R topics documented:

Co.LPM  ......................................................... 2
Co.UPM  ......................................................... 3
D.LPM  ......................................................... 4
### Description

This function generates a co-lower partial moment for between two equal length variables for any degree or target.
Usage

Co.LPM(degree.x, degree.y, x, y, target.x = mean(x), target.y = mean(y))

Arguments

degree.x integer; Degree for variable X. (degree.x = 0) is frequency, (degree.x = 1) is area.
degree.y integer; Degree for variable Y. (degree.y = 0) is frequency, (degree.y = 1) is area.
x a numeric vector.
y a numeric vector of equal length to x.
target.x numeric; Typically the mean of Variable X for classical statistics equivalences, but does not have to be. (Vectorized)
target.y numeric; Typically the mean of Variable Y for classical statistics equivalences, but does not have to be. (Vectorized)

Value

Co-LPM of two variables

Author(s)

Fred Viole, OVVO Financial Systems

References

https://www.amazon.com/dp/1490523995/ref=cm_sw_su_dp

Examples

set.seed(123)
x <- rnorm(100); y <- rnorm(100)
Co.LPM(0, 0, x, y, mean(x), mean(y))

Co.UPM

Co-Upper Partial Moment (Upper Right Quadrant 1)

Description

This function generates a co-upper partial moment between two equal length variables for any degree or target.

Usage

Co.UPM(degree.x, degree.y, x, y, target.x = mean(x), target.y = mean(y))
D.LPM

Divergent-Lower Partial Moment (Lower Right Quadrant 3)

Description
This function generates a divergent lower partial moment between two equal length variables for any degree or target.

Usage
D.LPM(degree.x, degree.y, x, y, target.x = mean(x), target.y = mean(y))
Arguments

degree.x  integer; Degree for variable X. (degree.x = 0) is frequency, (degree.x = 1) is area.

degree.y  integer; Degree for variable Y. (degree.y = 0) is frequency, (degree.y = 1) is area.

x  a numeric vector.

y  a numeric vector of equal length to x.

target.x  numeric; Typically the mean of Variable X for classical statistics equivalences, but does not have to be. (Vectorized)

target.y  numeric; Typically the mean of Variable Y for classical statistics equivalences, but does not have to be. (Vectorized)

Value

Divergent LPM of two variables

Author(s)

Fred Viole, OVVO Financial Systems

References

https://www.amazon.com/dp/1490523995/ref=cm_sw_su_dp

Examples

```r
set.seed(123)
x <- rnorm(100); y <- rnorm(100)
D.LPM(0, 0, x, y, mean(x), mean(y))
```

Description

This function generates a divergent upper partial moment between two equal length variables for any degree or target.

Usage

```r
D.UPM(degree.x, degree.y, x, y, target.x = mean(x), target.y = mean(y))
```
Arguments

degree.x integer; Degree for variable X. (degree.x = 0) is frequency, (degree.x = 1) is area.

degree.y integer; Degree for variable Y. (degree.y = 0) is frequency, (degree.y = 1) is area.

x a numeric vector.

y a numeric vector of equal length to x.

target.x numeric; Typically the mean of Variable X for classical statistics equivalences, but does not have to be. (Vectorized)

target.y numeric; Typically the mean of Variable Y for classical statistics equivalences, but does not have to be. (Vectorized)

Value

Divergent UPM of two variables

Author(s)

Fred Viole, OVVO Financial Systems

https://www.amazon.com/dp/1490523995/ref=cm_sw_su_dp

Examples

set.seed(123)
x <- rnorm(100) ; y <- rnorm(100)
D.UPM(0, 0, x, y, mean(x), mean(y))

dy.dx

Partial Derivative dy/dx

Description

Returns the numerical partial derivative of y wrt x for a point of interest.

Usage

dy.dx(x, y, eval.point = median(x), deriv.method = "FD")
Arguments

- **x**: a numeric vector.
- **y**: a numeric vector.
- **eval.point**: numeric or ("overall"); x point to be evaluated. Defaults to (eval.point = median(x)). Set to (eval.point = "overall") to find an overall partial derivative estimate (1st derivative only).
- **deriv.method**: method of derivative estimation, options: ("NNS", "FD"); Determines the partial derivative from the coefficient of the NNS.reg output when (deriv.method = "NNS") or generates a partial derivative using the finite difference method (deriv.method = "FD") (Default).

Value

Returns a list of both 1st and 2nd derivative:

- **dy.dx(...)$First**: the 1st derivative.
- **dy.dx(...)$Second**: the 2nd derivative.

Note

If a vector of derivatives is required, ensure (deriv.method = "FD").

Author(s)

Fred Viole, OVVO Financial Systems

References

Examples

```r
# Not run:
x <- seq(0, 2 * pi, pi / 100); y <- sin(x)
dy.dx(x, y, eval.point = 1.75)

# Vector of derivatives
dy.dx(x, y, eval.point = c(1.75, 2.5), deriv.method = "FD")
```

```r
## End(Not run)
```
dy.d_  Partial Derivative dy/d_[wrt]

Description

Returns the numerical partial derivative of \( y \) with respect to \([\text{wrt}]\) any regressor for a point of interest. Finite difference method is used with NNS.reg estimates as \( f(x + h) \) and \( f(x - h) \) values.

Usage

dy.d_\( (x, y, \text{wrt}, \text{eval.points} = \"obs\", \text{mixed} = \text{FALSE}, \text{messages} = \text{TRUE}) \)

Arguments

x a numeric matrix or data frame.
y a numeric vector with compatible dimensions to \( x \).
wrt integer; Selects the regressor to differentiate with respect to (vectorized).
eval.points numeric or options: ("obs", "apd", "mean", "median", "last"); Regressor points to be evaluated.

• Numeric values must be in matrix or data.frame form to be evaluated for each regressor, otherwise, a vector of points will evaluate only at the \( \text{wrt} \) regressor. See examples for use cases.
• Set to (eval.points = "obs") (default) to find the average partial derivative at every observation of the variable with respect to for specific tuples of given observations.
• Set to (eval.points = "apd") to find the average partial derivative at every observation of the variable with respect to over the entire distribution of other regressors.
• Set to (eval.points = "mean") to find the partial derivative at the mean of value of every variable.
• Set to (eval.points = "median") to find the partial derivative at the median value of every variable.
• Set to (eval.points = "last") to find the partial derivative at the last observation of every value (relevant for time-series data).
mixed logical; FALSE (default) If mixed derivative is to be evaluated, set (mixed = TRUE).
messages logical; TRUE (default) Prints status messages.

Value

Returns column-wise matrix of \( \text{wrt} \) regressors:

• dy.d_(\( \ldots \))[\( ,\text{wrt} \)]$First the 1st derivative
• dy.d_(\( \ldots \))[\( ,\text{wrt} \)]$Second the 2nd derivative
• dy.d_(\( \ldots \))[\( ,\text{wrt} \)]$Mixed the mixed derivative (for two independent variables only).
dy.d_

Note

For binary regressors, it is suggested to use eval.points = seq(0,1,.05) for a better resolution around the midpoint.

Author(s)

Fred Viole, OVVO Financial Systems

References

Examples

```r
## Not run:
set.seed(123) ; x_1 <- runif(1000) ; x_2 <- runif(1000) ; y <- x_1 ^ 2 * x_2 ^ 2
B <- cbind(x_1, x_2)

## To find derivatives of y wrt 1st regressor for specific points of both regressors
dy.d_(B, y, wrt = c(1, 2), eval.points = t(c(.5, .5)))

## To find average partial derivative of y wrt 1st regressor,
## only supply 1 value in [eval.points], or a vector of [eval.points]:
dy.d_(B, y, wrt = 1, eval.points = .5)
dy.d_(B, y, wrt = 1, eval.points = fivenum(B[,1]))

## To find average partial derivative of y wrt 1st regressor,
## for every observation of 1st regressor:
apd <- dy.d_(B, y, wrt = 1, eval.points = "apd")
plot(B[,1], apd[,1]$First)

## 95% Confidence Interval to test if 0 is within
### Lower CI
LPM.VaR(.025, 0, apd[,1]$First)

### Upper CI
UPM.VaR(.025, 0, apd[,1]$First)

## End(Not run)
```
Description

This function generates a univariate lower partial moment for any degree or target.

Usage

LPM(degree, target, variable)

Arguments

degree integer; (degree = 0) is frequency, (degree = 1) is area.
target numeric; Typically set to mean, but does not have to be. (Vectorized)
variable a numeric vector.

Value

LPM of variable

Author(s)

Fred Viole, OVVO Financial Systems

References

https://www.amazon.com/dp/1490523995/ref=cm_sw_su_dp

Examples

set.seed(123)
x <- rnorm(100)
LPM(0, mean(x), x)
**LPM.ratio**

*Lower Partial Moment RATIO*

---

**Description**

This function generates a standardized univariate lower partial moment for any degree or target.

