Package ‘RAINBOWR’

November 14, 2019

Type Package
Title Genome-Wide Association Study with SNP-Set Methods
Version 0.1.14
Maintainer Kosuke Hamazaki <hamazaki@ut-biomet.org>
Description By using ‘RAINBOWR’ (Reliable Association INference By Optimizing Weights with R), users can test multiple SNPs (Single Nucleotide Polymorphisms) simultaneously by kernel-based (SNP-set) methods. This package can also be applied to haplotype-based GWAS (Genome-Wide Association Study). Users can test not only additive effects but also dominance and epistatic effects. In detail, please check our preprint on bioRxiv: Kosuke Hamazaki and Hiroyoshi Iwata (2019) <doi:10.1101/612028>.

**CalcThreshold**

*Function to calculate threshold for GWAS*

---

**Description**

Calculate thresholds for the given GWAS (genome-wide association studies) result by the Benjamini-Hochberg method or Bonferroni method.

**Usage**

```r
CalcThreshold(input, sig.level = 0.05, method = "BH")
```

**Arguments**

- **input**: Data frame of GWAS results where the first column is the marker names, the second and third column is the chromosome and map position, and the forth column is -log10(p) for each marker.
- **sig.level**: Significance level for the threshold. The default is 0.05. You can also assign vector of significance levels.
- **method**: Two methods are offered: "BH" : Benjamini-Hochberg method. To control FDR, use this method. "Bonf" : Bonferroni method. To perform simple correction of multiple testing, use this method. You can also assign both of them by `method = c("BH", "Bonf")`

**Value**

The value of the threshold. If there is no threshold, it returns NA.

**References**

cumsumPos

*Function to calculate cumulative position (beyond chromosome)*

**Description**

Function to calculate cumulative position (beyond chromosome)

**Usage**

cumsumPos(map)

**Arguments**

- **map**
  Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position.

**Value**

Cumulative position (beyond chromosome) will be returned.

---

design.Z

*Function to generate design matrix (Z)*

**Description**

Function to generate design matrix (Z)

**Usage**

design.Z(pheno.labels, geno.names)

**Arguments**

- **pheno.labels**
  A vector of genotype (line; accession; variety) names which correspond to phenotypic values.

- **geno.names**
  A vector of genotype (line; accession; variety) names for marker genotype data (duplication is not recommended).

**Value**

\[ Z \text{ of } y = X\beta + Zu + e \] Design matrix, which is useful for GS or GWAS.
Description

This function solves the following multi-kernel linear mixed effects model.

\[ y = X\beta + \sum_{l=1}^{L} Z_l u_l + \epsilon \]

where \( \text{Var}(y) = \sum_{l=1}^{L} Z_l K_l Z_l' \sigma^2_l + I \sigma^2_{\epsilon} \).

Usage

```r
EM3.cpp(y, X0 = NULL, ZETA, eigen.G = NULL, eigen.SGS = NULL, tol = NULL, optimizer = "nlminb", traceInside = 0, n.thres = 450, REML = TRUE, pred = TRUE)
```

Arguments

- **y** A \( n \times 1 \) vector. A vector of phenotypic values should be used. NA is allowed.
- **X0** A \( n \times p \) matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.
- **ZETA** A list of variance matrices and its design matrices of random effects. You can use more than one kernel matrix. For example, `ZETA = list(A = list(Z = Z.A, K = K.A), D = list(Z = Z.D, K = K.D))` (A for additive, D for dominance) Please set names of lists "Z" and "K"!
- **eigen.G** A list with
  - \$values Eigen values
  - \$vectors Eigen vectors
  The result of the eigen decompsition of \( G = ZKZ' \). You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.
- **eigen.SGS** A list with
  - \$values Eigen values
  - \$vectors Eigen vectors
  The result of the eigen decompsition of \( SGS \), where \( S = I - X(X'X)^{-1}X' \), \( G = ZKZ' \). You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.
- **tol** The tolerance for detecting linear dependencies in the columns of \( G = ZKZ' \). Eigen vectors whose eigen values are less than "tol" argument will be omitted from results. If tol is NULL, top `n` eigen values will be effective.
optimizer The function used in the optimization process. We offer "optim", "optimx", and "nlminb" functions.

traceInside Perform trace for the optimization if traceInside >= 1, and this argument shows the frequency of reports.

n.thres If n >= n.thres, perform EMM1.cpp. Else perform EMM2.cpp.

REML You can choose which method you will use, "REML" or "ML". If REML = TRUE, you will perform "REML", and if REML = FALSE, you will perform "ML".

pred If TRUE, the fitting values of y is returned.

Value

$y.pred$ The fitting values of $y = X\beta + Zu$

$Vu$ Estimator for $\sigma^2_u$, all of the genetic variance

$Ve$ Estimator for $\sigma^2_e$

$\beta$ BLUE($\beta$)

$u$ BLUP($u$)

$weights$ The proportion of each genetic variance (corresponding to each kernel of ZETA) to $Vu$

$LL$ Maximized log-likelihood (full or restricted, depending on method)

$Vinv$ The inverse of $V = Vu \times ZKZ' + Ve \times I$

$Hinv$ The inverse of $H = ZKZ' + \lambda I$

References

     cex = 1.5)

---

**EM3.linker.cpp**

*Equation of mixed model for multi-kernel (fast, for limited cases)*

---

**Description**

This function solves multi-kernel mixed model using fastlmm.snpset approach (Lippert et al., 2014). This function can be used only when the kernels other than genomic relationship matrix are linear kernels.

**Usage**

```r
EM3.linker.cpp(y0, X0 = NULL, ZETA = NULL, Zs0 = NULL, Ws0,
               Gammas0 = lapply(Ws0, function(x) diag(ncol(x))), gammas.diag = TRUE,
               X.fix = TRUE, eigen.SGS = NULL, eigen.G = NULL, tol = NULL,
               bounds = c(1e-06, 1e+06), optimizer = "nlminb", traceInside = 0,
               n.thres = 450, spectral.method = NULL, REML = TRUE, pred = TRUE)
```
Arguments

**y0**
A $n \times 1$ vector. A vector of phenotypic values should be used. NA is allowed.

**X0**
A $n \times p$ matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.

**ZETA**
A list of variance (relationship) matrix ($K; m \times m$) and its design matrix ($Z; n \times m$) of random effects. You can use only one kernel matrix. For example, $ZETA = list(A = list(Z = Z, K = K))$ Please set names of list "Z" and "K"!

**Zs0**
A list of design matrices ($Z; n \times m$ matrix) for $W_s$. For example, $Zs0 = list(A.part = Z.A.part, D.part = Z.D.part)$

**Ws0**
A list of low rank matrices ($W; m \times k$ matrix). This forms linear kernel $K = WTW'$. For example, $Ws0 = list(A.part = W.A, D.part = W.D)$

**Gammas0**
A list of matrices for weighting SNPs (Gamma; $k \times k$ matrix). This forms linear kernel $K = WTW'$. For example, if there is no weighting, $Gammas0 = lapply(Ws0, function(x) diag(ncol(x)))$

**gammas.diag**
If each Gamma is the diagonal matrix, please set this argument TRUE. The calculation time can be saved.

**X.fix**
If you repeat this function and when $X0$ is fixed during iterations, please set this argument TRUE.

**eigen.SGS**
A list with

- `$values` Eigen values
- `$vectors` Eigen vectors

The result of the eigen decomposition of $SGS$, where $S = I - X(X'X)^{-1}X'$, $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.

**eigen.G**
A list with

- `$values` Eigen values
- `$vectors` Eigen vectors

The result of the eigen decomposition of $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.

**tol**
The tolerance for detecting linear dependencies in the columns of $G = ZKZ'$. Eigen vectors whose eigen values are less than "tol" argument will be omitted from results. If tol is NULL, top 'n' eigen values will be effective.

**bounds**
Lower and upper bounds for weights.

**optimizer**
The function used in the optimization process. We offer "optim", "optimx", and "nlminb" functions.

**traceInside**
Perform trace for the optimization if traceInside >= 1, and this argument shows the frequency of reports.

**n.thres**
If $n >= n.thres$, perform EMM1.cpp. Else perform EMM2.cpp.
spectral.method

The method of spectral decomposition. In this function, "eigen" : eigen decomposition and "cholesky" : cholesky and singular value decomposition are offered. If this argument is NULL, either method will be chosen according to the dimension of Z and X.

REML

You can choose which method you will use, "REML" or "ML". If REML = TRUE, you will perform "REML", and if REML = FALSE, you will perform "ML".

pred

If TRUE, the fitting values of y is returned.

Value

$y_{pred}$ The fitting values of $y = X\beta + Zu$

$Vu$ Estimator for $\sigma_u^2$, all of the genetic variance

$Ve$ Estimator for $\sigma_e^2$

$\beta$ BLUE(\(\beta\))

$u$ BLUP(\(u\))

$\text{weights}$ The proportion of each genetic variance (corresponding to each kernel of ZETA) to $Vu$

$\text{LL}$ Maximized log-likelihood (full or restricted, depending on method)

