Package ‘OncoBayes2’

May 2, 2022

**Type** Package

**Title** Bayesian Logistic Regression for Oncology Dose-Escalation Trials

**Version** 0.8-6

**Date** 2022-05-02

**Depends** R (>= 3.4.0)

**Imports** methods, Rcpp (>= 0.12.0), RcppParallel (>= 5.0.1), rstan (>= 2.19.3), rstantools (>= 5.0.1), assertthat (>= 0.2.1), checkmate, Formula, bayesplot (>= 1.4.0), ggplot2 (>= 2.2.1), dplyr (>= 0.8.0), tibble, tidyrr (>= 1.0.0), abind, scales, rlang (>= 0.3.0), tidyselect, utils, stats

**LinkingTo** BH (>= 1.72.0), Rcpp (>= 0.12.0), RcppEigen (>= 0.3.3.3.0), RcppParallel (>= 5.0.1), rstan (>= 2.19.3), StanHeaders (>= 2.19.0)

**License** GPL (>= 3)

**LazyData** true

**NeedsCompilation** yes

**Suggests** rmarkdown, knitr, testthat (>= 2.0.0), mvtnorm, vdifffr, cmdstanr (>= 0.4.0)

**VignetteBuilder** knitr

**Biarch** true

**SystemRequirements** GNU make, pandoc (>= 1.12.3), pandoc-citeproc

**Encoding** UTF-8

**RoxygenNote** 7.1.1

**bind_rows_0**  
*Bind rows of multiple data frames with zero fill*

**Description**
A version of `bind_rows` out of `dplyr` that fills non-common columns with zeroes instead of NA. Gives an error if any of the input data contains NA already.

**Usage**

`bind_rows_0(...)`

**Arguments**

`...`  
Data frames to combine, passed into `bind_rows` (see `dplyr` documentation)

**Examples**

```r
## Setting up dummy sampling for fast execution of example  
## Please use 4 chains and 100x more warmup & iter in practice  
.onuser_mc_options <- options(OncoBayes2.MC.warmup=10, OncoBayes2.MC.iter=20, OncoBayes2.MC.chains=1,  
OncoBayes2.MC.save_warmup=FALSE)
library(tibble)
dose_info_A <- tibble(  
group_id = "hist_A",  
drug_A = 1  
)
dose_info_B <- tibble(  
group_id = "hist_B",  
drug_B = 100 * (1:2)  
)
bind_rows_0(dose_info_A, dose_info_B)
## Recover user set sampling defaults  
options(.onuser_mc_options)
```

**blrm_exnex**  
*Bayesian Logistic Regression Model for N-compounds with EXNEX*

**Description**
Bayesian Logistic Regression Model (BLRM) for N compounds using EXchangability and NonEX-changability (EXNEX) modeling.
Usage

```r
blrm_exnex(
  formula,
  data,
  prior_EX_mu_mean_comp,
  prior_EX_mu_sd_comp,
  prior_EX_tau_mean_comp,
  prior_EX_tau_sd_comp,
  prior_EX_corr_eta_comp,
  prior_EX_mu_mean_inter,
  prior_EX_mu_sd_inter,
  prior_EX_tau_mean_inter,
  prior_EX_tau_sd_inter,
  prior_EX_corr_eta_inter,
  prior_is_EXNEX_inter,
  prior_is_EXNEX_comp,
  prior_EX_prob_comp,
  prior_EX_prob_inter,
  prior_NEX_mu_mean_comp,
  prior_NEX_mu_sd_comp,
  prior_NEX_mu_mean_inter,
  prior_NEX_mu_sd_inter,
  prior_tau_dist,
  iter = getOption("OncoBayes2.MC.iter","2000"),
  warmup = getOption("OncoBayes2.MC.warmup","1000"),
  save_warmup = getOption("OncoBayes2.MC.save_warmup","TRUE"),
  thin = getOption("OncoBayes2.MC.thin","1"),
  init = getOption("OncoBayes2.MC.init","0.5"),
  chains = getOption("OncoBayes2.MC.chains",4),
  cores = getOption("mc.cores",1L),
  control = getOption("OncoBayes2.MC.control",list()),
  backend = getOption("OncoBayes2.MC.backend","rstan"),
  prior_PD = FALSE,
  verbose = FALSE
)
```

## S3 method for class 'blrmfit'
print(x, ..., prob = 0.95, digits = 2)

Arguments

- **formula**: the model formula describing the linear predictors of the model. The lhs of the formula is a two-column matrix which are the number of occurred events and the number of times no event occurred. The rhs of the formula defines the linear predictors for the marginal models for each drug component, then the interaction model and at last the grouping and optional stratum factors of the models. These elements of the formula are separated by a vertical bar. The marginal models must follow a intercept and slope form while the interaction
model must not include an interaction term. See the examples below for an example instantiation.

**data**

optional data frame containing the variables of the model. If not found in data, the variables are taken from `environment(formula)`.

**prior_EX_mu_mean_comp, prior_EX_mu_sd_comp**

Mean and sd for the prior on the mean parameters $\mu_i = (\mu_\alpha i, \mu_\beta i)$ of each component. Two column matrix (intercept, log-slope) with one row per component.

**prior_EX_tau_mean_comp, prior_EX_tau_sd_comp**

Prior mean and sd for heterogeneity parameter $\tau_{si} = (\tau_{\alpha si}, \tau_{\beta si})$ of each stratum. If no differential discounting is required (i.e. if there is only one stratum $s = 1$), then it is a two-column matrix (intercept, log-slope) with one row per component. Otherwise it is a three-dimensional array whose first dimension indexes the strata, second dimension indexes the components, and third dimension of length two for (intercept, log-slope).

**prior_EX_corr_eta_comp**

Prior LKJ correlation parameter for each component given as numeric vector. If missing, then a 1 is assumed corresponding to a marginal uniform prior of the correlation.

**prior_EX_mu_mean_inter, prior_EX_mu_sd_inter**

Prior mean and sd for population mean parameters $\mu_{\eta k}$ of each interaction parameter. Vector of length equal to the number of interactions.

**prior_EX_tau_mean_inter, prior_EX_tau_sd_inter**

Prior mean and sd for heterogeneity parameter $\tau_{\eta sk}$ of each stratum. Matrix with one column per interaction and one row per stratum.

**prior_EX_corr_eta_inter**

Prior LKJ correlation parameter for interaction given as numeric. If missing, then a 1 is assumed corresponding to a marginal uniform prior of the correlations.

**prior_is_EXNEX_inter**

Defines if non-exchangability is admitted for a given interaction parameter. Logical vector of length equal to the number of interactions. If missing FALSE is assumed for all interactions.

**prior_is_EXNEX_comp**

Defines if non-exchangability is admitted for a given component. Logical vector of length equal to the number of components. If missing TRUE is assumed for all components.

**prior_EX_prob_comp**

Prior probability $p_{ij}$ for exchangability of each component per group. Matrix with one column per component and one row per group. Values must lie in [0-1] range.

**prior_EX_prob_inter**

Prior probability $p_{\eta kj}$ for exchangability of each interaction per group. Matrix with one column per interaction and one row per group. Values must lie in [0-1] range.

**prior_NEX_mu_mean_comp, prior_NEX_mu_sd_comp**

Prior mean $m_{ij}$ and sd $s_{ij} = \text{diag}(S_{ij})$ of each component for non-exchangable case. Two column matrix (intercept, log-slope) with one row per component. If
missing set to the same prior as given for the EX part. It is required that the specification be the same across groups j.

prior_NEX_mu_mean_inter, prior_NEX_mu_sd_inter
Prior mean $m_{nkj}$ and sd $s_{nkj}$ for each interaction parameter for non-exchangable case. Vector of length equal to the number of interactions. If missing set to the same prior as given for the EX part.

prior_tau_dist Defines the distribution used for heterogeniety parameters. Choices are 0=fixed to it's mean, 1=log-normal, 2=truncated normal.

iter number of iterations (including warmup).

warmup number of warmup iterations.

save_warmup save warmup samples (TRUE / FALSE). Only if set to TRUE, then all random variables are saved in the posterior. This substantially increases the storage needs of the posterior.

thin period of saving samples.

init positive number to specify uniform range on unconstrained space for random initialization. See stan.

chains number of Markov chains.

cores number of cores for parallel sampling of chains.

control additional sampler parameters for NuTS algorithm.

backend sets Stan backend to be used. Possible choices are "rstan" (default) or "cmdstanr".

prior_PD Logical flag (defaults to FALSE) indicating if to sample the prior predictive distribution instead of conditioning on the data.

verbose Logical flag (defaults to FALSE) controlling if additional output like stan progress is reported.

x bllrmfit object to print

... not used in this function

prob central probability mass to report, i.e. the quantiles 0.5-prob/2 and 0.5+prob/2 are displayed. Multiple central widths can be specified.

digits number of digits to show

Details

bllrm_exnex is a flexible function for Bayesian meta-analytic modeling of binomial count data. In particular, it is designed to model counts of the number of observed dose limiting toxicities (DLTs) by dose, for guiding dose-escalation studies in Oncology. To accommodate dose escalation over more than one agent, the dose may consist of combinations of study drugs, with any number of treatment components.