**Usage**

\[ \text{LPM.ratio}(\text{degree, target, variable}) \]

**Arguments**

- **degree**: integer; (degree = 0) is frequency, (degree = 1) is area.
- **target**: numeric; Typically set to mean, but does not have to be. (Vectorized)
- **variable**: a numeric vector.

**Value**

Standardized LPM of variable

**Author(s)**

Fred Viole, OVVO Financial Systems

**References**

Viole, F. (2017) "Continuous CDFs and ANOVA with NNS"  

**Examples**

```r
set.seed(123)
x <- rnorm(100)
LPM.ratio(0, mean(x), x)

## Not run:
## Empirical CDF (degree = 0)
lpm_cdf <- LPM.ratio(0, sort(x), x)
plot(sort(x), lpm_cdf)

## Continuous CDF (degree = 1)
lpm_cdf_1 <- LPM.ratio(1, sort(x), x)
plot(sort(x), lpm_cdf_1)

## Joint CDF
```

\begin{verbatim}
x <- rnorm(5000); y <- rnorm(5000)
plot3d(x, y, Co.LPM(0, 0, sort(x), sort(y), x, y), col = "blue", xlab = "X", ylab = "Y", zlab = "Probability", box = FALSE)
## End(Not run)
\end{verbatim}

---

**LPM.VaR**  
**LPM VaR**

---

**Description**
Generates a value at risk (VaR) quantile based on the Lower Partial Moment ratio.

**Usage**

\[
\text{LPM.VaR}(\text{percentile, degree, x})
\]

**Arguments**

- **percentile**: numeric \([0, 1]\); The percentile for left-tail VaR (vectorized).
- **degree**: integer; \((\text{degree} = 0)\) for discrete distributions, \((\text{degree} = 1)\) for continuous distributions.
- **x**: a numeric vector.

**Value**
Returns a numeric value representing the point at which "percentile" of the area of \(x\) is below.

**Author(s)**
Fred Viole, OVVO Financial Systems

**References**
https://www.amazon.com/dp/1490523995/ref=cm_sw_su_dp

**Examples**

\begin{verbatim}
set.seed(123)
x <- rnorm(100)
## For 5th percentile, left-tail
LPM.VaR(0.05, 0, x)
\end{verbatim}
Description

Analysis of variance (ANOVA) based on lower partial moment CDFs for multiple variables. Returns a degree of certainty the difference in sample means is zero, not a p-value.

Usage

\[
\text{NNS.ANOVA}(\text{control}, \text{treatment}, \text{confidence.interval} = 0.95, \text{tails} = "Both", \text{pairwise} = \text{FALSE}, \text{plot} = \text{TRUE}, \text{robust} = \text{FALSE})
\]

Arguments

- **control**: a numeric vector, matrix or data frame.
- **treatment**: NULL (default) a numeric vector, matrix or data frame.
- **confidence.interval**: numeric \([0, 1]\); The confidence interval surrounding the control mean, defaults to \(\text{confidence.interval} = 0.95\).
- **tails**: options: ("Left", "Right", "Both"). \(\text{tails} = "Both"\) (Default) Selects the tail of the distribution to determine effect size.
- **pairwise**: logical; \text{FALSE} (default) Returns pairwise certainty tests when set to \text{pairwise} = \text{TRUE}.
- **plot**: logical; \text{TRUE} (default) Returns the boxplot of all variables along with grand mean identification and confidence interval thereof.
- **robust**: logical; \text{FALSE} (default) Generates 100 independent random permutations to test results, and returns / plots 95 percent confidence intervals along with robust central tendency of all results.

Value

Returns the following:

- "Control Mean" control mean.
- "Treatment Mean" treatment mean.
- "Grand Mean" mean of means.
- "Control CDF" CDF of the control from the grand mean.
• “Treatment CDF” CDF of the treatment from the grand mean.
• "Certainty" the certainty of the same population statistic.
• "Lower Bound Effect" and "Upper Bound Effect" the effect size of the treatment for the specified confidence interval.
• "Robust Certainty Estimate" and "95 CI" are the robust certainty estimate and its 95 percent confidence interval after permutations if robust = TRUE.

Examples

### Binary analysis and effect size
```r
set.seed(123)
x <- rnorm(100) ; y <- rnorm(100)
NNS.ANOVA(control = x, treatment = y)
```

### Two variable analysis with no control variable
```r
A <- cbind(x, y)
NNS.ANOVA(A)
```

### Multiple variable analysis with no control variable
```r
set.seed(123)
x <- rnorm(100) ; y <- rnorm(100) ; z <- rnorm(100)
A <- cbind(x, y, z)
NNS.ANOVA(A)
```

Description

Autoregressive model incorporating nonlinear regressions of component series.
Usage

NNS.ARMA(
  variable,
  h = 1,
  training.set = NULL,
  seasonal.factor = TRUE,
  weights = NULL,
  best.periods = 1,
  modulo = NULL,
  mod.only = TRUE,
  negative.values = FALSE,
  method = "nonlin",
  dynamic = FALSE,
  shrink = FALSE,
  plot = TRUE,
  seasonal.plot = TRUE,
  conf.intervals = NULL,
  ncores = NULL
)

Arguments

variable  a numeric vector.

h  integer; 1 (default) Number of periods to forecast.

training.set  numeric; NULL (default) Sets the number of variable observations
(variable[1 : training.set]) to monitor performance of forecast over in-

seasonal.factor  logical or integer(s); TRUE (default) Automatically selects the best seasonal lag
from the seasonality test. To use weighted average of all seasonal lags set to
(seasonal.factor = FALSE). Otherwise, directly input known frequency integer
lag to use, i.e. (seasonal.factor = 12) for monthly data. Multiple fre-

weights  numeric or "equal"; NULL (default) sets the weights of the seasonal.factor
vector when specified as integers. If (weights = NULL) each seasonal.factor
is weighted on its NNS.seas result and number of observations it contains, else
an "equal" weight is used.

best.periods  integer; [2] (default) used in conjunction with (seasonal.factor = FALSE),
uses the best.periods number of detected seasonal lags instead of ALL lags
when (seasonal.factor = FALSE,best.periods = NULL).

modulo  integer(s); NULL (default) Used to find the nearest multiple(s) in the reported
seasonal period.

mod.only  logical; TRUE (default) Limits the number of seasonal periods returned to the
specified modulo.
negative.values

logical; FALSE (default) If the variable can be negative, set to (negative.values = TRUE). If there are negative values within the variable, negative.values will automatically be detected.

method

options: ("lin", "nonlin", "both", "means"); "nonlin" (default) To select the regression type of the component series, select (method = "both") where both linear and nonlinear estimates are generated. To use a nonlinear regression, set to (method = "nonlin"); to use a linear regression set to (method = "lin"). Means for each subset are returned with (method = "means").

dynamic

logical; FALSE (default) To update the seasonal factor with each forecast point, set to (dynamic = TRUE). The default is (dynamic = FALSE) to retain the original seasonal factor from the inputted variable for all ensuing h.

shrink

logical; FALSE (default) Ensembles forecasts with method = "means".

plot

logical; TRUE (default) Returns the plot of all periods exhibiting seasonality and the variable level reference in upper panel. Lower panel returns original data and forecast.

seasonal.plot

logical; TRUE (default) Adds the seasonality plot above the forecast. Will be set to FALSE if no seasonality is detected or seasonal.factor is set to an integer value.

conf.intervals

numeric [0, 1]; NULL (default) Plots and returns the associated confidence intervals for the final estimate. Constructed using the maximum entropy bootstrap meboot on the final estimates.

ncores

integer; value specifying the number of cores to be used in the parallelized procedure. If NULL (default), the number of cores to be used is equal to half the number of cores of the machine - 1.

Value

Returns a vector of forecasts of length (h) if no conf.intervals specified. Else, returns a data.table with the forecasts as well as lower and upper confidence intervals per forecast point.

Note

For monthly data series, increased accuracy may be realized from forcing seasonal factors to multiples of 12. For example, if the best periods reported are: {37, 47, 71, 73} use (seasonal.factor = c(36, 48, 72)).

(seasonal.factor = FALSE) can be a very computationally expensive exercise due to the number of seasonal periods detected.

If error encountered when (seasonal.factor = TRUE):

"NaNs produced Error in seq.default(length(variable)+1,1,-lag[i]) : wrong sign in 'by' argument"

use the combination of (seasonal.factor = FALSE,best.periods = 1).

Author(s)

Fred Viole, OVVO Financial Systems
NNS.ARM Optimizer

Description

Wrapper function for optimizing any combination of a given seasonal.factor vector in NNS.ARM. Minimum sum of squared errors (forecast-actual) is used to determine optimum across all NNS.ARM methods.