$Vinv$ The inverse of $V = Vu \times ZKZ' + Ve \times I$

$Hinv$ The inverse of $H = ZKZ' + \lambda I$

u <- EM3/linker.res$u ### estimated genotypic values (all chromosomes, chromosome 12)
See(u)
```

---

**EMM.cpp**  
*Equation of mixed model for one kernel, a wrapper of two methods*
Description

This function estimates maximum-likelihood (ML/REML; restricted maximum likelihood) solutions for the following mixed model.

\[ y = X\beta + Zu + \epsilon \]

where \( \beta \) is a vector of fixed effects and \( u \) is a vector of random effects with \( \text{Var}[u] = K\sigma_u^2 \). The residual variance is \( \text{Var}[\epsilon] = I\sigma_e^2 \).

Usage

`EMM.cpp(y, X = NULL, ZETA, eigen.G = NULL, eigen.SGS = NULL, n.thres = 450, reestimation = FALSE, lam.len = 4, init.range = c(1e-06, 100), init.one = 0.5, conv.param = 1e-06, count.max = 20, bounds = c(1e-06, 1e+06), tol = NULL, optimizer = "nlminb", traceInside = 0, REML = TRUE, silent = TRUE, plot.l = FALSE, SE = FALSE, return.Hinv = TRUE)`

Arguments

- **y** A \( n \times 1 \) vector. A vector of phenotypic values should be used. NA is allowed.
- **X** A \( n \times p \) matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.
- **ZETA** A list of variance (relationship) matrix (\( K; m \times m \)) and its design matrix (\( Z; n \times m \)) of random effects. You can use only one kernel matrix. For example, \( ZETA = list(A = list(Z = Z, K = K)) \) Please set names of list "Z" and "K"!
- **eigen.G** A list with
  - $values$ Eigen values
  - $vectors$ Eigen vectors
  The result of the eigen decomposition of \( G = ZZ' \). You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.
- **eigen.SGS** A list with
  - $values$ Eigen values
  - $vectors$ Eigen vectors
  The result of the eigen decomposition of \( SGS \), where \( S = I - X(X'X)^{-1}X' \), \( G = ZZ' \). You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.
- **n.thres** If \( n > n.thres \), perform EMM1.cpp. Else perform EMM2.cpp.
- **reestimation** If TRUE, EMM2.cpp is performed when the estimation by EMM1.cpp may not be accurate.
lam.len The number of initial values you set. If this number is large, the estimation will be more accurate, but computational cost will be large. We recommend setting this value 3 <= lam.len <= 6.

init.range The range of the initial parameters. For example, if lam.len = 5 and init.range = c(1e-06, 1e02), corresponding initial heritabilities will be calculated as seq(1e-06, 1 - 1e-02, length = 5), and then initial lambdas will be set.

init.one The initial parameter if lam.len = 1.

conv.param The convergence parameter. If the difference of log-likelihood by updating the parameter "lambda" is smaller than this conv.param, the iteration steps will be stopped.

count.max Sometimes algorithms won't converge for some initial parameters. So if the iteration steps reache to this argument, you can stop the calculation even if algorithm doesn't converge.

bounds Lower and Upper bounds of the parameter lambda. If the updated parameter goes out of this range, the parameter is reset to the value in this range.

tol The tolerance for detecting linear dependencies in the columns of G = ZKZ'. Eigen vectors whose eigen values are less than "tol" argument will be omitted from results. If tol is NULL, top 'n' eigen values will be effective.

optimizer The function used in the optimization process. We offer "optim", "optimx", and "nlminb" functions.

traceInside Perform trace for the optimization if traceInside >= 1, and this argument shows the frequency of reports.

REML You can choose which method you will use, "REML" or "ML". If REML = TRUE, you will perform "REML", and if REML = FALSE, you will perform "ML".

silent If this argument is TRUE, warning messages will be shown when estimation is not accurate.

plot.l If you want to plot log-likelihood, please set plot.l = TRUE. We don’t recommend plot.l = TRUE when lam.len >= 2.

SE If TRUE, standard errors are calculated.

return.Hinv If TRUE, the function returns the inverse of $H = ZKZ' + \lambda I$ where $\lambda = \sigma_e^2 / \sigma_u^2$. This is useful for GWAS.

Value

$\hat{\sigma}_u^2$ Estimator for $\sigma_u^2$

$\hat{\sigma}_e^2$ Estimator for $\sigma_e^2$

$\hat{\beta}$ BLUE($\beta$)

$\hat{u}$ BLUP($u$)

$L$LL Maximized log-likelihood (full or restricted, depending on method)

$\hat{\beta}SE$ Standard error for $\beta$ (If SE = TRUE)

$\hat{u}SE$ Standard error for $u^* - u$ (If SE = TRUE)

$\hat{H}inv$ The inverse of $H = ZKZ' + \lambda I$ (If return.Hinv = TRUE)
$Hinv2$ The inverse of $H2 = ZKZ' / \lambda + I$ (If return.Hinv = TRUE)

$\lambda$ Estimators for $\lambda = \sigma^2_e / \lambda^2$ (If $n \geq n.thres$)

$\lambda$s Lambdas for each initial values (If $n \geq n.thres$)

$reest$ If parameter estimation may not be accurate, reest = 1, else reest = 0 (If $n \geq n.thres$)

$counts$ The number of iterations until convergence for each initial values (If $n \geq n.thres$)

EMM1.cpp

Equation of mixed model for one kernel, GEMMA-based method (implemented by Rcpp)

Description

This function solves the single-kernel linear mixed effects model by GEMMA (genome wide efficient mixed model association; Zhou et al., 2012) approach.

Usage

EMM1.cpp(y, X = NULL, ZETA, eigen.G = NULL, lam.len = 4,
init.range = c(1e-04, 100), init.one = 0.5, conv.param = 1e-06,
count.max = 15, bounds = c(1e-06, 1e+06), tol = NULL,
REML = TRUE, silent = TRUE, plot.l = FALSE, SE = FALSE,
return.Hinv = TRUE)

Arguments

y
A n × 1 vector. A vector of phenotypic values should be used. NA is allowed.

X
A n × p matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.

ZETA
A list of variance (relationship) matrix (K; m × m) and its design matrix (Z; n × m) of random effects. You can use only one kernel matrix. For example, ZETA = list(A = list(Z = Z, K = K)) Please set names of list "Z" and "K"!

eigen.G
A list with

$values
Eigen values

$vectors
Eigen vectors

The result of the eigen decomposition of $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.

lam.len
The number of initial values you set. If this number is large, the estimation will be more accurate, but computational cost will be large. We recommend setting this value 3 <= lam.len <= 6.

init.range
The range of the initial parameters. For example, if lam.len = 5 and init.range = c(1e-06, 1e02), corresponding initial heritabilities will be calculated as seq(1e-06, 1 - 1e-02, length = 5), and then initial lambdas will be set.

init.one
The initial parameter if lam.len = 1.

conv.param
The convergence parameter. If the difference of log-likelihood by updating the parameter "lambda" is smaller than this conv.param, the iteration steps will be stopped.

count.max
Sometimes algorithms won’t converge for some initial parameters. So if the iteration steps reache to this argument, you can stop the calculation even if algorithm doesn’t converge.
bounds  Lower and Upper bounds of the parameter 1 / lambda. If the updated parameter goes out of this range, the parameter is reset to the value in this range.

tol  The tolerance for detecting linear dependencies in the columns of G = ZKZ'. Eigen vectors whose eigen values are less than "tol" argument will be omitted from results. If tol is NULL, top 'n' eigen values will be effective.

REML  You can choose which method you will use, "REML" or "ML". If REML = TRUE, you will perform "REML", and if REML = FALSE, you will perform "ML".

silent  If this argument is TRUE, warning messages will be shown when estimation is not accurate.

plot.l  If you want to plot log-likelihood, please set plot.l = TRUE. We don’t recommend plot.l = TRUE when lam.len >= 2.

SE  If TRUE, standard errors are calculated.

return.Hinv  If TRUE, the function returns the inverse of $H = ZZ' + \lambda I$ where $\lambda = \sigma_e^2 / \sigma_u^2$. This is useful for GWAS.

Value

$s_{Vu}$  Estimator for $\sigma_u^2$

$s_{Ve}$  Estimator for $\sigma_e^2$

$s_{beta}$  BLUE($\beta$)

$s_u$  BLUP($u$)

$s_{LL}$  Maximized log-likelihood (full or restricted, depending on method)

$s_{beta.SE}$  Standard error for $\beta$ (If SE = TRUE)

$s_{u.SE}$  Standard error for $u^* - u$ (If SE = TRUE)

$s_{Hinv}$  The inverse of $H = ZZ' + \lambda I$ (If return.Hinv = TRUE)

$s_{Hinv2}$  The inverse of $H2 = ZZ' / \lambda + I$ (If return.Hinv = TRUE)

$s_{lambda}$  Estimators for $\lambda = \sigma_e^2 / \sigma_u^2$

$s_{lambdas}$  Lambdas for each initial values

$s_{reest}$  If parameter estimation may not be accurate, reest = 1, else reest = 0

$s_{counts}$  The number of iterations until convergence for each initial values

References

EMM2.cpp

Equation of mixed model for one kernel, EMMA-based method (implemented by Rcpp)

Description

This function solves single-kernel linear mixed model by EMMA (efficient mixed model association; Kang et al., 2008) approach.

Usage

EMM2.cpp(y, X = NULL, ZETA, eigen.G = NULL, eigen.SGS = NULL, 
tol = NULL, optimizer = "nlminb", traceInside = 0, REML = TRUE, 
bounds = c(1e-09, 1e+09), SE = FALSE, return.Hinv = FALSE)

Arguments

y A n × 1 vector. A vector of phenotypic values should be used. NA is allowed.
X A n × p matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.
ZETA A list of variance (relationship) matrix (K; m × m) and its design matrix (Z; n × m) of random effects. You can use only one kernel matrix. For example, ZETA = list(A = list(Z = Z, K = K)) Please set names of list "Z" and "K"!
eigen.G A list with
  $values Eigen values
  $vectors Eigen vectors
The result of the eigen decomposition of \( G = ZKZ' \). You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.
eigen.SGS A list with
  $values Eigen values
  $vectors Eigen vectors
The result of the eigen decomposition of \( SGS \), where \( S = I - X(X'X)^{-1}X' \), \( G = ZKZ' \). You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.
tol The tolerance for detecting linear dependencies in the columns of \( G = ZKZ' \). Eigen vectors whose eigen values are less than "tol" argument will be omitted from results. If tol is NULL, top 'n' eigen values will be effective.
optimizer The function used in the optimization process. We offer "optim", "optimx", and "nlminb" functions.
genesetmap

traceInside
- Perform trace for the optimization if traceInside >= 1, and this argument shows the frequency of reports.

REML
- You can choose which method you will use, "REML" or "ML". If REML = TRUE, you will perform "REML", and if REML = FALSE, you will perform "ML".

bounds
- Lower and Upper bounds of the parameter lambda. If the updated parameter goes out of this range, the parameter is reset to the value in this range.

SE
- If TRUE, standard errors are calculated.

return.Hinv
- If TRUE, the function returns the inverse of $H = ZKZ' + \lambda I$ where $\lambda = \sigma_e^2 / \sigma_u^2$. This is useful for GWAS.

Value

$Vu$ Estimator for $\sigma_u^2$

$Ve$ Estimator for $\sigma_e^2$

$\beta$ BLUE($\beta$)

$u$ BLUP($u$)

$LL$ Maximized log-likelihood (full or restricted, depending on method)

$\beta$.SE Standard error for $\beta$ (If SE = TRUE)

$u$.SE Standard error for $u^* - u$ (If SE = TRUE)

$Hinv$ The inverse of $H = ZKZ' + \lambda I$ (If return.Hinv = TRUE)

References

genesetmap

Function to generate map for gene set

Description

Function to generate map for gene set

Usage

```r
genesetmap(map, gene.set, cumulative = FALSE)
```

Arguments

map
- Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position.

gene.set
- Gene information with the format of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "map" argument.

cumulative
- If this argument is TRUE, cumulative position will be returned.
Value

Map for gene set.

---

**genetrait**

*Generate pseudo phenotypic values*

---

**Description**

This function generates pseudo phenotypic values according to the following formula.

\[ y = X\beta + Zu + e \]

where effects of major genes are regarded as fixed effects \( \beta \) and polygenetic effects are regarded as random effects \( u \). The variances of \( u \) and \( e \) are automatically determined by the heritability.

**Usage**

```
genetrait(x, sample.sets = NULL, candidate = NULL, pos = NULL, 
          x.par = NULL, ZETA = NULL, x2 = NULL, num.qtn = 3, 
          weight = c(2, 1, 1), qtn.effect = rep("A", num.qtn), prop = 1, 
          polygene.weight = 1, polygene = TRUE, h2 = 0.6, 
          h.correction = FALSE, seed = NULL, plot = TRUE, saveAt = NULL, 
          subpop = NULL, return.all = FALSE, seed.env = TRUE)
```

**Arguments**

- `x`: A n.sample x n.mark genotype matrix where n.sample is sample size and n.mark is the number of markers.
- `sample.sets`: A n.sample x n.mark genotype matrix. Markers with fixed effects (QTNs) are chosen from sample.sets. If sample.sets = NULL, sample.sets = x.
- `candidate`: If you want to fix QTN positions, please set the number where SNPs to be fixed are located in your data (so not position). If candidate = NULL, QTNs were randomly sampled from sample.sets or x.
- `pos`: A n.mark x 1 vector. Cumulative position (over chromosomes) of each marker.
- `x.par`: If you don’t want to match the sampling population and the genotype data to QTN effects, then use this argument as the latter.
- `ZETA`: A list of covariance (relationship) matrix (\( K: m \times m \)) and its design matrix (\( Z: n \times m \)) of random effects. Please set names of list "Z" and "K"! You can use more than one kernel matrix. For example, ZETA = list(A = list(Z = Z.A, K = K.A), D = list(Z = Z.D, K = K.D))
- `Z.A, Z.D`: Design matrix \((n \times m)\) for the random effects. So, in many cases, you can use the identity matrix.
- `K.A, K.D`: Different kernels which express some relationships between lines.
For example, K.A is additive relationship matrix for the covariance between lines, and K.D is dominance relationship matrix.

x2 A genotype matrix to calculate additive relationship matrix when Z.ETA = NULL. If Z.ETA = NULL & x2 = NULL, A.mat(x) will be calculated as kernel matrix.

num.qtn The number of QTNs

weight The weights for each QTN by their standard deviations. Negative value is also allowed.

qtn.effect Additive of dominance for each marker effect. This argument should be the same length as num.qtn.

prop The proportion of effects of QTNs to polygenic effects.

polygene.weight If there are multiple kernels, this argument determines the weights of each kernel effect.

polygene If polygene = FALSE, pseudo phenotypes with only QTN effects will be generated.

h2 The wide-sense heritability for generating phenotypes. 0 <= h2 < 1

h.correction If TRUE, this function will generate phenotypes to match the genomic heritability and "h2".

seed If seed is not NULL, some fixed phenotypic values will be generated according to set.seed(seed)

plot If TRUE, boxplot for generated phenotypic values will be drawn.

saveAt When drawing any plot, you can save plots in png format. In saveAt, you should substitute the name you want to save. When saveAt = NULL, the plot is not saved.

subpop If there is subpopulation structure, you can draw boxplots divide by subpopulations. n.sample x n.subpop matrix. Please indicate the subpopulation information by (0, 1) for each element. (0 means that line doesn’t belong to that subpopulation, and 1 means that line belongs to that subpopulation)

return.all If FALSE, only returns generated phenotypic values. If TRUE, this function will return other information such as positions of candidate QTNs.

seed.env If TRUE, this function will generate different environment effects every time.

Value

trait Generated phenotypic values

u Generated genotype values

e Generated environmental effects

candidate The numbers where QTNs are located in your data (so not position).

qtn.position QTN positions

heritability Genomic heritability for generated phenotypic values.
MAF.cut  

*Function to remove the minor alleles*

**Description**

Function to remove the minor alleles

**Usage**

