Package ‘NMOF’

October 20, 2022

Type Package
Title Numerical Methods and Optimization in Finance
Version 2.7-1
Date 2022-10-20
Maintainer Enrico Schumann <es@enricoschumann.net>
Depends R (>= 2.14)
Imports grDevices, graphics, parallel, stats, utils
Suggests MASS, PMwR, RUnit, Rglpk, datatimeutils, openxlsx, quadprog, readxl, tinytest
Description Functions, examples and data from the first and the second edition of ‘Numerical Methods and Optimization in Finance’ by M. Gilli, D. Maringer and E. Schumann (2019, ISBN:978-0128150658). The package provides implementations of optimisation heuristics (Differential Evolution, Genetic Algorithms, Particle Swarm Optimisation, Simulated Annealing and Threshold Accepting), and other optimisation tools, such as grid search and greedy search. There are also functions for the valuation of financial instruments such as bonds and options, for portfolio selection and functions that help with stochastic simulations.
License GPL-3
LazyLoad yes
LazyData yes
ByteCompile yes

Description

Functions, data and other R code from the book ‘Numerical Methods and Optimization in Finance’. Comments/corrections/remarks/suggestions are very welcome (please contact the maintainer directly).

Details

The package contains implementations of several optimisation heuristics: Differential Evolution (DEopt), Genetic Algorithms (GAopt), (Stochastic) Local Search (LSopt), Particle Swarm (PSopt), Simulated Annealing (SAopt) and Threshold Accepting (TAopt). The term heuristic is meant in the sense of general-purpose optimisation method.

Dependencies: The package is completely written in R. A number of packages are suggested, but they are not strictly required when using the NMOF package, and most of the package’s functionality is available without them. Specifically, package MASS is needed to run the complete example for PSopt and also in one of the vignettes (PSlms). Package parallel is optional for functions bracketing, GAopt, gridSearch and restartOpt, and may become an option for other functions. Package quadprog is needed for a vignette (TAportfolio), some tests, and it may be used for computing mean-variance efficient portfolios. Package Rglpk is needed for function minCVaR. Package readxl is needed to process the raw data in function Shiller; package datetimeutils is used by French and Shiller. PMwR would be needed to run the examples of the backtesting examples in the NMOF book. Finally, packages RUnit and tinytest are needed to run the tests in subdirectory ‘unitTests’.

Version numbering: package versions are numbered in the form major-minor-patch. The patch level is incremented with any published change in a version. Minor version numbers are incremented when a feature is added or an existing feature is substantially revised. (Such changes will be reported in the NEWS file.) The major version number will only be increased if there were a new edition of the book.

The source code of the NMOF package is also hosted at https://github.com/enricoschumann/NMOF/. Updates to the package and new features are described at http://enricoschumann.net/notes/NMOF/.
Optimisation:
There are functions for Differential Evolution (`DEopt`), Genetic Algorithms (`GAopt`), (Stochastic) Local Search (`LSopt`), Simulated Annealing (`SAopt`), Particle Swarm (`SAopt`), and Threshold Accepting (`TAopt`). The function `restartOpt` helps with running restarts of these methods; also available are functions for grid search (`gridSearch`) and greedy search (`greedySearch`).

Pricing Financial Instruments:
For options: See `vanillaOptionEuropean`, `vanillaOptionAmerican`, `putCallParity`. For pricing methods that use the characteristic function, see `callCF`.
For bonds and bond futures: See `vanillaBond`, `bundFuture` and `xtContractValue`.

Simulation:
See `resampleC` and `mc`.

Data:
See `bundData`, `fundData` and `optionData`.

### bracketing

#### Zero-Bracketing

**Description**
Bracket the zeros (roots) of a univariate function

**Usage**
```r
bracketing(fun, interval, ..., 
  lower = min(interval), upper = max(interval), 
  n = 20L, 
  method = c("loop", "vectorised", "multicore", "snow"), 
  mc.control = list(), cl = NULL)
```

**Arguments**
- **fun**: a univariate function; it will be called as `fun(x, ...)` with `x` being a numeric vector
- **interval**: a numeric vector, containing the end-points of the interval to be searched
- **...**: further arguments passed to `fun`
- **lower**: lower end-point. Ignored if `interval` is specified.
- **upper**: upper end-point. Ignored if `interval` is specified.
- **n**: the number of function evaluations. Must be at least 2 (in which case `fun` is evaluated only at the end-points); defaults to 20.
bracketing

method can be loop (the default), vectorised, multicore or snow. See Details.
mc.control a list containing settings that will be passed to mclapply if method is multicore. Must be a list of named elements. See the documentation of mclapply in package parallel.
c1 default is NULL. If method is snow, this must be a cluster object or an integer (the number of cores to be used). See the documentation of packages parallel and snow.

Details

bracketing evaluates fun at equal-spaced values of x between (and including) lower and upper. If the sign of fun changes between two consecutive x-values, bracketing reports these two x-values as containing ('bracketing') a root. There is no guarantee that there is only one root within a reported interval. bracketing will not narrow the chosen intervals.

The argument method determines how fun is evaluated. Default is loop. If method is "vectorised", fun must be written such that it can be evaluated for a vector x (see Examples). If method is multicore, function mclapply from package parallel is used. Further settings for mclapply can be passed through the list mc.control. If multicore is chosen but the functionality is not available (eg. currently on Windows), then method will be set to loop and a warning is issued. If method is snow, function clusterApply from package parallel is used. In this case, the argument cl must either be a cluster object (see the documentation of clusterApply) or an integer. If an integer, a cluster will be set up via makeCluster(c(rep("localhost", cl)), type = "SOCK"), and stopCluster is called when the function is exited. If snow is chosen but the package is not available or cl is not specified, then method will be set to loop and a warning is issued. In case that cl is a cluster object, stopCluster will not be called automatically.

Value

A numeric matrix with two columns, named lower and upper. Each row contains one interval that contains at least one root. If no roots were found, the matrix has zero rows.

**bundData**  
*German Government Bond Data*

**Description**

A sample of data on 44 German government bonds. Contains ISIN, coupon, maturity and dirty price as of 2010-05-31.

**Usage**

`bundData`

**Format**

`bundData` is a list with three components: `cfList`, `tmList` and `bM`. `cfList` is list of 44 numeric vectors (the cash flows). `tmList` is a list of 44 character vectors (the payment dates) formatted as `YYYY-MM-DD`. `bM` is a numeric vector with 44 elements (the dirty prices of the bonds).

**Details**

All prices are as of 31 May 2010. See chapter 14 in Gilli et al. (2011).

**Source**

The data was obtained from [https://www.deutsche-finanzagentur.de/en/](https://www.deutsche-finanzagentur.de/en/). The data is also freely available from the website of the Bundesbank [https://www.bundesbank.de/en/](https://www.bundesbank.de/en/).

**callCF**

*Price a Plain-Vanilla Call with the Characteristic Function*

**Description**

Price a European plain-vanilla call with the characteristic function.
callCF

Usage

callCF(cf, S, X, tau, r, q = 0, ..., implVol = FALSE, uniroot.control = list(), uniroot.info = FALSE)

Arguments

- **cf**: characteristic function
- **S**: spot
- **X**: strike
- **tau**: time to maturity
- **r**: the interest rate
- **q**: the dividend rate
- **implVol**: logical: compute implied vol?
- **uniroot.control**: A list. If there are elements named interval, tol or maxiter, these are passed to uniroot. Any other elements of the list are ignored.
- **uniroot.info**: logical; default is FALSE. If TRUE, the function will return the information returned by uniroot. See paragraph Value below.
- **om**: a (usually complex) argument
- **v0**: a numeric vector of length one
- **vT**: a numeric vector of length one
- **v**: a numeric vector of length one
- **rho**: a numeric vector of length one
- **k**: a numeric vector of length one
- **sigma**: a numeric vector of length one
- **lambda**: a numeric vector of length one
- **muJ**: a numeric vector of length one
- **vJ**: a numeric vector of length one
- **nu**: a numeric vector of length one
- **theta**: a numeric vector of length one
Details

The function computes the value of a plain vanilla European call under different models, using the representation of Bakshi/Madan. Put values can be computed through put–call parity (see putCallParity).

If implVol is TRUE, the function will compute the implied volatility necessary to obtain the same value under Black–Scholes–Merton. The implied volatility is computed with uniroot from the stats package. The default search interval is c(0.00001, 2); it can be changed through uniroot.control.

The function uses variances as inputs (not volatilities).

The function is not vectorised (but see the NMOF Manual for examples of how to efficiently price more than one option at once).

Value

Returns the value of the call (numeric) under the respective model or, if implVol is TRUE, a list of the value and the implied volatility. (If, in addition, uniroot.info is TRUE, the information provided by uniroot is also returned.)

Note

If implVol is TRUE, the function will return a list with elements named value and impliedVol. Prior to version 0.26-3, the first element was named callPrice.

**callHestoncf**  
*Price of a European Call under the Heston Model*

**Description**

Computes the price of a European Call under the Heston model (and the equivalent Black–Scholes–Merton volatility)

**Usage**

```r
callHestoncf(S, X, tau, r, q, v0, vT, rho, k, sigma, implVol = FALSE, ...)
```

**Arguments**

- `S` current stock price
- `X` strike price
- `tau` time to maturity
The function computes the value of a plain vanilla European call under the Heston model. Put values can be computed through put–call-parity. If \( \text{implVol} \) is TRUE, the function will compute the implied volatility necessary to obtain the same price under Black–Scholes–Merton. The implied volatility is computed with \texttt{uniroot} from the \texttt{stats} package.

Note that the function takes variances as inputs (not volatilities).

Value

Returns the value of the call (numeric) under the Heston model or, if \( \text{implVol} \) is \texttt{TRUE}, a list of the value and the implied volatility.

Note

If \( \text{implVol} \) is \texttt{TRUE}, the function will return a list with elements named \texttt{value} and \texttt{impliedVol}. Prior to version 0.26-3, the first element was named \texttt{callPrice}.

callMerton

Price of a European Call under Merton's Jump–Diffusion Model

Description

Computes the price of a European Call under Merton’s jump–diffusion model (and the equivalent Black–Scholes–Merton volatility)

Usage

callMerton(S, X, tau, r, q, v, lambda, muJ, vJ, N, implVol = FALSE)

Arguments

S current stock price
X strike price
tau time to maturity
r risk-free rate
q dividend rate
v variance
lambda jump intensity
muJ mean jump-size
vJ variance of log jump-size
N The number of jumps. See Details.
implVol compute equivalent Black–Scholes–Merton volatility? Default is FALSE.
Details

The function computes the value of a plain-vanilla European call under Merton's jump–diffusion model. Put values can be computed through put–call-parity (see `putCallParity`). If `implVol` is TRUE, the function also computes the implied volatility necessary to obtain the same price under Black–Scholes–Merton. The implied volatility is computed with `uniroot` from the `stats` package.

Note that the function takes variances as inputs (not volatilities).

The number of jumps `N` typically can be set 10 or 20. (Just try to increase `N` and see how the results change.)

Value

Returns the value of the call (numeric) or, if `implVol` is TRUE, a list of the value and the implied volatility.

CPPI

Constant-Proportion Portfolio Insurance

Description

Simulate constant-proportion portfolio insurance (CPPI) for a given price path.

Usage

CPPI(S, multiplier, floor, r, tau = 1, gap = 1)

Arguments

S   numeric: price path of risky asset
multiplier  numeric
floor   numeric: a percentage, should be smaller than 1
r   numeric: interest rate (per time period tau)
tau  numeric: time periods
gap  numeric: how often to rebalance. 1 means every timestep, 2 means every second timestep, and so on.

