Package ‘MarkowitzR’

January 8, 2020

Maintainer  Steven E. Pav <shabbychef@gmail.com>
Version  1.0.2
Date  2019-12-27
License  LGPL-3
Title  Statistical Significance of the Markowitz Portfolio

BugReports  https://github.com/shabbychef/MarkowitzR/issues
Description  A collection of tools for analyzing significance of
Markowitz portfolios.
Depends  R (>= 3.0.2)
Imports  matrixcalc, gtools
Suggests  sandwich, SharpeR, testthat, knitr
URL  https://github.com/shabbychef/MarkowitzR
VignetteBuilder  knitr
Collate  'MarkowitzR.r' 'portinf.r' 'utils.r' 'vcov.r'
RoxygenNote  7.0.0
NeedsCompilation  no
Author  Steven E. Pav [aut, cre]
Repository  CRAN
Date/Publication  2020-01-08 12:40:20 UTC

Compute variance covariance of Inverse 'Unified' Second Moment

Description

Computes the variance covariance matrix of the inverse unified second moment matrix.

Usage

itheta_vcov(X, vcov.func=vcov, fit.intercept=TRUE)

Arguments

- **X**: an \( n \times p \) matrix of observed returns.
- **vcov.func**: a function which takes an object of class `lm`, and computes a variance-covariance matrix. If equal to the string "normal", we assume multivariate normal returns.
- **fit.intercept**: a boolean controlling whether we add a column of ones to the data, or fit the raw uncentered second moment. For now, must be true when assuming normal returns.

Details

Given \( p \)-vector \( x \) with mean \( \mu \) and covariance, \( \Sigma \), let \( y \) be \( x \) with a one prepended. Then let \( \Theta = E(yy^T) \), the uncentered second moment matrix. The inverse of \( \Theta \) contains the (negative) Markowitz portfolio and the precision matrix.

Given \( n \) contemporaneous observations of \( p \)-vectors, stacked as rows in the \( n \times p \) matrix \( X \), this function estimates the mean and the asymptotic variance-covariance matrix of \( \Theta^{-1} \).

One may use the default method for computing covariance, via the `vcov` function, or via a 'fancy' estimator, like `sandwich::vcovHAC`, `sandwich::vcovHC`, etc.

Value

- **mu**: a \( q = (p+1)(p+2)/2 \) vector of 1 + squared maximum Sharpe, the negative Markowitz portfolio, then the vech'd precision matrix of the sample data
- **Ohat**: the \( q \times q \) estimated variance covariance matrix.
- **n**: the number of rows in \( X \).
- **pp**: the number of assets plus as.numeric(fit.intercept).

Note

By flipping the sign of \( X \), the inverse of \( \Theta \) contains the positive Markowitz portfolio and the precision matrix on \( X \). Performing this transform before passing the data to this function should be considered idiomatic.

A more general form of this function exists as `mp_vcov`.

Replaces similar functionality from SharpeR package, but with modified API.

Examples
X <- matrix(rnorm(1000*3),ncol=3)
# putting in -X is idiomatic:
ism <- itheta_vcov(-X)
isigmans <- itheta_vcov(-X,vcov.func="normal")
isigmans <- itheta_vcov(-X,fit.intercept=FALSE)
# compute the marginal Wald test statistics:
qidx <- 2:ism$pp
wald.stats <- ism$mu[qidx] / sqrt(diag(ism$Ohat[qidx,qidx]))

# make it fat tailed:
X <- matrix(rt(1000*3,df=5),ncol=3)
ism <- itheta_vcov(X)
qidx <- 2:ism$pp
wald.stats <- ism$mu[qidx] / sqrt(diag(ism$Ohat[qidx,qidx]))

if (require(sandwich)) {
  ism <- itheta_vcov(X,vcov.func=vcovHC)
  qidx <- 2:ism$pp
  wald.stats <- ism$mu[qidx] / sqrt(diag(ism$Ohat[qidx,qidx]))
}

# add some autocorrelation to X
Xf <- filter(X,c(0.2),"recursive")
colnames(Xf) <- colnames(X)
ism <- itheta_vcov(Xf)
qidx <- 2:ism$pp
wald.stats <- ism$mu[qidx] / sqrt(diag(ism$Ohat[qidx,qidx]))

if (require(sandwich)) {
  ism <- itheta_vcov(Xf,vcov.func=vcovHAC)
  qidx <- 2:ism$pp
  wald.stats <- ism$mu[qidx] / sqrt(diag(ism$Ohat[qidx,qidx]))
}

}
Description

Inference on the Markowitz portfolio.

Markowitz Portfolio

Suppose \( x \) is a \( p \)-vector of returns of some assets with expected value \( \mu \) and covariance \( \Sigma \). The Markowitz Portfolio is the portfolio \( w = \Sigma^{-1}\mu \). Scale multiples of this portfolio solve various portfolio optimization problems, among them

\[
\arg\max_{w:\, w^\top \Sigma w \leq R^2} \frac{\mu^\top w - r_0}{\sqrt{w^\top \Sigma w}}
\]

This package supports various statistical tests around the elements of the Markowitz Portfolio, and its Sharpe ratio, including the possibility of hedging, and scalar conditional heteroskedasticity and conditional expectation.

News for package 'MarkowitzR':

Description

News for package ‘MarkowitzR’

Changes in MarkowitzR Version 1.0.2 (2020-01-07)

• emergency fix for broken tests under atlas on CRAN.

• move figures around for README on CRAN.