```r
MAF.cut(x.0, map.0 = NULL, min.MAF = 0.05, max.MS = 0.05, return.MAF = FALSE)
```

**Arguments**

- `x.0`: A $n \times m$ original marker genotype matrix.
- `map.0`: Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position.
- `min.MAF`: Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is removed from the original marker genotype data.
- `max.MS`: Specifies the maximum missing rate (MS). If a marker has a MS more than max.MS, it is removed from the original marker genotype data.
- `return.MAF`: If TRUE, MAF will be returned.

**Value**

- `$x$`: The modified marker genotype data whose SNPs with MAF <= min.MAF were removed.
- `$map$`: The modified map information whose SNPs with MAF <= min.MAF were removed.
- `$before$`: Minor allele frequencies of the original marker genotype.
- `$after$`: Minor allele frequencies of the modified marker genotype.

---

make.full  

*Change a matrix to full-rank matrix*

**Description**

Change a matrix to full-rank matrix

**Usage**

```r
make.full(X)
```

**Arguments**

- `X`: A $n \times p$ matrix which you want to change into full-rank matrix.
**manhattan**

**Value**
A full-rank matrix

---

**Description**
Draw manhattan plot

**Usage**
```r
manhattan(input, sig.level = 0.05, method.thres = "BH", y.max = NULL, cex.lab = 1, lwd.thres = 1, plot.col1 = c("dark blue", "cornflowerblue"), cex.axis.x = 1, cex.axis.y = 1, plot.type = "p", plot.pch = 16)
```

**Arguments**
- **input** Data frame of GWAS results where the first column is the marker names, the second and third column is the chromosome and map position, and the forth column is \(-\log_{10}(p)\) for each marker.
- **sig.level** Significance level for the threshold. The default is 0.05.
- **method.thres** Method for determining threshold of significance. "BH" and "Bonferroni" are offered.
- **y.max** The maximum value for the vertical axis of manhattan plot. If NULL, automatically determined.
- **cex.lab** The font size of the labels.
- **lwd.thres** The line width for the threshold.
- **plot.col1** This argument determines the color of the manhattan plot. You should substitute this argument as color vector whose length is 2. `plot.col1[1]` for odd chromosomes and `plot.col1[2]` for even chromosomes.
- **cex.axis.x** The font size of the x axis.
- **cex.axis.y** The font size of the y axis.
- **plot.type** This argument determines the type of the manhattan plot. See the help page of "plot".
- **plot.pch** This argument determines the shape of the dot of the manhattan plot. See the help page of "plot".

**Value**
Draw manhattan plot
### manhattan.plus

Add points of \(-\log_{10}(p)\) corrected by kernel methods to manhattan plot

**Description**

Add points of \(-\log_{10}(p)\) corrected by kernel methods to manhattan plot

**Usage**

```r
manhattan.plus(input, checks, plot.col1 = c("dark blue", 
     "cornflowerblue"), plot.col3 = c("red3", "orange3"), plot.type = "p", 
     plot.pch = 16)
```

**Arguments**

- **input**: Data frame of GWAS results where the first column is the marker names, the second and third column is the chromosome and map position, and the forth column is \(-\log_{10}(p)\) for each marker.
- **checks**: The marker numbers whose \(-\log_{10}(p)\)s are corrected by kernel methods.
- **plot.col1**: This argument determines the color of the manhattan plot. You should substitute this argument as a color vector whose length is 2. plot.col1[1] for odd chromosomes and plot.col1[2] for even chromosomes.
- **plot.type**: This argument determines the type of the manhattan plot. See the help page of "plot".
- **plot.pch**: This argument determines the shape of the dot of the manhattan plot. See the help page of "plot".

**Value**

Draw manhattan plot

### manhattan2

Draw manhattan plot (another method)

**Description**

Draw manhattan plot (another method)

**Usage**

```r
manhattan2(input, sig.level = 0.05, method.thres = "BH", 
     plot.col2 = 1, plot.type = "p", plot.pch = 16, cum.pos = NULL, 
     lwd.thres = 1, cex.lab = 1, cex.axis = 1)
```
**Arguments**

- **input**
  Data frame of GWAS results where the first column is the marker names, the second and third column is the chromosome and map position, and the forth column is -log10(p) for each marker.

- **sig.level**
  Significance level for the threshold. The default is 0.05.

- **method.thres**
  Method for determining threshold of significance. "BH" and "Bonferroni" are offered.

- **plot.col2**
  Color of the manhattan plot. color changes with chromosome and it starts from plot.col2 + 1 (so plot.col2 = 1 means color starts from red.)

- **plot.type**
  This argument determines the type of the manhattan plot. See the help page of "plot".

- **plot.pch**
  This argument determines the shape of the dot of the manhattan plot. See the help page of "plot".

- **cum.pos**
  Cumulative position (over chromosomes) of each marker

- **lwd.thres**
  The line width for the threshold.

- **cex.lab**
  The font size of the labels.

- **cex.axis**
  The font size of the axes.

**Value**

Draw manhattan plot

---

**manhattan3**

*Draw the effects of epistasis (3d plot and 2d plot)*

**Description**

Draw the effects of epistasis (3d plot and 2d plot)

**Usage**