Usage

NNS.ARM.optim(
  variable,
  h = NULL,
  training.set = NULL,
  seasonal.factor,
  negative.values = FALSE,
  obj.fn = expression(cor(predicted, actual, method = "spearman")/sum((predicted - actual)^2)),
  objective = "max",
  linear.approximation = TRUE,
  lin.only = FALSE,
  print.trace = TRUE,
  ncores = NULL
)
Arguments

variable  a numeric vector.

h  integer; NULL (default) Number of periods to forecast out of sample. If NULL, \( h = \text{length}(\text{variable}) - \text{training.set}. \)

training.set  integer; NULL (default) Sets the number of variable observations as the training set. See Note below for recommended uses.

seasonal.factor  integers; Multiple frequency integers considered for NNS.ARMA model, i.e. \( \text{seasonal.factor} = c(12,24,36) \)

negative.values  logical; FALSE (default) If the variable can be negative, set to (negative.values = TRUE). It will automatically select (negative.values = TRUE) if the minimum value of the variable is negative.

obj.fn  expression; expression(\(\text{cor}(\text{predicted},\text{actual},\text{method} = "\text{spearman}") / \text{sum}((\text{predicted} - \text{actual})^2)\)) (default) Rank correlation / sum of squared errors is the default objective function. Any expression() using the specific terms \(\text{predicted}\) and \(\text{actual}\) can be used.

objective  options: ("min", "max") "max" (default) Select whether to minimize or maximize the objective function \(\text{obj.fn}\).

linear.approximation  logical; TRUE (default) Uses the best linear output from NNS.reg to generate a nonlinear and mixture regression for comparison. FALSE is a more exhaustive search over the objective space.

lin.only  logical; FALSE (default) Restricts the optimization to linear methods only.

print.trace  logical; TRUE (default) Prints current iteration information. Suggested as backup in case of error, best parameters to that point still known and copyable!

ncores  integer; value specifying the number of cores to be used in the parallelized procedure. If NULL (default), the number of cores to be used is equal to half the number of cores of the machine.

Value

Returns a list containing:

- \$period a vector of optimal seasonal periods
- \$weights the optimal weights of each seasonal period between an equal weight or NULL weighting
- \$obj.fn the objective function value
- \$method the method identifying which NNS.ARMA method was used.
- \$shrink whether to use the shrink parameter in NNS.ARMA.
- \$bias.shift a numerical result of the overall bias of the optimum objective function result. To be added to the final result when using the NNS.ARMA with the derived parameters.
- \$errors a vector of model errors from internal calibration.
- \$results a vector of length h.
Note

- Typically, \( (\text{training.set} = \text{length(variable)} - 2 \times \text{length(forecast horizon)}) \) is used for optimization. Smaller samples would use \( (\text{training.set} = \text{length(variable)} - \text{length(forecast horizon)}) \) in order to preserve information.
- The number of combinations will grow prohibitively large, they should be kept as small as possible. \text{seasonal.factor} containing an element too large will result in an error. Please reduce the maximum \text{seasonal.factor}.
- If variable cannot logically assume negative values, then the \$bias.shift must be limited to 0 via a \text{pmax(0, ...)} call.

Examples

```r
## Nonlinear NNS.ARMA period optimization using 2 yearly lags on AirPassengers monthly data
## Not run:
nns.optims <- NNS.ARMA.optim(AirPassengers[1:132], training.set = 120,
seasonal.factor = seq(12, 24, 6))

## Then use optimal parameters in NNS.ARMA to predict 12 periods in-sample.
## Note the \$bias.shift usage in the \{NNS.ARMA\} function:
nns.estimates <- NNS.ARMA(AirPassengers, h = 12, training.set = 132,
seasonal.factor = nns.optims$periods, method = nns.optims$method) + nns.optims$bias.shift

## If variable cannot logically assume negative values
nns.estimates <- \text{pmax(0, nns.estimates)}

## To predict out of sample using best parameters:
NNS.ARMA.optim(AirPassengers[1:132], h = 12, seasonal.factor = seq(12, 24, 6))

## End(Not run)
```

Description

Ensemble method for classification using the predictions of the NNS multivariate regression \text{NNS.reg} collected from uncorrelated feature combinations.
Usage

NNS.boost(
   IVs.train,  
   DV.train,  
   IVs.test = NULL,  
   type = NULL,  
   inference = FALSE,  
   depth = NULL,  
   learner.trials = 100,  
   epochs = NULL,  
   CV.size = 0.25,  
   balance = FALSE,  
   ts.test = NULL,  
   folds = 5,  
   threshold = NULL,  
   obj.fn = expression(sum((predicted - actual)^2)),  
   objective = "min",  
   extreme = FALSE,  
   features.only = FALSE,  
   feature.importance = TRUE,  
   status = TRUE  
)

Arguments

IVs.train a matrix or data frame of variables of numeric or factor data types.

DV.train a numeric or factor vector with compatible dimensions to (IVs.train).

IVs.test a matrix or data frame of variables of numeric or factor data types with compatible dimensions to (IVs.train). If NULL, will use (IVs.train) as default.

type NULL (default). To perform a classification of discrete integer classes from factor target variable (DV.train) with a base category of 1, set to (type = "CLASS"), else for continuous (DV.train) set to (type = NULL).

inference logical; FALSE (default) For inferential tasks, otherwise inference = FALSE is faster for predictive tasks.

depth options: (integer, NULL, "max"); (depth = NULL)(default) Specifies the order parameter in the NNS.reg routine, assigning a number of splits in the regressors, analogous to tree depth.

learner.trials integer; 100 (default) Sets the number of trials to obtain an accuracy threshold level. If the number of all possible feature combinations is less than selected value, the minimum of the two values will be used.

epochs integer; 2*length(DV.train) (default) Total number of feature combinations to run.

CV.size numeric [0, 1]; (CV.size = .25) (default) Sets the cross-validation size. Defaults to 0.25 for a 25 percent random sampling of the training set.

balance logical; FALSE (default) Uses both up and down sampling from caret to balance the classes. type="CLASS" required.
NNS.boost

**ts.test** integer; NULL (default) Sets the length of the test set for time-series data; typically 2*h parameter value from NNS arma or double known periods to forecast.

**folds** integer; 5 (default) Sets the number of folds in the NNS.stack procedure for optimal n.best parameter.

**threshold** numeric; NULL (default) Sets the obj.fn threshold to keep feature combinations.

**obj.fn** expression; expression( sum((predicted - actual)^2) ) (default) Sum of squared errors is the default objective function. Any expression() using the specific terms predicted and actual can be used. Automatically selects an accuracy measure when (type = "CLASS").

**objective** options: ("min", "max") "max" (default) Select whether to minimize or maximize the objective function obj.fn.

**extreme** logical; FALSE (default) Uses the maximum (minimum) threshold obtained from the learner.trials, rather than the upper (lower) quintile level for maximization (minimization) objective.

**features.only** logical; FALSE (default) Returns only the final feature loadings along with the final feature frequencies.

**feature.importance** logical; TRUE (default) Plots the frequency of features used in the final estimate.

**status** logical; TRUE (default) Prints status update message in console.

**Value**

Returns a vector of fitted values for the dependent variable test set $results, and the final feature loadings $feature.weights, along with final feature frequencies $feature.frequency.

**Note**

Like a logistic regression, the (type = "CLASS") setting is not necessary for target variable of two classes e.g. [0, 1]. The response variable base category should be 1 for classification problems.

**Examples**

```r
## Using 'iris' dataset where test set [IVs.test] is 'iris' rows 141:150.
## Not run:
a <- NNS.boost(iris[1:140, 1:4], iris[1:140, 5],
  IVs.test = iris[141:150, 1:4],
  epochs = 100, learner.trials = 100,
  type = "CLASS", depth = NULL)
```
## Test accuracy

```r
mean(a$results == as.numeric(iris[141:150, 5]))
```

## End (Not run)

---

### NNS.caus

#### NNS Causation

**Description**

Returns the causality from observational data between two variables.

**Usage**

```r
NNS.caus(x, y = NULL, factor.2.dummy = FALSE, tau = 0, plot = FALSE)
```

**Arguments**

- `x`: a numeric vector, matrix or data frame.
- `y`: NULL (default) or a numeric vector with compatible dimensions to `x`.
- `factor.2.dummy`: logical; FALSE (default) Automatically augments variable matrix with numerical dummy variables based on the levels of factors. Includes dependent variable `y`.
- `tau`: options: ("cs", "ts", integer); 0 (default) Number of lagged observations to consider (for time series data). Otherwise, set (tau = "cs") for cross-sectional data. (tau = "ts") automatically selects the lag of the time series data, while (tau = [integer]) specifies a time series lag.
- `plot`: logical; FALSE (default) Plots the raw variables, tau normalized, and cross-normalized variables.

**Value**

Returns the directional causation (x —> y) or (y —> x) and net quantity of association. For causal matrix, directional causation is returned as ([column variable] —> [row variable]). Negative numbers represent causal direction attributed to [row variable].