Changes in MarkowitzR Version 0.9900 (2016-09-15)

• yet again, conform to CRAN rules.

Changes in MarkowitzR Version 0.1502 (2015-01-26)

• conform to CRAN rules.

Changes in MarkowitzR Version 0.1403 (2014-06-01)

• fix bug preventing multi-row hedging or constraint matrices.

MarkowitzR Initial Version 0.1402 (2014-02-14)

• first CRAN release.

Description

Estimates the Markowitz Portfolio or Markowitz Coefficient subject to subspace and hedging constraints, and heteroskedasticity.

Usage

```r
mp_vcov(X, feat=NULL, vcov.func=vcov, fit.intercept=TRUE, weights=NULL, Jmat=NULL, Gmat=NULL)
```
Arguments

X

an $n \times p$ matrix of observed returns.

feat

an $n \times f$ matrix of observed features. defaults to none, in which case fit.intercept must be TRUE. If fit.intercept is true, ones will be prepended to the features.

vcov.func

a function which takes an object of class lm, and computes a variance-covariance matrix. If equal to the string "normal", we assume multivariate normal returns.

fit.intercept

a boolean controlling whether we add a column of ones to the data, or fit the raw uncentered second moment. For now, must be true when assuming normal returns.

weights

an optional $n$ vector of the weights. The returns and features will be multiplied by the weights. Weights should be inverse volatility estimates. Defaults to homoskedasticity.

Jmat

an optional $p_j \times p$ matrix of the subspace in which we constrain portfolios. Defaults essentially to the $p \times p$ identity matrix.

Gmat

an optional $p_g \times p$ matrix of the subspace to which we constrain portfolios to have zero covariance. The rowspace of Gmat must be spanned by the rowspace of Jmat. Defaults essentially to the $0 \times p$ empty matrix.

Details

Suppose that the expectation of $p$-vector $x$ is linear in the $f$-vector $f$, but the covariance of $x$ is stationary and independent of $f$. The 'Markowitz Coefficient' is the $p \times f$ matrix $W$ such that, conditional on observing $f$, the portfolio $Wf$ maximizes Sharpe. When $f$ is the constant 1, the Markowitz Coefficient is the traditional Markowitz Portfolio.

Given $n$ observations of the returns and features, given as matrices $X, F$, this code computes the Markowitz Coefficient along with the variance-covariance matrix of the Coefficient and the precision matrix. One may give optional weights, which are inverse conditional volatility. One may also give optional matrix $J, G$ which define subspace and hedging constraints. Briefly, they constrain the portfolio optimization problem to portfolios in the row space of $J$ and with zero covariance with the rows of $G$. It must be the case that the rows of $J$ span the rows of $G$. $J$ defaults to the $p \times p$ identity matrix, and $G$ defaults to a null matrix.

One may use the default method for computing covariance, via the vcov function, or via a 'fancy' estimator, like sandwich:vcovHAC, sandwich:vcovHC, etc.

Value

a list containing the following components:

mu

Letting $r = f + p + \text{fit.intercept}$, this is a $q = (r)(r + 1)/2$ vector...

Ohat

The $q \times q$ estimated variance covariance matrix of mu.

W

The estimated Markowitz coefficient, a $p \times (\text{fit.intercept} + f)$ matrix. The first column corresponds to the intercept term if it is fit. Note that for convenience this function performs the sign flip, which is not performed on mu.

What

The estimated variance covariance matrix of vech(W). Letting $s = p(\text{fit.intercept} + f)$, this is a $s \times s$ matrix.
The indices into \( \mu \) giving \( W \), and into \( \Omega^{\text{hat}} \) giving \( \Omega^{\text{hat}} \).

The number of rows in \( X \).

The number of features plus \( \text{as.numeric(fit.intercept)} \).

The number of assets.

Note

Should also modify to include the theta estimates.

Zerr <- solve(t(chol(ism$What)),errs)

---

**theta_vcov**

*Compute variance covariance of 'Unified' Second Moment*

**Description**

Computes the variance covariance matrix of sample mean and second moment.

**Usage**

```r
theta_vcov(X,vcov.func=vcov,fit.intercept=TRUE)
```

**Arguments**

- **X**: an \( n \times p \) matrix of observed returns.
- **vcov.func**: a function which takes an object of class `lm`, and computes a variance-covariance matrix. If equal to the string "normal", we assume multivariate normal returns.
- **fit.intercept**: a boolean controlling whether we add a column of ones to the data, or fit the raw uncentered second moment. For now, must be true when assuming normal returns.

**Details**

Given \( p \)-vector \( x \), the 'unified' sample is the \((p+1)(p+2)/2\) vector of \( 1, x \), and \( \text{vech}(xx^\top) \) stacked on top of each other. Given \( n \) contemporaneous observations of \( p \)-vectors, stacked as rows in the \( n \times p \) matrix \( X \), this function computes the mean and the variance-covariance matrix of the 'unified' sample.

One may use the default method for computing covariance, via the `vcov` function, or via a 'fancy' estimator, like `sandwich:vcovHAC`, `sandwich:vcovHC`, etc.
theta_vcov

Value

a list containing the following components:

- mu: a $q = (p + 1)(p + 2)/2$ vector of 1, then the mean, then the vech’d second moment of the sample data.
- Ohat: the $q \times q$ estimated variance covariance matrix. When fit.intercept is true, the left column and top row are all zeros.
- n: the number of rows in X.
- pp: the number of assets plus as.numeric(fit.intercept).

Note

Replaces similar functionality from SharpeR package, but with modified API.