```r
manhattan3(input, cum.pos, plot.epi.3d = TRUE, plot.epi.2d = TRUE,
            main.epi.3d = NULL, main.epi.2d = NULL, saveName = NULL)
```

**Arguments**

- **input**
  Data frame of GWAS results where the first column is the marker names, the second and third column is the chromosome and map position, and the forth column is -log10(p) for each marker.

- **cum.pos**
  Cumulative position (over chromosomes) of each marker

- **plot.epi.3d**
  If TRUE, draw 3d plot

- **plot.epi.2d**
  If TRUE, draw 2d plot

- **main.epi.3d**
  The title of 3d plot. If this argument is NULL, trait name is set as the title.
modify.data

The title of 2d plot. If this argument is NULL, trait name is set as the title.

saveName

When drawing any plot, you can save plots in png format. In saveName, you should substitute the name you want to save. When saveAt = NULL, the plot is not saved.

Value

Draw 3d plot and 2d plot to show epistatic effects

modify.data  

Function to modify genotype and phenotype data to match

Description

Function to modify genotype and phenotype data to match

Usage

modify.data(pheno.mat, geno.mat, pheno.labels = NULL, geno.names = NULL, map = NULL, return.ZETA = TRUE, return.GWAS.format = FALSE)

Arguments

pheno.mat A \( n_1 \times p \) matrix of phenotype data. rownames(pheno.mat) should be genotype (line; accession; variety) names.

geno.mat A \( n_2 \times m \) matrix of marker genotype data. rownames(geno.mat) should be genotype (line; accession; variety) names.

pheno.labels A vector of genotype (line; accession; variety) names which correspond to phenotypic values.

geno.names A vector of genotype (line; accession; variety) names for marker genotype data (duplication is not recommended).

map Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position.

return.ZETA If this argument is TRUE, the list for mixed model equation (ZETA) will be returned.

return.GWAS.format If this argument is TRUE, phenotype and genotype data for GWAS will be returned.

Value

$geno.modi The modified marker genotype data.

$pheno.modi The modified phenotype data.

$ZETA The list for mixed model equation (ZETA).

$pheno.GWAS GWAS formatted phenotype data.

$geno.GWAS GWAS formatted marker genotype data.
**qq**

*Draw qq plot*

**Description**

Draw qq plot

**Usage**

qq(scores)

**Arguments**

scores  A vector of -log10(p) for each marker

**Value**

Draw qq plot

---

**RAINBOWR**

*RAINBOWR: Perform Genome-Wide Association Study (GWAS) By Kernel-Based Methods*

**Description**

By using 'RAINBOWR' (Reliable Association INference By Optimizing Weights with R), users can test multiple SNPs (Single Nucleotide Polymorphisms) simultaneously by kernel-based (SNP-set) methods. Users can test not only additive effects but also dominance and epistatic effects. In detail, please check our preprint on bioRxiv: Kosuke Hamazaki and Hiroyoshi Iwata (2019) <doi:10.1101/612028>.

---

**RGWAS.epistasis**

*Check epistatic effects by kernel-based GWAS (genome-wide association studies)*

**Description**

Check epistatic effects by kernel-based GWAS (genome-wide association studies)
Usage

RGWAS.epistasis(pheno, geno, ZETA = NULL, covariate = NULL, 
  covariate.factor = NULL, structure.matrix = NULL, n.PC = 0, 
  min.MAF = 0.02, n.core = 1, test.method = "LR", 
  dominance.eff = TRUE, haplotype = TRUE, num.hap = NULL, 
  window.size.half = 5, window.slide = 1, chi0.mixture = 0.5, 
  optimizer = "nlminb", gene.set = NULL, plot.epi.3d = TRUE, 
  plot.epi.2d = TRUE, main.epi.3d = NULL, main.epi.2d = NULL, 
  saveName = NULL, verbose = TRUE, verbose2 = FALSE, count = TRUE, 
  time = TRUE)

Arguments

pheno  Data frame where the first column is the line name (gid). The remaining columns 
       should be a phenotype to test.

geno   Data frame with the marker names in the first column. The second and 
       third columns contain the chromosome and map position. Columns 4 and higher 
       contain the marker scores for each line, coded as -1, 0, 1 = aa, Aa, AA.

ZETA   A list of covariance (relationship) matrix (K: \( m \times m \)) and its design 
       matrix (Z: \( n \times m \)) of random effects. Please set names of list "Z" and "K"! 
       You can use more than one kernel matrix. For example, 
       ZETA = list(A = list(Z = Z.A, K = K.A), D = list(Z = Z.D, K = K.D))

Z.A, Z.D Design matrix (\( n \times m \)) for the random effects. So, in many cases, you 
       can use the identity matrix.

K.A, K.D Different kernels which express some relationships between lines.

For example, K.A is additive relationship matrix for the covariance between 
lines, and K.D is dominance relationship matrix.

covariate A \( n \times 1 \) vector or a \( n \times p_1 \) matrix. You can insert continuous values, such as 
          other traits or genotype score for special markers. This argument is regarded as 
          one of the fixed effects.

covariate.factor 

A \( n \times p_2 \) dataframe. You should assign a factor vector for each column. Then 
RGWAS changes this argument into model matrix, and this model matrix will 
be included in the model as fixed effects.

structure.matrix

You can use structure matrix calculated by structure analysis when there are 
population structure. You should not use this argument with n.PC > 0.

n.PC   Number of principal components to include as fixed effects. Default is 0 (equals 
       K model).

min.MAF Specifies the minimum minor allele frequency (MAF). If a marker has a MAF 
       less than min.MAF, it is assigned a zero score.

n.core Setting n.core > 1 will enable parallel execution on a machine with multiple 
       cores (use only at UNIX command line).

test.method RGWAS supports two methods to test effects of each SNP-set.

"LR"  Likelihood-ratio test, relatively slow, but accurate (default).
"score" Score test, much faster than LR, but sometimes overestimate -log10(p).

`dominance.eff` If this argument is TRUE, dominance effect is included in the model, and additive x dominance and dominance x dominance are also tested as epistatic effects. When you use inbred lines, please set this argument FALSE.

`haplotype` If the number of lines of your data is large (maybe > 100), you should set haplotype = TRUE. When haplotype = TRUE, haplotype-based kernel will be used for calculating -log10(p). (So the dimension of this gram matrix will be smaller.) The result won’t be changed, but the time for the calculation will be shorter.

`num.hap` When haplotype = TRUE, you can set the number of haplotypes which you expect. Then similar arrays are considered as the same haplotype, and then make kernel(K.SNP) whose dimension is num.hap x num.hap. When num.hap = NULL (default), num.hap will be set as the maximum number which reflects the difference between lines.

`window.size.half` This argument decides how many SNPs (around the SNP you want to test) are used to calculated K.SNP. More precisely, the number of SNPs will be 2 * window.size.half + 1.

`window.slide` This argument determines how often you test markers. If window.slide = 1, every marker will be tested. If you want to perform SNP set by bins, please set window.slide = 2 * window.size.half + 1.

`chi0.mixture` RAINBOWR assumes the deviance is considered to follow a x chisq(df = 0) + (1 - a) x chisq(df = r), where r is the degree of freedom. The argument chi0.mixture is a (0 <= a < 1), and default is 0.5.

`optimizer` The function used in the optimization process. We offer "optim", "optimx", and "nlminb" functions.

`gene.set` If you have information of gene (or haplotype block), you can use it to perform kernel-based GWAS. You should assign your gene information to gene.set in the form of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.

`plot.epi.3d` If TRUE, draw 3d plot

`plot.epi.2d` If TRUE, draw 2d plot

`main.epi.3d` The title of 3d plot. If this argument is NULL, trait name is set as the title.

`main.epi.2d` The title of 2d plot. If this argument is NULL, trait name is set as the title.

`saveName` When drawing any plot, you can save plots in png format. In saveName, you should substitute the name you want to save. When saveName = NULL, the plot is not saved.

`verbose` If this argument is TRUE, messages for the current steps will be shown.

`verbose2` If this argument is TRUE, welcome message will be shown.

`count` When count is TRUE, you can know how far RGWAS has ended with percent display.

`time` When time is TRUE, you can know how much time it took to perform RGWAS.
Value

$\text{map}$  Map information for SNPs which are tested epistatic effects.

$\text{scores}$  This is the matrix which contains -log10(p) calculated by the test about epistasis effects.

$x, y$  The information of the positions of SNPs detected by regular GWAS. These vectors are used when drawing plots. Each output correspond to the replication of row and column of scores.

$z$  This is a vector of $\text{scores}$. This vector is also used when drawing plots.

**Print the R code which you should perform for RAINBOWR GWAS**

**Description**

Print the R code which you should perform for RAINBOWR (Reliable Association INference By Optimizing Weights with R).
 RGWAS.multisnp

Usage
RGWAS.menu()

Value
The R code which you should perform for RAINBOWR GWAS

Description
This function performs SNP-set GWAS (genome-wide association studies), which tests multiple SNPs (single nucleotide polymorphisms) simultaneously. The model of SNP-set GWAS is

\[ y = X\beta + Qv + Z_c u_c + Z_r u_r + \epsilon, \]

where \( y \) is the vector of phenotypic values, \( X\beta \) and \( Qv \) are the terms of fixed effects, \( Z_c u_c \) and \( Z_r u_r \) are the term of random effects and \( \epsilon \) is the vector of residuals. \( X\beta \) indicates all of the fixed effects other than population structure, and often this term also plays a role as an intercept. \( Qv \) is the term to correct the effect of population structure. \( Z_c u_c \) is the term of polygenetic effects, and suppose that \( u_c \) follows the multivariate normal distribution whose variance-covariance matrix is the genetic covariance matrix. \( u_r \sim MVN(0, K_r \sigma_r^2) \). \( Z_r u_r \) is the term of effects for SNP-set of interest, and suppose that \( u_r \) follows the multivariate normal distribution whose variance-covariance matrix is the Gram matrix (linear, exponential, or gaussian kernel) calculated from marker genotype which belong to that SNP-set. Therefore, \( u_r \sim MVN(0, K_r \sigma_r^2) \). Finally, the residual term is assumed to identically and independently follow a normal distribution as shown in the following equation. \( \epsilon \sim MVN(0, I \sigma_e^2) \).

Usage
RGWAS.multisnp(pheno, geno, ZETA = NULL, covariate = NULL, covariate.factor = NULL, structure.matrix = NULL, n.PC = 0, min.MAF = 0.02, test.method = "LR", n.core = 1, kernel.method = "linear", kernel.h = "tuned", haplotype = TRUE, num.hap = NULL, test.effect = "additive", window.size.half = 5, window.slide = 1, chi0.mixture = 0.5, gene.set = NULL, weighting.center = TRUE, weighting.other = NULL, sig.level = 0.05, method.thres = "BH", plot.qq = TRUE, plot.Manhattan = TRUE, plot.method = 1, plot.col1 = c("dark blue", "cornflowerblue"), plot.col2 = 1, plot.type = "p", plot.pch = 16, saveName = NULL, main.qq = NULL, main.man = NULL, plot.add.last = FALSE, return.EMM.res = FALSE, optimizer = "nlminb", thres = TRUE, verbose = TRUE, verbose2 = FALSE, count = TRUE, time = TRUE)
**Arguments**

**pheno**  
Data frame where the first column is the line name (gid). The remaining columns should be a phenotype to test.

**geno**  
Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position. Columns 4 and higher contain the marker scores for each line, coded as -1, 0, 1 = aa, Aa, AA.

**ZETA**  
A list of covariance (relationship) matrix (K: m × m) and its design matrix (Z: n × m) of random effects. Please set names of list "Z" and "K"! You can use more than one kernel matrix. For example,  
ZETA = list(A = list(Z = Z.A, K = K.A), D = list(Z = Z.D, K = K.D))  
**Z.A, Z.D** Design matrix (n × m) for the random effects. So, in many cases, you can use the identity matrix.

**K.A, K.D** Different kernels which express some relationships between lines. For example, K.A is additive relationship matrix for the covariance between lines, and K.D is dominance relationship matrix.

**covariate**  
A n × 1 vector or a n × p1 matrix. You can insert continuous values, such as other traits or genotype score for special markers. This argument is regarded as one of the fixed effects.

**covariate.factor**  
A n × p2 dataframe. You should assign a factor vector for each column. Then RGWAS changes this argument into model matrix, and this model matrix will be included in the model as fixed effects.

**structure.matrix**  
You can use structure matrix calculated by structure analysis when there are population structure. You should not use this argument with n.PC > 0.

**n.PC**  
Number of principal components to include as fixed effects. Default is 0 (equals K model).

**min.MAF**  
Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.

**test.method**  
RGWAS supports two methods to test effects of each SNP-set.  
"LR" Likelihood-ratio test, relatively slow, but accurate (default).  
"score" Score test, much faster than LR, but sometimes overestimate -log10(p).

**n.core**  
Setting n.core > 1 will enable parallel execution on a machine with multiple cores (use only at UNIX command line).

**kernel.method**  
It determines how to calculate kernel. There are three methods.  
"gaussian" It is the default method. Gaussian kernel is calculated by distance matrix.  
"exponential" When this method is selected, exponential kernel is calculated by distance matrix.  
"linear" When this method is selected, linear kernel is calculated by A.mat. So local genomic relation matrix is regarded as kernel.

**kernel.h**  
The hyper parameter for gaussian or exponential kernel. If kernel.h = "tuned", this hyper parameter is calculated as the median of off-diagonals of distance matrix of genotype data.
If the number of lines of your data is large (maybe > 100), you should set haplotype = TRUE. When haplotype = TRUE, haplotype-based kernel will be used for calculating -log10(p). (So the dimension of this gram matrix will be smaller.) The result won’t be changed, but the time for the calculation will be shorter.

When haplotype = TRUE, you can set the number of haplotypes which you expect. Then similar arrays are considered as the same haplotype, and then make kernel(K.SNP) whose dimension is num.hap x num.hap. When num.hap = NULL (default), num.hap will be set as the maximum number which reflects the difference between lines.

Effect of each marker to test. You can choose "test.effect" from "additive", "dominance" and "additive+dominance". You also can choose more than one effect, for example, test.effect = c("additive", "additive+dominance")

This argument decides how many SNPs (around the SNP you want to test) are used to calculated K.SNP. More precisely, the number of SNPs will be 2 * window.size.half + 1.

This argument determines how often you test markers. If window.slide = 1, every marker will be tested. If you want to perform SNP set by bins, please set window.slide = 2 * window.size.half + 1.

RAINBOWR assumes the deviance is considered to follow a x chisq(df = 0) + (1 - a) x chisq(df = r). where r is the degree of freedom. The argument chi0.mixture is a (0 <= a < 1), and default is 0.5.

If you have information of gene (or haplotype block), you can use it to perform kernel-based GWAS. You should assign your gene information to gene.set in the form of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.

In kernel-based GWAS, weights according to the Gaussian distribution (centered on the tested SNP) are taken into account when calculating the kernel if Rainbow = TRUE. If weighting.center = FALSE, weights are not taken into account.

You can set other weights in addition to weighting.center. The length of this argument should be equal to the number of SNPs. For example, you can assign SNP effects from the information of gene annotation.

Significance level for the threshold. The default is 0.05.

Method for determining threshold of significance. "BH" and "Bonferroni are offered.

If TRUE, draw qq plot.

If TRUE, draw manhattan plot.

If this argument = 1, the default manhattan plot will be drawn. If this argument = 2, the manhattan plot with axis based on Position (bp) will be drawn. Also, this plot’s color is changed by all chromosomes.
plot.col1  This argument determines the color of the manhattan plot. You should substitute this argument as color vector whose length is 2. plot.col1[1] for odd chromosomes and plot.col1[2] for even chromosomes.

plot.col2  Color of the manhattan plot. color changes with chromosome and it starts from plot.col2 + 1 (so plot.col2 = 1 means color starts from red.)

plot.type  This argument determines the type of the manhattan plot. See the help page of "plot".

plot.pch  This argument determines the shape of the dot of the manhattan plot. See the help page of "plot".

saveName  When drawing any plot, you can save plots in png format. In saveName, you should substitute the name you want to save. When saveName = NULL, the plot is not saved.

main.qq  The title of qq plot. If this argument is NULL, trait name is set as the title.

main.man  The title of manhattan plot. If this argument is NULL, trait name is set as the title.

plot.add.last  If saveName is not NULL and this argument is TRUE, then you can add lines or dots to manhattan plots. However, you should also write "dev.off()" after adding something.

return.EMM.res  When return.EMM.res = TRUE, the results of equation of mixed models are included in the result of RGWAS.

optimizer  The function used in the optimization process. We offer "optim", "optimx", and "nlmnb" functions.

thres  If thres = TRUE, the threshold of the manhattan plot is included in the result of RGWAS. When return.EMM.res or thres is TRUE, the results will be "list" class.

verbose  If this argument is TRUE, messages for the current steps will be shown.

verbose2  If this argument is TRUE, welcome message will be shown.

count  When count is TRUE, you can know how far RGWAS has ended with percent display.

time  When time is TRUE, you can know how much time it took to perform RGWAS.

Details

P-value for each SNP-set is calculated by performing the LR test or the score test (Lippert et al., 2014).

In the LR test, first, the function solves the multi-kernel mixed model and calculates the maximum restricted log likelihood. Then it performs the LR test by using the fact that the deviance

\[
D = 2 \times (LL_{alt} - LL_{null})
\]

follows the chi-square distribution.

In the score test, the maximization of the likelihood is only performed for the null model. In other words, the function calculates the score statistic without solving the multi-kernel mixed model for each SNP-set. Then it performs the score test by using the fact that the score statistic follows the chi-square distribution.
Value

$\text{Dataframe which contains the information of the map you input and the results of RGWAS (-log10(p)) which correspond to the map. If there are more than one test.effects, then multiple lists for each test.effect are returned respectively.}$

$\text{A vector which contains the information of threshold determined by FDR = 0.05.}$

$\text{This output is a list which contains the information about the results of "EMM" performed at first in regular GWAS. If you want to know details, see the description for the function "EMM1" or "EMM2".}$

See(SNP_set.res2$D) ### Column 4 contains -log10(p) values for markers
```
**Description**