**Author(s)**

Fred Viole, OVVO Financial Systems

**References**

[https://www.amazon.com/dp/1490523995/ref=cm_sw_su_dp](https://www.amazon.com/dp/1490523995/ref=cm_sw_su_dp)
Examples

```r
## Not run:
## x causes y...
set.seed(123)
x <- rnorm(1000); y <- x ^ 2
NNS.caus(x, y, tau = "cs")

## Causal matrix without per factor causation
NNS.caus(iris, tau = 0)

## Causal matrix with per factor causation
NNS.caus(iris, factor.2.dummy = TRUE, tau = 0)

## End(Not run)
```

Description

This function generates an empirical CDF using partial moment ratios `LPM.ratio`, and resulting survival, hazard and cumulative hazard functions.

Usage

```r
NNS.CDF(variable, degree = 0, target = NULL, type = "CDF", plot = TRUE)
```

Arguments

- **variable**: a numeric vector or data.frame of 2 variables for joint CDF.
- **degree**: integer; (degree = 0) (default) is frequency, (degree = 1) is area.
- **target**: numeric; NULL (default) Must lie within support of each variable.
- **type**: options("CDF", "survival", "hazard", "cumulative hazard"); "CDF" (default) Selects type of function to return for bi-variate analysis. Multivariate analysis is restricted to "CDF".
- **plot**: logical; plots CDF.

Value

Returns:

- "Function" a data.table containing the observations and resulting CDF of the variable.
- "target.value" value from the target argument.

Author(s)

Fred Viole, OVVO Financial Systems
References

https://www.amazon.com/dp/1490523995/ref=cm_sw_su_dp

Examples

```r
set.seed(123)
x <- rnorm(100)
NNS.CDF(x)

## Not run:
## Empirical CDF (degree = 0)
NNS.CDF(x)

## Continuous CDF (degree = 1)
NNS.CDF(x, 1)

## Joint CDF
x <- rnorm(5000); y <- rnorm(5000)
A <- cbind(x, y)
NNS.CDF(A, 0)

## Joint CDF with target
NNS.CDF(A, 0, target = c(0, 0))

## End(Not run)
```

NNS.copula

NNS Co-Partial Moments Higher Dimension Dependence

Description

Determines higher dimension dependence coefficients based on co-partial moment matrices ratios.

Usage

```r
NNS.copula(
  X,
  target = NULL,
  continuous = TRUE,
  plot = FALSE,
  independence.overlay = FALSE,
  ncores = NULL
)
```
NNS.copula

Arguments

X a numeric matrix or data frame.

target numeric; Typically the mean of Variable X for classical statistics equivalences, but does not have to be. (Vectorized) (target = NULL) (default) will set the target as the mean of every variable.

continuous logical; TRUE (default) Generates a continuous measure using degree 1 PM.matrix, while discrete FALSE uses degree 0 PM.matrix.

plot logical; FALSE (default) Generates a 3d scatter plot with regression points using plot3d.

independence.overlay logical; FALSE (default) Creates and overlays independent Co.LPM and Co.UPM regions to visually reference the difference in dependence from the data.frame of variables being analyzed. Under independence, the light green and red shaded areas would be occupied by green and red data points respectively.

ncores integer; value specifying the number of cores to be used in the parallelized procedure. If NULL (default), the number of cores to be used is equal to the number of cores of the machine - 1.

Value

Returns a multivariate dependence value [0,1].

Author(s)

Fred Viole, OVVO Financial Systems

References

Examples

```R
set.seed(123)
x <- rnorm(1000); y <- rnorm(1000); z <- rnorm(1000)
A <- data.frame(x, y, z)
NNS.copula(A, plot = TRUE, independence.overlay = TRUE, ncores = 1)

### Target 0
NNS.copula(A, target = rep(0, ncol(A)), plot = TRUE, independence.overlay = TRUE, ncores = 1)
```
NNS.dep

NNS Dependence

Description

Returns the dependence and nonlinear correlation between two variables based on higher order partial moment matrices measured by frequency or area.

Usage

NNS.dep(
  x,
  y = NULL,
  asym = FALSE,
  p.value = FALSE,
  print.map = FALSE,
  ncores = NULL
)

Arguments

x    a numeric vector, matrix or data frame.
y    NULL (default) or a numeric vector with compatible dimensions to x.
asym logical; FALSE (default) Allows for asymmetrical dependencies.
p.value logical; FALSE (default) Generates 100 independent random permutations to test results against and plots 95 percent confidence intervals along with all results.
print.map logical; FALSE (default) Plots quadrant means, or p-value replicates.
ncores integer; value specifying the number of cores to be used in the parallelized procedure. If NULL (default), the number of cores to be used is equal to the number of cores of the machine - 1.

Value

Returns the bi-variate "Correlation" and "Dependence" or correlation / dependence matrix for matrix input.

Note

NNS.cor has been deprecated (NNS >= 0.5.4) and can be called via NNS.dep.

Author(s)

Fred Viole, OVVO Financial Systems

Examples

## Not run:
set.seed(123)
x <- rnorm(100) ; y <- rnorm(100)
NNS.dep(x, y)

## Correlation / Dependence Matrix
x <- rnorm(100) ; y <- rnorm(100) ; z <- rnorm(100)
B <- cbind(x, y, z)
NNS.dep(B)

## End(Not run)

---

### NNS.diff

**NNS Numerical Differentiation**

**Description**

Determines numerical derivative of a given univariate function using projected secant lines on the y-axis. These projected points infer finite steps \( h \), in the finite step method.

**Usage**

NNS.diff(f, point, h = 0.1, tol = 1e-10, digits = 12, print.trace = FALSE)

**Arguments**

- **f**: an expression or call or a formula with no lhs.
- **point**: numeric; Point to be evaluated for derivative of a given function \( f \).
- **h**: numeric \([0, ...]\); Initial step for secant projection. Defaults to \( h = 0.1 \).
- **tol**: numeric; Sets the tolerance for the stopping condition of the inferred \( h \). Defaults to \( \text{tol} = 1e-10 \).
- **digits**: numeric; Sets the number of digits specification of the output. Defaults to \( \text{digits} = 12 \).
- **print.trace**: logical; FALSE (default) Displays each iteration, lower y-intercept, upper y-intercept and inferred \( h \).

**Value**

Returns a matrix of values, intercepts, derivatives, inferred step sizes for multiple methods of estimation.
Author(s)

Fred Viole, OVVO Financial Systems

References

https://www.amazon.com/dp/1490523995/ref=cm_sw_su_dp

Examples

```r
f <- function(x) sin(x) / x
NNS.diff(f, 4.1)
```

---

**NNS.distance**  

**NNS Distance**

Description

Internal kernel function for NNS multivariate regression NNS.reg parallel instances.

Usage

```r
NNS.distance(rpm, rpm_class, dist.estimate, type, k, class)
```

Arguments

- `rpm`: REGRESSION.POINT.MATRIX from NNS.reg
- `rpm_class`: integer rpm.
- `dist.estimate`: Vector to generate distances from.
- `type`: "L1", "L2", "DTW" or "FACTOR"
- `k`: n.best from NNS.reg
- `class`: if classification problem.

Value

Returns sum of weighted distances.
**Description**

Bi-directional test of first degree stochastic dominance using lower partial moments.

**Usage**

```r
NNS.FSD(x, y, type = "discrete", plot = TRUE)
```

**Arguments**

- `x` : a numeric vector.
- `y` : a numeric vector.
- `type` : options: ("discrete", "continuous"); "discrete" (default) selects the type of CDF.
- `plot` : logical; TRUE (default) plots the FSD test.

**Value**

Returns one of the following FSD results: "X FSD Y", "Y FSD X", or "NO FSD EXISTS".

**Author(s)**

Fred Viole, OVVO Financial Systems

**References**

**Examples**

```r
set.seed(123)
x <- rnorm(100) ; y <- rnorm(100)
NNS.FSD(x, y)
```
**NNS.FSD.uni**  

**NNS FSD Test uni-directional**

**Description**

Uni-directional test of first degree stochastic dominance using lower partial moments used in SD Efficient Set routine.

**Usage**

NNS.FSD.uni(x, y, type = "discrete")

**Arguments**

- **x**  
  a numeric vector.

- **y**  
  a numeric vector.

- **type**  
  options: ("discrete", "continuous"); "discrete" (default) selects the type of CDF.

**Value**

Returns (1) if "X FSD Y", else (0).

**Author(s)**

Fred Viole, OVVO Financial Systems

**References**

**Examples**

```r
set.seed(123)
x <- rnorm(100) ; y <- rnorm(100)
NNS.FSD.uni(x, y)
```
NNS.meboot

Description

Adapted maximum entropy bootstrap routine from meboot https://cran.r-project.org/package=meboot.