Details

Based on Dietmar Maringer’s MATLAB code (function CPPIgap, Listing 9.1).
See Gilli, Maringer and Schumann, 2011, chapter 9.
Value

A list:

- **V**: normalised value (always starts at 1)
- **C**: cushion
- **B**: bond investment
- **F**: floor
- **E**: exposure
- **N**: units of risky asset
- **S**: price path

Author(s)

Original MATLAB code: Dietmar Maringer. R implementation: Enrico Schumann.

plot(0:(length(S)-1), 100*sol$E/sol$V, type = "s",
     main = "% invested in risky asset")
DEopt

Optimisation with Differential Evolution

Description

The function implements the standard Differential Evolution algorithm.

Usage

DEopt(OF, algo = list(), ...)

Arguments

OF The objective function, to be minimised. See Details.
algo A list with the settings for algorithm. See Details and Examples.
... Other pieces of data required to evaluate the objective function. See Details and Examples.

Details

The function implements the standard Differential Evolution (no jittering or other features). Differential Evolution (DE) is a population-based optimisation heuristic proposed by Storn and Price (1997). DE evolves several solutions (collected in the ‘population’) over a number of iterations (‘generations’). In a given generation, new solutions are created and evaluated; better solutions replace inferior ones in the population. Finally, the best solution of the population is returned. See the references for more details on the mechanisms.

To allow for constraints, the evaluation works as follows: after a new solution is created, it is (i) repaired, (ii) evaluated through the objective function, (iii) penalised. Step (ii) is done by a call to OF; steps (i) and (iii) by calls to algo$repair and algo$pen. Step (i) and (iii) are optional, so the respective functions default to NULL. A penalty is a positive number added to the ‘clean’ objective function value, so it can also be directly written in the OF. Writing a separate penalty function is often clearer; it can be more efficient if either only the objective function or only the penalty function can be vectorised. (Constraints can also be added without these mechanisms. Solutions that violate constraints can, for instance, be mapped to feasible solutions, but without actually changing them. See Maringer and Oyewumi, 2007, for an example.)

Conceptually, DE consists of two loops: one loop across the generations and, in any given generation, one loop across the solutions. DEopt indeed uses, as the default, two loops. But it does not matter in what order the solutions are evaluated (or repaired or penalised), so the second loop can be vectorised. This is controlled by the variables algo$loopOF, algo$loopRepair and algo$loopPen, which all default to TRUE. Examples are given in the vignettes and in the book. The respective algo$loopFun must then be set to FALSE.

All objects that are passed through ... will be passed to the objective function, to the repair function and to the penalty function.

The list algo collects the the settings for the algorithm. Strictly necessary are only min and max (to initialise the population). Here are all possible arguments:
CR probability for crossover. Defaults to 0.9. Using default settings may not be a good idea.

F The step size. Typically a numeric vector of length one; default is 0.5. Using default settings may not be a good idea. (F can also be a vector with different values for each decision variable.)

nP population size. Defaults to 50. Using default settings may not be a good idea.

nG number of generations. Defaults to 300. Using default settings may not be a good idea.

min, max vectors of minimum and maximum parameter values. The vectors min and max are used to determine the dimension of the problem and to randomly initialise the population. Per default, they are no constraints: a solution may well be outside these limits. Only if algo$minmaxConstr is TRUE will the algorithm repair solutions outside the min and max range.

minmaxConstr if TRUE, algo$min and algo$max are considered constraints. Default is FALSE.

pen a penalty function. Default is NULL (no penalty).

initP optional: the initial population. A matrix of size length(algo$min) times algo$nP, or a function that creates such a matrix. If a function, it should take no arguments.

repair a repair function. Default is NULL (no repairing).

loopOF logical. Should the OF be evaluated through a loop? Defaults to TRUE.

loopPen logical. Should the penalty function (if specified) be evaluated through a loop? Defaults to TRUE.

loopRepair logical. Should the repair function (if specified) be evaluated through a loop? Defaults to TRUE.

printDetail If TRUE (the default), information is printed. If an integer i greater then one, information is printed at very i th generation.

printBar If TRUE (the default), a txtProgressBar is printed.

storeF if TRUE (the default), the objective function values for every solution in every generation are stored and returned as matrix Fmat.

storeSolutions default is FALSE. If TRUE, the solutions (ie, decision variables) in every generation are stored and returned as a list P in list xlist (see Value section below). To check, for instance, the solutions at the end of the i th generation, retrieve xlist[[c(1L, i)]] . This will be a matrix of size length(algo$min) times algo$nP. (To be consistent with other functions, xlist is itself a list. In the case of DEopt, it contains just one element.)

classify Logical; default is FALSE. If TRUE, the result will have a class attribute TAopt attached. This feature is experimental: the supported methods may change without warning.

drop If FALSE (the default), the dimension is not dropped from a single solution when it is passed to a function. (That is, the function will receive a single-column matrix.)

Value
A list:

xbest the solution (the best member of the population), which is a numeric vector

OFvalue objective function value of best solution

popF a vector. The objective function values in the final population.

Fmat if algo$storeF is TRUE, a matrix of size algo$nG times algo$nP containing the objective function values of all solutions over the generations; else NA.
if algo$storeSolutions is TRUE, a list that contains a list P of matrices and a matrix initP (the initial solution); else NA.

initial.state  the value of .Random.seed when the function was called.

**divRatio**

**Diversification Ratio**

**Description**

Compute the diversification ratio of a portfolio.

**Usage**

`divRatio(w, var)`

**Arguments**

- **w**: numeric: a vector of weights
- **var**: numeric matrix: the variance–covariance matrix
Details

The function provides an efficient implementation of the diversification ratio, suitable for optimisation.

Value

a numeric vector of length one

vols <- seq(v_min, v_max, length.out = na)
S <- outer(vols, vols) * C

w <- rep(1/na, na)  ## weights
divRatio(w, S)

drawdown  Drawdown

Description

Compute the drawdown of a time series.
Usage

drawdown(v, relative = TRUE, summary = TRUE)

Arguments

v 
a price series (a numeric vector)
relative 
if TRUE, maximum drawdown is chosen according to percentage losses; else in units of v
summary 
if TRUE, provide maximum drawdown and time when it occurred; else return drawdown vector

Details

The drawdown at position \( t \) of a time series \( v \) is the difference between the highest peak that was reached before \( t \) and the current value. If the current value represents a new high, the drawdown is zero.

Value

If summary is FALSE, a vector of the same length as \( v \). If summary is TRUE, a list

- `maximum` maximum drawdown
- `high` the max of \( v \)
- `high.position` position of `high`
- `low` the min of \( v \)
- `low.position` position of `low`

EuropeanCall  

Computing Prices of European Calls with a Binomial Tree

Description

Computes the fair value of a European Call with the binomial tree of Cox, Ross and Rubinstein.

Usage

EuropeanCall(S0, X, r, tau, sigma, M = 101)
EuropeanCallBE(S0, X, r, tau, sigma, M = 101)

Arguments

S0  current stock price
X  strike price
r  risk-free rate
tau  time to maturity
sigma  volatility
M  number of time steps

Details

Prices a European Call with the tree approach of Cox, Ross, Rubinstein.
The algorithm in EuropeanCallBE does not construct and traverse a tree, but computes the terminal prices via a binomial expansion (see Higham, 2002, and Chapter 5 in Gilli/Maringer/Schumann, 2011).

Value

Returns the value of the call (numeric).

Download Datasets from Kenneth French’s Data Library

Description

Download datasets from Kenneth French’s Data Library.

Usage

French(dest.dir, 
dataset = "F-F_Research_Data_Factors_CSR.zip", 
weighting = "value", frequency = "monthly", 
price.series = FALSE, na.rm = FALSE, 
adjust.frequency = TRUE)

Arguments

dest.dir character: a path to a directory
dataset a character string: the CSV file name. Also supported are the keywords ‘market’
weighting a character string: “equal” or “value”
frequency a character string: daily, monthly or annual. Whether it is used or ignored
price.series logical: convert the returns series into prices series?
na.rm logical: remove missing values in the calculation of price series?
adjust.frequency logical: if TRUE, frequency is switched to “daily” when the word “daily”
appears in the dataset’s name
Details

The function downloads data provided by Kenneth French at http://mba.tuck.dartmouth.edu/pages/faculty/ken.french/data_library.html. The download file gets a date prefix (current date in format YYYYMMDD) and is stored in directory dest.dir. Before any download is attempted, the function checks whether a file with today’s prefix exist in dest.dir; if yes, the file is used.

In the original data files, missing values are coded as -99 or similar. These numeric values are replaced by NA.

Calling the function without any arguments will print the names of the supported datasets (and return them insivibly).

Value

A data.frame, with contents depending on the particular dataset. If the download failes, the function evaluates to NULL.

**GAopt**

*Optimisation with a Genetic Algorithm*

---

**Description**

A simple Genetic Algorithm for minimising a function.

**Usage**

`GAopt (OF, algo = list(), ...)`

**Arguments**

- **OF**
  The objective function, to be minimised. See Details.
- **algo**
  A list with the settings for algorithm. See Details and Examples.
- **...**
  Other pieces of data required to evaluate the objective function. See Details and Examples.

**Details**

The function implements a simple Genetic Algorithm (GA). A GA evolves a collection of solutions (the so-called population), all of which are coded as vectors containing only zeros and ones. (In GAopt, solutions are of mode logical.) The algorithm starts with randomly-chosen or user-supplied population and aims to iteratively improve this population by mixing solutions and by switching single bits in solutions, both at random. In each iteration, such randomly-changed solutions are compared with the original population and better solutions replace inferior ones. In GAopt, the population size is kept constant.

GA language: iterations are called generations; new solutions are called offspring or children (and the existing solutions, from which the children are created, are parents); the objective function is called a fitness function; mixing solutions is a crossover; and randomly changing solutions is called mutation. The choice which solutions remain in the population and which ones are discarded is called selection. In GAopt, selection is pairwise: a given child is compared with a given parent; the better of the two is kept. In this way, the best solution is automatically retained in the population.

To allow for constraints, the evaluation works as follows: after new solutions are created, they are (i) repaired, (ii) evaluated through the objective function, (iii) penalised. Step (ii) is done by a call to OF; steps (i) and (iii) by calls to algo$repair and algo$pen. Step (i) and (iii) are optional, so the respective functions default to NULL. A penalty can also be directly written in the OF, since it amounts to a positive number added to the ‘clean’ objective function value; but a separate function is often clearer. A separate penalty function is advantageous if either only the objective function or only the penalty function can be vectorised.

Conceptually a GA consists of two loops: one loop across the generations and, in any given generation, one loop across the solutions. This is the default, controlled by the variables algo$loopOF, algo$loopRepair and algo$loopPen, which all default to TRUE. But it does not matter in what order the solutions are evaluated (or repaired or penalised), so the second loop can be vectorised. The respective algo$loopFun must then be set to FALSE. (See also the examples for DEopt and PSopt.)
The evaluation of the objective function in a given generation can even be distributed. For this, an argument `algo$methodOF` needs to be set; see below for details (and Schumann, 2011, for examples).

All objects that are passed through ... will be passed to the objective function, to the repair function and to the penalty function.