This function performs single-SNP GWAS (genome-wide association studies). The model of GWAS is

\[ y = X\beta + S_i\alpha_i + Qv + Zu + \epsilon, \]

where \( y \) is the vector of phenotypic values, \( X\beta \), \( S_i\alpha_i \), \( Qv \) are the terms of fixed effects, \( Zu \) is the term of random effects and \( \epsilon \) is the vector of residuals. \( X\beta \) indicates all of the fixed effects other than the effect of SNPs to be tested and of population structure, and often this term also plays a role as an intercept. For \( S_i\alpha_i \), \( S_i \) is the \( i \)th marker of genotype data and \( \alpha_i \) is the effect of that marker. \( Qv \) is the term to correct the effect of population structure. \( Zu \) is the term of polygenetic effects, and suppose that \( u \) follows the multivariate normal distribution whose variance-covariance matrix is the genetic covariance matrix. \( u \sim MVN(0, K\sigma_u^2) \). Finally, the residual term is assumed to identically and independently follow a normal distribution as shown in the following equation. \( \epsilon \sim MVN(0, I\sigma_e^2) \).

**Usage**

```r
RGWAS.normal(pheno, geno, ZETA = NULL, covariate = NULL, covariate.factor = NULL, structure.matrix = NULL, n.PC = 0, min.MAF = 0.02, P3D = TRUE, n.core = 1, sig.level = 0.05, method.thres = "BH", plot.qq = TRUE, plot.Manhattan = TRUE, plot.method = 1, plot.col1 = c("dark blue", "cornflowerblue"), plot.col2 = 1, plot.type = "p", plot.pch = 16, saveName = NULL, main.qq = NULL, main.man = NULL, plot.add.last = FALSE, return.EMM.res = FALSE, optimizer = "nlminb", thres = TRUE, verbose = TRUE, verbose2 = FALSE, count = TRUE, time = TRUE)
```

**Arguments**

- **pheno**: Data frame where the first column is the line name (gid). The remaining columns should be a phenotype to test.
- **geno**: Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position. Columns 4 and higher contain the marker scores for each line, coded as -1, 0, 1 = aa, Aa, AA.
- **ZETA**: A list of covariance (relationship) matrix \((K: m \times m)\) and its design matrix \((Z: n \times m)\) of random effects. Please set names of list "Z" and "K"! You can use more than one kernel matrix. For example, 
  ```r
  ZETA = list(A = list(Z = Z.A, K = K.A), D = list(Z = Z.D, K = K.D))
  ```
- **Z.A, Z.D**: Design matrix \((n \times m)\) for the random effects. So, in many cases, you can use the identity matrix.
- **K.A, K.D**: Different kernels which express some relationships between lines. For example, K.A is additive relationship matrix for the covariance between lines, and K.D is dominance relationship matrix.
- **covariate**: A n \( \times 1 \) vector or a \( n \times p_1 \) matrix. You can insert continuous values, such as other traits or genotype score for special markers. This argument is regarded as one of the fixed effects.
covariate.factor
A \( n \times p_2 \) dataframe. You should assign a factor vector for each column. Then RGWAS changes this argument into model matrix, and this model matrix will be included in the model as fixed effects.

structure.matrix
You can use structure matrix calculated by structure analysis when there are population structure. You should not use this argument with \( n.PC > 0 \).

n.PC
Number of principal components to include as fixed effects. Default is 0 (equals K model).

min.MAF
Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.

P3D
When P3D = TRUE, variance components are estimated by REML only once, without any markers in the model. When P3D = FALSE, variance components are estimated by REML for each marker separately.

n.core
Setting n.core > 1 will enable parallel execution on a machine with multiple cores.

sig.level
Significance level for the threshold. The default is 0.05.

method.thres
Method for determining threshold of significance. "BH" and "Bonferroni are offered.

plot.qq
If TRUE, draw qq plot.

plot.Manhattan
If TRUE, draw manhattan plot.

plot.method
If this argument = 1, the default manhattan plot will be drawn. If this argument = 2, the manhattan plot with axis based on Position (bp) will be drawn. Also, this plot’s color is changed by all chromosomes.

plot.col1
This argument determines the color of the manhattan plot. You should substitute this argument as color vector whose length is 2. plot.col1[1] for odd chromosomes and plot.col1[2] for even chromosomes.

plot.col2
Color of the manhattan plot. color changes with chromosome and it starts from plot.col2 + 1 (so plot.col2 = 1 means color starts from red.)

plot.type
This argument determines the type of the manhattan plot. See the help page of "plot".

plot.pch
This argument determines the shape of the dot of the manhattan plot. See the help page of "plot".

saveName
When drawing any plot, you can save plots in png format. In saveName, you should substitute the name you want to save. When saveName = NULL, the plot is not saved.

main.qq
The title of qq plot. If this argument is NULL, trait name is set as the title.

main.man
The title of manhattan plot. If this argument is NULL, trait name is set as the title.

plot.add.last
If saveName is not NULL and this argument is TRUE, then you can add lines or dots to manhattan plots. However, you should also write "dev.off()" after adding something.

return.EMM.res
When return.EMM.res = TRUE, the results of equation of mixed models are included in the result of RGWAS.
optimizer The function used in the optimization process. We offer "optim", "optimx", and "nlminb" functions.

thres If thres = TRUE, the threshold of the manhattan plot is included in the result of RGWAS. When return.EMM.res or thres is TRUE, the results will be "list" class.

verbose If this argument is TRUE, messages for the current steps will be shown.

verbose2 If this argument is TRUE, welcome message will be shown.

count When count is TRUE, you can know how far RGWAS has ended with percent display.

time When time is TRUE, you can know how much time it took to perform RGWAS.

Details

P-value for each marker is calculated by performing F-test against the F-value as follows (Kennedy et al., 1992).

\[
F = \frac{(L^T \hat{b})' [L' (X' H^{-1} X)^{-1} L]^{-1} (L^T \hat{b})}{f \hat{\sigma}^2_u},
\]

where \( b \) is the vector of coefficients of the fixed effects, which combines \( \beta, \alpha_i, v \) in the horizontal direction and \( L \) is a matrix to indicate which effects in \( b \) are tested. \( H \) is calculated by dividing the estimated variance-covariance matrix for the phenotypic values by \( \sigma^2_u \), and is calculated by \( H = ZZ' + \hat{\lambda} I \). \( \hat{\lambda} \) is the maximum likelihood estimator of the ratio between the residual variance and the additive genetic variance. \( \hat{b} \) is the maximum likelihood estimator of \( b \) and is calculated by \( \hat{b} = (X' H^{-1} X)^{-1} X' H^{-1} Y \). \( f \) is the number of the fixed effects to be tested, and \( \hat{\sigma}^2_u \) is estimated by the following formula.

\[
\hat{\sigma}^2_u = \frac{(y - X \hat{b})' H^{-1} (y - X \hat{b})}{n - p},
\]

where \( n \) is the sample size and \( p \) is the number of the all fixed effects. We calculated each p-value using the fact that the above F-value follows the F distribution with the degree of freedom \((f, n - p)\).

Value

$D$ Dataframe which contains the information of the map you input and the results of RGWAS (-log10(p)) which correspond to the map.

$thres$ A vector which contains the information of threshold determined by FDR = 0.05.

$EMM.res$ This output is a list which contains the information about the results of "EMM" performed at first in regular GWAS. If you want to know details, see the description for the function "EMM1" or "EMM2".

**geno**
Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position. Columns 4 and higher contain the marker scores for each line, coded as -1, 0, 1 = aa, Aa, AA.

**ZETA**
A list of covariance (relationship) matrix \((K: m \times m)\) and its design matrix \((Z: n \times m)\) of random effects. Please set names of list "Z" and "K"! You can use more than one kernel matrix. For example,

\[
ZETA = \text{list}(A = \text{list}(Z = Z.A, K = K.A), D = \text{list}(Z = Z.D, K = K.D))
\]

**Z.A, Z.D**
Design matrix \((n \times m)\) for the random effects. So, in many cases, you can use the identity matrix.

**K.A, K.D**
Different kernels which express some relationships between lines.

For example, K.A is additive relationship matrix for the covariance between lines, and K.D is dominance relationship matrix.

**covariate**
A \(n \times 1\) vector or a \(n \times p\) matrix. You can insert continuous values, such as other traits or genotype score for special markers. This argument is regarded as one of the fixed effects.

**covariate.factor**
A \(n \times p_2\) dataframe. You should assign a factor vector for each column. Then RGWAS changes this argument into model matrix, and this model matrix will be included in the model as fixed effects.

**structure.matrix**
You can use structure matrix calculated by structure analysis when there are population structure. You should not use this argument with n.PC > 0.

**n.PC**
Number of principal components to include as fixed effects. Default is 0 (equals K model).

**min.MAF**
Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.

**n.core**
Setting n.core > 1 will enable parallel execution on a machine with multiple cores (use only at UNIX command line).

**check.size**
This argument determines how many SNPs (around the SNP detected by normal GWAS) you will recalculate -log10(p).

**check.gene.size**
This argument determines how many genes (around the genes detected by normal GWAS) you will recalculate -log10(p). This argument is valid only when you assign "gene.set" argument.

**kernel.percent**
This argument determines how many SNPs are detected by normal GWAS. For example, when kernel.percent = 0.1, SNPs whose value of -log10(p) is in the top 0.1 percent are chosen as candidate for recalculation by SNP-set GWAS.

**GWAS.res.first**
If you have already performed normal GWAS and have the result, you can skip performing normal GWAS.

**P3D**
When P3D = TRUE, variance components are estimated by REML only once, without any markers in the model. When P3D = FALSE, variance components are estimated by REML for each marker separately.
RGWAS supports two methods to test effects of each SNP-set for 1st GWAS.

"normal" Normal GWAS (default).
"score" Score test, much faster than LR, but sometimes overestimate -log10(p).

RGWAS supports two methods to test effects of each SNP-set for 2nd GWAS.

"LR" Likelihood-ratio test, relatively slow, but accurate (default).
"score" Score test, much faster than LR, but sometimes overestimate -log10(p).

It determines how to calculate kernel. There are three methods.

"gaussian" It is the default method. Gaussian kernel is calculated by distance matrix.
"exponential" When this method is selected, exponential kernel is calculated by distance matrix.
"linear" When this method is selected, linear kernel is calculated by A.mat.