Usage

NNS.meboot(
  x,
  reps = 999,
  rho = NULL,
  type = "spearman",
  drift = TRUE,
  trim = 0.1,
  xmin = NULL,
  xmax = NULL,
  reachbnd = TRUE,
  expand.sd = TRUE,
  force.clt = TRUE,
  scl.adjustment = FALSE,
  sym = FALSE,
  elaps = FALSE,
  digits = 6,
  colsubj,
  coldata,
  coltimes,
  ...
)

Arguments

x vector of data.
reps numeric; number of replicates to generate.
rho numeric [0,1]; The default setting rho = NULL assumes that the user does not want to generate replicates that are perfectly dependent on original time series, rho=1 recovers the original meboot(...) settings. rho < 1 admits less perfect (more realistic for some purposes) dependence.
type options("spearman", "pearson", "NNScor", "NNSdep"); type = "spearman"(default) dependence metric desired.
drift logical; TRUE default preserves the drift of the original series.
trim numeric [0,1]; The mean trimming proportion, defaults to trim=0.1.
xmin numeric; the lower limit for the left tail.
xmax numeric; the upper limit for the right tail.
reachbnd logical; If TRUE potentially reached bounds (xmin = smallest value - trimmed mean and xmax = largest value + trimmed mean) are given when the random draw happens to be equal to 0 and 1, respectively.
expand.sd logical; If TRUE the standard deviation in the ensemble is expanded. See expand.sd in meboot::meboot.
force.clt logical; If TRUE the ensemble is forced to satisfy the central limit theorem. See force.clt in meboot::meboot.
scl.adjustment logical; If TRUE scale adjustment is performed to ensure that the population variance of the transformed series equals the variance of the data.
sym logical; If TRUE an adjustment is performed to ensure that the ME density is symmetric.
elaps logical; If TRUE elapsed time during computations is displayed.
digits integer; 6 (default) number of digits to round output to.
colsubj numeric; the column in x that contains the individual index. It is ignored if the input data x is not a pdata.frame object.
coldata numeric; the column in x that contains the data of the variable to create the ensemble. It is ignored if the input data x is not a pdata.frame object.
coltimes numeric; an optional argument indicating the column that contains the times at which the observations for each individual are observed. It is ignored if the input data x is not a pdata.frame object.
...
possible argument fiv to be passed to expand.sd.

Value

• x original data provided as input.
• replicates maximum entropy bootstrap replicates.
• ensemble average observation over all replicates.
• xx sorted order stats (xx[1] is minimum value).
• z class intervals limits.
• dv deviations of consecutive data values.
• dvtrim trimmed mean of dv.
• xmin data minimum for ensemble=xx[1]-dvtrim.
• xmax data x maximum for ensemble=xx[n]+dvtrim.
• desintxb desired interval means.
• ordxx ordered x values.
• kappa scale adjustment to the variance of ME density.
• elaps elapsed time.
References

Examples

```r
## Not run:
# To generate an orthogonal rank correlated time-series to AirPassengers
boots <- NNS.meboot(AirPassengers, reps=100, rho = 0, xmin = 0)
# Verify correlation of replicates ensemble to original
cor(boots$ensemble, AirPassengers, method = "spearman")
# Plot all replicates
matplot(boots$replicates, type = "l")
# Plot ensemble
lines(boots$ensemble, lwd = 3)
## End(Not run)
```

NNS.norm

*NNS Normalization*

Description

Normalizes a matrix of variables based on nonlinear scaling normalization method.

Usage

`NNS.norm(X, linear = FALSE, chart.type = NULL, location = "topleft")`

Arguments

- `X` a numeric matrix or data frame.
- `linear` logical; FALSE (default) Performs a linear scaling normalization, resulting in equal means for all variables.
- `chart.type` options: ("l", "b"); NULL (default). Set (chart.type = "l") for line, (chart.type = "b") for boxplot.
- `location` Sets the legend location within the plot, per the x and y co-ordinates used in base graphics legend.
NNS.nowcast

Value

Returns a \texttt{data.frame} of normalized values.

Author(s)

Fred Viole, OVVO Financial Systems

References

https://www.amazon.com/dp/1490523995/ref=cm_sw_su_dp

Examples

```r
set.seed(123)
x <- rnorm(100); y <- rnorm(100)
A <- cbind(x, y)
NNS.norm(A)
```

NNS.nowcast

\textit{NNS Nowcast}

Description

Usage

```r
NNS.nowcast(
  h = 12,
  additional.regressors = NULL,
  start.date = "2000-01-03",
  Quandl.key = NULL,
  status = TRUE,
  ncores = NULL
)
```

Arguments

- `h` integer; \(h = 12\) (default) Number of periods to forecast. \(h = 0\) will return just the interpolated and extrapolated values.
- `additional.regressors` character; NULL (default) add more regressors to the base model. The format must utilize the Quandl exchange format as described in \url{https://docs.data.nasdaq.com/docs/data-organization}. For example, the 10-year US Treasury yield using the St. Louis Federal Reserve data is "FRED/DGS10".
start.date character; "2000-01-03" (default) Starting date for all data series download.
Quandl.key character; NULL (default) User provided Quandl API key WITH QUOTES. If previously entered in the current environment via Quandl::Quandl.api_key, no further action required.
status logical; TRUE (default) Prints status update message in console.
ncores integer; value specifying the number of cores to be used in the parallelized subroutine NNS.ARMA.optim. If NULL (default), the number of cores to be used is equal to the number of cores of the machine - 1.

Value
Returns the following matrices of forecasted variables:

- "interpolated_and_extrapolated" Returns a data.frame of the linear interpolated and NNS.ARMA extrapolated values to replace NA values in the original variables argument. This is required for working with variables containing different frequencies, e.g. where NA would be reported for intra-quarterly data when indexed with monthly periods.
- "relevant_variables" Returns the relevant variables from the dimension reduction step.
- "univariate" Returns the univariate NNS.ARMA forecasts.
- "multivariate" Returns the multi-variate NNS.reg forecasts.
- "ensemble" Returns the ensemble of both "univariate" and "multivariate" forecasts.

Note
- This function requires an API key from Quandl. Sign up via https://data.nasdaq.com/.

Author(s)
Fred Viole, OVVO Financial Systems

References

Examples

## Not run:
NNS.nowcast(h = 12)

## End(Not run)
NNS.partition

Description

Creates partitions based on partial moment quadrant centroids, iteratively assigning identifications to observations based on those quadrants (unsupervised partitional and hierarchical clustering method). Basis for correlation, dependence NNS.dep, regression NNS.reg routines.

Usage

NNS.partition(
  x,
  y,
  Voronoi = FALSE,
  type = NULL,
  order = NULL,
  obs.req = 8,
  min.obs.stop = TRUE,
  noise.reduction = "off"
)

Arguments

x  
a numeric vector.
y  
a numeric vector with compatible dimensions to x.
Voronoi  
logical; FALSE (default) Displays a Voronoi type diagram using partial moment quadrants.
type  
NULL (default) Controls the partitioning basis. Set to (type = "XONLY") for X-axis based partitioning. Defaults to NULL for both X and Y-axis partitioning.
order  
integer; Number of partial moment quadrants to be generated. (order = "max") will institute a perfect fit.
obs.req  
integer; (8 default) Required observations per cluster where quadrants will not be further partitioned if observations are not greater than the entered value. Reduces minimum number of necessary observations in a quadrant to 1 when (obs.req = 1).
min.obs.stop  
logical; TRUE (default) Stopping condition where quadrants will not be further partitioned if a single cluster contains less than the entered value of obs.req.
noise.reduction  
the method of determining regression points options for the dependent variable y: ("mean", "median", "mode", "off"); (noise.reduction = "mean") uses means for partitions. (noise.reduction = "median") uses medians instead of means for partitions, while (noise.reduction = "mode") uses modes instead of means for partitions. Defaults to (noise.reduction = "off") where an overall central tendency measure is used, which is the default for the independent variable x.
Value

Returns:

• "dt" a `data.table` of x and y observations with their partition assignment "quadrant" in the 3rd column and their prior partition assignment "prior.quadrant" in the 4th column.
• "regression.points" the `data.table` of regression points for that given (order = ...).
• "order" the order of the final partition given "min.obs.stop" stopping condition.

Note

min.obs.stop = FALSE will not generate regression points due to unequal partitioning of quadrants from individual cluster observations.

Author(s)

Fred Viole, OVVO Financial Systems

References

https://www.amazon.com/dp/1490523995/ref=cm_sw_su_dp

Examples

```r
set.seed(123)
x <- rnorm(100) ; y <- rnorm(100)
NNS.part(x, y)

## Data.table of observations and partitions
NNS.part(x, y, order = 1)$dt

## Regression points
NNS.part(x, y, order = 1)$regression.points

## Voronoi style plot
NNS.part(x, y, Voronoi = TRUE)

## Examine final counts by quadrant
DT <- NNS.part(x, y)$dt
DT[, counts := .N, by = quadrant]
DT
```
Description

This function generates an empirical PDF using dy.dx on NNS.CDF.

Usage

NNS.PDF(variable, degree = 1, target = NULL, bins = NULL, plot = TRUE)

Arguments

variable a numeric vector.
degree integer; (degree = 0) is frequency, (degree = 1) (default) is area.
target a numeric range of values [a,b] where a < b. NULL (default) uses the variable
min and max observations respectively.
bins integer; NULL Selects number of bins. Bin width defaults to density(x)$bw.
plot logical; plots PDF.

