revised Universal Soil Loss Equation (RUSLE) to estimate soil loss caused by rainfall erosion. The equation combines the interrelated physical and management parameters of climate, soils, topography, and land use. The full equation is:

\[ A = R\times K\times LS\times C\times P \]

C factor: Cover Management Cover management is considered by RUSLE through the C factor. The C factor represents the effect of surface cover and roughness on soil erosion. The cover factor is the most common factor used to assess the impact of BMPs on reducing erosion because the C factor represents the effect of land use on soil erosion (Renard et al., 1997). Erosion control blankets and surface applied BMPs such as blown straw are represented as C factors within RUSLE. By definition, \( C = 1 \) under standard fallow conditions. As surface cover is added to the soil, the C factor value approaches zero. The unitless cover management factor can be determined in different ways. The remote sensing data, useful for reconstructing the temporal variation of C factor. The relationship between the C factor and NDVI is the same applied to the regional scale that is the following (Knijff et al., 2000):

\[ C = \exp(2.5 \times \text{NDVI}/(1-\text{NDVI})) \]

And another equation (Durigon et al., 2014):

\[ c = (-1 \times \text{NDVI} + 0.5) \]

Usage

C.factor(a = "NIR", b = "Red", method, na.rm = TRUE)

Arguments

a
NIR satellite band (format:TIF)

b
Red satellite band (format:TIF)

method
based on Knijff or Durigon equation

na.rm
remove missing values

Examples

```r
### The function is currently defined as
function (a = "NIR", b = "Red", method, na.rm = TRUE)
{
    name <- C.factor (a,b, method="Knijff",na.rm = TRUE)
    areaXY <- c(xmin, xmax, ymin, ymax)
    cropXY <- crop(name, areaXY)
    plot(cropXY,lwd=4,main= "C.factor ",
         xlab="easting", ylab="northing")
    hist(cropXY,main= "C.factor ",
         xlab="C.factor ",col="red", ylab="Frequency of Pixels")
}
```

Description

Enhanced Built-Up and Bareness Index (EBBI): The EBBI is a remote sensing index that applies bands of NIR, SWIR, and TIR. The NIR and SWIR bands are associated with a high contrast level for detecting built-up and bare land areas. In addition, in these bands, there is an inverse reflectance ratio with respect to detecting built-up or bare land areas compared to vegetation. Vegetation has a high reflectance in NIR band, but the reflectance of built-up or bare land in NIR band is low. Subtraction of NIR band from SWIR band will result in positive values for built-up and barren pixels and will result in negative values for vegetation. In addition, a summation of SWIR band and TIR band will result in higher values pixel for built-up and bare land than for vegetation. The difference between the subtraction of NIR band from SWIR band and the summation of SWIR band and TIR band will result in virtually 0 water pixels as well as negative values for vegetation and positive values for built-up and barren pixels. This outcome allows for easy distinguishing between built-up and bare land areas. EBBI can be calculated as:

EBBI = SWIR-Red/10*sqrt(SWIR+TIR)

Usage

```r
EBBI(x = "NIR", y = "SWIR", z = "TIR", Pixel.Depth)
```
Arguments

x       Red satellite band (format:TIF)
y       SWIR satellite band (format:TIF)
z       TIR satellite band (format:TIF)
Pixel.Depth  for satellite image with digital numbers (DN) of 0 to 255, Pixel.Depth = null and for the larger DN, Pixel.Depth = 1