So local genomic relation matrix is regarded as kernel.

The hyper parameter for gaussian or exponential kernel. If kernel.h = "tuned", this hyper parameter is calculated as the median of off-diagonals of distance matrix of genotype data.

If the number of lines of your data is large (maybe > 100), you should set haplotype = TRUE. When haplotype = TRUE, haplotype-based kernel will be used for calculating -log10(p). (So the dimension of this gram matrix will be smaller.) The result won’t be changed, but the time for the calculation will be shorter.

When haplotype = TRUE, you can set the number of haplotypes which you expect. Then similar arrays are considered as the same haplotype, and then make kernel(K.SNP) whose dimension is num.hap x num.hap. When num.hap = NULL (default), num.hap will be set as the maximum number which reflects the difference between lines.

Effect of each marker to test for 1st GWAS. You can choose "test.effect" from "additive", "dominance" and "additive+dominance". You can assign only one test effect for the 1st GWAS!

Effect of each marker to test for 2nd GWAS. You can choose "test.effect" from "additive", "dominance" and "additive+dominance". You also can choose more than one effect, for example, test.effect = c("additive", "additive+dominance")

This argument decides how many SNPs (around the SNP you want to test) are used to calculated K.SNP. More precisely, the number of SNPs will be 2 * window.size.half + 1.

This argument determines how often you test markers. If window.slide = 1, every marker will be tested. If you want to perform SNP set by bins, please set window.slide = 2 * window.size.half + 1.

RAINBOWR assumes the deviance is considered to follow a x chisq(df = 0) + (1 - a) x chisq(df = r). where r is the degree of freedom. The argument chi0.mixture is a (0 <= a < 1), and default is 0.5.

The function used in the optimization process. We offer "optim", "optimx", and "nlminb" functions.
If you have information of gene (or haplotype block), you can use it to perform kernel-based GWAS. You should assign your gene information to gene.set in the form of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.

In kernel-based GWAS, weights according to the Gaussian distribution (centered on the tested SNP) are taken into account when calculating the kernel if Rainbow = TRUE. If weighting.center = FALSE, weights are not taken into account.

You can set other weights in addition to weighting.center. The length of this argument should be equal to the number of SNPs. For example, you can assign SNP effects from the information of gene annotation.

Significance level for the threshold. The default is 0.05.

Method for determining threshold of significance. "BH" and "Bonferroni" are offered.

If TRUE, draw qq plot for normal GWAS.

If TRUE, draw manhattan plot for normal GWAS.

If TRUE, draw qq plot for SNP-set GWAS.

If TRUE, draw manhattan plot for SNP-set GWAS.

If this argument = 1, the default manhattan plot will be drawn. If this argument = 2, the manhattan plot with axis based on Position (bp) will be drawn. Also, this plot's color is changed by all chromosomes.

This argument determines the color of the manhattan plot. You should substitute this argument as color vector whose length is 2. plot.col1[1] for odd chromosomes and plot.col1[2] for even chromosomes

Color of the manhattan plot. color changes with chromosome and it starts from plot.col2 + 1 (so plot.col2 = 1 means color starts from red.)

Color of the points of manhattan plot which are added after the reestimation by SNP-set method. You should substitute this argument as color vector whose length is 2. plot.col3[1] for odd chromosomes and plot.col3[2] for even chromosomes.

This argument determines the type of the manhattan plot. See the help page of "plot".

This argument determines the shape of the dot of the manhattan plot. See the help page of "plot".

When drawing any plot, you can save plots in png format. In saveName, you should substitute the name you want to save. When saveName = NULL, the plot is not saved.

The title of qq plot for normal GWAS. If this argument is NULL, trait name is set as the title.
main.man.1 The title of manhattan plot for normal GWAS. If this argument is NULL, trait name is set as the title.

main.qq.2 The title of qq plot for SNP-set GWAS. If this argument is NULL, trait name is set as the title.

main.man.2 The title of manhattan plot for SNP-set GWAS. If this argument is NULL, trait name is set as the title.

plot.add.last If saveName is not NULL and this argument is TRUE, then you can add lines or dots to manhattan plots. However, you should also write "dev.off()" after adding something.

return.EMM.res When return.EMM.res = TRUE, the results of equation of mixed models are included in the result of RGWAS.

thres If thres = TRUE, the threshold of the manhattan plot is included in the result of RGWAS. When return.EMM.res or thres is TRUE, the results will be "list" class.

verbose If this argument is TRUE, messages for the current steps will be shown.

verbose2 If this argument is TRUE, welcome message will be shown.

count When count is TRUE, you can know how far RGWAS has ended with percent display.

time When time is TRUE, you can know how much time it took to perform RGWAS.

Value

$D Dataframe which contains the information of the map you input and the results of RGWAS (-log10(p)) which correspond to the map. -log10(p) by normal GWAS and recalculated -log10(p) by SNP-set GWAS will be obtained. If there are more than one test.effects, then multiple lists for each test.effect are returned respectively.

$thres A vector which contains the information of threshold determined by FDR = 0.05.

$EMM.res This output is a list which contains the information about the results of "EMM" performed at first in normal GWAS. If you want to know details, see the description for the function "EMM1" or "EMM2".

**RGWAS.twostep.epi**

**Perform normal GWAS (genome-wide association studies) first, then check epistatic effects for relatively significant markers**

### Description

Perform normal GWAS (genome-wide association studies) first, then check epistatic effects for relatively significant markers

### Usage

```
RGWAS.twostep.epi(pheno, geno, ZETA = NULL, covariate = NULL,
covariate.factor = NULL, structure.matrix = NULL, n.PC = 0,
min.MAF = 0.02, n.core = 1, check.size.epi = 4,
epistasis.percent = 0.05, check.epi.max = 200, your.check = NULL,
GWAS.res.first = NULL, P3D = TRUE, test.method = "LR",
dominance.eff = TRUE, haplotype = TRUE, num.hap = NULL,
chi0.mixture = 0.5, gene.set = NULL, sig.level = 0.05,
method.thres = "BH", plot.qq.1 = TRUE, plot.Manhattan.1 = TRUE,
plot.epi.3d = TRUE, plot.epi.2d = TRUE, plot.method = 1,
plot.col1 = c("dark blue", "cornflowerblue"), plot.col2 = 1,
plot.type = "p", plot.pch = 16, saveName = NULL,
main.qq.1 = NULL, main.man.1 = NULL, main.epi.3d = NULL,
main.epi.2d = NULL, verbose = TRUE, verbose2 = FALSE,
count = TRUE, time = TRUE)
```
Arguments

**pheno**
Data frame where the first column is the line name (gid). The remaining columns should be a phenotype to test.

**geno**
Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position. Columns 4 and higher contain the marker scores for each line, coded as -1, 0, 1 = aa, Aa, AA.

**ZETA**
A list of covariance (relationship) matrix (K: \( m \times m \)) and its design matrix (Z: \( n \times m \)) of random effects. Please set names of list "Z" and "K"! You can use more than one kernel matrix. For example,

\[
ZETA = \text{list}(A = \text{list}(Z = \text{Z.A}, K = \text{K.A}), D = \text{list}(Z = \text{Z.D}, K = \text{K.D}))
\]

**Z.A, Z.D** Design matrix \((n \times m)\) for the random effects. So, in many cases, you can use the identity matrix.

**K.A, K.D** Different kernels which express some relationships between lines.
For example, K.A is additive relationship matrix for the covariance between lines, and K.D is dominance relationship matrix.

**covariate**
A \((n \times 1)\) vector or a \((n \times p_1)\) matrix. You can insert continuous values, such as other traits or genotype score for special markers. This argument is regarded as one of the fixed effects.

**covariate.factor**
A \((n \times p_2)\) dataframe. You should assign a factor vector for each column. Then RGWAS changes this argument into model matrix, and this model matrix will be included in the model as fixed effects.

**structure.matrix**
You can use structure matrix calculated by structure analysis when there are population structure. You should not use this argument with n.PC > 0.

**n.PC**
Number of principal components to include as fixed effects. Default is 0 (equals K model).

**min.MAF**
Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.

**n.core**
Setting n.core > 1 will enable parallel execution on a machine with multiple cores (use only at UNIX command line).

**check.size.epi**
This argument determines how many SNPs (around the SNP detected by normal GWAS) you will check epistasis.

**epistasis.percent**
This argument determines how many SNPs are detected by normal GWAS. For example, when epistasis.percent = 0.1, SNPs whose value of \(-\log_{10}(p)\) is in the top 0.1 percent are chosen as candidate for checking epistasis.

**check.epi.max**
It takes a lot of time to check epistasis, so you can decide the maximum number of SNPs to check epistasis.

**your.check**
Because there are less SNPs that can be tested in epistasis than in kernel-based GWAS, you can select which SNPs you want to test. If you use this argument, please set the number where SNPs to be tested are located in your data (so not position). In the default setting, your_check = NULL and epistasis between SNPs detected by GWAS will be tested.
GWAS.res.first  If you have already performed regular GWAS and have the result, you can skip performing normal GWAS.

P3D  When P3D = TRUE, variance components are estimated by REML only once, without any markers in the model. When P3D = FALSE, variance components are estimated by REML for each marker separately.

test.method  RGWAS supports two methods to test effects of each SNP-set.
   "LR"  Likelihood-ratio test, relatively slow, but accurate (default).
   "score"  Score test, much faster than LR, but sometimes overestimate -log10(p).

dominance.eff  If this argument is TRUE, dominance effect is included in the model, and additive x dominance and dominance x dominance are also tested as epistatic effects. When you use inbred lines, please set this argument FALSE.

haplotype  If the number of lines of your data is large (maybe > 100), you should set haplotype = TRUE. When haplotype = TRUE, haplotype-based kernel will be used for calculating -log10(p). (So the dimension of this gram matrix will be smaller.) The result won’t be changed, but the time for the calculation will be shorter.

num.hap  When haplotype = TRUE, you can set the number of haplotypes which you expect. Then similar arrays are considered as the same haplotype, and then make kernel(K.SNP) whose dimension is num.hap x num.hap. When num.hap = NULL (default), num.hap will be set as the maximum number which reflects the difference between lines.

optimizer  The function used in the optimization process. We offer "optim", "optimx", and "nlminb" functions.

window.size.half  This argument decides how many SNPs (around the SNP you want to test) are used to calculated K.SNP. More precisely, the number of SNPs will be 2 * window.size.half + 1.

window.slide  This argument determines how often you test markers. If window.slide = 1, every marker will be tested. If you want to perform SNP set by bins, please set window.slide = 2 * window.size.half + 1.

chi0.mixture  RAINBOWR assumes the deviance is considered to follow a x chisq(df = 0) + (1 - a) x chisq(df = r). where r is the degree of freedom. The argument chi0.mixture is a (0 <= a < 1), and default is 0.5.

gene.set  If you have information of gene (or haplotype block), you can use it to perform kernel-based GWAS. You should assign your gene information to gene.set in the form of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.

sig.level  Significance level for the threshold. The default is 0.05.

method.thres  Method for determining threshold of significance. "BH" and "Bonferroni are offered.

plot.qq.1  If TRUE, draw qq plot for normal GWAS.

plot.Manhattan.1  If TRUE, draw manhattan plot for normal GWAS.
plot.epi.3d If TRUE, draw 3d plot
plot.epi.2d If TRUE, draw 2d plot
plot.method If this argument = 1, the default manhattan plot will be drawn. If this argument = 2, the manhattan plot with axis based on Position (bp) will be drawn. Also, this plot's color is changed by all chromosomes.
plot.col1 This argument determines the color of the manhattan plot. You should substitute this argument as color vector whose length is 2. plot.col1[1] for odd chromosomes and plot.col1[2] for even chromosomes
plot.col2 Color of the manhattan plot. color changes with chromosome and it starts from plot.col2 + 1 (so plot.col2 = 1 means color starts from red.)
plot.type This argument determines the type of the manhattan plot. See the help page of "plot".
plot.pch This argument determines the shape of the dot of the manhattan plot. See the help page of "plot".
saveName When drawing any plot, you can save plots in png format. In saveName, you should substitute the name you want to save. When saveName = NULL, the plot is not saved.
main.qq.1 The title of qq plot for normal GWAS. If this argument is NULL, trait name is set as the title.
main.man.1 The title of manhattan plot for normal GWAS. If this argument is NULL, trait name is set as the title.
main.epi.3d The title of 3d plot. If this argument is NULL, trait name is set as the title.
main.epi.2d The title of 2d plot. If this argument is NULL, trait name is set as the title.
verbose If this argument is TRUE, messages for the current steps will be shown.
verbose2 If this argument is TRUE, welcome message will be shown.
count When count is TRUE, you can know how far RGWAS has ended with percent display.
time When time is TRUE, you can know how much time it took to perform RGWAS.