Value

Returns a data.table containing the intervals used and resulting PDF of the variable.

Author(s)

Fred Viole, OVVO Financial Systems

References

https://www.amazon.com/dp/1490523995/ref=cm_sw_su_dp

Examples

## Not run:
set.seed(123)
x <- rnorm(100)
NNS.PDF(x)

## Custom target range
NNS.PDF(x, target = c(-5, 5))

## End(Not run)
NNS.reg

Description
Generates a nonlinear regression based on partial moment quadrant means.

Usage
NNS.reg(
  x,
  y,
  factor.2.dummy = TRUE,
  order = NULL,
  stn = 0.95,
  dim.red.method = NULL,
  tau = NULL,
  type = NULL,
  inference = FALSE,
  point.est = NULL,
  location = "top",
  return.values = TRUE,
  plot = TRUE,
  plot.regions = FALSE,
  residual.plot = TRUE,
  std.errors = FALSE,
  confidence.interval = NULL,
  threshold = 0,
  n.best = NULL,
  noise.reduction = "off",
  dist = "L2",
  ncores = NULL,
  point.only = FALSE,
  multivariate.call = FALSE
)

Arguments
- **x**: a vector, matrix or data frame of variables of numeric or factor data types.
- **y**: a numeric or factor vector with compatible dimensions to x.
- **factor.2.dummy**: logical; TRUE (default) Automatically augments variable matrix with numerical dummy variables based on the levels of factors.
- **order**: integer; Controls the number of partial moment quadrant means. Users are encouraged to try different (order = ...) integer settings with (noise.reduction = "off"). (order = "max") will force a limit condition perfect fit.
NNS.reg

**stn**
- numeric [0, 1]: Signal to noise parameter, sets the threshold of (NNS.dep) which reduces ("order") when (order = NULL). Defaults to 0.95 to ensure high dependence for higher ("order") and endpoint determination.

**dim.red.method**
- options: ("cor", "NNS.dep", "NNS.caus", "all", "equal", numeric vector, NULL) method for determining synthetic X* coefficients. Selection of a method automatically engages the dimension reduction regression. The default is NULL for full multivariate regression. (dim.red.method = "NNS.dep") uses NNS.dep for nonlinear dependence weights, while (dim.red.method = "NNS.caus") uses NNS.caus for causal weights. (dim.red.method = "cor") uses standard linear correlation for weights. (dim.red.method = "all") averages all methods for further feature engineering. (dim.red.method = "equal") uses unit weights. Alternatively, user can specify a numeric vector of coefficients.

**tau**
- options("ts", NULL); NULL (default) To be used in conjunction with (dim.red.method = "NNS.caus") or (dim.red.method = "all"). If the regression is using time-series data, set (tau = "ts") for more accurate causal analysis.

**type**
- NULL (default). To perform a classification, set to (type = "CLASS"). Like a logistic regression, it is not necessary for target variable of two classes e.g. [0, 1].

**inference**
- logical; FALSE (default) For inferential tasks, otherwise inference = FALSE is faster for predictive tasks.

**point.est**
- a numeric or factor vector with compatible dimensions to x. Returns the fitted value y.hat for any value of x.

**location**
- Sets the legend location within the plot, per the x and y co-ordinates used in base graphics legend.

**return.values**
- logical; TRUE (default), set to FALSE in order to only display a regression plot and call values as needed.

**plot**
- logical; TRUE (default) To plot regression.

**plot.regions**
- logical; FALSE (default). Generates 3d regions associated with each regression point for multivariate regressions. Note, adds significant time to routine.

**residual.plot**
- logical; TRUE (default) To plot y.hat and Y.

**std.errors**
- logical; FALSE (default) To provide standard errors of each linear segment in the "Fitted.xy" output.

**confidence.interval**
- numeric [0, 1]; NULL (default) Plots the associated confidence interval with the estimate and reports the standard error for each individual segment.

**threshold**
- numeric [0, 1]; (threshold = 0) (default) Sets the threshold for dimension reduction of independent variables when (dim.red.method) is not NULL.

**n.best**
- integer; NULL (default) Sets the number of nearest regression points to use in weighting for multivariate regression at sqrt(# of regressors). (n.best = "all") will select and weight all generated regression points. Analogous to k in a k Nearest Neighbors algorithm. Different values of n.best are tested using cross-validation in NNS.stack.

**noise.reduction**
- the method of determining regression points options: ("mean", "median", "mode", "off"); In low signal:noise situations,(noise.reduction = "mean") uses means
for \texttt{NNS.dep} restricted partitions, \texttt{(noise.reduction = \textit{"median"})} uses medians instead of means for \texttt{NNS.dep} restricted partitions, while \texttt{(noise.reduction = \textit{"mode"})} uses modes instead of means for \texttt{NNS.dep} restricted partitions. \texttt{(noise.reduction = \textit{"off"})} uses an overall central tendency measure for partitions.

\textbf{dist} options: (\texttt{"L1"}, \texttt{"L2"}, \texttt{"DTW"}, \texttt{"FACTOR"}) the method of distance calculation; selects the distance calculation used. \texttt{dist = \textit{"L2"}} (default) selects the Euclidean distance and \texttt{(dist = \textit{"L1"})} selects the Manhattan distance; \texttt{(dist = \textit{"DTW"})} selects the dynamic time warping distance; \texttt{(dist = \textit{"FACTOR"})} uses a frequency.

\textbf{ncores} integer; value specifying the number of cores to be used in the parallelized procedure. If NULL (default), the number of cores to be used is equal to the number of cores of the machine - 1.

\textbf{point.only} Internal argument for abbreviated output.

\textbf{multivariate.call} Internal argument for multivariate regressions.

\textbf{Value}

**UNIVARIATE REGRESSION RETURNS THE FOLLOWING VALUES:**

- \textit{"R2"} provides the goodness of fit;
- \textit{"SE"} returns the overall standard error of the estimate between \(y\) and \(y.hat\);
- \textit{"Prediction.Accuracy"} returns the correct rounded \textit{"Point.est"} used in classifications versus the categorical \(y\);
- \textit{"derivative"} for the coefficient of the \(x\) and its applicable range;
- \textit{"Point.est"} for the predicted value generated;
- \textit{"regression.points"} provides the points used in the regression equation for the given order of partitions;
- \textit{"Fitted.xy"} returns a \texttt{data.table} of \(x, y, y.hat, resid, NNS.ID, gradient\);

**MULTIVARIATE REGRESSION RETURNS THE FOLLOWING VALUES:**

- \textit{"R2"} provides the goodness of fit;
- \textit{"equation"} returns the numerator of the synthetic X$^*$ dimension reduction equation as a \texttt{data.table} consisting of regressor and its coefficient. Denominator is simply the length of all coefficients $> 0$, returned in last row of \texttt{equation} \texttt{data.table}.
- \textit{"x.star"} returns the synthetic X$^*$ as a vector;
- \textit{"rhs.partitions"} returns the partition points for each regressor \(x\);
- \textit{"RPM"} provides the Regression Point Matrix, the points for each \(x\) used in the regression equation for the given order of partitions;
- \textit{"Point.est"} returns the predicted value generated;
- \textit{"Fitted.xy"} returns a \texttt{data.table} of \(x, y, y.hat, gradient, and NNS.ID\).
Note

• Please ensure point.est is of compatible dimensions to x, error message will ensue if not compatible.
• Like a logistic regression, the (type = "CLASS") setting is not necessary for target variable of two classes e.g. [0, 1]. The response variable base category should be 1 for classification problems.
• For low signal:noise instances, increasing the dimension may yield better results using NNS.stack(cbind(x,x), y, method = 1,...).

```r
## Not run:
set.seed(123)
x <- rnorm(100) ; y <- rnorm(100)
NNS.reg(x, y)

## Manual {order} selection
NNS.reg(x, y, order = 2)

## Maximum {order} selection
NNS.reg(x, y, order = "max")

## x-only paritioning (Univariate only)
NNS.reg(x, y, type = "XONLY")

## For Multiple Regression:
x <- cbind(rnorm(100), rnorm(100), rnorm(100)) ; y <- rnorm(100)
NNS.reg(x, y, point.est = c(.25, .5, .75))

## For Multiple Regression based on Synthetic X\* (Dimension Reduction):
x <- cbind(rnorm(100), rnorm(100), rnorm(100)) ; y <- rnorm(100)
NNS.reg(x, y, point.est = c(.25, .5, .75), dim.red.method = "cor", ncores = 1)

## IRIS dataset examples:
# Dimension Reduction:
NNS.reg(iris[,1:4], iris[,5], dim.red.method = "cor", order = 5, ncores = 1)
```
# Dimension Reduction using causal weights:
NNS.reg(iris[,1:4], iris[,5], dim.red.method = "NNS.caus", order = 5, ncores = 1)

# Multiple Regression:
NNS.reg(iris[,1:4], iris[,5], order = 2, noise.reduction = "off")

# Classification:
NNS.reg(iris[,1:4], iris[,5], point.est = iris[1:10, 1:4], type = "CLASS")$Point.est

## To call fitted values:
set.seed(1)
x <- rnorm(100); y <- rnorm(100)
NNS.reg(x, y)$Fitted

## To call partial derivative (univariate regression only):
NNS.reg(x, y)$derivative

## End(Not run)

---

NNS.SD.efficient.set  \textit{NNS SD Efficient Set}

**Description**

Determines the set of stochastic dominant variables for various degrees.