       xlab=" EBBI ",col="red", ylab="Frequency of Pixels")
}
```

Description

Enhanced Vegetation Index

In areas of dense canopy where the leaf area index (LAI) is high, the NDVI values can be improved by leveraging information in the blue wavelength. Information in this portion of the spectrum can help correct for soil background signals and atmospheric influences. The enhanced vegetation index (EVI) is an 'optimized' vegetation index designed to enhance the vegetation signal with improved sensitivity in high biomass regions and improved vegetation monitoring through a de-coupling of the canopy background signal and a reduction in atmosphere influences. EVI is computed following this equation:

\[
VALUE = 2.5 \times (NIR - Red) / (NIR + 6 \times Red - 7.5 \times Blue + 1)
\]
Modified Soil-Adjusted Vegetation Index

Usage

\[ \text{EVI}(a=\text{"NIR"}, b=\text{"Red"}, c=\text{"Blue"}, \text{Pixel\_Depth}) \]

Arguments

- **a**: NIR satellite band (format:TIF)
- **b**: Red satellite band (format:TIF)
- **c**: Blue satellite band (format:TIF)
- **Pixel\_Depth**: for satellite image with digital numbers (DN) of 0 to 255, Pixel\_Depth=null and for the larger DN, Pixel\_Depth=1

Note

in some cases for satellite image with very large digital numbers it need to be multiplied with 0.1,0.01,.001,...

Examples

```r
## The function is currently defined as
function (a = NIR, b = Red, c = Blue, Pixel\_Depth)
{
  name=EVI(a,b,c,Pixel\_Depth=null)
  areaXY <-c(xmin, xmax, ymin, ymax)
  cropXY <- crop(name, areaXY)
  plot(cropXY,lwd=4, main="EVI",xlab="easting", ylab="northing")
  hist(cropXY, main="EVI",
       xlab="EVI",col="red", ylab="Frequency of Pixels")
}
```
Modified Soil-Adjusted Vegetation Index

Description
The modified soil-adjusted vegetation index (MSAVI) is the soil adjusted vegetation index that seeks to address some of the limitations of NDVI when applied to areas with a high degree of exposed soil surface. The problem with the original soil-adjusted vegetation index (SAVI) is that it required specifying the soil-brightness correction factor (L) through trial-and-error based on the amount of vegetation in the study area. Not only did this lead to the majority of people just using the default L value of 0.5, but it also created a circular logic problem of needing to know what the vegetation amount/cover was before you could apply SAVI which was supposed to give you information on how much vegetation there was. Qi et al. (1994a) developed the MSAVI to more reliably and simply calculate a soil brightness correction factor.

$$\text{MSAVI} = \frac{(\text{NIR}-\text{Red})}{(\text{NIR}+\text{Red}+L)* (1+L)}$$

where RED is the red band reflectance from a sensor, NIR is the near infrared band reflectance, and L is the soil brightness correction factor. The difference between SAVI and MSAVI, however, comes in how L is calculated. In SAVI, L is estimated based on how much vegetation there is (but it’s generally left alone at a compromise of 0.5). MSAVI uses the following formula to calculate L:

$$L = 2*s*(\text{NIR}-\text{Red})*(\text{NIR}-s*\text{Red})/(\text{NIR}+\text{Red})$$

where s is the slope of the soil line from a plot of red versus near infrared brightness values.

Usage
MSAVI(a = "NIR", b = "Red", Pixel.Depth)

Arguments
- a: NIR satellite band (format:TIF)
- b: Red satellite band (format:TIF)
- Pixel.Depth: for satellite image with digital numbers (DN) of 0 to 255, Pixel.Depth=null and for the larger DN, Pixel.Depth=1

Note
in some cases for satellite image with very large digital numbers it need to be multiplied with 0.1,0.01,.001,...

Normalized Burn Ratio

Examples

```r
## The function is currently defined as
function (a = "NIR", b = "Red", Pixel.Depth)
{
  name=MSAVI(a,b,Pixel.Depth=null)
  areaXY <-c(xmin, xmax, ymin, ymax)
  cropXY <- crop(name, areaXY)
  plot(cropXY,lwd=4, main="MSAVI",
       xlab="easting", ylab="northing")
  hist(cropXY, 
       main="MSAVI",
       xlab="MSAVI",col="red", ylab="Frequency of Pixels")
}
```

Description

The Normalized Burn Ratio (NBR) was designed to highlight burned areas and estimate fire severity. The formula is similar to NDVI, except that it uses near-infrared (NIR) and shortwave-infrared (SWIR) wavelengths.

\[
\text{NBR} = \frac{\text{NIR} - \text{SWIR}}{\text{NIR} + \text{SWIR}}
\]

Usage