In the simplest case, the aim is to model the probability $\pi$ that a patient experiences a DLT, by complementing the binomial likelihood with a monotone logistic regression

$$\logit \pi(d) = \log \alpha + \beta t(d),$$
where $\beta > 0$. Most typically, $d$ represents the dose, and $t(d)$ is an appropriate transformation, such as $t(d) = \log(d/d^*)$. A joint prior on $\theta = (\log \alpha, \log \beta)$ completes the model and ensures monotonicity $\beta > 0$.

Many extensions are possible. The function supports general combination regimens, and also provides framework for Bayesian meta-analysis of dose-toxicity data from multiple historical and concurrent sources.

For an example of a single-agent trial refer to example-single-agent.

Value

The function returns a S3 object of type blrmfit.

Methods (by generic)

- print: print function.

Combination of two treatments

For a combination of two treatment components, the basic modeling framework is that the DLT rate $\pi(d_1, d_2)$ is comprised of (1) a "no-interaction" baseline model $\tilde{\pi}(d_1, d_2)$ driven by the single-agent toxicity of each component, and (2) optional interaction terms $\gamma(d_1, d_2)$ representing synergy or antagonism between the drugs. On the log-odds scale,

$$\logit \pi(d_1, d_2) = \logit \tilde{\pi}(d_1, d_2) + \eta \gamma(d_1, d_2).$$

The "no interaction" part $\tilde{\pi}(d_1, d_2)$ represents the probability of a DLT triggered by either treatment component acting independently. That is,

$$\tilde{\pi}(d_1, d_2) = 1 - (1 - \pi_1(d_1))(1 - \pi_2(d_2)).$$

In simple terms, $P(\text{no DLT for combination}) = P(\text{no DLT for drug 1}) \times P(\text{no DLT from drug 2})$. To complete this part, the treatment components can then be modeled with monotone logistic regressions as before.

$$\logit \pi_i(d_i) = \log \alpha_i + \beta_i t(d_i),$$

where $t(d_i)$ is a monotone transformation of the doses, such as $t(d_i) = \log(d_i/d_i^*)$.

The inclusion of an interaction term $\gamma(d_1, d_2)$ allows DLT rates above or below the "no-interaction" rate. The magnitude of the interaction term may also be made dependent on the doses (or other covariates) through regression. As an example, one could let

$$\gamma(d_1, d_2) = \frac{d_1}{d_1^*} \frac{d_2}{d_2^*}.$$
General combinations

The model is extended to general combination treatments consisting of $N$ components by expressing the probability $\pi$ on the logit scale as

$$\text{logit} \pi(d_1, \ldots, d_N) = \text{logit} \left( 1 - \prod_{i=1}^{N} (1 - \pi_i(d_i)) \right) + \sum_{k=1}^{K} \eta_k \gamma_k(d_1, \ldots, d_N),$$

Multiple drug-drug interactions among the $N$ components are now possible, and are represented through the $K$ interaction terms $\gamma_k$.

Regression models can be again be specified for each $\pi_i$ and $\gamma_k$, such as

$$\text{logit} \pi_i(d_i) = \log(\alpha_i + \beta_i t(d_i))$$

Interactions for some subset $I(k) \subset \{1, \ldots, N\}$ of the treatment components can be modeled with regression as well, for example on products of doses,

$$\gamma_k(d_1, \ldots, d_N) = \prod_{i \in I(k)} \frac{d_i}{d_i^*}.$$

For example, $I(k) = \{1, 2, 3\}$ results in the three-way interaction term

\[
\frac{d_1 d_2 d_3}{d_1^* d_2^* d_3^*}
\]

for drugs 1, 2, and 3.

For a triple combination example please refer to example-combo3.

Meta-analytic framework

Information on the toxicity of a drug may be available from multiple studies or sources. Furthermore, one may wish to stratify observations within a single study (for example into groups of patients corresponding to different geographic regions, or multiple dosing corresponding to different schedules).

b1rm_exnex provides tools for robust Bayesian hierarchical modeling to jointly model data from multiple sources. An additional index $j = 1, \ldots, J$ on the parameters and observations denotes the $J$ groups. The resulting model allows the DLT rate to differ across the groups. The general $N$-component model becomes

$$\text{logit} \pi_j(d_1, \ldots, d_N) = \text{logit} \left( 1 - \prod_{i=1}^{N} (1 - \pi_{ij}(d_i)) \right) + \sum_{k=1}^{K} \eta_{kj} \gamma_k(d_1, \ldots, d_N),$$

for groups $j = 1, \ldots, J$. The component toxicities $\pi_{ij}$ and interaction terms $\gamma_k$ are modelled, as before, through regression. For example, $\pi_{ij}$ could be a logistic regression on $t(d_i) = \log(d_i/d_i^*)$ with intercept and log-slope $\theta_{ij}$, and $\gamma_k$ regressed with coefficient $\eta_{kj}$ on a product $\prod_{i \in I(k)} (d_i/d_i^*)$ for some subset $I(k)$ of components.
Thus, for \( j = 1, \ldots, J \), we now have group-specific parameters \( \theta_{ij} = (\log \alpha_{ij}, \log \beta_{ij}) \) and \( \nu_j = (\eta_{1j}, \ldots, \eta_{Kj}) \) for each component \( i = 1, \ldots, N \) and interaction \( k = 1, \ldots, K \).

The structure of the prior on \((\theta_{11}, \ldots, \theta_{1J})\) and \((\nu_1, \ldots, \nu_J)\) determines how much information will be shared across groups \( j \). Several modeling choices are available in the function.

- **EX (Full exchangeability):** One can assume the parameters are conditionally exchangeable given hyperparameters

  \[
  \theta_{ij} \sim N(\mu_{\theta_i}, \Sigma_{\theta_i}),
  \]

  independently across groups \( j = 1, \ldots, J \) and treatment components \( i = 1, \ldots, N \). The covariance matrix \( \Sigma_{\theta_i} \) captures the patterns of cross-group heterogeneity, and is parametrized with standard deviations \( \tau_{\alpha_i}, \tau_{\beta_i} \) and the correlation \( \rho_i \). Similarly for the interactions, the fully-exchangeable model is

  \[
  \nu_j \sim N(\mu_{\nu}, \Sigma_{\nu})
  \]

  for groups \( j = 1, \ldots, J \) and interactions \( k = 1, \ldots, K \), and the prior on the covariance matrix \( \Sigma_{\nu} \) captures the amount of heterogeneity expected in the interaction terms a-priori. The covariance is again parametrized with standard deviations \( \tau_{\eta_1}, \ldots, \tau_{\eta_K} \) and its correlation matrix.

- **Differential discounting:** For one or more of the groups \( j = 1, \ldots, J \), larger deviations of \( \theta_{ij} \) may be expected from the mean \( \mu_i \), or of the interactions \( \eta_{kj} \) from the mean \( \mu_{\eta,k} \). Such differential heterogeneity can be modeled by mapping the groups \( j = 1, \ldots, J \) to strata through \( s_j \in \{1, \ldots, S\} \), and modifying the model specification to

  \[
  \theta_{ij} \sim N(\mu_{\theta_i}, \Sigma_{\theta_{ij}}),
  \]

  where

  \[
  \Sigma_{\theta_{ij}} = \begin{pmatrix}
  \tau_{\alpha s_j i}^2 & \rho_{ij} \tau_{\alpha s_j i} \tau_{\beta s_j i} \\
  \rho_{ij} \tau_{\alpha s_j i} \tau_{\beta s_j i} & \tau_{\beta s_j i}^2 
  \end{pmatrix}.
  \]

  For the interactions, the model becomes

  \[
  \nu_j \sim N(\mu_{\nu}, \Sigma_{\nu_j}),
  \]

  where the covariance matrix \( \Sigma_{\nu_j} \) is modelled as stratum specific standard deviations \( \tau_{\eta_{s_1j}}, \ldots, \tau_{\eta_{Ks_j}} \) and a stratum independent correlation matrix. Each stratum \( s = 1, \ldots, S \) then corresponds to its own set of standard deviations \( \tau \) leading to different discounting per stratum. Independent priors are specified for the component parameters \( \tau_{\alpha s_i} \) and \( \tau_{\beta s_i} \) and for the interaction parameters \( \tau_{\eta s_k} \) for each stratum \( s = 1, \ldots, S \). Inference for strata \( s \) where the prior is centered on larger values of the \( \tau \) parameters will exhibit less shrinkage towards the the means, \( \mu_{\theta_i} \) and \( \mu_{\nu} \) respectively.

- **EXNEX (Partial exchangeability):** Another mechanism for increasing robustness is to introduce mixture priors for the group-specific parameters, where one mixture component is shared across groups, and the other is group-specific. The result, known as an EXchangeable-NonEXchangeable (EXNEX) type prior, has a form

  \[
  \theta_{ij} \sim p_{ij} N(\mu_{\theta_i}, \Sigma_{\theta_i}) + (1 - p_{ij}) N(\mu_{\theta_{ij}}, \Sigma_{\theta_{ij}})
  \]
when applied to the treatment-component parameters, and
\[
\nu_{kj} \sim p_{\nu_{kj}} N(\mu_{\nu}, \Sigma_{\nu}) + (1 - p_{\nu_{kj}}) N(m_{\nu_{kj}}, s_{\nu_{kj}}^2)
\]
when applied to the interaction parameters. The exchangeability weights \(p_{\theta_{ij}}\) and \(p_{\nu_{kj}}\) are fixed constants in the interval \([0, 1]\) that control the degree to which inference for group \(j\) is informed by the exchangeable mixture components. Larger values for the weights correspond to greater exchange of information, while smaller values increase robustness in case of outlying observations in individual groups \(j\).

