Package ‘MBSP’

May 17, 2023

**Type**  Package

**Title**  Multivariate Bayesian Model with Shrinkage Priors

**Version**  4.0

**Date**  2023-05-17

**Author**  Ray Bai, Malay Ghosh

**Maintainer**  Ray Bai <raybaistat@gmail.com>

**Description**  Gibbs sampler for fitting multivariate Bayesian linear regression with shrinkage priors (MBSP), using the three parameter beta normal family. The method is described in Bai and Ghosh (2018) <doi:10.1016/j.jmva.2018.04.010>.

**License**  GPL-3

**Depends**  R (>= 3.6.0)

**Imports**  stats, MCMCpack, GIGrvg, utils, mvtnorm

**NeedsCompilation**  yes

**Repository**  CRAN

**Date/Publication**  2023-05-17 21:00:03 UTC

### Description

This function provides a way to draw a sample from the matrix-normal distribution, given the mean matrix, the covariance structure of the rows, and the covariance structure of the columns.
Usage

\texttt{matrix\_normal(M, U, V)}

Arguments

- \texttt{M}: mean $a \times b$ matrix
- \texttt{U}: $a \times a$ covariance matrix (covariance of rows).
- \texttt{V}: $b \times b$ covariance matrix (covariance of columns).

Details

This function provides a way to draw a random $a \times b$ matrix from the matrix-normal distribution, $\mathcal{MN}(M, U, V)$, where $M$ is the $a \times b$ mean matrix, $U$ is an $a \times a$ covariance matrix, and $V$ is a $b \times b$ covariance matrix.

Value

A randomly drawn $a \times b$ matrix from $\mathcal{MN}(M, U, V)$.

Author(s)

Ray Bai and Malay Ghosh

Examples

```r
# Draw a random 50x20 matrix from \texttt{MN(O,U,V)},
# where:
# \texttt{O} = zero matrix of dimension 50x20
# \texttt{U} has AR(1) structure,
# \texttt{V} has \(\sigma^2I\) structure

# Specify Mean.mat
p <- 50
q <- 20
Mean_mat <- matrix(0, nrow=p, ncol=q)

# Construct U
rho <- 0.5
times <- 1:p
H <- abs(outer(times, times, "-"))
U <- rho^H

# Construct V
sigma_sq <- 2
V <- sigma_sq*diag(q)
```
MBSP

MBSP Model with Three Parameter Beta Normal (TPBN) Family

Description

This function provides a fully Bayesian approach for obtaining a (nearly) sparse estimate of the \(p \times q\) regression coefficients matrix \(B\) in the multivariate linear regression model,

\[
Y = XB + E,
\]

using the three parameter beta normal (TPBN) family. Here \(Y\) is the \(n \times q\) matrix with \(n\) samples of \(q\) response variables, \(X\) is the \(n \times p\) design matrix with \(n\) samples of \(p\) covariates, and \(E\) is the \(n \times q\) noise matrix with independent rows. The complete model is described in Bai and Ghosh (2018).

If there are \(r\) confounding variables which must remain in the model and should not be regularized, then these can be included in the model by putting them in a separate \(n \times r\) confounding matrix \(Z\). Then the model that is fit is

\[
Y = XB + ZC + E,
\]

where \(C\) is the \(r \times q\) regression coefficients matrix corresponding to the confounders. In this case, we put a flat prior on \(C\). By default, confounders are not included.

If the user desires, two information criteria can be computed: the Deviance Information Criterion (DIC) of Spiegelhalter et al. (2002) and the widely applicable information criterion (WAIC) of Watanabe (2010).

Usage

\[
\text{MBSP}(Y, X, \text{confounders=NULL, } u=0.5, a=0.5, \text{tau=NA, max_steps=6000, burnin=1000, save_samples=TRUE, model_criteria=FALSE})
\]

Arguments

- **Y** Response matrix of \(n\) samples and \(q\) response variables.
- **X** Design matrix of \(n\) samples and \(p\) covariates. The MBSP model regularizes the regression coefficients \(B\) corresponding to \(X\).
- **confounders** Optional design matrix \(Z\) of \(n\) samples of \(r\) confounding variables. By default, confounders are not included in the model (confounders=NULL). However, if there are some confounders that must remain in the model and should not be regularized, then the user can include them here.
- **u** The first parameter in the TPBN family. Defaults to \(u = 0.5\) for the horseshoe prior.
The second parameter in the TPBN family. Defaults to $a = 0.5$ for the horseshoe prior.