The list `algo` contains the following items:

- `nB` number of bits per solution. Must be specified.
- `nP` population size. Defaults to 50. Using default settings may not be a good idea.
- `nG` number of iterations ('generations'). Defaults to 300. Using default settings may not be a good idea.
- `crossover` The crossover method. Default is "onePoint"; also possible is "uniform".
- `prob` The probability for switching a single bit. Defaults to 0.01; typically a small number.
- `pen` a penalty function. Default is `NULL` (no penalty).
- `repair` a repair function. Default is `NULL` (no repairing).
- `initP` optional: the initial population. A logical matrix of size `length(algo$nB)` times `algo$nP`, or a function that creates such a matrix. If a function, it must take no arguments. If `mode(mP)` is not logical, then `storage.mode(mP)` will be tried (and a warning will be issued).
- `loopOF` logical. Should the `OF` be evaluated through a loop? Defaults to `TRUE`.
- `loopPen` logical. Should the penalty function (if specified) be evaluated through a loop? Defaults to `TRUE`.
- `loopRepair` logical. Should the repair function (if specified) be evaluated through a loop? Defaults to `TRUE`.
- `methodOF` loop (the default), vectorised, snow or multicore. Setting vectorised is equivalent to having `algo$loopOF` set to `FALSE` (and `methodOF` overrides `loopOF`). snow and multicore use functions `clusterApply` and `mclapply`, respectively. For snow, an object `algo$cl` needs to be specified (see below). For multicore, optional arguments can be passed through `algo$mc.control` (see below).
- `cl` a cluster object or the number of cores. See documentation of package `parallel`.
- `mc.control` a list of named elements; optional settings for `mclapply` (for instance, `list(mc.set.seed = FALSE)`)  
- `printDetail` If `TRUE` (the default), information is printed.
- `printBar` If `TRUE` (the default), a `txtProgressBar` is printed.
- `storeF` If `TRUE` (the default), the objective function values for every solution in every generation are stored and returned as matrix `Fmat`.
- `storeSolutions` If `TRUE`, the solutions (ie, binary strings) in every generation are stored and returned as a list `P` in list `xlist` (see Value section below). To check, for instance, the solutions at the end of the `i`th generation, retrieve `xlist[[c(1L, i)]]`. This will be a matrix of size `algo$nB` times `algo$nP`.
- `classify` Logical; default is `FALSE`. If `TRUE`, the result will have a class attribute `TAopt` attached. This feature is experimental: the supported methods may change without warning.
**Value**

A list:
- `xbest`: the solution (the best member of the population)
- `OFvalue`: objective function value of best solution
- `popF`: a vector. The objective function values in the final population.
- `Fmat`: if `algo$storeF` is `TRUE`, a matrix of size `algo$nG` times `algo$nP` containing the objective function values of all solutions over the generations; else `NA`.
- `xlist`: if `algo$storeSolutions` is `TRUE`, a list that contains a list `P` of matrices and a matrix `initP` (the initial solution); else `NA`.
- `initial.state`: the value of `Random.seed` when the function was called.

greedySearch

**Description**

Greedy Search

**Usage**

`greedySearch(OF, algo, ...)`

**Arguments**

- **OF** The objective function, to be minimised. Its first argument needs to be a solution; ... arguments are also passed.
- **algo** List of settings. See Details.
- **...** Other variables to be passed to the objective function and to the neighbourhood function. See Details.

**Details**

A greedy search works starts at a provided initial solution (called the current solution) and searches a defined neighbourhood for the best possible solution. If this best neighbour is not better than the current solution, the search stops. Otherwise, the best neighbour becomes the current solution, and the search is repeated.

**Value**

A list:

- **xbest** best solution found.
- **OFvalue** objective function value associated with best solution.
- **Fmat** a matrix with two columns. `Fmat[,1L]` contains the proposed solution over all iterations; `Fmat[,2L]` contains the accepted solutions.
- **xlist** a list
- **initial.state** the value of `.Random.seed` when the function was called.
- **x0** the initial solution
- **iterations** the number of iterations after which the search stopped

system.time(sol.gs <- greedySearch(OF, algo = algo, S = S))
sqrt(sol.gs$OFvalue)
```
gridSearch

Grid Search

Description

Evaluate a function for a given list of arguments.

Usage

gridSearch(fun, levels, ..., lower, upper, npar = 1L, n = 5L,
  printDetail = TRUE,
  method = NULL,
  mc.control = list(), cl = NULL,
  keepNames = FALSE, asList = FALSE)

Arguments

- **fun**: a function of the form `fun(x, ...)`, with `x` being a numeric vector or a list
- **levels**: a list of levels for the arguments (see Examples)
- **...**: objects passed to `fun`
- **lower**: a numeric vector. Ignored if levels are explicitly specified.
- **upper**: a numeric vector. Ignored if levels are explicitly specified.
- **npar**: the number of parameters. Must be supplied if lower and upper are to be expanded; see Details. Ignored when levels are explicitly specified, or when lower/upper are used and at least one has length greater than one. See Examples.
- **n**: the number of levels. Default is 5. Ignored if levels are explicitly specified.
- **printDetail**: print information on the number of objective function evaluations
- **method**: can be `loop` (the default), `multicore` or `snow`. See Details.
- **mc.control**: a list containing settings that will be passed to `mclapply` if `method` is `multicore`. Must be a list of named elements; see the documentation of `mclapply` in `parallel`.
- **cl**: default is NULL. If `method` is `snow`, this must be a cluster object or an integer (the number of cores).
- **keepNames**: logical: should the names of `levels` be kept?
- **asList**: does `fun` expect a list? Default is `FALSE`.
A grid search can be used to find ‘good’ parameter values for a function. In principle, a grid search has an obvious deficiency: as the length of x (the first argument to fun) increases, the number of necessary function evaluations grows exponentially. Note that gridSearch will not warn about an unreasonable number of function evaluations, but if printDetail is TRUE it will print the required number of function evaluations.

In practice, grid search is often better than its reputation. If a function takes only a few parameters, it is often a reasonable approach to find ‘good’ parameter values.

The function uses the mechanism of expand.grid to create the list of parameter combinations for which fun is evaluated; it calls lapply to evaluate fun if method == "loop" (the default).

If method is multicore, then function mclapply from package parallel is used. Further settings for mclapply can be passed through the list mc.control. If multicore is chosen but the functionality is not available, then method will be set to loop and a warning is issued. If method == "snow", the function clusterApply from package parallel is used. In this case, the argument cl must either be a cluster object (see the documentation of clusterApply) or an integer. If an integer, a cluster will be set up via makeCluster(c(rep("localhost", cl), type = "SOCK")) (and stopCluster is called when the function is exited). If snow is chosen but not available or cl is not specified, then method will be set to loop and a warning is issued.

Value

A list.

- minfun: the minimum of fun.
- minlevels: the levels that give this minimum.
- values: a list. All the function values of fun.
- levels: a list. All the levels for which fun was evaluated.

## non-numeric inputs

```r
test_fun <- function(x) {
  -(length(x$S) + x$N1 + x$N2)
}
```

ans <- gridSearch(test_fun,
levels = list(S = list("a", c("a", "b"), c("a", "b", "c")),
N1 = 1:5,
N2 = 101:105),
asList = TRUE, keepNames = TRUE)

ans$minlevels

```
## $S
## [1] "a" "b" "c"

## $N1
## [1] 5

## $N2
## [1] 105
```
Description

The function can be called from the objective and neighbourhood function during a run of `LSopt`; it provides information such as the current iteration.

Usage

```r
LS.info(n = 0L)
```

Arguments

- `n`  
  generational offset; see Details.

Details

This function is still experimental.

The function can be called in the neighbourhood function or the objective function during a run of `LSopt`. It evaluates to a list with the state of the optimisation run, such as the current iteration.

`LS.info` relies on `parent.frame` to retrieve its information. If the function is called within another function in the neighbourhood or objective function, the argument `n` needs to be increased.

Value

A list

- `iteration`  
  current iteration
- `step`  
  same as ‘iteration’

             printBar = FALSE)
ignore <- LSopt(fun, algo)

---

**LSopt**

*Stochastic Local Search*

Description

Performs a simple stochastic Local Search.

Usage

`LSopt(OF, algo = list(), ...)`

Arguments

- `OF` The objective function, to be minimised. Its first argument needs to be a solution; ... arguments are also passed.
- `algo` List of settings. See Details.
- `...` Other variables to be passed to the objective function and to the neighbourhood function. See Details.

Details

Local Search (LS) changes an initial solution for a number of times, accepting only such changes that lead to an improvement in solution quality (as measured by the objective function `OF`). More specifically, in each iteration, a current solution `xc` is changed through a function `algo$neighbour`. 
This function takes \( x_c \) as an argument and returns a new solution \( x_n \). If \( x_n \) is not worse than \( x_c \), i.e., if \( \text{OF}(x_n, \ldots) \leq \text{OF}(x_c, \ldots) \), then \( x_n \) replaces \( x_c \).

The list \( \text{algo} \) contains the following items:

- \( nS \) The number of steps. The default is 1000; but this setting depends very much on the problem.
- \( nI \) Total number of iterations, with default NULL. If specified, it will override \( nS \). The option is provided to make it easier to compare and switch between functions \( \text{LSopt}, \text{TAopt} \) and \( \text{SAopt} \).
- \( x0 \) The initial solution. This can be a function; it will then be called once without arguments to compute an initial solution, i.e., \( x_0 \leftarrow \text{algo}$x0() \). This can be useful when \( \text{LSopt} \) is called in a loop of restarts and each restart is to have its own starting value.
- \( \text{neighbour} \) The neighborhood function, called as \( \text{neighbour}(x, \ldots) \). Its first argument must be a solution \( x \); it must return a changed solution.
- \( \text{printDetail} \) If TRUE (the default), information is printed. If an integer \( i \) greater than one, information is printed at every \( i \)th step.
- \( \text{printBar} \) If TRUE (the default), a \text{txtProgressBar} (from package \text{utils}) is printed. The progress bar is not shown if \( \text{printDetail} \) is an integer greater than 1.
- \( \text{storeF} \) If TRUE (the default), the objective function values for every solution in every generation are stored and returned as matrix \( \text{Fmat} \).
- \( \text{storeSolutions} \) default is FALSE. If TRUE, the solutions (i.e., decision variables) in every generation are stored and returned in list \( \text{xlist} \) (see Value section below). To check, for instance, the current solution at the end of the \( i \)th generation, retrieve \( \text{xlist}[[c(2L, i)]] \).
- \( \text{OF.target} \) Numeric; when specified, the algorithm will stop when an objective-function value as low as \( \text{OF.target} \) (or lower) is achieved. This is useful when an optimal objective-function value is known: the algorithm will then stop and not waste time searching for a better solution.

At the minimum, \( \text{algo} \) needs to contain an initial solution \( x_0 \) and a \text{neighbour} function.

\( \text{LS} \) works on solutions through the functions \text{neighbour} and \text{OF}, which are specified by the user. Thus, a solution need not be a numeric vector, but can be any other data structure as well (e.g., a list or a matrix).

To run silently (except for warnings and errors), \( \text{algo}$\text{printDetail} \) and \( \text{algo}$\text{printBar} \) must be FALSE.

### Value

A list:

- \( \text{xbest} \) best solution found.
- \( \text{OFvalue} \) objective function value associated with best solution.
- \( \text{Fmat} \) a matrix with two columns. \( \text{Fmat}[\, 1L] \) contains the proposed solution over all iterations; \( \text{Fmat}[\, 2L] \) contains the accepted solutions.
- \( \text{xlist} \) if \( \text{algo}$\text{storeSolutions} \) is TRUE, a list; else NA. Contains the neighbour solutions at a given iteration \( (x_n) \) and the current solutions \( (x_c) \). Example: \( \text{Fmat}[i, \, 2L] \) is the objective function value associated with \( \text{xlist}[[c(2L, i)]] \).
- \( \text{initial.state} \) the value of \text{.Random.seed} when the function was called.

**MA**

**Simple Moving Average**

**Description**

The function computes a moving average of a vector.

**Usage**

`MA(y, order, pad = NULL)`

**Arguments**

- `y` a numeric vector
order  An integer. The order of the moving average. The function is defined such that order one returns y (see Examples).

pad  Defaults to NULL. If not NULL, all elements of the returned moving average with position smaller than order are replaced by the value of pad. Sensible values may be NA or 0.

Value

Returns a vector of length length(y).

Author(s)

Enrico Schumann

References

Examples

MA(1:10, 3)
MA(1:10, 3, pad = NA)

y <- seq(1, 4, by = 0.3)
z <- MA(y, 1)
all(y == z)    ### (typically) FALSE
all.equal(y, z)    ### should be TRUE

## 'Relative strength index'
rsi <- function(y, t) {
  y <- diff(y)
  ups  <- y + abs(y)
  downs <- y - abs(y)
  RS  <- -MA(ups, t) / MA(downs, t)
  RS/(1 + RS)
}
x <- cumprod(c(100, 1 + rnorm(100, sd = 0.01)))
par(mfrow = c(2,1))
plot(x, type = "l")
plot(rsi(x, 14), ylim = c(0,1), type = "l")
maxSharpe  
Maximum-Sharpe-Ratio/Tangency Portfolio

Description

Compute maximum Sharpe-ratio portfolios, subject to lower and upper bounds on weights.

Usage