**blrm_formula_linear**  
*Build a BLRM formula with linear interaction term in logit-space*

**Description**

`blrm_formula_linear` is a convenience function for generating a formula for `blrm_trial` and `blrm_exnex` with an interaction of the form:

$$\eta \prod_{i=1}^{N} (d_i / d_i^*)$$

**Usage**

```r
blrm_formula_linear(
  ref_doses,
  max_interaction_level = 2,
  specific_interaction_terms = NULL
)
```

**Arguments**

- `ref_doses`: Numeric vector of reference doses with names corresponding to drug names
- `max_interaction_level`: Highest interaction order to consider [1 - Inf]. Default: 2
- `specific_interaction_terms`: List of custom interaction terms to generate (e.g. `list(c("drug1", "drug2"), c("drug1", "drug3")))`. Default: NULL

**Value**

The function returns an object of class `blrm_formula`. 
**blrm_formula_saturating**

Build a BLRM formula with saturating interaction term in logit-space

**Examples**

```r
text <- c(drug_A=10, drug_B=20)
# can be used with blrm_trial
blrm_formula_linear(text)
```

**Description**

`blrm_formula_saturating` is a convenience function for generating a formula for `blrm_trial` and `blrm_exnex` with an interaction of the form:

\[
2\eta \frac{\prod_{i=1}^{N} (d_i / d_{i*})}{1 + \prod_{i=1}^{N} (d_i / d_{i*})}
\]

**Usage**

```r
blrm_formula_saturating(
  ref_doses,
  max_interaction_level = 2,
  specific_interaction_terms = NULL
)
```

**Arguments**

- `ref_doses`: Numeric vector of reference doses with names corresponding to drug names
- `max_interaction_level`: Highest interaction order to consider [1 - Inf]. Default: 2
- `specific_interaction_terms`: List of custom interaction terms to generate (e.g. `list(c("drug1", "drug2"), c("drug1", "drug3"))`). Default: NULL

**Value**

The function returns an object of class `blrm_formula`.

**Examples**

```r
text <- c(drug_A=10, drug_B=20)
# can be used with blrm_trial
blrm_formula_saturating(text)
```
**blrm_trial**

*Dose-Escalation Trials guided by Bayesian Logistic Regression Model*

**Description**

`blrm_trial` facilitates the conduct of dose escalation studies guided by Bayesian Logistic Regression Models (BLRM). While the `blrm_exnex` only fits the BLRM model to data, the `blrm_trial` function standardizes the specification of the entire trial design and provides various standardized functions for trial data accrual and derivation of model summaries needed for dose-escalation decisions.

**Usage**

```r
blrm_trial(
  data,
  dose_info,
  drug_info,
  simplified_prior = FALSE,
  EXNEX_comp = FALSE,
  EX_prob_comp_hist = 1,
  EX_prob_comp_new = 0.8,
  EXNEX_inter = FALSE,
  EX_prob_inter = 1,
  formula_generator = blrm_formula_saturating,
  interval_prob = c(0, 0.16, 0.33, 1),
  interval_max_mass = c(prob_underdose = 1, prob_target = 1, prob_overdose = 0.25),
  ...
)
```

## S3 method for class 'blrm_trial'

```r
print(x, ...)
```

**Arguments**

- **data**
  - dose-toxicity data available at design stage of trial
- **dose_info**
  - specification of the dose levels as planned for the ongoing trial arms.
- **drug_info**
  - specification of drugs used in trial arms.
- **simplified_prior**
  - logical (defaults to FALSE) indicating whether a simplified prior should be employed based on the `reference_p_dlt` values provided in `drug_info`. **Warning:** The simplified prior will change between releases. Please read instructions below in the respective section for the simplified prior.
- **EXNEX_comp**
  - logical (default to TRUE) indicating whether EXchangeable-NonEXchangeable priors should be employed for all component parameters.
EX_prob_comp_hist
prior weight ([0, 1], default to 1) on exchangeability for the component parameters in groups representing historical data

EX_prob_comp_new
prior weight ([0, 1], default to 0.8) on exchangeability for the component parameters in groups representing new or concurrent data

EXNEX_inter
logical (default to FALSE) indicating whether EXchangeable-NonEXchangeable priors should be employed for all interaction parameters

EX_prob_inter
prior weight ([0, 1], defaults to 0.8) on exchangeability for the interaction parameters

formula_generator
formula generation function (see for example blrm_formula_linear or blrm_formula_saturating). The formula generator defines the employed interaction model.

interval_prob
defines the interval probabilities reported in the standard outputs. Defaults to c(0, 0.16, 0.33, 1).

interval_max_mass
named vector defining for each interval of the interval_prob vector a maximal admissible probability mass for a given dose level. Whenever the posterior probability mass in a given interval exceeds the threshold, then the Escalation With Overdose Control (EWOC) criterion is considered to be not fullfilled. Dose levels not fulfilling EWOC are ineligible for the next cohort of patients. The default restricts the overdose probability to less than 0.25.

Additional arguments are forwarded to blrm_exnex, i.e. for the purpose of prior specification.

x
blrm_trial object to print

Details

blrm_trial constructs an object of class blrm_trial which stores the complete information about the study design of a dose-escalation trial. The study design is defined through the data sets (see sections below for a definition of the columns):

data (historical data) The data argument defines available dose-toxicity data at the design stage of the trial. Together with the prior of model (without any data) this defines the prior used for the trial conduct.

dose_info Definition of the pre-specified dose levels explored in the ongoing trial arms. Thus, all dose-toxicity trial data added to the object is expected correspond to one of the dose levels in the pre-defined set of dose_info.

drug_info Determines the drugs used in the trial, their units, reference dose level and optionally defines the expected probability for a toxicity at the reference dose.

Once the blrm_trial object is setup the complete trial design is specified and the model is fitted to the given data. This allows evaluation of the pre-specified dose levels of the trial design wrt. to safety, i.e. whether the starting dose of the trial fullfills the escalate with overdose criterion (EWOC) condition.
The `blrm_trial` trial can also be constructed in a 2-step process which allows for a more convenient specification of the prior since meta data like number of drugs and the like can be used. See the example section for details.

After setup of the initial `blrm_trial` object additional data is added through the use of the update method which has a `add_data` argument intended to add data from the ongoing trial. The summary function finally allows to extract various model summaries. In particular, the EWOC criterion can be calculated for the pre-defined dose levels of the trial.

Value

The function returns an object of class `blrm_trial`.

Methods (by generic)

- `print`: print function.

Simplified prior

As a convenience for the user, a simplified prior can be specified whenever the `reference_p_dlt` column is present in the `drug_info` data set. However, the user is warned that the simplified prior will change in future releases of the package and thus **we strongly discourage the use of the simplified prior for setting up trial designs**. The functionality is intended to provide the user a quick start and as a starting point. The actually instantiated prior can be seen as demonstrated below in the examples.

Input data

The data given to the `data` argument of `blrm_trial` is considered as the available at design stage of the trial. The collected input data thus does not necessarily need to have the same dose levels as the pre-specified dose_info for the ongoing trial(s). It's data columns must include, but are not limited to:

- `group_id` study
- `stratum_id` optional, only required for differential discounting of groups
- `num_patients` number of patients
- `num_toxicities` number of toxicities
- `drug_A` Columns for the dose of each treatment component, with column names matching the `drug_name` values specified in the `drug_info` argument of `blrm_trial`

Drug info data

The drug information data-set defines drug properties. The fields included are:

- `drug_name` name of drug which is also used as column name for the dose
- `dose_ref` reference dose
- `dose_unit` units used for drug amounts
- `reference_p_dlt` optional; if provided, allows setup of a simplified prior
Dose info data

The drug_info data-set pre-specifies the dose levels of the ongoing trial. Thus, all data added to
the blrm_trial through the update command must be consistent with the pre-defined dose levels
as no other than those pre-specified ones can be explored in an ongoing trial.

**dose_id** optional column which assigns a unique id to each group_id/dose combination. If not
specified the column is internally generated.