```r
NBR(a = "NIR", b = "SWIR")
```

Arguments

- `a`: NIR satellite band (format:TIF)
- `b`: SWIR satellite band (format:TIF)

Author(s)

Mehdi Sarparast

References

Examples

```r
## The function is currently defined as
function (a = "NIR", b = "SWIR")
{
  name=NBR(a,b)
  areaXY <-c(xmin, xmax, ymin, ymax)
  cropXY <- crop(name, areaXY)
  plot(cropXY,lwd=4,
      main="NBR",
      xlab="easting", ylab="northing")
  hist(cropXY,
      main="Histogram of NBR"
      ,
      xlab="NBR",col="red", ylab="Frequency of Pixels")
}
```

Description

The Normalized Burn Ratio 2 (NBR2) is calculated as a ratio between the SWIR values, substituting the SWIR1 band for the NIR band used in NBR to highlight sensitivity to water in vegetation.

\[
NBR2 = \frac{SWIR1 - SWIR2}{SWIR1 + SWIR2}
\]

Usage

NBR2(a = "SWIR1", b = "SWIR2")

Arguments

- **a**  
  SWIR1 satellite band (Wavelength:1.566 - 1.651 micrometer) (format:TIF)
- **b**  
  SWIR2 satellite band (Wavelength:2.107 - 2.294 micrometer) (format:TIF)

Author(s)

  cropXY <- crop(name, areaXY)
  plot(cropXY,lwd=4,
       main="NBR2",
       xlab="easting", ylab="northing")
  hist(cropXY,
       main="NBR2" ,
       xlab="NBR2",col="red", ylab="Frequency of Pixels")
}
```

Description

The Normalized Difference Moisture (Water) Index (NDMI or NDWI) is a satellite-derived index from the Near-Infrared (NIR) and Short Wave Infrared (SWIR) channels. The SWIR reflectance reflects changes in both the vegetation water content and the spongy mesophyll structure in vegetation canopies, while the NIR reflectance is affected by leaf internal structure and leaf dry matter content but not by water content. The combination of the NIR with the SWIR removes variations induced by leaf internal structure and leaf dry matter content, improving the accuracy in retrieving the vegetation water content. The amount of water available in the internal leaf structure largely controls the spectral reflectance in the SWIR interval of the electromagnetic spectrum. SWIR reflectance is therefore negatively related to leaf water content. NDWI is computed using the near infrared (NIR) and the short wave infrared (SWIR) reflectance’s:

\[
\text{NDMI} = \frac{(\text{NIR} - \text{SWIR})}{(\text{NIR} + \text{SWIR})}
\]

Usage

```r
NDMI(a = "NIR", b = "SWIR")
```

Arguments

- **a**: NIR satellite band (format:TIF)
- **b**: SWIR satellite band (format:TIF)

}
```

Normalized Difference Vegetation Index

Description

Normalized Difference Vegetation Index (NDVI) quantifies vegetation by measuring the difference between near-infrared (which vegetation strongly reflects) and red light (which vegetation absorbs). NDVI always ranges from -1 to +1. But there isn’t a distinct boundary for each type of land cover. For example, when you have negative values, it’s highly likely that it’s water. On the other hand, if you have a NDVI value close to +1, there’s a high possibility that it’s dense green leaves. But when NDVI is close to zero, there isn’t green leaves and it could even be an urbanized area. As shown below, Normalized Difference Vegetation Index (NDVI) uses the NIR and red channels in its formula. NDVI=NIR-Red/NIR+Red

The result of this formula generates a value between -1 and +1. If you have low reflectance (or low values) in the red channel and high reflectance in the NIR channel, this will yield a high NDVI value. And vice versa. Overall, NDVI is a standardized way to measure healthy vegetation. When you have high NDVI values, you have healthier vegetation. When you have low NDVI, you have less or no vegetation. Satellites like Sentinel-2, Landsat and SPOT produce red and near infrared images.

Usage