Value

$first The results of first normal GWAS will be returned.
$epistasis $map Map information for SNPs which are tested epistatic effects.
$scores This is the matrix which contains -log10(p) calculated by the test about epistasis effects.
$x, $y The information of the positions of SNPs detected by regular GWAS. These vectors are used when drawing plots. Each output correspond to the repliction of row and column of scores.
$z This is a vector of $scores. This vector is also used when drawing plots.

score.calc  
**Calculate -log10(p) for single-SNP GWAS**

Description
Calculate -log10(p) of each SNP by the Wald test.

Usage
```r
score.calc(M.now, ZETA.now, y, X.now, Hinv, P3D = TRUE, optimizer = "nlminb", eigen.G = NULL, min.MAF = 0.02, count = TRUE)
```

Arguments
- `M.now`: A n.sample x n.mark genotype matrix where n.sample is sample size and n.mark is the number of markers.
- `ZETA.now`: A list of variance (relationship) matrix (K; m x m) and its design matrix (Z; n x m) of random effects. You can use only one kernel matrix. For example, ZETA = list(A = list(Z = Z, K = K)) Please set names of list "Z" and "K"!
- `y`: A n x 1 vector. A vector of phenotypic values should be used. NA is allowed.
- `X.now`: A n x p matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.
- `Hinv`: The inverse of $H = KZ' + \lambda I$ where $\lambda = \sigma_e^2 / \sigma_u^2$.
- `P3D`: When P3D = TRUE, variance components are estimated by REML only once, without any markers in the model. When P3D = FALSE, variance components are estimated by REML for each marker separately.
- `optimizer`: The function used in the optimization process. We offer "optim", "optimx", and "nlminb" functions.
- `eigen.G`: A list with
The result of the eigen decomposition of $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.

**min.MAF**

Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.

**count**

When count is TRUE, you can know how far RGWAS has ended with percent display.

Value

- $-\log_{10}(p)$ for each marker

References

---

**score.calc.epistasis.LR**

*Calculate $-\log_{10}(p)$ of epistatic effects by LR test*

**Description**

Calculate $-\log_{10}(p)$ of epistatic effects by LR test

**Usage**

```r
score.calc.epistasis.LR(M.now, y, X.now, ZETA.now, eigen.SGS = NULL, eigen.G = NULL, optimizer = "nlminb", map, haplotype = TRUE, num.hap = NULL, window.size.half = 5, window.slide = 1, chi0.mixture = 0.5, gene.set = NULL, dominance.eff = TRUE, min.MAF = 0.02, count = TRUE)
```
Arguments

M.now A n.sample x n.mark genotype matrix where n.sample is sample size and n.mark is the number of markers.

y A n x 1 vector. A vector of phenotypic values should be used. NA is allowed.

X.now A n x p matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.

ZETA.now A list of variance (relationship) matrix (K; m x m) and its design matrix (Z; n x m) of random effects. You can use only one kernel matrix. For example, ZETA = list(A = list(Z = Z, K = K)) Please set names of list "Z" and "K"!

eigen.SGS A list with

$\textbf{$values$} \text{ Eigen values}$

$\textbf{$vectors$} \text{ Eigen vectors}$

The result of the eigen decompsition of $SGS$, where $S = I - X(X'X)^{-1}X'$, $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decompsition will be performed in this function. We recommend you assign the result of the eigen decompsition beforehand for time saving.

eigen.G A list with

$\textbf{$values$} \text{ Eigen values}$

$\textbf{$vectors$} \text{ Eigen vectors}$

The result of the eigen decompsition of $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decompsition will be performed in this function. We recommend you assign the result of the eigen decompsition beforehand for time saving.

optimizer The function used in the optimization process. We offer "optim", "optimx", and "nlminb" functions.

map Data frame of map information where the first column is the marker names, the second and third column is the chromosome amd map position, and the forth column is -log10(p) for each marker.

haplotype If the number of lines of your data is large (maybe > 100), you should set haplotype = TRUE. When haplotype = TRUE, haplotype-based kernel will be used for calculating -log10(p). (So the dimension of this gram matrix will be smaller.) The result won’t be changed, but the time for the calculation will be shorter.

num.hap When haplotype = TRUE, you can set the number of haplotypes which you expect. Then similar arrays are considered as the same haplotype, and then make kernel(K.SNP) whose dimension is num.hap x num.hap. When num.hap = NULL (default), num.hap will be set as the maximum number which reflects the difference between lines.

window.size.half This argument decides how many SNPs (around the SNP you want to test) are used to calculated K.SNP. More precisely, the number of SNPs will be 2 * window.size.half + 1.
**window.slide**
This argument determines how often you test markers. If window.slide = 1, every marker will be tested. If you want to perform SNP set by bins, please set window.slide = 2 * window.size.half + 1.

**chi0.mixture**
RAINBOWR assumes the tdeviance is considered to follow a \( x \ \text{chisq}(df = 0) + (1 - a) \ \text{chisq}(df = r) \), where \( r \) is the degree of freedom. The argument chi0.mixture is a \( (0 \leq a < 1) \), and default is 0.5.

**gene.set**
If you have information of gene, you can use it to perform kernel-based GWAS. You should assign your gene information to gene.set in the form of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.

**dominance.eff**
If this argument is TRUE, dominance effect is included in the model, and additive x dominance and dominance x dominance are also tested as epistatic effects. When you use inbred lines, please set this argument FALSE.

**min.MAF**
Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.

**count**
When count is TRUE, you can know how far RGWAS has ended with percent display.

**Value**
-\( \log_{10}(p) \) of epistatic effects for each SNP-set

**References**

**Arguments**

**M.now**
A n.sample x n.mark genotype matrix where n.sample is sample size and n.mark is the number of markers.

**y**
A n x 1 vector. A vector of phenotypic values should be used. NA is allowed.

**X.now**
A n x p matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.

**ZETA.now**
A list of variance (relationship) matrix (K; m x m) and its design matrix (Z; n x m) of random effects. You can use only one kernel matrix. For example, ZETA = list(A = list(Z = Z, K = K)) Please set names of list "Z" and "K"!

**Gu**
A n x n matrix. You should assign ZKZ', where K is covariance (relationship) matrix and Z is its design matrix.

**Ge**
A n x n matrix. You should assign identity matrix I (diag(n)).

**P0**
A n x n matrix. The Moore-Penrose generalized inverse of SV0S, where S = X(X'X)^{-1}X' and V0 = σ^2_u Gu + σ^2_e Ge. σ^2_u and σ^2_e are estimators of the null model.

**map**
Data frame of map information where the first column is the marker names, the second and third column is the chromosome and map position, and the forth column is -log10(p) for each marker.

**haplotype**
If the number of lines of your data is large (maybe > 100), you should set haplotype = TRUE. When haplotype = TRUE, haplotype-based kernel will be used for calculating -log10(p). (So the dimension of this gram matrix will be smaller.) The result won’t be changed, but the time for the calculation will be shorter.

**num.hap**
When haplotype = TRUE, you can set the number of haplotypes which you expect. Then similar arrays are considered as the same haplotype, and then make kernel(K.SNP) whose dimension is num.hap x num.hap. When num.hap = NULL (default), num.hap will be set as the maximum number which reflects the difference between lines.

**window.size.half**
This argument decides how many SNPs (around the SNP you want to test) are used to calculated K.SNP. More precisely, the number of SNPs will be 2 * window.size.half + 1.

**window.slide**
This argument determines how often you test markers. If window.slide = 1, every marker will be tested. If you want to perform SNP set by bins, please set window.slide = 2 * window.size.half + 1.

**chi0.mixture**
RAINBOWR assumes the test statistic l'F1l is considered to follow a x chisq(df = 0) + (1 - a) x chisq(df = r), where l is the first derivative of the log-likelihood and F is the Fisher information. And r is the degree of freedom. The argument chi0.mixture is a (0 <= a < 1), and default is 0.5.

**gene.set**
If you have information of gene, you can use it to perform kernel-based GWAS. You should assign your gene information to gene.set in the form of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.
If this argument is TRUE, dominance effect is included in the model, and additive x dominance and dominance x dominance are also tested as epistatic effects. When you use inbred lines, please set this argument FALSE.

Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.

When count is TRUE, you can know how far RGWAS has ended with percent display.

-log10(p) of epistatic effects for each SNP-set

This function calculates -log10(p) of each SNP-set by the LR (likelihood-ratio) test. First, the function solves the multi-kernel mixed model and calculates the maximum restricted log likelihood. Then it performs the LR test by using the fact that the deviance

\[ D = 2 \times (LL_{alt} - LL_{null}) \]

follows the chi-square distribution.

score.calc.LR(M.now, y, X.now, ZETA.now, LL0, eigen.SGS = NULL, eigen.G = NULL, optimizer = "nlminb", map, kernel.method = "linear", kernel.h = "tuned", haplotype = TRUE, num.hap = NULL, test.effect = "additive", window.size.half = 5, window.slide = 1, chi0.mixture = 0.5, weighting.center = TRUE, weighting.other = NULL, gene.set = NULL, min.MAF = 0.02, count = TRUE)
Arguments

**M.now**
A \( n \times n \) genotype matrix where \( n \) is sample size and \( n \) is the number of markers.

**y**
A \( n \times 1 \) vector. A vector of phenotypic values should be used. NA is allowed.

**X.now**
A \( n \times p \) matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.

**ZETA.now**
A list of variance (relationship) matrix (\( K; m \times m \)) and its design matrix (\( Z; n \times m \)) of random effects. You can use only one kernel matrix. For example, 
\[ ZETA = list(A = list(Z = Z, K = K)) \]
Please set names of list "Z" and "K"!

**LL0**
The log-likelihood for the null model.

**eigen.SGS**
A list with

- **$values** Eigen values
- **$vectors** Eigen vectors

The result of the eigen decomposition of \( SGS \), where 
\[ S = I - X(X'X)^{-1}X' \], 
\[ G = ZKZ' \]. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.

**eigen.G**
A list with

- **$values** Eigen values
- **$vectors** Eigen vectors

The result of the eigen decomposition of \( G = ZKZ' \). You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.

**optimizer**
The function used in the optimization process. We offer "optim", "optimx", and "nlminb" functions.

**map**
Data frame of map information where the first column is the marker names, the second and third column is the chromosome and map position, and the forth column is -log10(p) for each marker.

**kernel.method**
It determines how to calculate kernel. There are three methods.

- **"gaussian"** It is the default method. Gaussian kernel is calculated by distance matrix.
- **"exponential"** When this method is selected, exponential kernel is calculated by distance matrix.
- **"linear"** When this method is selected, linear kernel is calculated by A.mat.

**kernel.h**
The hyper-parameter for gaussian or exponential kernel. If kernel.h = "tuned", this hyper parameter is calculated as the median of off-diagonals of distance matrix of genotype data.