**Usage**

NNS.SD.efficient.set(x, degree, type = "discrete", status = TRUE)

**Arguments**

- **x**: a numeric matrix or data frame.
- **degree**: numeric options: (1, 2, 3); Degree of stochastic dominance test from (1, 2 or 3).
- **type**: options: ("discrete", "continuous"); "discrete" (default) selects the type of CDF.
- **status**: logical; TRUE (default) Prints status update message in console.

**Value**

Returns set of stochastic dominant variable names.

**Author(s)**

Fred Viole, OVVO Financial Systems
References

Examples

```r
set.seed(123)
x <- rnorm(100); y <- rnorm(100); z <- rnorm(100)
A <- cbind(x, y, z)
NNS.SD.efficient.set(A, 1)
```

---

**NNS.seas**

*NNS Seasonality Test*

Description

Seasonality test based on the coefficient of variation for the variable and lagged component series. A result of 1 signifies no seasonality present.

Usage

```r
NNS.seas(variable, modulo = NULL, mod.only = TRUE, plot = TRUE)
```

Arguments

- `variable` a numeric vector.
- `modulo` integer(s); NULL (default) Used to find the nearest multiple(s) in the reported seasonal period.
- `mod.only` logical; codeTRUE (default) Limits the number of seasonal periods returned to the specified modulo.
- `plot` logical; TRUE (default) Returns the plot of all periods exhibiting seasonality and the variable level reference.

Value

Returns a matrix of all periods exhibiting less coefficient of variation than the variable with "all.periods"; and the single period exhibiting the least coefficient of variation versus the variable with "best.period"; as well as a vector of "periods" for easy call into NNS.ARMA.optim. If no seasonality is detected, NNS.seas will return ("No Seasonality Detected").

Author(s)

Fred Viole, OVVO Financial Systems
NNS.SSD

References

https://www.amazon.com/dp/1490523995/ref=cm_sw_su_dp

Examples

```r
set.seed(123)
x <- rnorm(100)

## To call strongest period based on coefficient of variation:
NNS.seas(x, plot = FALSE)$best.period

## Using modulus for logical seasonal inference:
NNS.seas(x, modulo = c(2,3,5,7), plot = FALSE)
```

<table>
<thead>
<tr>
<th>NNS.SSD</th>
<th>NNS SSD Test</th>
</tr>
</thead>
</table>

Description

Bi-directional test of second degree stochastic dominance using lower partial moments.

Usage

```r
NNS.SSD(x, y, plot = TRUE)
```

Arguments

- `x`: a numeric vector.
- `y`: a numeric vector.
- `plot`: logical; TRUE (default) plots the SSD test.

Value

Returns one of the following SSD results: "X SSD Y", "Y SSD X", or "NO SSD EXISTS".

Author(s)

Fred Viole, OVVO Financial Systems

References

Examples

```r
set.seed(123)
x <- rnorm(100) ; y <- rnorm(100)
NNS.SSD(x, y)
```
NNS.SSD.uni  

**Description**

Uni-directional test of second degree stochastic dominance using lower partial moments used in SD Efficient Set routine.

**Usage**

NNS.SSD.uni(x, y)

**Arguments**

- **x**  
a numeric vector.
- **y**  
a numeric vector.

**Value**

Returns (1) if "X SSD Y", else (0).

**Author(s)**

Fred Viole, OVVO Financial Systems

**References**

**Examples**

```
set.seed(123)
x <- rnorm(100); y <- rnorm(100)
NNS.SSD.uni(x, y)
```

NNS.stack  

**Description**

Prediction model using the predictions of the NNS base models NNS.reg as features (i.e. meta-features) for the stacked model.
NNS.stack

Usage

NNS.stack(
  IVs.train,
  DV.train,
  IVs.test = NULL,
  type = NULL,
  obj.fn = expression(sum((predicted - actual)^2)),
  objective = "min",
  inference = FALSE,
  optimize.threshold = TRUE,
  dist = "L2",
  CV.size = NULL,
  balance = FALSE,
  ts.test = NULL,
  folds = 5,
  order = NULL,
  norm = NULL,
  method = c(1, 2),
  stack = TRUE,
  dim.red.method = "cor",
  status = TRUE,
  ncores = NULL
)

Arguments

IVs.train a vector, matrix or data frame of variables of numeric or factor data types.

DV.train a numeric or factor vector with compatible dimensions to (IVs.train).

IVs.test a vector, matrix or data frame of variables of numeric or factor data types with compatible dimensions to (IVs.train). If NULL, will use (IVs.train) as default.

type NULL (default). To perform a classification of discrete integer classes from factor target variable (DV.train) with a base category of 1, set to (type = "CLASS"), else for continuous (DV.train) set to (type = NULL). Like a logistic regression, this setting is not necessary for target variable of two classes e.g. [0, 1].

obj.fn expression; expression(sum((predicted - actual)^2)) (default) Sum of squared errors is the default objective function. Any expression() using the specific terms predicted and actual can be used.

objective options: ("min", "max") "min" (default) Select whether to minimize or maximize the objective function obj.fn.

inference logical; FALSE (default) For inferential tasks, otherwise inference = FALSE is faster for predictive tasks.

optimize.threshold logical; TRUE (default) Will optimize the probability threshold value for rounding in classification problems. If FALSE, returns 0.5.
dist

Options: ("L1", "L2", "DTW", "FACTOR") the method of distance calculation; Selects the distance calculation used. dist = "L2" (default) selects the Euclidean distance and (dist = "L1") selects the Manhattan distance; (dist = "DTW") selects the dynamic time warping distance; (dist = "FACTOR") uses a frequency.

CV.size

Numeric [0, 1]; NULL (default) Sets the cross-validation size if (IVs.test = NULL). Defaults to 0.25 for a 25 percent random sampling of the training set under (CV.size = NULL).

balance

Logical; FALSE (default) Uses both up and down sampling from caret to balance the classes. type="CLASS" required.

ts.test

Integer; NULL (default) Sets the length of the test set for time-series data; typically 2*h parameter value from NNS.ARMA or double known periods to forecast.

folds

Integer; folds = 5 (default) Select the number of cross-validation folds.

order

Options: (Integer, "max", NULL); NULL (default) Sets the order for NNS.reg, where (order = "max") is the k-nearest neighbors equivalent, which is suggested for mixed continuous and discrete (unordered, ordered) data.

norm

Options: ("std", "NNS", NULL); NULL (default) 3 settings offered: NULL, "std", and "NNS". Selects the norm parameter in NNS.reg.

method

Numeric Options: (1, 2); Select the NNS method to include in stack. (method = 1) Selects NNS.reg; (method = 2) Selects NNS.reg dimension reduction regression. Defaults to method = c(1,2), which will reduce the dimension first, then find the optimal n.best.

stack

Logical; TRUE (default) Uses dimension reduction output in n.best optimization, otherwise performs both analyses independently.

dim.red.method

Options: ("cor", "NNS.dep", "NNS.caus", "equal", "all") method for determining synthetic X* coefficients. (dim.red.method = "cor") (default) uses standard linear correlation for weights. (dim.red.method = "NNS.dep") uses NNS.dep for nonlinear dependence weights, while (dim.red.method = "NNS.caus") uses NNS.caus for causal weights. (dim.red.method = "all") averages all methods for further feature engineering.

status

Logical; TRUE (default) Prints status update message in console.

ncores

Integer; value specifying the number of cores to be used in the parallelized subroutine NNS.reg. If NULL (default), the number of cores to be used is equal to the number of cores of the machine - 1.

Value

Returns a vector of fitted values for the dependent variable test set for all models.

- "NNS.reg.n.best" returns the optimum "n.best" parameter for the NNS.reg multivariate regression. "SSE.reg" returns the SSE for the NNS.reg multivariate regression.
- "OBJfn.reg" returns the obj.fn for the NNS.reg regression.
- "NNS.dim.red.threshold" returns the optimum "threshold" from the NNS.reg dimension reduction regression.
• "OBJfn.dim.red" returns the obj.fn for the NNS.reg dimension reduction regression.
• "probability.threshold" returns the optimum probability threshold for classification, else 0.5 when set to FALSE.
• "reg" returns NNS.reg output.
• "dim.red" returns NNS.reg dimension reduction regression output.
• "stack" returns the output of the stacked model.