```r
maxSharpe(m, var, min.return,
          wmin = -Inf, wmax = Inf, method = "qp",
          groups = NULL, groups.wmin = NULL, groups.wmax = NULL)
```

Arguments

- `m`: vector of expected (excess) returns.
- `var`: the covariance matrix: a numeric (real), symmetric matrix.
- `min.return`: minimum required return. This is a technical parameter, used only for QP.
- `wmin`: numeric: a lower bound on weights. May also be a vector that holds specific bounds for each asset.
- `wmax`: numeric: an upper bound on weights. May also be a vector that holds specific bounds for each asset.
- `method`: character. Currently, only "qp" is supported.
- `groups`: a list of group definitions
- `groups.wmin`: a numeric vector
- `groups.wmax`: a numeric vector

Details

The function uses `solve.QP` from package `quadprog`. Because of the algorithm that `solve.QP` uses, `var` has to be positive definite (i.e. must be of full rank).

Value

a numeric vector (the portfolio weights) with an attribute `variance` (the portfolio’s variance)

Author(s)

Enrico Schumann

```r
S <- var(R <- NMOF::randomReturns(3, 10, 0.03))
x <- solve(S, colMeans(R))
x/sum(x)
x <- coef(lm(rep(1, 10) ~ -1 + R))
unname(x/sum(x))

maxSharpe(m = colMeans(R), var = S)
maxSharpe(m = colMeans(R), var = S, wmin = 0, wmax = 1)
```

---

**mc**  
*Option Pricing via Monte-Carlo Simulation*

Description

Functions to calculate the theoretical prices of options through simulation.

Usage

```r
gbm(npaths, timesteps, r, v, tau, S0,  
   exp.result = TRUE, antithetic = FALSE)
gbb(npaths, timesteps, S0, ST, v, tau,  
   log = FALSE, exp.result = TRUE)
```

Arguments

- `npaths` the number of paths
- `timesteps` timesteps per path
- `r` the mean per unit of time
- `v` the variance per unit of time
- `tau` time
S0 | initial value
ST | final value of Brownian bridge
log | logical: construct bridge from log series?
exp.result | logical: compute exp of the final path, or return log values?
antithetic | logical: if TRUE, random numbers for only npaths/2 are drawn, and the random numbers are mirrored

Details

gbm generates sample paths of geometric Brownian motion.
gbb generates sample paths of a Brownian bridge by first creating paths of Brownian motion \( \mathbb{W} \) from time 0 to time \( T \), with \( \mathbb{W}_0 \) equal to zero. Then, at each \( t \), it subtracts \( t/T \times \mathbb{W}_T \) and adds \( S_0 \times (1-t/T) + S_T \times (t/T) \).

Value

A matrix of sample paths; each column contains the price path of an asset. Even with only a single time-step, the matrix will have two rows (the first row is \( S_0 \)).

  col = col, border = NA)}`
minCVaR

Minimum Conditional-Value-at-Risk (CVaR) Portfolios

Description

Compute minimum-CVaR portfolios, subject to lower and upper bounds on weights.

Usage

minCVaR(R, q = 0.1, wmin = 0, wmax = 1,
         min.return = NULL, m = NULL,
         method = "Rglpk",
         groups = NULL, groups.wmin = NULL, groups.wmax = NULL,
         Rglpk.control = list())

Arguments

R       the scenario matrix: a numeric (real) matrix
q       the Value-at-Risk level: a number between 0 and 0.5
wmin   numeric: a lower bound on weights. May also be a vector that holds specific
       bounds for each asset.
wmax   numeric: an upper bound on weights. May also be a vector that holds specific
       bounds for each asset.
m       vector of expected returns. Only used if min.return is specified.
min.return minimal required return. If m is not specified, the column means of R are used.
method  character. Currently, only "Rglpk" is supported.
groups  a list of group definitions
groups.wmin a numeric vector
groups.wmax a numeric vector
Rglpk.control a list: settings passed to Rglpk_solve_LP

Details

Compute the minimum CVaR portfolio for a given scenario set. The default method uses the formulation as a Linear Programme, as described in Rockafellar/Uryasev (2000).

The function uses Rglpk_solve_LP from package Rglpk.
### minvar

**Value**

a numeric vector (the portfolio weights); attached is an attribute whose name matches the method name

**Author(s)**

Enrico Schumann

**References**

  res <- minCVaR(R, 0.25)
  c(res)  ## portfolio weights
}
```

---

### minvar

**Minimum-Variance Portfolios**

**Description**

Compute minimum-variance portfolios, subject to lower and upper bounds on weights.

**Usage**

```r
minvar(var, wmin = 0, wmax = 1, method = "qp",
       groups = NULL, groups.wmin = NULL, groups.wmax = NULL)
```
Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>var</td>
<td>the covariance matrix: a numeric (real), symmetric matrix</td>
</tr>
<tr>
<td>wmin</td>
<td>numeric: a lower bound on weights. May also be a vector that holds specific bounds for each asset.</td>
</tr>
<tr>
<td>wmax</td>
<td>numeric: an upper bound on weights. May also be a vector that holds specific bounds for each asset.</td>
</tr>
<tr>
<td>method</td>
<td>character. Currently, only &quot;qp&quot; is supported.</td>
</tr>

Computing Mean–Variance Efficient Portfolios

```r
library(mvFrontier)

# Load example data
data(examp)

# Create a variance-covariance matrix
var <- cov(examp)

# Define minimum and maximum weights
wmin <- c(0.1, 0, 0, 0, 0) # enforce at least 10% weight in CBK.DE
wmax <- 0.5

# No bounds
minvar(var, wmin = -Inf, wmax = Inf)
# [1] 0.100 0.100 0.100 0.363 0.337

# Group constraints:
# group 1 consists of asset 1 only, and must have weight [0.25, 0.30]
# group 2 consists of assets 4 and 5, and must have weight [0.10, 0.20]
# => unconstrained
minvar(var, wmin = 0, wmax = 0.40)
# [1] 0.0097 0.1149 0.0754 0.4000 0.4000

# => with group constraints
minvar(var, wmin = 0, wmax = 0.40,
   groups = list(1, 4:5),
   groups.wmin = c(0.25, 0.1),
   groups.wmax = c(0.30, 0.2))
# [1] 0.250 0.217 0.333 0.149 0.051
```
Description

Compute mean–variance efficient portfolios and efficient frontiers.

Usage

\begin{verbatim}
mvFrontier(m, var, wmin = 0, wmax = 1, n = 50, rf = NA,
            groups = NULL, groups.wmin = NULL, groups.wmax = NULL)
mvPortfolio(m, var, min.return, wmin = 0, wmax = 1, lambda = NULL,
            groups = NULL, groups.wmin = NULL, groups.wmax = NULL)
\end{verbatim}

Arguments

- **m**: vector of expected returns
- **var**: expected variance–covariance matrix
- **wmin**: numeric: minimum weights
- **wmax**: numeric: maximum weights
- **n**: number of points on the efficient frontier
- **min.return**: minimal required return
- **rf**: risk-free rate
- **lambda**: risk–reward trade-off
- **groups**: a list of group definitions
- **groups.wmin**: a numeric vector
- **groups.wmax**: a numeric vector

Details

\texttt{mvPortfolio} computes a single mean–variance efficient portfolio, using package \texttt{quadprog}. It does so by minimising portfolio variance, subject to constraints on minimum return and budget (weights need to sum to one), and min/max constraints on the weights.

If \( \lambda \) is specified, the function ignores the \texttt{min.return} constraint and instead solves the model

\[
\min_w -\lambda m'w + (1 - \lambda)w'\var w
\]

in which \( w \) are the weights. If \( \lambda \) is a vector of length 2, then the model becomes

\[
\min_w -\lambda_1 m'w + \lambda_2 w'\var w
\]

which may be more convenient (e.g. for setting \( \lambda_1 \) to 1).

\texttt{mvFrontier} computes returns, volatilities and compositions for portfolios along an efficient frontier. If \( rf \) is not \( NA \), cash is included as an asset.
value

For `mvPortfolio`, a numeric vector of weights.

For `mvFrontier`, a list of three components:

- `return` returns of portfolios
- `volatility` volatilities of portfolios
- `weights` A matrix of portfolio weights. Each column holds the weights for one portfolio on the frontier. If `rf` is specified, an additional row is added, providing the cash weight.

The $i$-th portfolio on the frontier corresponds to the $i$-th elements of `return` and `volatility`, and the $i$-th column of `portfolio`.

```
Zero Rates for Nelson–Siegel–Svensson Model

Description

Usage

NS(param, tm)
NSS(param, tm)

Arguments

param a vector. For NS: $\beta_1$, $\beta_2$, $\beta_3$, $\lambda$. For NSS: a vector: $\beta_1$, $\beta_2$, $\beta_3$, $\beta_4$, $\lambda_1$, $\lambda_2$.

tm a vector of maturities

Details

See Chapter 14 in Gilli/Maringer/Schumann (2011).
Maturities (tm) need to be given in time (not dates).

Value

The function returns a vector of length length(tm).

Author(s)

Enrico Schumann

u <- url("http://www.ssc.upenn.edu/~fdiebold/papers/paper49/FBFITTED.txt")
open(u); BliDiLi <- scan(u, skip = 14); close(u)
mat <- NULL
for (i in 1:372)
  mat <- rbind(mat, BliDiLi[(19*(i-1)+1):(19*(i-1)+19)])
mats <- c(1,3,6,9,12,15,18,21,24,30,36,48,60,72,84,96,108,120)/12

## the obligatory perspective plot
persp(x = mat[,1], y = mats, mat[,-1L],
      phi = 30, theta = 30, ticktype = "detailed",
      xlab = "time",
      ylab = "time to maturity in years",
      zlab = "zero rates in %")
```

## End(Not run)

---

**NSf**

*Factor Loadings for Nelson–Siegel and Nelson–Siegel–Svensson*

**Description**

Computes the factor loadings for Nelson–Siegel (NS) and Nelson–Siegel–Svensson (NSS) model for given lambda values.
Usage

NSf(lambda, tm)
NSSf(lambda1, lambda2, tm)

Arguments

lambda the \( \lambda \) parameter of the NS model (a scalar)
lambda1 the \( \lambda_1 \) parameter of the NSS model (a scalar)
lambda2 the \( \lambda_2 \) parameter of the NSS model (a scalar)
tm a numeric vector with times-to-payment/maturity

Details

The function computes the factor loadings for given \( \lambda \) parameters. Checking the correlation between these factor loadings can help to set reasonable \( \lambda \) values for the NS/NSS models.

Value

For NS, a matrix with \( \text{length}(tm) \) rows and three columns. For NSS, a matrix with \( \text{length}(tm) \) rows and four columns.

Author(s)

Enrico Schumann

**optionData**

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Closing prices of DAX index options as of 2012-02-10.</td>
</tr>
</tbody>
</table>

**Usage**

```
optionData
```

**Format**

`optionData` is a list with six components:

- `pricesCall` a matrix of size 124 times 10. The rows are the strikes; each column belongs to one expiry date.
- `pricesPut` a matrix of size 124 times 10
- `index` The DAX index (spot).
- `future` The available future settlement prices.
- `Euribor` Euribor rates.
- `NSSpar` Parameters for German government bond yields, as estimated by the Bundesbank.

**Details**

Settlement prices for EUREX options are computed at 17:30, Frankfurt Time, even though trading continues until 22:00.