**tau**
The global parameter. If the user does not specify this ($\text{tau} = \text{NA}$), the Gibbs sampler will use $\tau = 1/(p \times n \times \log(n))$. The user may also specify any value for $\tau$ strictly greater than 0; otherwise it defaults to $1/(p \times n \times \log(n))$.

**max_steps**
The total number of iterations to run in the Gibbs sampler. Defaults to 6000.

**burnin**
The number of burn-in iterations for the Gibbs sampler. Defaults to 1000.

**save_samples**
A Boolean variable for whether to save all of the posterior samples of the regression coefficients matrix $B$ and the covariance matrix $\Sigma$. Defaults to "TRUE".

**model_criteria**
A Boolean variable for whether to compute the following information criteria: DIC (Deviance Information Criterion) and WAIC (widely applicable information criterion). Can be used to compare models with (for example) different choices of $u$, $a$, or $\tau$. Defaults to "FALSE".

**Details**
The function performs (nearly) sparse estimation of the regression coefficients matrix $B$ and variable selection from the $p$ covariates. The lower and upper endpoints of the 95 percent posterior credible intervals for each of the $pq$ elements of $B$ are also returned so that the user may assess uncertainty quantification.

In the three parameter beta normal (TPBN) family, $(u, a) = (0.5, 0.5)$ corresponds to the horseshoe prior, $(u, a) = (1, 0.5)$ corresponds to the Strawderman-Berger prior, and $(u, a) = (1, a), a > 0$ corresponds to the normal-exponential-gamma (NEG) prior. This function uses the horseshoe prior as the default shrinkage prior.

The user also has the option of including an $n \times r$ matrix with $r$ confounding variables. These confounders are variables which are included in the model but should not be regularized.

Finally, if the user specifies $\text{model_criteria} = \text{TRUE}$, then the MBSP function will compute two model selection criteria: the Deviance Information Criterion (DIC) of Spiegelhalter et al. (2002) and the widely applicable information criterion (WAIC) of Watanabe (2010). This permits model comparisons between (for example) different choices of $u$, $a$, and $\tau$. The default horseshoe prior and choice of $\tau$ performs well, but the user may wish to experiment with $u$, $a$, and $\tau$. In general, models with lower DIC or WAIC are preferred.

**Value**
The function returns a list containing the following components:

- **B_est**
The point estimate of the $p \times q$ matrix $B$ (taken as the componentwise posterior median for all $pq$ entries).

- **B_CI_lower**
The 2.5th percentile of the posterior density (or the lower endpoint of the 95 percent credible interval) for all $pq$ entries of $B$.

- **B_CI_upper**
The 97.5th percentile of the posterior density (or the upper endpoint of the 95 percent credible interval) for all $pq$ entries of $B$.

- **active_predictors**
The row indices of the active (nonzero) covariates chosen by our model from the $p$ total predictors.
MBSP

B_samples  All max_steps-burnin samples of B.

C_est  The point estimate of the $r \times q$ matrix $C$ corresponding to the confounders (taken as the componentwise posterior median for all $rq$ entries). This matrix is not returned if there are no confounders (i.e. confounders=NULL).

C_CI_lower  The 2.5th percentile of the posterior density (or the lower endpoint of the 95 percent credible interval) for all $rq$ entries of $C$. This is not returned if there are no confounders (i.e. confounders=NULL).

C_CI_upper  The 97.5th percentile of the posterior density (or the upper endpoint of the 95 percent credible interval) for all $rq$ entries of $C$. This is not returned if there are no confounders (i.e. confounders=NULL).

C_samples  All max_steps-burnin samples of $C$. This is not returned if there are no confounders (i.e. confounders=NULL)

Sigma_est  The point estimate of the $q \times q$ covariance matrix $\Sigma$ (taken as the componentwise posterior median for all $q^2$ entries).

Sigma_CI_lower  The 2.5th percentile of the posterior density (or the lower endpoint of the 95 percent credible interval) for all $q^2$ entries of $\Sigma$.

Sigma_CI_upper  The 97.5th percentile of the posterior density (or the upper endpoint of the 95 percent credible interval) for all $q^2$ entries of $\Sigma$.

Sigma_samples  All max_steps-burnin samples of $C$.

DIC  The Deviance Information Criterion (DIC), which can be used for model comparison. Models with smaller DIC are preferred. This only returns a numeric value if model_criteria=TRUE is specified.

WAIC  The widely applicable information criterion (WAIC), which can be used for model comparison. Models with smaller WAIC are preferred. This only returns a numeric value if model_criteria=TRUE is specified. The WAIC tends to be more stable than DIC.