```r
NDVI(a="NIR",b="Red")
```
Soil-Adjusted Vegetation Index

Arguments

- a: NIR satellite band (format:TIF)
- b: Red satellite band (format:TIF)

function (a, b){
  name <- NDVI(a,b)
  areaXY <- c(xmin, xmax, ymin, ymax)
  cropXY <- crop(name, areaXY)
  plot(cropXY,lwd=4,
       main="NDVI",
       xlab="easting", ylab="northing")
  hist(cropXY,
       main="NDVI",
       xlab="NDVI",col="red", ylab="Frequency of Pixels")
}
```

Soil-Adjusted Vegetation Index

Description

In areas where vegetative cover is low (i.e., < 40 percent) and the soil surface is exposed, the reflectance of light in the red and near-infrared spectra can influence vegetation index values. This is especially problematic when comparisons are being made across different soil types that may reflect different amounts of light in the red and near infrared wavelengths (i.e., soils with different brightness values). The soil-adjusted vegetation index was developed as a modification of the Normalized Difference Vegetation Index to correct for the influence of soil brightness when vegetative cover is low. The SAVI is structured similar to the NDVI but with the addition of a “soil brightness correction factor,”

\[
SAVI = \frac{NIR - Red}{NIR + Red + L}(1+L)
\]

The SAVI is structured similar to the NDVI but with the addition of a “soil brightness correction factor,” where NIR is the reflectance value of the near infrared band, RED is reflectance of the red band, and L is the soil brightness correction factor. The value of L varies by the amount or cover of green vegetation: in very high vegetation regions, L=0; and in areas with no green vegetation, L=1. Generally, an L=0.5 works well in most situations and is the default value used. When L=0, then SAVI = NDVI.
Topsoil Grain Size Index

Usage

```
SAVI(a="NIR",b="Red")
```

Arguments

- **a**: NIR satellite band (format:TIF)
- **b**: Red satellite band (format:TIF)

  cropXY <- crop(name, areaXY)
  plot(cropXY, lwd=4,
       main="SAVI",
       xlab="easting", ylab="northing")
  hist(cropXY,
       main="SAVI"
       ,
       xlab="SAVI", col="red", ylab="Frequency of Pixels")
}
```

Topsoil Grain Size Index

Topsoil Grain Size Index

Description

Topsoil Grain Size Index (TGSI): Topsoil Grain Size Index (TGSI) was developed based on the field survey of soil surface spectral reflectance and laboratory analyses of soil grain composition. Even one rainfall can significantly increase the vegetation cover. Thus, NDVI is misinterpret the actual degree of desertification (Xiao et al., 2006). To overcome this problem, Xiao et al. (2006) proposed a new index, topsoil grain size index (TGSI), which is associated with the mechanical composition of topsoil. It indicates the coarsening of topsoil grain size which has a positive correlation with fine sand content (this class of sand is dominated by the finer sizes of sand particle, and somewhat less coarse than either sand or coarse sand) of surface soil texture, as a manifestation of undergoing desertification. The more severe the desertification, the coarser the topsoil grain size composition.
(grain size refers to the mean or effective diameter of individual mineral grains or particles. A high TGSI value corresponds to an area with high content of fine sand in the topsoil or low content of clay-silt grains. The TGSI can be calculated as:

\[ \text{TGSI} = \frac{(\text{Red}-\text{Blue})}{(\text{Red}+\text{Blue}+\text{green})} \]

where R, B, and G are the red, blue, and green bands of the remote sensing data, respectively. TGSI is an index used to detect the texture of the topsoil layer, or grain size. Negative values or those near 0 represent zones with vegetation or water bodies and values near 0.20 indicate high contents of fine sand.

**Usage**

\[ \text{TGSI}(a = "\text{Red}", b = "\text{Blue}", c = "\text{green}") \]

**Arguments**

- **a**: Red satellite band (format:TIF)
- **b**: Blue satellite band (format:TIF)
- **c**: green satellite band (format:TIF)