**group_id** study
drug_A Columns for the dose of each treatment component, with column names matching the
drug_name values specified in the drug_info argument of blrm_trial

```
**Description**

One of two datasets from the application described in Neuenschwander et al (2016). In the study `trial_AB`, the risk of DLT was studied as a function of dose for two drugs, drug A and drug B. Historical information on the toxicity profiles of these two drugs is available from single agent trials `trial_A` and `trial_B`. Another study IIT was run concurrently to `trial_AB`, and studies the same combination. A second dataset `hist_combo2` is available from this example, which includes only the data from the single agent studies, prior to the initiation of `trial_AB` and IIT.

**Usage**

codata_combo2

**Format**

A data frame with 20 rows and 5 variables:

- `group_id` study
- `drug_A` dose of Drug A
- `drug_B` dose of Drug B
- `num_patients` number of patients
- `num_toxicities` number of DLTs
- `cohort_time` cohort number of patients

critical_quantile

Description

Calculates the critical value of a model covariate for which a fixed quantile of the crude rate is equal to the specified (tail or interval) probability. The specified quantile can relate to the posterior or the predictive distribution of the response rate.

Usage

critical_quantile(object, ...)

## S3 method for class 'blrmfit'
critical_quantile(
  object,
  newdata,
  x,
  p,
  qc,
  lower.tail,
  interval.x,
  extendInt.x = c("auto", "no", "yes", "downX", "upX"),
  log.x,
  predictive = FALSE,
  maxiter = 100,
  ...
)

## S3 method for class 'blrm_trial'
critical_quantile(
  object,
  newdata,
  x,
  p,
  qc,
  lower.tail,
  interval.x,
  extendInt.x = c("auto", "no", "yes", "downX", "upX"),
  log.x,
  predictive = FALSE,
  maxiter = 100,
  ...
)

Arguments

- **object**: fitted model object
- **...**: not used in this function
- **newdata**: optional data frame specifying for what to predict; if missing, then the data of the input model object is used
critical_quantile

x character giving the covariate name which is being search for to meet the critical conditions. This also supports 'tidy' parameter selection by specifying x = vars(...), where ... is specified the same way as in dplyr::select() and similar functions. Examples of using x in this way can be found in the examples. For blrm_trial methods, it defaults to the first entry in summary(blrm_trial,"drug_info")$drug_name.

p cumulative probability corresponding to the critical quantile range.

qc if given as a sorted vector of length 2, then the two entries define the interval on the response rate scale which must correspond to the cumulative probability p. In this case lower.tail must be NULL or left missing. If qc is only a single number, then lower.tail must be set to complete the specification of the tail area.

lower.tail defines if probabilities are lower or upper tail areas. Must be defined if qc is a single number and must not be defined if qc denotes an interval.

interval.x interval the covariate x is searched. Defaults to the minimal and maximal value of x in the data set used. Whenever lower.tail is set such that it is known that a tail area is used, then the function will automatically attempt to enlarge the search interval since the direction of the inverted function is determined around the critical value.

extendInt.x controls if the interval given in interval.x should be extended during the root finding. The default "auto" attempts to guess an adequate setting in cases that possible. Other possible values are the same as for the extendInt argument of the stats::uniroot() function.

log.x determines if during the numerical search for the critical value the covariate space is logarithmized. By default x is log transformed whenever all values are positive.

predictive logical indicates if the critical quantile relates to the posterior (FALSE) or the predictive (TRUE) distribution. Defaults to FALSE.

maxiter maximal number of iterations for root finding. Defaults to 100.

Details

The function searches for a critical value \( x_c \) of the covariate \( x \) at which the integral over the model response in the specified interval \( \pi_1 \) to \( \pi_2 \) (qc) is equal to the given probability \( p \) (p). The given interval is considered a tail area when lower.tail is used such that \( \pi_1 = 0 \) for TRUE and \( \pi_2 = 1 \) for FALSE. At the critical value \( x_c \) the equality holds

\[
p = \int_{\pi_1}^{\pi_2} p(\pi | x_c) \, d\pi.
\]

Note that a solution not guaranteed to exist under all circumstances. However, for a single agent model and when requesting a tail probability then a solution does exist. In case an interval probability is specified, then the solution may not necessarily exist and the root finding is confined to the range specified in interval.x.

In case the solution is requested for the predictive distribution (predictive=TRUE), then the respective problem solved leads to the equality of
\[ p = \left\lfloor \frac{n \pi_2}{2} \right\rfloor \sum_{y=r_1=\left\lfloor \frac{n \pi_1}{2} \right\rfloor} p(y|\pi, n) p(\pi|x_c) d\pi. \]

Furthermore, the covariate space is log transformed by default whenever all values of the covariate \( x \) are positive in the data set. Values of 0 are shifted into the positive domain by the machine precision to avoid issues with an ill-defined \( \log(0) \).

For `blrm_trial` objects the default arguments for \( p, \ qc \) and `lower.tail` are set to correspond to the highest interval of `interval_prob` to be constrained by the respective `interval_max_mass` (which are defined as part of the `blrm_trial` objects). This will in the default case correspond to the EWOC metric. These defaults are only applied if \( p, \ qc \) and `lower.tail` are missing.

**Value**

Vector of length equal to the number of rows of the input data set with the critical value for the covariate specified as \( x \) which fulfills the requirements as detailed above. May return `NA` for cases where no solution is found on the specified interval \( x \).

**Examples**

```r
## Setting up dummy sampling for fast execution of example
## Please use 4 chains and 100x more warmup & iter in practice
.user_mc_options <- options(OncoBayes2.MC.warmup=10, OncoBayes2.MC.iter=20, OncoBayes2.MC.chains=1,
  OncoBayes2.MC.save_warmup=FALSE)

# fit an example model. See documentation for "combo2" example
element_model("combo2", silent=TRUE)

# Find dose of drug_A at which EWOC criterium is just fulfilled
data_trial_ab <- subset(codata_combo2, group_id="trial_AB")
drug_A_crit <- critical_quantile(blrmfit, newdata=data_trial_ab,
  x="drug_A", p=0.25, qc=0.33,
  lower.tail=FALSE)

data_trial_ab$drug_A <- drug_A_crit
summary(blrmfit, newdata=data_trial_ab, interval_prob=c(0,0.16,0.33,1))

**dose_info_combo2**

**Dataset: trial dose information for a dual-agent combination study**

**Description**

The data set defines all pre-defined dose-levels which can be explored in the dual-agent example trial.
Usage
drug_info_combo2

Format
An object of class tbl_df (inherits from tbl.data.frame) with 42 rows and 4 columns.

Details
group_id  study
drug_A    drug A dose amount
drug_B    drug B dose amount
dose_id   unique id of record

See Also
Other blrm_trial combo2 example: blrm_trial(), drug_info_combo2, example-combo2_trial

Description
Data set describing the two drugs involved in the example for a dual-agent combination study.

Usage
drug_info_combo2

Format
A tibble with 2 rows (one per drug) and 4 columns:
drug_name  name of drug
dose_ref   reference dose
dose_unit  units used for drug amounts
reference_p_dlt  a-priori probability for a DLT at the reference dose

See Also
Other blrm_trial combo2 example: blrm_trial(), dose_info_combo2, example-combo2_trial
Two-drug combination example

Description

Example using a combination of two experimental drugs.

Details

The following example is described in the reference Neuenschwander, B. et al (2016). The data are described in the help page for `coda data combo2`. In the study `trial_AB`, the risk of DLT was studied as a function of dose for two drugs, drug A and drug B. Historical information on the toxicity profiles of these two drugs was available from single agent trials `trial_A` and `trial_B`. Another study `IIT` was run concurrently to `trial_AB`, and studies the same combination.

The model described in Neuenschwander, et al (2016) is adapted as follows. For groups \( j = 1, \ldots, 4 \) representing each of the four sources of data mentioned above,

\[
\logit \pi_{1j}(d_1) = \log\alpha_{1j} + \beta_{1j} \log \left( \frac{d_1}{d_1^*} \right),
\]

and

\[
\logit \pi_{2j}(d_2) = \log\alpha_{2j} + \beta_{2j} \log \left( \frac{d_2}{d_2^*} \right),
\]

are logistic regressions for the single-agent toxicity of drugs A and B, respectively, when administered in group \( j \). Conditional on the regression parameters \( \theta_{1j} = (\log\alpha_{1j}, \log\beta_{1j}) \) and \( \theta_{2j} = (\log\alpha_{2j}, \log\beta_{2j}) \), the toxicity \( \pi_j(d_1, d_2) \) for the combination is modeled as the "no-interaction" DLT rate,

\[
\tilde{\pi}_j(d_1, d_2) = 1 - (1 - \pi_{1j}(d_1))(1 - \pi_{2j}(d_2))
\]

with a single interaction term added on the log odds scale,

\[
\logit \pi_j(d_1, d_2) = \logit \tilde{\pi}_j(d_1, d_2) + \eta_j \frac{d_1}{d_1^*} \frac{d_2}{d_2^*}.
\]

A hierarchical model across the four groups \( j \) allows dose-toxicity information to be shared through common hyperparameters.

For the component parameters \( \theta_{ij} \),

\[
\theta_{ij} \sim \text{BVN}(\mu_i, \Sigma_i).
\]

For the mean, a further prior is specified as

\[
\mu_i = (\mu_{\alpha i}, \mu_{\beta i}) \sim \text{BVN}(m_i, S_i),
\]

while in the manuscript the prior \( m_i = (\log 0.1, \log 1) \) and \( S_i = \text{diag}(3.33^2, 1^2) \) for each \( i = 1, 2 \) is used, we deviate here and use instead \( m_i = (\log 0.2, \log 1) \) and \( S_i = \text{diag}(2^2, 1^2) \). For the standard deviations and correlation parameters in the covariance matrix,

\[
\Sigma_i = \begin{pmatrix}
\tau_{\alpha i}^2 & \rho_i \tau_{\alpha i} \tau_{\beta i} \\
\rho_i \tau_{\alpha i} \tau_{\beta i} & \tau_{\beta i}^2
\end{pmatrix},
\]
the specified priors are $\tau_{\alpha i} \sim \text{Log-Normal}(\log 0.25, ((\log 4)/1.96)^2)$, 
$\tau_{\beta i} \sim \text{Log-Normal}(\log 0.125, ((\log 4)/1.96)^2)$, and $\rho_i \sim U(-1, 1)$ for $i = 1, 2$.