**Source**

The data was obtained from several websites: close prices of EUREX products were collected from [https://www.eurex.com/ex-en/](https://www.eurex.com/ex-en/); Euribor rates and the parameters of the Nelson-Siegel-Svensson can be found at [https://www.bundesbank.de/en/](https://www.bundesbank.de/en/).

NSS(optionData$NSSpar, 1:10)
```

---

**pm**

Partial Moments

**Description**

Compute partial moments.

**Usage**

```r
pm(x, xp = 2, threshold = 0, lower = TRUE, normalise = FALSE, na.rm = FALSE)
```

**Arguments**

- `x`: a numeric vector or a matrix
- `xp`: exponent
- `threshold`: a numeric vector of length one
- `lower`: logical
- `normalise`: logical
- `na.rm`: logical

**Details**

For a vector `x` of length `n`, partial moments are computed as follows:

upper partial moment = \( \frac{1}{n} \sum_{x > t} (x - t)^{e} \)

lower partial moment = \( \frac{1}{n} \sum_{x < t} (t - x)^{e} \)

The threshold is denoted `t`, the exponent `xp` is labelled `e`.

If `normalise` is `TRUE`, the result is raised to `1/xp`. If `x` is a matrix, the function will compute the partial moments column-wise.

See Gilli, Maringer and Schumann (2019), chapter 14.

**PSopt**

*Particle Swarm Optimisation*

**Description**

The function implements Particle Swarm Optimisation.

**Usage**

`PSopt(OF, algo = list(), ...)`

**Arguments**

- **OF**
  - the objective function to be minimised. See Details.
- **algo**
  - a list with the settings for algorithm. See Details and Examples.
- **...**
  - pieces of data required to evaluate the objective function. See Details.
Details

The function implements Particle Swarm Optimisation (PS); see the references for details on the implementation. PS is a population-based optimisation heuristic. It develops several solutions (a ‘population’) over a number of iterations. PS is directly applicable to continuous problems since the population is stored in real-valued vectors. In each iteration, a solution is updated by adding another vector called velocity. Think of a solution as a position in the search space, and of velocity as the direction into which this solution moves. Velocity changes over the course of the optimization: it is biased towards the best solution found by the particular solution and the best overall solution. The algorithm stops after a fixed number of iterations.

To allow for constraints, the evaluation works as follows: after a new solution is created, it is (i) repaired, (ii) evaluated through the objective function, (iii) penalised. Step (ii) is done by a call to OF; steps (i) and (iii) by calls to algo$repair and algo$pen. Step (i) and (iii) are optional, so the respective functions default to NULL. A penalty can also be directly written in the OF, since it amounts to a positive number added to the ‘clean’ objective function value. It can be advantageous to write a separate penalty function if either only the objective function or only the penalty function can be vectorised. (Constraints can also be added without these mechanisms. Solutions that violate constraints can, for instance, be mapped to feasible solutions, but without actually changing them. See Maringer and Oyewumi, 2007, for an example with Differential Evolution.)

Conceptually, PS consists of two loops: one loop across the iterations and, in any given generation, one loop across the solutions. This is the default, controlled by the variables algo$loopOF, algo$loopRepair, algo$loopPen and loopChangeV which all default to TRUE. But it does not matter in what order the solutions are evaluated (or repaired or penalised), so the second loop can be vectorised. Examples are given in the vignettes and in the book. The respective algo$loopFun must then be set to FALSE.

The objective function, the repair function and and the penalty function will be called as fun(solution, ...).

The list algo contains the following items:

nP population size. Defaults to 100. Using default settings may not be a good idea.

nG number of iterations. Defaults to 500. Using default settings may not be a good idea.

c1 the weight towards the individual’s best solution. Typically between 0 and 2; defaults to 1. Using default settings may not be a good idea. In some cases, even negative values work well: the solution is then driven off its past best position. For ‘simple’ problems, setting c1 to zero may work well: the population moves then towards the best overall solution.

c2 the weight towards the populations’s best solution. Typically between 0 and 2; defaults to 1. Using default settings may not be a good idea. In some cases, even negative values work well: the solution is then driven off the population’s past best position.

iner the inertia weight (a scalar), which reduces velocity. Typically between 0 and 1. Default is 0.9.

initV the standard deviation of the initial velocities. Defaults to 1.

maxV the maximum (absolute) velocity. Setting limits to velocity is sometimes called velocity clamping. Velocity is the change in a given solution in a given iteration. A maximum velocity can be set so to prevent unreasonable velocities (‘overshooting’): for instance, if a decision variable may lie between 0 and 1, then an absolute velocity much greater than 1 makes rarely sense.
min, max vectors of minimum and maximum parameter values. The vectors min and max are used to determine the dimension of the problem and to randomly initialise the population. Per default, they are no constraints: a solution may well be outside these limits. Only if algo$minmaxConstr is TRUE will the algorithm repair solutions outside the min and max range. minmaxConstr if TRUE, algo$min and algo$max are considered constraints. Default is FALSE. pen a penalty function. Default is NULL (no penalty). repair a repair function. Default is NULL (no repairing). changeV a function to change velocity. Default is NULL (no change). This function is called before the velocity is added to the current solutions; it can be used to impose restrictions like changing only a number of decision variables. initP optional: the initial population. A matrix of size length(algo$min) times algo$nP, or a function that creates such a matrix. If a function, it should take no arguments. loopOF logical. Should the OF be evaluated through a loop? Defaults to TRUE. loopPen logical. Should the penalty function (if specified) be evaluated through a loop? Defaults to TRUE. loopRepair logical. Should the repair function (if specified) be evaluated through a loop? Defaults to TRUE. loopChangeV logical. Should the changeV function (if specified) be evaluated through a loop? Defaults to TRUE. printDetail If TRUE (the default), information is printed. If an integer i greater then one, information is printed at very i th iteration. printBar If TRUE (the default), a txtProgressBar (from package utils) is printed. storeF If TRUE (the default), the objective function values for every solution in every generation are stored and returned as matrix Fmat. storeSolutions default is FALSE. If TRUE, the solutions (ie, decision variables) in every generation are stored as lists P and Pbest, both stored in the list xlist which the function returns. To check, for instance, the solutions at the end of the i th iteration, retrieve xlist[[c(1L, i)]]; the best solutions at the end of this iteration are in xlist[[c(2L, i)]]; P[[i]] and Pbest[[i]] will be matrices of size length(algo$min) times algo$nP. classify Logical; default is FALSE. If TRUE, the result will have a class attribute TAopt attached. This feature is experimental: the supported methods may change without warning. drop Default is TRUE. If FALSE, the dimension is not dropped from a single solution when it is passed to a function. (That is, the function will receive a single-column matrix.)

Value

Returns a list:

xbest the solution
OFvalue objective function value of best solution
popF a vector: the objective function values in the final population
Fmat if algo$storeF is TRUE, a matrix of size algo$nG times algo$nP. Each column contains the best objective function value found by the particular solution.
xlist if algo$storeSolutions is TRUE, a list that contains two lists P and Pbest of matrices, and a matrix initP (the initial solution); else NA.
initial.state the value of .Random.seed when PSopt was called.

putCallParity      Put-Call Parity

Description

Put–call parity

Usage

putCallParity(what, call, put, S, X, tau, r, q = 0, tauD = 0, D = 0)

Arguments

what character: what to compute. Currently only call or put are supported.
call call price
put put price
S underlier
X strike
tau time to expiry
r interest rate
q dividend rate
tauD numeric vector: time to dividend
D numeric vector: dividends
Details

Put–call parity only works for European options. The function is vectorised (like vanillaOptionEuropean), except for dividends.

Value

Numeric vector.

Author(s)

Enrico Schumann

(ccf <- callCF(cf = cfBSM, S = S, X = X, tau = tau, r = r, q = q, v = v, implVol = TRUE))
all.equal(ccf$value, vanillaOptionEuropean(S, X, tau, r, q, v, type = "call")$value)

all.equal(putCallParity("put", call=ccf$value, S=S, X=X, tau=tau, r=r, q=q, v = v, type = "put")$value)
```
Prepare LaTeX Table with Quartile Plots

Description

The function returns the skeleton of a LaTeX tabular that contains the median, minimum and maximum of the columns of a matrix X. For each column, a quartile plot is added.

Usage

\begin{verbatim}
qTable(X, xmin = NULL, xmax = NULL, labels = NULL, at = NULL,
unitlength = "5cm", linethickness = NULL,
cnames = colnames(X), circlesize = 0.01,
offset = 0, offset = 0, dec = 2, filename = NULL,
funs = list(median = median, min = min, max = max),
tabular.format, skip = TRUE)
\end{verbatim}

Arguments

- **X**: a numeric matrix (or an object that can be coerced to a numeric matrix with as.matrix)
- **xmin**: optional: the minimum for the x-axis. See Details.
- **xmax**: optional: the maximum for the x-axis. See Details.
- **labels**: optional: labels for the x-axis.
- **at**: optional: where to put labels.
- **unitlength**: the unitlength for LaTeX's picture environment. See Details.
- **linethickness**: the linethickness for LaTeX's picture environment. See Details.
- **cnames**: the column names of X
- **circlesize**: the size of the circle in LaTeX's picture environment
- **offset**: defaults to 0. See Details.
- **yoffset**: defaults to 0. See Details.
- **dec**: the number of decimals
- **filename**: if provided, output is cat into a file
- **funs**: A list of functions; the functions should be named. Default is list(median = median, min = min, max = max)
- **tabular.format**: optional: character string like "rrrrr" that defines the format of the tabular.
- **skip**: Adds a newline at the end of the tabular. Default is TRUE. (The behaviour prior to package version 0.27-0 corresponded to FALSE.)
Details

The function creates a one-column character matrix that can be put into a LaTeX file (the matrix holds a tabular). It relies on LaTeX’s picture environment and should work for LaTeX and pdfLaTeX. Note that the tabular needs generally be refined, depending on the settings and the data.

The tabular has one row for every column of \( X \) (and header and footer rows). A given row contains (per default) the median, the minimum and the maximum of the column; it also includes a picture environment the shows a quartile plot of the distribution of the elements in that column. Other functions can be specified via argument funs.

A number of parameters can be passed to LaTeX’s picture environment: unitlength, xoffset, yoffset, linethickness. Sizes and lengths are functions of unitlength (linethickness is an exception; and while circlesize is a multiple of unitlength, it will not translate into an actual diameter of more than 14mm).

The whole tabular environment is put into curly brackets so that the settings do not change settings elsewhere in the LaTeX document.

If xmin, xmax, labels and at are not specified, they are computed through a call to pretty from the base package. If limits are specified, then both xmin and xmax must be set; if labels are used, then both labels and at must be specified.

To use the function in a vignette, use \texttt{cat(tTable(X))} (and results=tex in the code chunk options). The vignette qTableEx shows some examples.

Value

A matrix of mode character. If filename is specified then qTable will have the side effect of writing a textfile with a LaTeX tabular.

Note

qTable returns a raw draft of a table for LaTeX. Please, spend some time on making it pretty.

             circlesize = 0.0125, xmin = -10, xmax = 10, dec = 2)
## End(Not run)

randomReturns Create a Random Returns

Description
Create a matrix of random returns.

Usage
randomReturns(na, ns, sd, mean = 0, rho = 0, exact = FALSE)

Arguments

na number of assets
ns number of return scenarios
sd the standard deviation: either a single number or a vector of length na
mean the mean return: either a single number or a vector of length na
rho correlation: either a scalar (i.e. a constant pairwise correlation) or a correlation matrix
exact logical: if TRUE, return a random matrix whose column means, standard deviations and correlations match the specified values exactly (up to numerical precision)
Details
The function corresponds to the function random_returns, described in the second edition of NMOF (the book).

Value
a numeric matrix of size na times ns

Note
The function corresponds to the function random_returns, described in the second edition of NMOF (the book).

  }
  summary(n)
}
repairMatrix

Description

The function ‘repairs’ an indefinite correlation matrix by replacing its negative eigenvalues by zero.