Note

• Like a logistic regression, the (type = "CLASS") setting is not necessary for target variable of two classes e.g. [0, 1]. The response variable base category should be 1 for multiple class problems.
• Missing data should be handled prior as well using na.omit or complete.cases on the full dataset.

If error received:
"Error in is.data.frame(x) : object 'RP' not found"
reduce the CV.size.

## Using 'iris' dataset to determine [n.best] and [threshold] with no test set.
NNS.stack(iris[ , 1:4], iris[ , 5], type = "CLASS")

## Selecting NNS.reg and dimension reduction techniques.
NNS.stack(iris[1:140, 1:4], iris[1:140, 5], iris[141:150, 1:4], method = c(1, 2), type = "CLASS")
## End(Not run)
```
NNS.term.matrix  

NNS Term Matrix

Description
Generates a term matrix for text classification use in NNS.reg.

Usage
NNS.term.matrix(x, oos = NULL, names = FALSE)

Arguments
x mixed data.frame; character/numeric; A two column dataset should be used. Concatenate text from original sources to comply with format. Also note the possibility of factors in "DV", so "as.numeric(as.character(...))" is used to avoid issues.
oos mixed data.frame; character/numeric; Out-of-sample text dataset to be classified.
names logical; Column names for "IV" and "oos". Defaults to FALSE.

Value
Returns the text as independent variables "IV" and the classification as the dependent variable "DV". Out-of-sample independent variables are returned with "OOS".

References

Examples
x <- data.frame(cbind(c("sunny", "rainy"), c(1, -1)))
NNS.term.matrix(x)

### Concatenate Text with space separator, cbind with "DV"
x <- data.frame(cbind(c("sunny", "rainy"), c("windy", "cloudy"), c(1, -1)))
x <- data.frame(cbind(paste(x[, 1], x[, 2], sep = " "), as.numeric(as.character(x[, 3]))))
NNS.term.matrix(x)

### NYT Example
## Not run:
require(RTextTools)
data(NYTimes)

### Concatenate Columns 3 and 4 containing text, with column 5 as DV
NNS.TSD

NYT <- data.frame(cbind(paste(NYTimes[, 3], NYTimes[, 4], sep = " "),
as.numeric(as.character(NYTimes[, 5]))))
NNS.term.matrix(NYT)
## End(Not run)

NNS.TSD

NNS TSD Test

Description

Bi-directional test of third degree stochastic dominance using lower partial moments.

Usage

NNS.TSD(x, y, plot = TRUE)

Arguments

x  a numeric vector.
y  a numeric vector.
plot logical; TRUE (default) plots the TSD test.

Value

Returns one of the following TSD results: "X TSD Y", "Y TSD X", or "NO TSD EXISTS".

Author(s)

Fred Viole, OVVO Financial Systems

References

Examples

set.seed(123)
x <- rnorm(100) ; y <- rnorm(100)
NNS.TSD(x, y)
NNS.TSD.uni

**Description**

Uni-directional test of third degree stochastic dominance using lower partial moments used in SD Efficient Set routine.

**Usage**

NNS.TSD.uni(x, y)

**Arguments**

- `x` a numeric vector.
- `y` a numeric vector.

**Value**

Returns (1) if "X TSD Y", else (0).

**Author(s)**

Fred Viole, OVVO Financial Systems

NNS.TSD.uni(x, y)
```

---

NNS.VAR

**Description**

Nonparametric vector autoregressive model incorporating NNS.ARMA estimates of variables into NNS.reg for a multi-variate time-series forecast.
Usage

NNS.VAR(
  variables,
  h,
  tau = 1,
  dim.red.method = "cor",
  obj.fn = expression(cor(predicted, actual, method = "spearman")/sum((predicted -
actual)^2)),
  objective = "max",
  status = TRUE,
  ncores = NULL,
  nowcast = FALSE
)

Arguments

variables a numeric matrix or data.frame of contemporaneous time-series to forecast.

h integer; 1 (default) Number of periods to forecast. (h = 0) will return just the
interpolated and extrapolated values.

tau positive integer [ > 0]; 1 (default) Number of lagged observations to consider
for the time-series data. Vector for single lag for each respective variable or list
for multiple lags per each variable.

dim.red.method options: ("cor", "NNS.dep", "NNS.caus", "all") method for reducing regressors
via NNS.stack. (dim.red.method = "cor") (default) uses standard linear correla-
tion for dimension reduction in the lagged variable matrix. (dim.red.method
= "NNS.dep") uses NNS.dep for nonlinear dependence weights, while (dim.red.method
= "NNS.caus") uses NNS.caus for causal weights. (dim.red.method = "all")
averages all methods for further feature engineering.

obj.fn expression; expression(cor(predicted,actual,method = "spearman") / sum((predicted
actual)^2)) (default) Rank correlation / sum of squared errors is the default
objective function. Any expression() using the specific terms predicted and
actual can be used.

objective options: ("min", "max") "max" (default) Select whether to minimize or maxi-
mize the objective function obj.fn.

status logical; TRUE (default) Prints status update message in console.

ncores integer; value specifying the number of cores to be used in the parallelized sub-
routine NNS.ARMA.optim. If NULL (default), the number of cores to be used
is equal to the number of cores of the machine - 1.

nowcast logical; FALSE (default) internal call for NNS.nowcast.

Value

Returns the following matrices of forecasted variables:

- "interpolated_and_extrapolated" Returns a data.frame of the linear interpolated and
  NNS.ARMA extrapolated values to replace NA values in the original variables argument.
This is required for working with variables containing different frequencies, e.g. where NA would be reported for intra-quarterly data when indexed with monthly periods.

- "relevant_variables" Returns the relevant variables from the dimension reduction step.
- "univariate" Returns the univariate NNS.ARM forecasts.
- "multivariate" Returns the multi-variate NNS.reg forecasts.
- "ensemble" Returns the ensemble of both "univariate" and "multivariate" forecasts.

**Note**

- dim.red.method = "cor" is significantly faster than the other methods, but comes at the expense of ignoring possible nonlinear relationships between lagged variables.
- Not recommended for factor variables, even after transformed to numeric. NNS.reg is better suited for factor or binary regressor extrapolation.

**PM.matrix**  
Partial Moment Matrix

**Description**

This function generates a co-partial moment matrix for the specified co-partial moment.

**Usage**

```r
PM.matrix(
  LPM.degree,  
```
UPM.degree,
target = NULL,
variable,
pop.adj = FALSE,
ncores = NULL
)

Arguments

LPM.degree integer; Degree for variable below target deviations. (degree = 0) is frequency, (degree = 1) is area.

UPM.degree integer; Degree for variable above target deviations. (degree = 0) is frequency, (degree = 1) is area.

target numeric; Typically the mean of Variable X for classical statistics equivalences, but does not have to be. (Vectorized) (target = NULL) (default) will set the target as the mean of every variable.

variable a numeric matrix or data.frame.

pop.adj logical; FALSE (default) Adjusts the sample co-partial moment matrices for population statistics.

ncores integer; value specifying the number of cores to be used in the parallelized procedure. If NULL (default), the number of cores to be used is equal to the number of cores of the machine - 1.

Value

Matrix of partial moment quadrant values (CUPM, DUPM, DLPM, CLPM), and overall covariance matrix. Uncalled quadrants will return a matrix of zeros.

Note

For divergent asymmetrical "D.LPM" and "D.UPM" matrices, matrix is D.LPM(column, row,...).

UPM.ratio

Upper Partial Moment RATIO

Description

This function generates a standardized univariate upper partial moment for any degree or target.

Usage

UPM.ratio(degree, target, variable)

Arguments

degree integer; (degree = 0) is frequency, (degree = 1) is area.
target numeric; Typically set to mean, but does not have to be. (Vectorized)
variable a numeric vector.

Value

Standardized UPM of variable

Author(s)

Fred Viole, OVVO Financial Systems

References

https://www.amazon.com/dp/1490523995/ref=cm_sw_su_dp

Examples

set.seed(123)
x <- rnorm(100)
UPM.ratio(0, mean(x), x)

## Joint Upper CDF
## Not run:
x <- rnorm(5000) ; y <- rnorm(5000)
plot3d(x, y, Co.UPM(0, 0, sort(x), sort(y), x, y), col = "blue", xlab = "X", ylab = "Y",
zlab = "Probability", box = FALSE)

## End(Not run)
Description

Generates an upside value at risk (VaR) quantile based on the Upper Partial Moment ratio.

Usage

UPM.VaR(percentile, degree, x)

Arguments

percentile numeric [0, 1]; The percentile for right-tail VaR (vectorized).
degree integer; (degree = 0) for discrete distributions, (degree = 1) for continuous distributions.
x a numeric vector.

Value

Returns a numeric value representing the point at which "percentile" of the area of x is above.

Examples

set.seed(123)
x <- rnorm(100)

## For 5th percentile, right-tail
UPM.VaR(0.05, 0, x)