For the interaction parameters $\eta_j$ in each group, the hierarchical model has

$$\eta_j \sim \mathcal{N}(\mu_\eta, \tau^2_\eta),$$

for $j = 1, \ldots, 4$, with $\mu_\eta \sim \mathcal{N}(0, 1.121^2)$ and $\tau_\eta \sim \text{Log-Normal}(\log 0.125, ((\log 4)/1.96)^2)$.

Below is the syntax for specifying this fully exchangeable model in blrm_exnex.

two-drug combination example using eBLRM Trial

### Description

Example using `blrm_trial` to guide the built-in two-drug combination study example.

### Details

`blrm_trial` is used to collect and store all relevant design information for the example. Subsequent use of the `update.blrm_trial` command allows convenient model fitting via `blrm_exnex`. The `summary.blrm_trial` method allows exploration of the design and modeling results.

To run this example, use `example_model("combo2_trial")`. See `example_model`.

Description

Example using a combination of two experimental drugs, with EXNEX and differential discounting.

Details

This dataset involves a hypothetical dose-escalation study of combination therapy with three treatment components. From two previous studies HistAgent1 and HistAgent2, historical data is available on each of the treatments as single-agents, as well as two of the two-way combinations. However, due to a difference in treatment schedule between the Combo study and the historical studies, a stratification (through stratum_id) is made between the groups to allow differential discounting of the alternate-schedule data. The association is as below.

\[ \text{group_id (j): } \text{stratum_id (s_j):} \]

- Combo (1) BID (1)
- HistAgent1 (2) QD (2)
- HistAgent2 (3) QD (2)

For additional robustness, EXNEX priors are used for all group-level treatment components while not for the interaction parameters. This is to limit the amount of borrowing in case of significant heterogeneity across groups.

The complete model is as follows. As a function of doses \( d_1, d_2, d_3 \), the DLT rate in group \( j \) is, for \( j = 1, \ldots, 3 \),

\[
\logit \pi_j(d_1, d_2, d_3) = \log(1 - \prod_{i=1}^{3}(1 - \pi_{ij}(d_i))) + \eta_j^{(12)} d_1 d_2 d_3 + \eta_j^{(13)} d_1 d_3 d_3 + \eta_j^{(23)} d_2 d_3 d_3 + \eta_j^{(123)} d_1 d_2 d_3.
\]

In group \( j \) each treatment component \( i \) toxicity is modeled with logistic regression,

\[
\logit \pi_{ij}(d_i) = \log \alpha_{ij} + \beta_{ij} \log \left( \frac{d_i}{d_i^*} \right).
\]

The intercept and log-slope parameters \( \theta_{ij} = (\log \alpha_{ij}, \log \beta_{ij}) \) are given an EXNEX prior

\[ \theta_{ij} \sim p_{ij} \text{BVN}(\mu_i, \Sigma_{ij}) + (1 - p_{ij}) \text{BVN}(m_{ij}, S_{ij}) \]

where the exchangeability weights are all \( p_{ij} = 0.9 \). The NEX parameters are set to \( m_{ij} = (\log(1/3), \log 1) \), \( S_{ij} = \text{diag}(2^2, 1^2) \) for all components \( i = 1, 2, 3 \) and groups \( j = 1, 2, 3 \), and the EX parameters are modeled hierarchically. The mean of the exchangeable part has the distribution

\[ \mu_i = (\mu_{\alpha i}, \mu_{\beta i}) \sim \text{BVN}(m_i, S_i) \]

with \( m_i = (\log(1/3), \log 1) \) and \( S_i = \text{diag}(2^2, 1^2) \) for each component \( i = 1, 2, 3 \). For differentially discounting data from each schedule (QD and BID), the covariance parameters for the exchangeable part

\[ \Sigma_{ij} = \begin{pmatrix}
\tau_{\alpha s_{ij}} & \rho_i \tau_{\alpha s_{ij}} \tau_{\beta s_{ij}} & \rho_i \tau_{\alpha s_{ij}} \\
\rho_i \tau_{\alpha s_{ij}} \tau_{\beta s_{ij}} & \tau_{\beta s_{ij}} & \rho_i \tau_{\alpha s_{ij}} \\
\rho_i \tau_{\alpha s_{ij}} & \rho_i \tau_{\alpha s_{ij}} \tau_{\beta s_{ij}} & \tau_{\beta s_{ij}}
\end{pmatrix}.
\]

are allowed to vary across groups \( j \) depending on their mapping to strata \( s(j) \) as described above. For stratum \( s = 1 \) (BID, which contains only the group \( j = 1 \) (Combo)), the standard deviations are modeled as

\[ \tau_{\alpha 11} \sim \text{Log-Normal}(\log 0.25, (\log 4/1.96)^2) \]
\[ \tau_{\beta i} \sim \text{Log-Normal}(\log 0.125, (\log 4/1.96)^2). \]

Whereas in stratum \( s = 2 \) (QD, which contains the historical groups \( j = 2, 3 \) (HistData1, HistData2)), the standard deviations are

\[ \begin{aligned} 
\tau_{\alpha 2i} & \sim \text{Log-Normal}(\log 0.5, (\log 4/1.96)^2) \\
\tau_{\beta 2i} & \sim \text{Log-Normal}(\log 0.25, (\log 4/1.96)^2). 
\end{aligned} \]

For all interaction parameters \( \eta_{ij}^{(12)}, \eta_{ij}^{(13)}, \eta_{ij}^{(23)} \), and \( \eta_{ij}^{(123)} \) \( (j = 1, 2, 3) \), the following prior is assumed:

\[ \eta_{ij}^{(\cdot)} \sim N(\mu_{\eta}^{(\cdot)}, \tau_{\eta s}^{(\cdot)^2}). \]

The exchangeability weights are \( p_{\eta j}^{(\cdot)} = 0.9 \) for all parameters with EXNEX. Here, for each \( \mu_{\eta}^{(12)}, \mu_{\eta}^{(13)}, \mu_{\eta}^{(23)} \), and \( \mu_{\eta}^{(123)} \), we take

\[ \mu_{\eta}^{(\cdot)} \sim N(0, 1/2), \]

and for each \( \tau_{\eta s}^{(12)}, \tau_{\eta s}^{(13)}, \tau_{\eta s}^{(23)}, \) and \( \tau_{\eta s}^{(123)} \),

\[ \tau_{\eta s}^{(\cdot)} \sim \text{Log-Normal}(\log(0.25), (\log 2/1.96)^2), \]

for both strata \( s = 1, 2 \).

Below is the syntax for specifying this model in `blrm_exnex`.

```r
## Setting up dummy sampling for fast execution of example
## Please use 4 chains and 100x more warmup & iter in practice
.user_mc_options <- options(OncoBayes2.MC.warmup=10, OncoBayes2.MC.iter=20, OncoBayes2.MC.chains=1, OncoBayes2.MC.save_warmup=FALSE)

## example combo3

library(abind)

dref <- c(500, 500, 1000)
num_comp <- 3
num_inter <- choose(3,2) + 1
num_strata <- nlevels(hist_combo3$stratum_id)
num_groups <- nlevels(hist_combo3$group_id)

blrmfit <- blrm_exnex(
  cbind(num_toxicities, num_patients-num_toxicities) ~
  1 + I(log(drug_A/dref[1])) | 
  1 + I(log(drug_B/dref[2])) | 
  1 + I(log(drug_C/dref[3])) |
  0
)```

---

\[ \begin{aligned} 
\tau_{\beta i} & \sim \text{Log-Normal}(\log 0.125, (\log 4/1.96)^2). 
\end{aligned} \]
Example using a single experimental drug.

Details

The single agent example is described in the reference Neuenschwander, B. et al (2008). The data are described in the help page for `hist_SA`. In this case, the data come from only one study, with the treatment being only single agent. Hence the model specified does not involve a hierarchical prior for the intercept and log-slope parameters. The model described in Neuenschwander, et al (2008) is adapted as follows:

\[
\text{logit} \pi(d) = \log \alpha + \beta \log \left( \frac{d}{d^*} \right),
\]

where \(d^* = 250\), and the prior for \(\theta = (\log \alpha, \log \beta)\) is

\[
\theta \sim \text{N}(m, S),
\]

and \(m = (\text{logit} 0.5, \log 1)\) and \(S = \text{diag}(2^2, 1^2)\) are constants.
In the blrm_exnex framework, in which the prior must be specified as a hierarchical model \( \theta \sim N(\mu, \Sigma) \) with additional priors on \( \mu \) and \( \Sigma \), the simple prior distribution above is accomplished by fixing the diagonal elements \( \tau^2_{\alpha} \) and \( \tau^2_{\beta} \) of \( \Sigma \) to zero, and taking
\[
\mu \sim N(m, S).
\]

The arguments prior_tau_dist and prior_EX_tau_mean_comp as specified below ensure that the \( \tau \)'s are fixed at zero.

example_model Run example models

Description

Runs example models

Usage

elementary_model(topic, envir = parent.frame(), silent = FALSE)

Arguments

topic example to run

envir environment which the example is loaded into. Defaults to the caller environment.

silent logical controlling if execution is run silently (defaults to FALSE)

Value

When topic is not specified a list of all possible topics is return. Whenever a valid topic is specified, the function inserts the example into the environment given and returns (invisibly) the updated environment.
Examples

```r
## Setting up dummy sampling for fast execution of example
## Please use 4 chains and 100x more warmup & iter in practice
.user_mc_options <- options(OncoBayes2.MC.warmup=10, OncoBayes2.MC.iter=20, OncoBayes2.MC.chains=1,
                              OncoBayes2.MC.save_warmup=FALSE)