Usage

repairMatrix(C, eps = 0)

Arguments

C a correlation matrix
eps a small number

Details

The function ‘repairs’ a correlation matrix: it replaces negative eigenvalues with eps and rescales the matrix such that all elements on the main diagonal become unity again.

Value

Returns a numeric matrix.

Note

This function may help to cure a numerical problem, but it will rarely help to cure an empirical problem. (Garbage in, garbage out.)

See also the function nearPD in the Matrix package.

w %*% S %*% w ## more reasonable
sqrt(w %*% S %*% w)
```

---

resampleC

**Resample with Specified Rank Correlation**

Description

Resample with replacement from a number of vectors; the sample will have a specified rank correlation.

Usage

```r
resampleC(..., size, cormat)
```

Arguments

- `...` numeric vectors; they need not have the same length.
- `size` an integer: the number of samples to draw
- `cormat` the rank correlation matrix

Details

See Gilli, Maringer and Schumann (2011), Section 7.1.2. The function samples with replacement from the vectors passed through `. . .`. The resulting samples will have an (approximate) rank correlation as specified in `cormat`.

The function uses the eigenvalue decomposition to generate the correlation; it will not break down in case of a semidefinite matrix. If an eigenvalue of `cormat` is smaller than zero, a warning is issued (but the function proceeds).

Value

A numeric matrix with `size` rows. The columns contain the samples; hence, there will be as many columns as vectors passed through `. . .`.

## a correlation matrix
cormat <- array(0.5, dim = c(3, 3))
diag(cormat) <- 1
cor(resampleC(a = v1, b = v2, v3, size = 100, cormat = cormat),
    method = "spearman")
```

---

**restartOpt**

**Restart an Optimisation Algorithm**

**Description**

The function provides a simple wrapper for the optimisation algorithms in the package.

**Usage**

```r
restartOpt(fun, n, OF, algo, ..., method = c("loop", "multicore", "snow"),
    mc.control = list(), cl = NULL,
    best.only = FALSE)
```
Arguments

- **fun**: the optimisation function: DEopt, GAopt, LSopt, TAopt or PSopt
- **n**: the number of restarts
- **OF**: the objective function
- **algo**: the list algo that is passed to the particular optimisation function
- **...**: additional data that is passed to the particular optimisation function
- **method**: can be loop (the default), multicore or snow. See Details.
- **mc.control**: a list containing settings that will be passed to mclapply if method is multicore. Must be a list of named elements. See the documentation of mclapply.
- **cl**: default is NULL. If method snow is used, this must be a cluster object or an integer (the number of cores).
- **best.only**: if TRUE, only the best run is reported. Default is FALSE.

Details

The function returns a list of lists. If a specific starting solution is passed, all runs will start from this solution. If this is not desired, initial solutions can be created randomly. This is done per default in DEopt, GAopt and PSopt, but LSopt and TAopt require to specify a starting solution.

In case of LSopt and TAopt, the passed initial solution algo$x0 is checked with is.function: if TRUE, the function is evaluated in each single run. For DEopt, GAopt and PSopt, the initial solution (which also can be a function) is specified with algo$initP.

The argument method determines how fun is evaluated. Default is loop. If method is "multicore", function mclapply from package parallel is used. Further settings for mclapply can be passed through the list mc.control. If multicore is chosen but the functionality is not available, then method will be set to loop and a warning is issued. If method == "snow", function clusterApply from package parallel is used. In this case, the argument cl must either be a cluster object (see the documentation of clusterApply) or an integer. If an integer, a cluster will be set up via makeCluster(c(rep("localhost", cl)), type = "SOCK"), and stopCluster is called when the function is exited. If snow is chosen but parallel is not available or cl is not specified, then method will be set to loop and a warning is issued. In case that cl is an cluster object, stopCluster will not be called automatically.

Value

If best.only is FALSE (the default), the function returns a list of n lists. Each of the n lists stores the output of one of the runs.

If best.only is TRUE, only the best restart is reported. The returned list has the structure specific to the used method.

### Ritter

**Description**

Download IPO data provided by Jay Ritter and transform them into a data frame.

**Usage**

```r
Ritter(dest.dir, 
url = "https://site.warrington.ufl.edu/ritter/files/IPO-age.xlsx")
```

**Arguments**

- `dest.dir` character: a path to a directory
- `url` the data URL

**Details**

The function downloads IPO data provided by Jay R. Ritter [https://site.warrington.ufl.edu/ritter](https://site.warrington.ufl.edu/ritter). Since the data are provided in Excel format, package `openxlsx` is required.

The downloaded Excel gets a date prefix (today in format YYYYMMDD) and is stored in directory `dest.dir`. Before any download is attempted, the function checks whether a file with today’s prefix exist in `dest.dir`; if yes, this file is used.

**Value**

A data frame:

<table>
<thead>
<tr>
<th>CUSIP</th>
<th>CUSIP</th>
</tr>
</thead>
<tbody>
<tr>
<td>Offer date</td>
<td>a Date</td>
</tr>
<tr>
<td>Company name</td>
<td>character: Company name</td>
</tr>
</tbody>
</table>

Description

The function can be called from the objective and neighbourhood function during a run of \code{SAopt}; it provides information such as the current iteration, the current solution, etc.

Usage

\code{SA.info(n = 0L)}
Arguments

n
gerational offset; see Details.

Details

This function is still experimental.

The function can be called in the neighbourhood function or the objective function during a run of \texttt{SAopt}. It evaluates to a list with information about the state of the optimisation run, such as the current iteration or the currently best solution.

\texttt{SA.info} relies on \texttt{parent.frame} to retrieve its information. If the function is called within another function within the neighbourhood or objective function, the argument \texttt{n} needs to be increased.

Value

A list

- \texttt{calibration}: logical: whether the algorithm is calibrating the acceptance probability
- \texttt{iteration}: current iteration
- \texttt{step}: current step for the given temperature level
- \texttt{temperature}: current temperature (the number, not the value)
- \texttt{xbest}: the best solution found so far

Examples

### MINIMAL EXAMPLE for \texttt{SAopt}

```r
# the objective function evaluates to a constant
fun <- function(x)
  0

# the neighbourhood function does not even change
# the solution; it only reports information
```
SAopt <- function(x) {
  info <- SA.info()
  cat("current step ", info$step,
       " | current iteration ", info$iteration, "\n")
  x
}

## run SA
algo <- list(nS = 5, nT = 2, nD = 10,
              initT = 1,
              x0 = rep(0, 5),
              neighbour = nb,
              printBar = FALSE)
ignore <- SAopt(fun, algo)

---

### Description

The function implements a Simulated-Annealing algorithm.

### Usage

```
SAopt(OF, algo = list(), ...)
```

### Arguments

- **OF**
  The objective function, to be minimised. Its first argument needs to be a solution `x`; it will be called as `OF(x, ...)`.  
- **algo**
  A list of settings for the algorithm. See Details.  
- **...**
  Other variables passed to `OF` and `algo$neighbour`. See Details.  

### Details

Simulated Annealing (SA) changes an initial solution iteratively; the algorithm stops after a fixed number of iterations. Conceptually, SA consists of a loop than runs for a number of iterations. In each iteration, a current solution `xc` is changed through a function `algo$neighbour`. If this new (or neighbour) solution `xn` is not worse than `xc`, i.e., if `OF(xn, ...) <= OF(xc, ...)`, then `xn` replaces `xc`. If `xn` is worse, it still replaces `xc`, but only with a certain probability. This probability is a function of the degree of the deterioration (the greater, the less likely the new solution is accepted) and the current iteration (the longer the algorithm has already run, the less likely the new solution is accepted).

The list `algo` contains the following items:

- **nS**
  The number of steps per temperature. The default is 1000; but this setting depends very much on the problem.

- **nT**
  The number of temperatures. Default is 10.
nI Total number of iterations, with default NULL. If specified, it will override nS with ceiling(nI/nT). Using this option makes it easier to compare and switch between functions LSopt, TAopt and SAopt.

nD The number of random steps to calibrate the temperature. Defaults to 2000.

initT Initial temperature. Defaults to NULL, in which case it is automatically chosen so that initProb is achieved.

finalT Final temperature. Defaults to 0.

alpha The cooling constant. The current temperature is multiplied by this value. Default is 0.9.

mStep Step multiplier. The default is 1, which implies constant number of steps per temperature. If greater than 1, the step number nS is increased to m*nS (and rounded).

x0 The initial solution. If this is a function, it will be called once without arguments to compute an initial solution, i.e., $x0 \leftarrow algo\$x0()$. This can be useful when the routine is called in a loop of restarts, and each restart is to have its own starting value.

neighbour The neighbourhood function, called as neighbour(x, ...). Its first argument must be a solution x; it must return a changed solution.

printDetail If TRUE (the default), information is printed. If an integer i greater then one, information is printed at every i'th iteration.

printBar If TRUE (default is FALSE), a txtProgressBar (from package utils) is printed. The progress bar is not shown if printDetail is an integer greater than 1.

storeF If TRUE (the default), the objective function values for every solution in every generation are stored and returned as matrix Fmat.

storeSolutions Default is FALSE. If TRUE, the solutions (i.e., decision variables) in every generation are stored and returned in list xlist (see Value section below). To check, for instance, the current solution at the end of the i'th generation, retrieve xlist[[c(2L, i)]].

classify Logical; default is FALSE. If TRUE, the result will have a class attribute SAopt attached.

OF.target Numeric; when specified, the algorithm will stop when an objective-function value as low as OF.target (or lower) is achieved. This is useful when an optimal objective-function value is known: the algorithm will then stop and not waste time searching for a better solution.

At the minimum, algo needs to contain an initial solution x0 and a neighbourhood function.

The total number of iterations equals algo\$nT times algo\$nS (plus possibly algo\$nD).

Value

SAopt returns a list with five components:

- xbest the solution
- OFvalue objective function value of the solution, i.e., OF(xbest, ...)
- Fmat if algo\$storeF is TRUE, a matrix with one row for each iteration (excluding the initial algo\$nD steps) and two columns. The first column contains the objective function values of the neighbour solution at a given iteration; the second column contains the value of the current solution. Since SA can walk away from locally-optimal solutions, the best solution can be monitored through cummin(Fmat[,2L]).
xlist if `algo$storeSolutions` is `TRUE`, a list; else `NA`. Contains the neighbour solutions at a given iteration (`xn`) and the current solutions (`xc`). Example: `Fmat[i, 2L]` is the objective function value associated with `xlist[[c(2L, i)]]`.

`initial.state` the value of `.Random.seed` when the function was called.

If `algo$classify` was set to `TRUE`, the resulting list will have a class attribute `TAopt`.

**Note**

If the ... argument is used, then all the objects passed with ... need to go into the objective function and the neighbourhood function. It is recommended to collect all information in a list `myList` and then write `OF` and `neighbour` so that they are called as `OF(x, myList)` and `neighbour(x, myList)`. Note that `x` need not be a vector but can be any data structure (eg, a matrix or a list).

Using an initial and final temperature of zero means that SA will be equivalent to a Local Search. The function `LSopt` may be preferred then because of smaller overhead.

### Shiller

**Download Robert Shiller's Data**

**Description**

Download the data provided by Robert Shiller and transform them into a data frame.

**Usage**

```r
Shiller(dest.dir,
```

**Arguments**

- `dest.dir`: character: a path to a directory
- `url`: the data URL

**Details**

The function downloads US stock-market data provided by Robert Shiller which he used in his book 'Irrational Exhuberance'. Since the data are provided in Excel format, package **readxl** is required.

The downloaded Excel gets a date prefix (today in format YYYYMMDD) and is stored in directory `dest.dir`. Before any download is attempted, the function checks whether a file with today’s prefix exist in `dest.dir`; if yes, the file is used.

**Value**

- a `data.frame`:
  - **Date**: end of month
  - **Price**: numeric
  - **Dividend**: numeric
showExample

Earnings numeric
CPI numeric
Long Rate numeric
Real Price numeric
Real Dividend numeric
Real Earnings numeric
CAPE numeric

showExample Display Code Examples

Description
Display the code examples from ‘Numerical Methods and Optimization and Finance’.