## get a list of available examples
example_model()

## run 3 component example
example_model("combo3")

## Recover user set sampling defaults
options(.user_mc_options)
```

hist Combo2

Dataset: historical data on two single-agents to inform a combination study

Description

One of two datasets from the application described in Neuenschwander et al (2016). The risk of DLT is to be studied as a function of dose for two drugs, drug A and drug B. Historical information on the toxicity profiles of these two drugs is available from single agent trials trial_A and trial_B. A second dataset codata Combo2 is available from this application, which includes additional dose-toxicity data from trial_AB and IIT of the combination of Drugs A and B.

Usage

`hist Combo2`

Format

A tibble with 11 rows and 5 variables:

- `group_id` study
- `drug_A` dose of Drug A
- `drug_B` dose of Drug B
- `num_patients` number of patients
- `num_toxicities` number of DLTs
- `cohort_time` cohort number of patients

References

hist_combo3

Dataset: historical and concurrent data on a three-way combination

Description

This dataset involves a hypothetical dose-escalation study of combination therapy with three treatment components. From two previous studies HistAgent1 and HistAgent2, historical data is available on each of the treatments as single-agents, as well as two of the two-way combinations. However, due to a difference in treatment schedule between the Combo study and the historical studies, a stratification (through stratum_id) is made between the groups to allow differential discounting of the alternate-dose data.

Usage

hist_combo3

Format

A data frame with 18 rows and 7 variables:

- group_id: study
- drug_A: dose of Drug A
- drug_B: dose of Drug B
- drug_C: dose of Drug C
- num_patients: number of patients
- num_toxicities: number of DLTs
- stratum_id: stratum for group_id's used for differential discounting

Examples

```r
## Setting up dummy sampling for fast execution of example
## Please use 4 chains and 100x more warmup & iter in practice
.user_mc_options <- options(OncoBayes2.MC.warmup=10, OncoBayes2.MC.iter=20, OncoBayes2.MC.chains=1, OncoBayes2.MC.save_warmup=FALSE)

## example combo3

library(abind)

dref <- c(500, 500, 1000)
num_comp <- 3
num_inter <- choose(3,2) + 1
num_strata <- nlevels(hist_combo3$stratum_id)
num_groups <- nlevels(hist_combo3$group_id)

blrmfit <- blrm_exnex(
    cbind(num_toxicities, num_patients-num_toxicities) ~
```
hist_SA

Single-agent example

Description

Example data from the application in Neuenschwander, et. al. 2008, from an "open-label, multicenter, non-comparative, dose-escalation cancer trial to characterize the safety, tolerability, and pharmacokinetic profile of a drug and to determine its MTD."

Usage

hist_SA

Format

A data frame with 5 rows and 4 variables:
group_id  study
drug_A  dose
num_patients  number of patients
num_toxicities  number of events

References

Examples

```r
## Setting up dummy sampling for fast execution of example

```
lodds

Logit (log-odds) and inverse-logit function.

Description
Calculates the logit (log-odds) and inverse-logit.

Usage
logit(mu)
inv_logit(eta)

Arguments
mu A numeric object with probabilities, with values in the in the range [0,1]. Missing values (NAs) are allowed.
eta A numeric object with log-odds values, with values in the range [-Inf,Inf]. Missing values (NAs) are allowed.

Details
Values of mu equal to 0 or 1 will return -Inf or Inf respectively.

Value
A numeric object of the same type as mu and eta containing the logits or inverse logit of the input values. The logit and inverse transformation equates to

\[
\text{logit}(\mu) = \log(\mu/(1 - \mu))
\]

\[
\text{logit}^{-1}(\eta) = \exp(\eta)/(1 + \exp(\eta)).
\]

prior_EX_tau_mean_comp = matrix(
  c(0, 0),
  nrow = num_comp,
  ncol = 2
),
prior_EX_tau_sd_comp = matrix(
  c(1, 1),
  nrow = num_comp,
  ncol = 2
),
prior_EX_prob_comp = matrix(1, nrow = num_comp, ncol = 1),
prior_tau_dist = 0,
prior_PD = FALSE
)
## Recover user set sampling defaults
options(.user_mc_options)
Examples

\[
\begin{align*}
\logit(0.2) \\
\text{inv-logit}(-1.386)
\end{align*}
\]

---

**nsamples.blrmfit**  
Return the number of posterior samples

---

### Description

Return the number of posterior samples

### Usage

```
## S3 method for class 'blrmfit'
nsamples(object, ...)
```

### Arguments

- `object`  
  fitted model object
- `...`  
  not used in this function

### Examples

```
## Setting up dummy sampling for fast execution of example
## Please use 4 chains and 100x more warmup & iter in practice
.user_mc_options <- options(OncoBayes2.MC.warmup=10, OncoBayes2.MC.iter=20, OncoBayes2.MC.chains=1, 
OncoBayes2.MC.save_warmup=FALSE)

## run single-agent analysis which defines blrmfit model object
example_model("single_agent", silent=TRUE)

nsamples(blrmfit)

## Recover user set sampling defaults
options(.user_mc_options)
```
Description

Bayesian logistic regression model with optional EXchangeability-NonEXchangeability parameter modelling for flexible borrowing from historical or concurrent data-sources. The safety model can guide dose-escalation decisions for adaptive Oncology phase I dose-escalation trials which involve an arbitrary number of drugs.

plot_blrm  

Plot a fitted model

Description

**Warning:** these methods are at an experimental stage of development, and may change with future releases.

Plotting methods for `blrmfit` and `blrm_trial` objects.

Usage

```r
plot_toxicity_curve(object, ...)

plot_toxicity_intervals(object, ...)

plot_toxicity_intervals_stacked(object, ...)
```

```r
## S3 method for class 'blrmfit'
plot_toxicity_curve(
  object,
  newdata,
  x,
  group,
  xlim,
  ylim,
  transform = TRUE,
  prob = 0.5,
  prob_outer = 0.95,
  size = 0.75,
  alpha = 1,
  facet_args = list(),
  hline_at = c(0.16, 0.33),
  grid_length = 100,
  ...)
```

```r
## S3 method for class 'blrm_trial'
plot_toxicity_curve(
  object,
  newdata,
  x,
  group,
  xlim,
  ylim,
  transform = TRUE,
  prob = 0.5,
```
```
plot_blrm

  prob_outer = 0.95,
  size = 0.75,
  alpha = 1,
  facet_args = list(),
  hline_at,
  grid_length = 100,
  ewoc_shading = TRUE,
  ...
)

## S3 method for class 'blrmfit'
plot_toxicity_intervals(
  object,
  newdata,
  x,
  group,
  interval_prob = c(0, 0.16, 0.33, 1),
  interval_max_mass = c(NA, NA, 0.25),
  ewoc_colors = c("green", "red"),
  ...
)

## S3 method for class 'blrm_trial'
plot_toxicity_intervals(
  object,
  newdata,
  x,
  group,
  interval_prob,
  interval_max_mass,
  ewoc_colors = c("green", "red"),
  ...
)

## S3 method for class 'blrmfit'
plot_toxicity_intervals_stacked(
  object,
  newdata,
  x,
  group,
  xlim,
  ylim = c(0, 0.5),
  predictive = FALSE,
  transform = !predictive,
  interval_prob,
  grid_length = 100,
  facet_args = list(),
  ...
)
```
## S3 method for class 'blrm_trial'
plot_toxicity_intervals_stacked(
  object,
  newdata,
  x,
  group,
  ylim = c(0, 0.5),
  predictive = FALSE,
  transform = !predictive,
  interval_prob,
  grid_length = 100,
  ewoc_shading = TRUE,
  facet_args = list(),
  ...
)

**Arguments**

- **object**: fitted model object
- **...**: currently unused
- **newdata**: optional data frame specifying for what to predict; if missing, then the data of the input model object is used. If object is a blrmfit object, newdata defaults to the data argument. If object is a blrm_trial, it defaults to summary(object, "dose_info").
- **x**: Character giving the parameter name to be mapped to the x-axis. This also supports 'tidy' parameter selection by specifying x = vars(...), where ... is specified the same way as in dplyr::select() and similar functions. Examples of using x in this way can be found in the examples. For blrm_trial methods, it defaults to the first entry in summary(blrm_trial, "drug_info")$drug_name.
- **group**: Grouping variable(s) whose levels will be mapped to different facets of the plot. group can be a character vector, tidy parameter(s) of the form group = vars(...), or a formula to be passed directly to ggplot2::facet_wrap(). For blrm_trial methods, it defaults to group_id, plus all entries of summary(blrm_trial, "drug_info")$drug_name except the first, which is mapped to x.
- **xlim**: x-axis limits
- **ylim**: y-axis limits on the probability scale
- **transform**: logical (defaults to FALSE) indicating if the linear predictor on the logit link scale is transformed with inv_logit to the 0-1 response scale.
- **prob**: central probability mass to report for the inner ribbon, i.e. the quantiles 0.5-prob/2 and 0.5+prob/2 are displayed.
- **prob_outer**: central probability mass to report for the outer ribbon, i.e. the quantiles 0.5-prob/2 and 0.5+prob/2 are displayed.
alpha, size  Arguments passed to geoms. For this plot, alpha is passed to `ggplot2::geom_ribbon()`, and size is passed to `ggplot2::geom_line()`.

facet_args  A named list of arguments (other than `‘facets’`) passed to `ggplot2::facet_wrap()`.

hline_at  Location(s) of horizontal guide lines (passed to `bayesplot::hline_at()`).

grid_length  Number of grid points within xlim for plotting.

ewoc_shading  logical indicates if doses violating EWOC should be shaded in gray. Applies only to blrm_trial methods. Defaults to TRUE.

interval_prob  defines the interval probabilities reported in the standard outputs. Defaults to `c(0, 0.16, 0.33, 1)`, when `predictive = FALSE` and/or `transform = TRUE`, or to intervals giving 0, 1, or 2+ DLTs when `predictive = TRUE` and `transform = FALSE`. For blrm_trial methods, this is taken from `summary(blrm_trial, "interval_prob")` by default.

interval_max_mass  vector defining for each interval of the interval_prob vector a maximal admissible probability mass for a given dose level. Whenever the posterior probability mass in a given interval exceeds the threshold, then the Escalation With Overdose Control (EWOC) criterion is considered to be not fulfilled. Dose levels not fulfilling EWOC are ineligible for the next cohort of patients. The default restricts the overdose probability to less than 0.25. For blrm_trial methods, this is taken from `summary(blrm_trial, "interval_max_mass")` by default.

ewoc_colors  Fill colors used for bars indicating EWOC OK or not. Vector of two characters, each of which must correspond to `bayesplot-package` color schemes (see `?bayesplot::color_scheme_get()`)

predictive  logical indicates if the posterior predictive is being summarized. Defaults to FALSE.

Details

`plot_toxicity_curve` plots continuous profiles of the dose-toxicity curve.

`plot_toxicity_intervals` plots the posterior probability mass in subintervals of \([0,1]\), at a discrete set of provisional doses.

`plot_toxicity_intervals_stacked` is similar to `plot_toxicity_intervals`, but over a continuous range of doses.

Value

A ggplot object that can be further customized using the `ggplot2` package.

Examples

```r
## Setting up dummy sampling for fast execution of example
## Please use 4 chains and 100x more warmup & iter in practice
.user_mc_options <- options(OncoBayes2.MC.warmup=10, OncoBayes2.MC.iter=20, OncoBayes2.MC.chains=1, OncoBayes2.MC.save_warmup=FALSE)

example_model("combo2", silent=TRUE)
```
# Plot the dose-toxicity curve

```r
plot_toxicity_curve(blrmfit,
    x = "drug_A",
    group = ~ group_id * drug_B,
    newdata = subset(dose_info_combo2, group_id == "trial_AB"),
    facet_args = list(ncol = 4))
```

# Plot posterior DLT-rate-interval probabilities at discrete dose levels

```r
plot_toxicity_intervals(blrmfit,
    x = "drug_A",
    group = ~ group_id * drug_B,
    newdata = subset(dose_info_combo2, group_id == "trial_AB"))
```

# Plot posterior DLT-rate-interval probabilities over continuous dose

```r
plot_toxicity_intervals_stacked(blrmfit,
    x = "drug_A",
    group = ~ group_id * drug_B,
    newdata = subset(dose_info_combo2, group_id == "trial_AB"))
```

# Plot predictive distribution probabilities over continuous dose

```r
plot_toxicity_intervals_stacked(blrmfit,
    x = "drug_A",
    group = ~ group_id * drug_B,
    predictive = TRUE,
    interval_prob = c(-1, 0, 1, 6),
    newdata = transform(subset(dose_info_combo2,
        group_id == "trial_AB"),
        num_patients = 6,
        num_toxicities = 0))
```

## Recover user set sampling defaults

```r
options(.user_mc_options)
```

---

**posterior_interval.blrmfit**

*Posterior intervals*

**Description**

Posterior intervals of all model parameters.

**Usage**

```r
## S3 method for class 'blrmfit'
posterior_interval(object, prob = 0.95, ...)
```
**Arguments**

- **object**: fitted model object
- **prob**: central probability mass to report, i.e. the quantiles 0.5-prob/2 and 0.5+prob/2 are displayed. Multiple central widths can be specified.
- **...**: not used in this function

**Details**

Reports the quantiles of posterior parameters which correspond to the central probability mass specified. The output includes the posterior of the hyper-parameters and the posterior of each group estimate.

**Value**

Matrix of two columns for the central probability interval prob for all parameters of the model.

**Examples**

```r
## Setting up dummy sampling for fast execution of example
## Please use 4 chains and 100x more warmup & iter in practice
.user_mc_options <- options(OncoBayes2.MC.warmup=10, OncoBayes2.MC.iter=20, OncoBayes2.MC.chains=1, OncoBayes2.MC.save_warmup=FALSE)

example_model("single_agent", silent=TRUE)

posterior_interval(blrmfit)

## Recover user set sampling defaults
options(.user_mc_options)
```

---

**Description**

Calculates the posterior of the linear predictor.

**Usage**

```r
## S3 method for class 'blrmfit'
posterior_linpred(object, transform = FALSE, newdata, draws, ...)
```
Arguments

- **object**: fitted model object
- **transform**: logical (defaults to FALSE) indicating if the linear predictor on the logit link scale is transformed with inv_logit to the 0-1 response scale.
- **newdata**: optional data frame specifying for what to predict; if missing, then the data of the input model object is used
- **draws**: number of returned posterior draws; by default the entire posterior is returned
  
  ... not used in this function

Details

Simulates the posterior of the linear predictor of the model object for the specified data set.

Value

Matrix of dimensions draws by nrow(newdata) where row correspond to a draw of the posterior and each column corresponds to a row in newdata. The columns are labelled with the row.names of newdata.

Group and strata definitions

The groups and strata as defined when running the blrm_exnex analysis cannot be changed at a later stage. As a result no evaluations can be performed for groups which have not been present in the data set used for running the analysis. However, it is admissible to code the group (and/or stratum) column as a factor which contains empty levels. These groups are thus not contained in the fitting data set and they are assigned by default to the first stratum. In addition priors must be setup for these groups (and/or strata). These empty group (and/or strata) levels are then allowed in subsequent evaluations. This enables the evaluation of the hierarchical model in terms of representing a prior for future groups.

Examples

```r
## Setting up dummy sampling for fast execution of example
## Please use 4 chains and 100x more warmup & iter in practice
.user_mc_options <- options(OncoBayes2.MC.warmup=10, OncoBayes2.MC.iter=20, OncoBayes2.MC.chains=1, OncoBayes2.MC.save_warmup=FALSE)

## run single-agent analysis which defines blrmfit model object
example_model("single_agent", silent=TRUE)

## obtain posterior of linear prediction on 0-1 scale
post_prob_dlt <- posterior_linpred(blrmfit, TRUE, newdata=hist_SA)
## name columns to obtain nice bayesplot labels
colnames(post_prob_dlt) <- hist_SA$drug_A

library(bayesplot)
library(ggplot2)
mcmc_intervals(post_prob_dlt, prob=0.5, prob_outer=0.95) +
```

coord_flip() +
    vline_at(c(0.16, 0.33), linetype=2) +
    ylab("Dose [mg]") +
    ggtitle("Posterior Probability of a DLT") +
    scale_x_continuous(breaks=c(0.1, 0.16, 0.33, 0.5, 0.75))

## Recover user set sampling defaults
options(.user_mc_options)

---

### posterior_predict.blrmfit

**Posterior of predictive**

#### Description

Simulation of the predictive distribution.

#### Usage

```r
## S3 method for class 'blrmfit'
posterior_predict(object, newdata, draws, ...)
```

#### Arguments

- **object**: fitted model object
- **newdata**: optional data frame specifying for what to predict; if missing, then the data of the input model object is used
- **draws**: number of returned posterior draws; by default the entire posterior is returned
- **...**: not used in this function

#### Details

Simulates the posterior predictive of the model object for the specified data set.

#### Value

Matrix of dimensions *draws* by *nrow(newdata)* where row correspond to a draw of the posterior and each column corresponds to a row in *newdata*. The columns are labelled with the *row.names* of *newdata*. 
Group and strata definitions

The groups and strata as defined when running the blrm_exnex analysis cannot be changed at a later stage. As a result no evaluations can be performed for groups which have not been present in the data set used for running the analysis. However, it is admissible to code the group (and/or stratum) column as a factor which contains empty levels. These groups are thus not contained in the fitting data set and they are assigned by default to the first stratum. In addition priors must be setup for these groups (and/or strata). These empty group (and/or strata) levels are then allowed in subsequent evaluations. This enables the evaluation of the hierarchical model in terms of representing a prior for future groups.

Examples

```r
## Setting up dummy sampling for fast execution of example
## Please use 4 chains and 100x more warmup & iter in practice
.user_mc_options <- options(OncoBayes2.MC.warmup=10, OncoBayes2.MC.iter=20, OncoBayes2.MC.chains=1, OncoBayes2.MC.save_warmup=FALSE)

eexample_model("single_agent", silent=TRUE)

post_pred <- posterior_predict(blrmfit)
## turn DLT counts into DLT rates
post_pred_rate <- sweep(post_pred, 2, hist_SA$num_patients, "/")

library(bayesplot)
library(ggplot2)