Usage
showExample(file = "", chapter = NULL, showfile = TRUE,
includepaths = FALSE, edition = 2, search,
..., ignore.case = TRUE)
showChapterNames(edition = 2)
showExample

Arguments

- **file**: a character vector of length one. See Details.
- **chapter**: optional: a character vector of length one, giving the chapter name (see Details), or an integer, indicating a chapter number. Default is NULL: look in all chapters.
- **showfile**: Should the file be displayed with `file.show`? Defaults to TRUE. A file will be displayed only if one single file only is identified by file and chapter.
- **includepaths**: Should the file paths be displayed? Defaults to FALSE.
- **...**: Arguments passed to `grepl`; see Details.
- **edition**: an integer: 1 and 2 are supported
- **search**: a regular expression: search in the code files. Not supported yet.
- **ignore.case**: passed to `grepl`; see Examples. Default is TRUE (which is much more helpful than the default FALSE before package version 2).

Details

`showExample` matches the specified file argument against the available file names via `grepl(file, all.filenames, ignore.case = ignore.case, ...)`. If chapter is specified, a second match is performed, `grepl(chapter, all.chapternames, ignore.case = ignore.case, ...)`. The chapternames are those in the book (e.g., ‘Modeling dependencies’). The selected files are then those for which file name and chapter name could be matched.

Value

`showExample` returns a `data.frame` of at least two character vectors, Chapter and File. If `includepaths` is TRUE, Paths are included. If no file is found, the `data.frame` has zero rows. If a single file is identified and `showfile` is TRUE, the function has the side effect of displaying that file.

`showChapterNames` returns a character vector: the names of the book’s chapters.

Note

The behaviour of the function changed slightly with version 2.0 to accommodate the code examples of the second edition of the book. Specifically, the function gained an argument edition, which defaults to 2. Also, the default for `ignore.case` was changed to TRUE. To get back the old behaviour of the function, set edition to 1 and `ignore.case` to FALSE.

The code files can also be downloaded from [https://gitlab.com/NMOF](https://gitlab.com/NMOF).

**TA.info**

**Threshold-Accepting Information**

**Description**

The function can be called from the objective and neighbourhood function during a run of `TAopt`; it provides information such as the current iteration, the current solution, etc.

**Usage**

```r
TA.info(n = 0L)
```

**Arguments**

- `n` : generational offset; see Details.
Details

This function is still experimental.

The function can be called in the neighbourhood function or the objective function during a run of TAopt. It evaluates to a list with the state of the optimisation run, such as the current iteration. TA.info relies on parent.frame to retrieve its information. If the function is called within another function in the neighbourhood or objective function, the argument n needs to be increased.

Value

A list

OF.sampling logical: if TRUE, is the algorithm sampling the objective function to compute thresholds; otherwise (i.e. during the actual optimisation) FALSE
iteration current iteration
step current step (i.e. for a given threshold)
threshold current threshold (the number, not the value)
xbest the best solution found so far
OF.xbest objective function value of best solution

## current threshold 2 | current step 4 | current iteration 9
## current threshold 2 | current step 5 | current iteration 10

---

TAopt

*Optimisation with Threshold Accepting*

**Description**

The function implements the Threshold Accepting algorithm.

**Usage**

`TAopt(OF, algo = list(), ...)`

**Arguments**

- **OF**
  The objective function, to be minimised. Its first argument needs to be a solution `x`; it will be called as `OF(x, ...)`.  

- **algo**
  A list of settings for the algorithm. See Details.  

- **...**
  other variables passed to `OF` and `algo$neighbour`. See Details.
Threshold Accepting (TA) changes an initial solution iteratively; the algorithm stops after a fixed number of iterations. Conceptually, TA consists of a loop than runs for a number of iterations. In each iteration, a current solution \( x_c \) is changed through a function \( \text{algo}\$\text{neighbour} \). If this new (or neighbour) solution \( x_n \) is not worse than \( x_c \), i.e., if \( \text{OF}(x_n,...) \leq \text{OF}(x_c,...) \), then \( x_n \) replaces \( x_c \). If \( x_n \) is worse, it still replaces \( x_c \) as long as the difference in 'quality' between the two solutions is less than a threshold \( \tau \); more precisely, as long as \( \text{OF}(x_n,...) - \tau \leq \text{OF}(x_c,...) \).

Thus, we also accept a new solution that is worse than its predecessor; just not too much worse. The threshold is typically decreased over the course of the optimisation. For zero thresholds TA becomes a stochastic local search.

The thresholds can be passed through the list \( \text{algo} \) (see below). Otherwise, they are automatically computed through the procedure described in Gilli et al. (2006). When the thresholds are created automatically, the final threshold is always zero.

The list \( \text{algo} \) contains the following items.

- \( nS \): The number of steps per threshold. The default is 1000; but this setting depends very much on the problem.
- \( nT \): The number of thresholds. Default is 10; ignored if \( \text{algo}\$vT \) is specified.
- \( nI \): Total number of iterations, with default NULL. If specified, it will override \( nS \) with \( \text{ceiling}(nI/nT) \). Using this option makes it easier to compare and switch between functions \( \text{LSopt}, \text{TAopt} \) and \( \text{SAopt} \).
- \( nD \): The number of random steps to compute the threshold sequence. Defaults to 2000. Only used if \( \text{algo}\$vT \) is NULL.
- \( q \): The highest quantile for the threshold sequence. Defaults to 0.5. Only used if \( \text{algo}\$vT \) is NULL. If \( q \) is zero, \( \text{TAopt} \) will run with \( \text{algo}\$nT \) zero-thresholds (i.e., like a Local Search).
- \( x0 \): The initial solution. If this is a function, it will be called once without arguments to compute an initial solution, i.e., \( x0 <- \text{algo}\$x0() \). This can be useful when the routine is called in a loop of restarts, and each restart is to have its own starting value.
- \( vT \): The thresholds. A numeric vector. If NULL (the default), \( \text{TAopt} \) will compute \( \text{algo}\$nT \) thresholds. Passing threshold can be useful when similar problems are handled. Then the time to sample the objective function to compute the thresholds can be saved (i.e., we save \( \text{algo}\$nD \) function evaluations). If the thresholds are computed and \( \text{algo}\$printDetail \) is TRUE, the time required to evaluate the objective function will be measured and an estimate for the remaining computing time is issued. This estimate is often very crude.
- \( \text{neighbour} \): The neighbourhood function, called as \( \text{neighbour}(x,\ldots) \). Its first argument must be a solution \( x \); it must return a changed solution.
- \( \text{printDetail} \): If TRUE (the default), information is printed. If an integer \( i \) greater than one, information is printed at very \( i \)th iteration.
- \( \text{printBar} \): If TRUE (default is FALSE), a \( \text{txtProgressBar} \) (from package \( \text{utils} \)) is printed. The progress bar is not shown if \( \text{printDetail} \) is an integer greater than 1.
- \( \text{scale} \): The thresholds are multiplied by \( \text{scale} \). Default is 1.
- \( \text{drop0} \): When thresholds are computed, should zero values be dropped from the sample of objective-function values? Default is FALSE.
stepUp Defaults to 0. If an integer greater than zero, then the thresholds are recycled, ie, vT is replaced by \( \text{rep}(vT, \text{algo$stepUp} + 1) \) (and the number of thresholds will be increased by \( \text{algo$nT} \) times \( \text{algo$stepUp} \)). This option works for supplied as well as computed thresholds. Practically, this will have the same effect as restarting from a returned solution. (In Simulated Annealing, this strategy goes by the name of 'reheating'.)

thresholds.only Defaults to FALSE. If TRUE, compute only threshold sequence, but do not actually run TA.

storeF if TRUE (the default), the objective function values for every solution in every generation are stored and returned as matrix Fmat.

storeSolutions Default is FALSE. If TRUE, the solutions (ie, decision variables) in every generation are stored and returned in list xlist (see Value section below). To check, for instance, the current solution at the end of the ith generation, retrieve \( \text{xlist[[c(2L, i)]]} \).

classify Logical; default is FALSE. If TRUE, the result will have a class attribute TAopt attached. This feature is experimental: the supported methods (plot, summary) may change without warning.

OF.target Numeric; when specified, the algorithm will stop when an objective-function value as low as OF.target (or lower) is achieved. This is useful when an optimal objective-function value is known: the algorithm will then stop and not waste time searching for a better solution.

At the minimum, algo needs to contain an initial solution x0 and a neighbour function.

The total number of iterations equals \( \text{algo$nT} \) times \( \text{algo$stepUp} + 1 \) times \( \text{algo$nS} \) (plus possibly \( \text{algo$nD} \)).

Value

TAopt returns a list with four components:

- **xbest** the solution
- **OFvalue** objective function value of the solution, ie, \( \text{OF(xbest, ...)} \)
- **Fmat** if \( \text{algo$storeF} \) is TRUE, a matrix with one row for each iteration (excluding the initial \( \text{algo$nD} \) steps) and two columns. The first column contains the objective function values of the neighbour solution at a given iteration; the second column contains the value of the current solution. Since TA can walk away from locally-optimal solutions, the best solution can be monitored through \( \text{cummin(Fmat[,2L])} \).
- **xlist** if \( \text{algo$storeSolutions} \) is TRUE, a list; else NA. Contains the neighbour solutions at a given iteration (\( \text{xn} \)) and the current solutions (\( \text{xc} \)). Example: \( \text{Fmat[i, 2L]} \) is the objective function value associated with \( \text{xlist[[c(2L, i)]]} \).

initial.state the value of .Random.seed when the function was called.

If \( \text{algo$classify} \) was set to TRUE, the resulting list will have a class attribute TAopt.

Note

If the \( \ldots \) argument is used, then all the objects passed with \( \ldots \) need to go into the objective function and the neighbourhood function. It is recommended to collect all information in a list myList.
and then write `OF` and `neighbour` so that they are called as `OF(x, myList)` and `neighbour(x, myList)`. Note that `x` need not be a vector but can be any data structure (eg, a matrix or a list).

Using thresholds of size 0 makes `TA` run as a Local Search. The function `LSopt` may be preferred then because of smaller overhead.

## testFunctions

Classical Test Functions for Unconstrained Optimisation

Description

A number of functions that have been suggested in the literature as benchmarks for unconstrained optimisation.

Usage

- `tfAckley(x)`
- `tfEggholder(x)`
- `tfGriewank(x)`
- `tfRastrigin(x)`
- `tfRosenbrock(x)`
- `tfSchwefel(x)`
- `tfTrefethen(x)`

Arguments

- `x` a numeric vector of arguments. See Details.

Details

All functions take as argument only one variable, a numeric vector `x` whose length determines the dimensionality of the problem.

The Ackley function is implemented as

\[
\exp(1) + 20 - 20 \exp \left( -0.2 \sqrt{\frac{1}{n} \sum_{i=1}^{n} x_i^2} \right) - \exp \left( \frac{1}{n} \sum_{i=1}^{n} \cos(2\pi x_i) \right).
\]
The minimum function value is zero; reached at \( x = 0 \).
The \textit{Eggholder} takes a two-dimensional \( x \), here written as \( x \) and \( y \). It is defined as
\[
-(y + 47) \sin \left( \sqrt{|y + \frac{x}{2} + 47|} \right) - x \sin \left( \sqrt{|x - (y + 47)|} \right).
\]
The minimum function value is -959.6407; reached at \( c(512, \ 404.2319) \).
The \textit{Griewank} function is given by
\[
1 + \frac{1}{4000} \sum_{i=1}^{n} x_i^2 - \prod_{i=1}^{n} \cos \left( \frac{x_i}{\sqrt{i}} \right).
\]
The function is minimised at \( x = 0 \); its minimum value is zero.
The \textit{Rastrigin} function:
\[
10n + \sum_{i=1}^{n} (x_i^2 - 10 \cos(2\pi x_i))
\]
The minimum function value is zero; reached at \( x = 0 \).
The \textit{Rosenbrock} (or banana) function:
\[
\sum_{i=1}^{n-1} \left( 100(x_{i+1} - x_i^2)^2 + (1 - x_i)^2 \right).
\]
The minimum function value is zero; reached at \( x = 1 \).
The \textit{Schwefel} function:
\[
\sum_{i=1}^{n} \left( -x_i \sin \left( \sqrt{|x_i|} \right) \right).
\]
The minimum function value (to about 8 digits) is \(-418.9829n\); reached at \( x = 420.9687 \).
\textit{Trefethen’s} function takes a two-dimensional \( x \) (here written as \( x \) and \( y \)); it is defined as
\[
\exp(\sin(50x)) + \sin(60e^y) + \sin(70\sin(x)) + \sin(\sin(80y)) - \sin(10(x + y)) + \frac{1}{4}(x^2 + y^2).
\]
The minimum function value is -3.3069; reached at \( c(-0.0244, \ 0.2106) \).

\textbf{Value}

The objective function evaluated at \( x \) (a numeric vector of length one).

\textbf{Warning}

These test functions represent artificial problems. It is practically not too helpful to fine-tune a method on such functions. (That would be like memorising all the answers to a particular multiple-choice test.) The functions’ main purpose is checking the numerical implementation of algorithms.

\textbf{Author(s)}

Enrico Schumann
trackingPortfolio

## Description

Computes a portfolio similar to a benchmark, e.g. for tracking the benchmark’s performance or identifying factors.

## Usage

```r
trackingPortfolio(var, wmin = 0, wmax = 1,
                   method = "qp", objective = "variance", R)
```

## Examples

### Ackley

```r
n <- 100L; surf <- matrix(NA, n, n)
x1 <- seq(from = -2, to = 2, length.out = n)
for (i in 1:n)
  for (j in 1:n)
    surf[i, j] <- tfAckley(c(x1[i], x1[j]))
persp(x1, x1, -surf, phi = 30, theta = 30, expand = 0.5,
      col = "goldenrod1", shade = 0.2, ticktype = "detailed",
      xlab = "x1", ylab = "x2", zlab = "-f", main = "Ackley (-f)",
      border = NA)
```

### Trefethen

```r
n <- 100L; surf <- matrix(NA, n, n)
x1 <- seq(from = -10, to = 10, length.out = n)
for (i in 1:n)
  for (j in 1:n)
    surf[i, j] <- tfTrefethen(c(x1[i], x1[j]))
persp(x1, x1, -surf, phi = 30, theta = 30, expand = 0.5,
      col = "goldenrod1", shade = 0.2, ticktype = "detailed",
      xlab = "x1", ylab = "x2", zlab = "-f", main = "Trefethen (-f)",
      border = NA)
```
Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>var</td>
<td>the covariance matrix: a numeric (real), symmetric matrix. The first asset is the benchmark.</td>
</tr>
<tr>
<td>R</td>
<td>a matrix of returns: each column holds the returns of one asset; each row holds the returns for one observation. The first asset is the benchmark.</td>
</tr>
<tr>
<td>wmin</td>
<td>numeric: a lower bound on weights. May also be a vector that holds specific bounds for each asset.</td>
</tr>
<tr>
<td>wmax</td>
<td>numeric: an upper bound on weights. May also be a vector that holds specific bounds for each asset.</td>
</tr>
<tr>
<td>method</td>
<td>character. Currently, &quot;qp&quot; and &quot;ls&quot; are supported.</td>
</tr>
<tr>
<td>objective</td>
<td>character. Currently, &quot;variance&quot; and &quot;sum.of.squares&quot; are supported.</td>
</tr>
</tbody>
</table>

Details

With method "qp", the function uses solve.QP from package quadprog. Because of the algorithm that solve.QP uses, var has to be positive definite (i.e. must be of full rank).

Value

a numeric vector (the portfolio weights)

---

vanillaBond

Pricing Plain-Vanilla Bonds

Description

Calculate the theoretical price and yield-to-maturity of a list of cashflows.

Usage

vanillaBond(cf, times, df, yields)
ytm(cf, times, y0 = 0.05, tol = 1e-05, maxit = 1000L, offset = 0)
duration(cf, times, yield, modified = TRUE, raw = FALSE)
convexity(cf, times, yield, raw = FALSE)

Arguments

cf       Cashflows; a numeric vector or a matrix. If a matrix, cashflows should be ar-
times    ranged in rows; times-to-payment correspond to columns.
df       times-to-payment; a numeric vector
yields   discount factors; a numeric vector
optional (instead of discount factors); zero yields to compute discount factor; if
of length one, a flat zero curve is assumed
yield    numeric vector of length one (both duration and convexity assume a flat yield
curve)
y0   starting value
tol     tolerance
maxit   maximum number of iterations
offset numeric: a ‘base’ rate over which to compute the yield to maturity. See Details and Examples.

modified logical: return modified duration? (default TRUE)

raw logical: default FALSE. Compute duration/convexity as derivative of cashflows’ present value? Use this if you want to approximate the change in the bond price by a Taylor series (see Examples).

Details

vanillaBond computes the present value of a vector of cashflows; it may thus be used to evaluate not just bonds but any instrument that can be reduced to a deterministic set of cashflows.

ytm uses Newton’s method to compute the yield-to-maturity of a bond (a.k.a. internal interest rate). When used with a bond, the initial outlay (i.e. the bonds dirty price) needs be included in the vector of cashflows. For a coupon bond, a good starting value $y_0$ is the coupon divided by the dirty price of the bond.

An offset can be specified either as a single number or as a vector of zero rates. See Examples.

Value

numeric

convexity(cf, times, yield = y, raw = TRUE)/2 * d^2
```
vanillaOptionEuropean  Pricing Plain-Vanilla (European and American) and Barrier Options (European)

Description

Functions to calculate the theoretical prices and (some) Greeks for plain-vanilla and barrier options.

Usage

vanillaOptionEuropean(S, X, tau, r, q, v, tauD = 0, D = 0, 
  type = "call", greeks = TRUE,  
  model = NULL, ...)
vanillaOptionAmerican(S, X, tau, r, q, v, tauD = 0, D = 0, 
  type = "call", greeks = TRUE, M = 101)

vanillaOptionImpliedVol(exercise = "european", price, S, X, tau, r, 
  q = 0, tauD = 0, D = 0, type = "call", 
  M = 101,  
  uniroot.control = list(), uniroot.info = FALSE)

barrierOptionEuropean(S, X, H, tau, r, q = 0, v, tauD = 0, D = 0, 
  type = "call", 
  barrier.type = "downin", 
  rebate = 0, 
  greeks = FALSE, 
  model = NULL, ...)

Arguments

S  spot
X  strike
H  barrier
tau  time-to-maturity in years
r  risk-free rate
q  continuous dividend yield, see Details.
v  variance (volatility squared)
tauD  vector of times-to-dividends in years. Only dividends with tauD greater than zero and not greater than tau are kept.
D  vector of dividends (in currency units); default is no dividends.
type  call or put; default is call.
barrier.type  string: combination of up/down and in/out, such as downin
vanillaOptionEuropean

</tr>
</tbody>
</table>

uniroot.control
A list. If there are elements named interval, tol or maxiter, these are passed to uniroot. Any other elements of the list are ignored.

uniroot.info
logical; default is FALSE. If TRUE, the function will return the information returned by uniroot. See paragraph Value below.

Details

For European options the formula of Messrs Black, Scholes and Merton is used. It can be used for equities (set q equal to the dividend yield), futures (Black, 1976; set q equal to r), currencies (Garman and Kohlhagen, 1983; set q equal to the foreign risk-free rate). For future-style options (e.g. options on the German Bund future), set q and r equal to zero.

The Greeks are provided in their raw (‘textbook’) form with only one exception: Theta is made negative. For practical use, the other Greeks are also typically adjusted: Theta is often divided by 365 (or some other yearly day count); Vega and Rho are divided by 100 to give the sensitivity for one percentage-point move in volatility/the interest rate. Raw Gamma is not much use if not adjusted for the actual move in the underlier.

For European options the Greeks are computed through the respective analytic expressions. For American options only Delta, Gamma and Theta are computed because they can be directly obtained from the binomial tree; other Greeks need to be computed through a finite difference (see Examples).

For the European-type options, the function understands vectors of inputs, except for dividends. American options are priced via a Cox-Ross-Rubinstein tree; no vectorisation is implemented here.

The implied volatility is computed with uniroot from the stats package (the default search interval is c(0.00001,2); it can be changed through uniroot.control).

Dividends (D) are modelled via the escrowed-dividend model.

Value

Returns the price (a numeric vector of length one) if greeks is FALSE, else returns a list.

Note

If greeks is TRUE, the function will return a list with named elements (value, delta and so on). Prior to version 0.26-3, the first element of this list was named price.

Description

Compute the contract value of an Australian government-bond future from its quoted price.

Usage

xtContractValue(quoted.price, coupon, do.round = TRUE)
xtTickValue(quoted.price, coupon, do.round = TRUE)

Arguments

quoted.price The price, as in 99.02.
coupon numeric; should be 6, not 0.06
do.round If TRUE, round as done by ASX clearing house.

Details

Australian government-bond futures, traded at the Australian Securities Exchange (ASX), are quoted as 100 - yield. The function computes the actual contract value from the quoted price.
xtTickValue computes the tick value via a central difference.

Value

A numeric vector.

Author(s)

Enrico Schumann

Examples

quoted.price <- 99
coupon <- 6
xtContractValue(quoted.price, coupon)
xtTickValue(quoted.price, coupon)
## convexity
quoted.price <- seq(90, 100, by = 0.1)
plot(100 - quoted.price,
     xtContractValue(quoted.price, coupon),
     xlab = "Yield", ylab = "Contract value")
**Description**

Compute nodes and weights for Gauss integration.

**Usage**

```r
xwGauss(n, method = "legendre")
changeInterval(nodes, weights, oldmin, oldmax, newmin, newmax)
```

**Arguments**

- `n`: number of nodes
- `method`: character. default is "legendre"; also possible are "laguerre" and "hermite"
- `nodes`: the nodes (a numeric vector)
- `weights`: the weights (a numeric vector)
- `oldmin`: the minimum of the interval (typically as tabulated)
- `oldmax`: the maximum of the interval (typically as tabulated)
- `newmin`: the desired minimum of the interval
- `newmax`: the desired maximum of the interval

**Details**

`xwGauss` computes nodes and weights for integration for the interval -1 to 1. It uses the method of Golub and Welsch (1969).

`changeInterval` is a utility that transforms nodes and weights to an arbitrary interval.

**Value**

a list with two elements

- `weights`: a numeric vector
- `nodes`: a numeric vector

Examples

```r
## examples from Gilli/Maringer/Schumann (2011), ch. 15

## a test function
f1 <- function(x) exp(-x)
m <- 5; a <- 0; b <- 5
h <- (b - a)/m

## rectangular rule -- left
w <- h; k <- 0:(m-1); x <- a + k * h
sum(w * f1(x))

## rectangular rule -- right
w <- h; k <- 1:m ; x <- a + k * h
sum(w * f1(x))

## midpoint rule
w <- h; k <- 0:(m-1); x <- a + (k + 0.5)*h
sum(w * f1(x))

## trapezoidal rule
w <- h
k <- 1:(m-1)
x <- c(a, a + k*h, b)
aux <- w * f1(x)
sum(aux) - (aux[1] + aux[length(aux)])/2

## R’s integrate (from package stats)
integrate(f1, lower = a, upper = b)

## Gauss--Legendre
temp <- xwGauss(m)
temp <- changeInterval(temp$nodes, temp$weights,
                      oldmin = -1, oldmax = 1, newmin = a, newmax = b)
x <- temp$nodes; w <- temp$weights
sum(w * f1(x))
```