## compare posterior predictive of the model for the response rates
## with observed data
with(hist_SA,
    ppc_intervals(num_toxicities / num_patients, post_pred_rate, x=drug_A, prob_outer=0.95)) +
xlab("Dose [mg]"
)

## Recover user set sampling defaults
options(.user_mc_options)
```

predictive_interval.blrmfit

*Posterior predictive intervals*

### Description

Posterior predictive intervals of the model.

### Usage

```r
## S3 method for class 'blrmfit'
predictive_interval(object, prob = 0.95, newdata, ...)
```
Arguments

- **object**: fitted model object
- **prob**: central probability mass to report, i.e. the quantiles 0.5-prob/2 and 0.5+prob/2 are displayed. Multiple central widths can be specified.
- **newdata**: optional data frame specifying for what to predict; if missing, then the data of the input model object is used
- **...**: not used in this function

Details

Reports for each row of the input data set the predictive interval according to the fitted model.

Value

Matrix with as many rows as the input data set and two columns which contain the lower and upper quantile corresponding to the central probability mass prob for the number of responses of the predictive distribution.

Examples

```r
## Setting up dummy sampling for fast execution of example
## Please use 4 chains and 100x more warmup & iter in practice
.onuser_mc_options <- options(OncoBayes2.MC.warmup=10, OncoBayes2.MC.iter=20, OncoBayes2.MC.chains=1, OncoBayes2.MC.save_warmup=FALSE)

example_model("single_agent", silent=TRUE)
predictive_interval(blrmfit)

## Recover user set sampling defaults
options(.user_mc_options)
```

Description

Extracts a summary of the prior in a structured data format.

Usage

```r
## S3 method for class 'blrmfit'
prior_summary(object, digits = 2, ...)
```
Arguments

object blrmfit (blrm_trial) object as returned from blrm_exnex (blrm_trial) analysis
digits number of digits to show
... ignored by the function

Details

The summary of the prior creates a structured representation of the specified prior from a blrm_exnex (blrm_trial) analysis.

Value

Returns an analysis specific list, which has it’s own print function. The returned list contains arrays which represent the prior in a structured format.

Examples

## Setting up dummy sampling for fast execution of example
## Please use 4 chains and 100x more warmup & iter in practice
.user_mc_options <- options(OncoBayes2.MC.warmup=10, OncoBayes2.MC.iter=20, OncoBayes2.MC.chains=1, OncoBayes2.MC.save_warmup=FALSE)

## run combo2 analysis which defines blrmfit model object
eexample_model("combo2", silent=TRUE)

prior_summary(blrmfit)
prior_sum <- prior_summary(blrmfit)
names(prior_sum)

## the entries of the prior list are labelled arrays
dimnames(prior_sum$EX_mu_log_beta)

## Recover user set sampling defaults
options(.user_mc_options)

Summary

Summary of model results

Description

Provides model summaries for blrm_exnex and blrm_trial analyses.
Usage

## S3 method for class 'blrmfit'
summary(
  object,
  newdata,
  transform = !predictive,
  prob = 0.95,
  interval_prob,
  predictive = FALSE,
  ...
)

Arguments

object fitted model object
newdata optional data frame specifying for what to predict; if missing, then the data of the input model object is used
transform logical (defaults to FALSE) indicating if the linear predictor on the logit link scale is transformed with inv_logit to the 0-1 response scale.
prob central probability mass to report, i.e. the quantiles 0.5-prob/2 and 0.5+prob/2 are displayed. Multiple central widths can be specified.
interval_prob optional vector of sorted quantiles for which the interval probabilities are calculated
predictive logical indicates if the posterior predictive is being summarized. Defaults to FALSE.
... not used in this function

Details

The calculated posterior summaries are returned as a data.frame and contain optional interval probabilities for the specified vector of sorted quantiles. These summaries are calculated on the response scale by default and can be obtained on the link scale when setting transform=FALSE.

When the results are requested for the predictive distribution with predictive=TRUE, then the link scale refers to the total counts while the transformed scale divides the (predictive) counts by the number of trials such that results are on the 0-1 scale.

Value

Returns a data.frame of the key summaries of the posterior mean, standard deviation, central probability interval, median and optional interval probabilities. Each row of the data.frame corresponds to the respective input data which is by default the same data set as used for the blrm_exnex analysis or the data specified in the newdata argument.

Examples

## Setting up dummy sampling for fast execution of example
## Please use 4 chains and 100x more warmup & iter in practice
.user_mc_options <- options(OncoBayes2.MC.warmup=10, OncoBayes2.MC.iter=20, OncoBayes2.MC.chains=1, OncoBayes2.MC.save_warmup=FALSE)

example_model("single_agent", silent=TRUE)

## obtain underdosing (0-0.16), target dosing (0.16-0.33) and overdosing (0.33-1) probabilities
summary(blrmfit, interval_prob=c(0,0.16,0.33,1))

## obtain predictive distribution for respective cohorts and calculate probability for no event, 1 event or >1 event note that this does the calculation for the cohort sizes as put into the data-set
summary(blrmfit, interval_prob=c(-1,0,1,10), predictive=TRUE)

## to obtain the predictive for a cohort-size of 6 for all patients in the data-set one would need to use the newdata argument, e.g.
summary(blrmfit, newdata=transform(hist_SA, num_patients=6), interval_prob=c(-1,0,1,10), predictive=TRUE)

## Recover user set sampling defaults
options(.user_mc_options)

---

### summary.blrm_trial

**Summarise trial**

#### Description

Provides model summaries for `blrm_trial` analyses.

#### Usage

```r
## S3 method for class 'blrm_trial'
summary(
  object,
  summarize = c("blrmfit", "blrm_exnex_call", "data", "drug_info", "dose_info", "dose_prediction", "data_prediction", "newdata_prediction", "dimensionality", "interval_prob", "interval_max_mass"),
  ...,
)
```

#### Arguments

- `object`: `blrm_trial` object
- `summarize`: one of the following options:
  - `blrmfit`: summary of the underlying blrmfit object with further arguments
update.blrmfit

Update data of a BLRM analysis

Description

Adds data rows to a blrm_exnex or blrm_trial analysis object.

- blrm_exnex_call: blrm_exnex call used to create the blrmfit object
- drug_info: drug_info for the trial, contains drugs, reference doses and units
- dose_info: dose_info that were defined
- dose_prediction prediction for the defined dose_info
- data: data that were observed
- data_prediction: prediction for the observed data
- newdata_prediction: prediction for data provided with the newdata= argument
- dimensionality: numeric vector with entries "num_components", "num_interaction_terms", "num_groups", "num_strata"
- interval_prob: interval probabilities reported in the standard outputs
- interval_max_mass: named vector defining for each interval of the interval_prob vector a maximal admissible probability mass for a given dose level

Examples

```r
## Setting up dummy sampling for fast execution of example
## Please use 4 chains and 100x more warmup & iter in practice
.user_mc_options <- options(OncoBayes2.MC.warmup=10, OncoBayes2.MC.iter=20, OncoBayes2.MC.chains=1,
                            OncoBayes2.MC.save_warmup=FALSE)

# construct initial blrm_trial object from built-in example datasets
combo2_trial_setup <- blrm_trial(
  data = hist_combo2,
  dose_info = dose_info_combo2,
  drug_info = drug_info_combo2,
  simplified_prior = TRUE
)

# extract blrm_call to see setup of the prior as passed to blrm_exnex
summary(combo2_trial_setup, "blrm_exnex_call")

## Recover user set sampling defaults
options(.user_mc_options)
```
## S3 method for class 'blrmfit'
update(object, ..., add_data)

### Arguments
- **object**: blrmfit analysis object
- **...**: passed to default update command
- **add_data**: The data in add_data will be combined with data in object using bind_rows. The indices for groups and stratums (if defined) are matched between add_data and the data of the analysis object. Note that the add_data argument must be named explicitly as demonstrated in the example.

### Examples
```r
## Setting up dummy sampling for fast execution of example
## Please use 4 chains and 100x more warmup & iter in practice
.user_mc_options <- options(OncoBayes2.MC.warmup=10, OncoBayes2.MC.iter=20, OncoBayes2.MC.chains=1, OncoBayes2.MC.save_warmup=FALSE)

eexample_model("single_agent", silent=TRUE)

library(tibble)
new_cohort <- tibble(group_id="trial_A", drug_A=50, num_patients=4, num_toxicities=1)

## this would fail, since add_data argument must be named
## new_blrmfit <- update(blrmfit, new_cohort)
new_blrmfit <- update(blrmfit, add_data=new_cohort)

## Recover user set sampling defaults
options(.user_mc_options)
```

### Description
- Adds data rows to a blrm_trial object (add_data argument)
- Replaces data of a blrm_trial object (data argument)
- Sets the prior of a blrm_trial object (... argument will be passed to blrm_exnex)

### Usage
```r
## S3 method for class 'blrm_trial'
update(object, ...)
```
Arguments

object: blrm_trial object
... passed to default update command of blrm_exnex

Examples

## Setting up dummy sampling for fast execution of example
## Please use 4 chains and 100x more warmup & iter in practice
.user_mc_options <- options(OncoBayes2.MC.warmup=10, OncoBayes2.MC.iter=20, OncoBayes2.MC.chains=1,
OncoBayes2.MC.save_warmup=FALSE)

# the combo2_trial example demonstrates the use of add_data of
# update.blrmfit
example_model("combo2_trial")

## Recover user set sampling defaults
options(.user_mc_options)