**haplotype**
If the number of lines of your data is large (maybe > 100), you should set haplotype = TRUE. When haplotype = TRUE, haplotype-based kernel will be used for calculating -log10(p). (So the dimension of this gram matrix will be smaller.) The result won’t be changed, but the time for the calculation will be shorter.
num.hap  When haplotype = TRUE, you can set the number of haplotypes which you expect. Then similar arrays are considered as the same haplotype, and then make kernel(K.SNP) whose dimension is num.hap x num.hap. When num.hap = NULL (default), num.hap will be set as the maximum number which reflects the difference between lines.

test.effect  Effect of each marker to test. You can choose "test.effect" from "additive", "dominance" and "additive+dominance". You also can choose more than one effect, for example, test.effect = c("additive", "additive+dominance")

window.size.half  This argument decides how many SNPs (around the SNP you want to test) are used to calculate K.SNP. More precisely, the number of SNPs will be 2 * window.size.half + 1.

window.slide  This argument determines how often you test markers. If window.slide = 1, every marker will be tested. If you want to perform SNP set by bins, please set window.slide = 2 * window.size.half + 1.

chi0.mixture  RAINBOWR assumes the deviance is considered to follow a x chisq(df = 0) + (1 - a) x chisq(df = r), where r is the degree of freedom. The argument chi0.mixture is a (0 <= a < 1), and default is 0.5.

weighting.center  In kernel-based GWAS, weights according to the Gaussian distribution (centered on the tested SNP) are taken into account when calculating the kernel if Rainbow = TRUE. If weighting.center = FALSE, weights are not taken into account.

weighting.other  You can set other weights in addition to weighting.center. The length of this argument should be equal to the number of SNPs. For example, you can assign SNP effects from the information of gene annotation.

gene.set  If you have information of gene, you can use it to perform kernel-based GWAS. You should assign your gene information to gene.set in the form of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.

min.MAF  Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.

count  When count is TRUE, you can know how far RGWAS has ended with percent display.

Value

-log10(p) for each SNP-set

References

Calculate -log10(p) of each SNP-set by the LR test (multi-cores)

Description

This function calculates -log10(p) of each SNP-set by the LR (likelihood-ratio) test. First, the function solves the multi-kernel mixed model and calculates the maximum restricted log likelihood. Then it performs the LR test by using the fact that the deviance

\[ D = 2 \times (LL_{alt} - LL_{null}) \]

follows the chi-square distribution.

Usage

```r
score.calc.LR.MC(M.now, y, X.now, ZETA.now, LL0, eigen.SGS = NULL, eigen.G = NULL, n.core = 2, map, kernel.method = "linear", kernel.h = "tuned", haplotype = TRUE, num.hap = NULL, test.effect = "additive", window.size.half = 5, window.slide = 1, optimizer = "nlminb", chi0.mixture = 0.5, weighting.center = TRUE, weighting.other = NULL, gene.set = NULL, min.MAF = 0.02, count = TRUE)
```

Arguments

- `M.now`: A n.sample x n.mark genotype matrix where n.sample is sample size and n.mark is the number of markers.
- `y`: A n x 1 vector. A vector of phenotypic values should be used. NA is allowed.
- `X.now`: A n x p matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.
- `ZETA.now`: A list of variance (relationship) matrix (K; m x m) and its design matrix (Z; n x m) of random effects. You can use only one kernel matrix. For example, `ZETA = list(A = list(Z = Z, K = K))` Please set names of list "Z" and "K"!
- `LL0`: The log-likelihood for the null model.
- `eigen.SGS`: A list with
  - `$values`: Eigen values
  - `$vectors`: Eigen vectors

The result of the eigen decomposition of SGS, where \( S = I - X(X'X)^{-1}X' \), \( G = ZKZ' \). You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.

- `eigen.G`: A list with
  - `$values`: Eigen values
**Svectors** Eigen vectors

The result of the eigen decomposition of $G = ZZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.

**n.core** Setting n.core > 1 will enable parallel execution on a machine with multiple cores.

**map** Data frame of map information where the first column is the marker names, the second and third column is the chromosome and map position, and the forth column is -log10(p) for each marker.

**kernel.method** It determines how to calculate kernel. There are three methods.

"gaussian" It is the default method. Gaussian kernel is calculated by distance matrix.

"exponential" When this method is selected, exponential kernel is calculated by distance matrix.

"linear" When this method is selected, linear kernel is calculated by A.mat.

**kernel.h** The hyper parameter for gaussian or exponential kernel. If kernel.h = "tuned", this hyper parameter is calculated as the median of off-diagonals of distance matrix of genotype data.

**haplotype** If the number of lines of your data is large (maybe > 100), you should set haplotype = TRUE. When haplotype = TRUE, haplotype-based kernel will be used for calculating -log10(p). (So the dimension of this gram matrix will be smaller.) The result won’t be changed, but the time for the calculation will be shorter.

**num.hap** When haplotype = TRUE, you can set the number of haplotypes which you expect. Then similar arrays are considered as the same haplotype, and then make kernel(K.SNP) whose dimension is num.hap x num.hap. When num.hap = NULL (default), num.hap will be set as the maximum number which reflects the difference between lines.

**test.effect** Effect of each marker to test. You can choose "test.effect" from "additive", "dominance" and "additive+dominance". You also can choose more than one effect, for example, test.effect = c("additive", "additive+dominance")

**window.size.half** This argument decides how many SNPs (around the SNP you want to test) are used to calculated K.SNP. More precisely, the number of SNPs will be 2 * window.size.half + 1.

**window.slide** This argument determines how often you test markers. If window.slide = 1, every marker will be tested. If you want to perform SNP set by bins, please set window.slide = 2 * window.size.half + 1.

**optimizer** The function used in the optimization process. We offer "optim", "optimx", and "nlminb" functions.

**chi0.mixture** RAINBOWR assumes the deviance is considered to follow a x chisq(df = 0) + (1 - a) x chisq(df = r). where r is the degree of freedom. The argument chi0.mixture is a (0 <= a < 1), and default is 0.5.
weighting.center

In kernel-based GWAS, weights according to the Gaussian distribution (centered on the tested SNP) are taken into account when calculating the kernel if Rainbow = TRUE. If weighting.center = FALSE, weights are not taken into account.

weighting.other

You can set other weights in addition to weighting.center. The length of this argument should be equal to the number of SNPs. For example, you can assign SNP effects from the information of gene annotation.

gene.set

If you have information of gene, you can use it to perform kernel-based GWAS. You should assign your gene information to gene.set in the form of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.

min.MAF

Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.

count

When count is TRUE, you can know how far RGWAS has ended with percent display.

Value

-\log_{10}(p) for each SNP-set

References

---

**score.calc.MC**

*Calculate -log10(p) for single-SNP GWAS (multi-cores)*

**Description**

Calculate -\log_{10}(p) of each SNP by the Wald test.

**Usage**

score.calc.MC(M.now, ZETA.now, y, X.now, Hinv, n.core = 2, P3D = TRUE, optimizer = "nlminb", eigen.G = NULL, min.MAF = 0.02, count = TRUE)
Arguments

**M.now**
A n.sample x n.mark genotype matrix where n.sample is sample size and n.mark is the number of markers.

**ZETA.now**
A list of variance (relationship) matrix (K; m x m) and its design matrix (Z; n x m) of random effects. You can use only one kernel matrix. For example, ZETA = list(A = list(Z = Z, K = K)) Please set names of list "Z" and "K"!

**y**
A n x 1 vector. A vector of phenotypic values should be used. NA is allowed.

**X.now**
A n x p matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.

**Hinv**
The inverse of $H = ZKZ' + \lambda I$ where $\lambda = \frac{\sigma_e^2}{\sigma_u^2}$.

**n.core**
Setting n.core > 1 will enable parallel execution on a machine with multiple cores.

**P3D**
When P3D = TRUE, variance components are estimated by REML only once, without any markers in the model. When P3D = FALSE, variance components are estimated by REML for each marker separately.

**optimizer**
The function used in the optimization process. We offer "optim", "optimx", and "nlminb" functions.

**eigen.G**
A list with
- **$values**
  Eigen values
- **$vectors**
  Eigen vectors

The result of the eigen decomposition of $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.

**min.MAF**
Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.

**count**
When count is TRUE, you can know how far RGWAS has ended with percent display.

Value

- $\log_{10}(p)$ for each marker

References

Calculate \(-\log_{10}(p)\) of each SNP-set by the score test

**Description**

This function calculates \(-\log_{10}(p)\) of each SNP-set by the score test. First, the function calculates the score statistic without solving the multi-kernel mixed model for each SNP-set. Then it performs the score test by using the fact that the score statistic follows the chi-square distribution.

**Usage**

```r
score.calc.score(M.now, y, X.now, ZETA.now, LL0, Gu, Ge, P0, map,
kernel.method = "linear", kernel.h = "tuned", haplotype = TRUE,
num.hap = NULL, test.effect = "additive", window.size.half = 5,
window.slide = 1, chi0.mixture = 0.5, weighting.center = TRUE,
weighting.other = NULL, gene.set = NULL, min.MAF = 0.02,
count = TRUE)
```

**Arguments**

- **M.now**  
  A n.sample x n.mark genotype matrix where n.sample is sample size and n.mark is the number of markers.

- **y**  
  A n x 1 vector. A vector of phenotypic values should be used. NA is allowed.

- **X.now**  
  A n x p matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.

- **ZETA.now**  
  A list of variance (relationship) matrix (K; m x m) and its design matrix (Z; n x m) of random effects. You can use only one kernel matrix. For example, `ZETA = list(A = list(Z = Z, K = K))` Please set names of list "Z" and "K"!

- **LL0**  
  The log-likelihood for the null model.

- **Gu**  
  A n x n matrix. You should assign ZKZ', where K is covariance (relationship) matrix and Z is its design matrix.

- **Ge**  
  A n x n matrix. You should assign identity matrix I (diag(n)).

- **P0**  
  n x n matrix. The Moore-Penrose generalized inverse of \(SV0S\), where \(S = X(X'X)^{-1}X'\) and \(V0 = \sigma^2_u Gu + \sigma^2_e Ge\). \(\sigma^2_u\) and \(\sigma^2_e\) are estimators of the null model.

- **map**  
  Data frame of map information where the first column is the marker names, the second and third column is the chromosome and map position, and the forth column is \(-\log_{10}(p)\) for each marker.

- **kernel.method**  
  It determines how to calculate kernel. There are three methods.

  - "gaussian" It is the default method. Gaussian kernel is calculated by distance matrix.

  - "exponential" When this method is selected, exponential kernel is calculated by distance matrix.
"linear"  When this method is selected, linear kernel is calculated by A.mat.

kernel.h  The hyper parameter for gaussian or exponential kernel. If kernel.h = "tuned", this hyper parameter is calculated as the median of off-diagonals of distance matrix of genotype data.

haplotype  If the number of lines of your data is large (maybe > 100), you should set haplotype = TRUE. When haplotype = TRUE, haplotype-based kernel will be used for calculating -log10(p). (So the dimension of this gram matrix will be smaller.) The result won’t be changed, but the time for the calculation will be shorter.

num.hap  When haplotype = TRUE, you can set the number of haplotypes which you expect. Then similar arrays are considered as the same haplotype, and then make kernel(K.SNP) whose dimension is num.hap x num.hap. When num.hap = NULL (default), num.hap will be set as the maximum number which reflects the difference between lines.

test.effect  Effect of each marker to test. You can choose "test.effect" from "additive", "dominance" and "additive+dominance". You also can choose more than one effect, for example, test.effect = c("additive", "aditive+dominance")

window.size.half  This argument decides how many SNPs (around the SNP you want to test) are used to calculated K.SNP. More precisely, the number of SNPs will be 2 * window.size.half + 1.

window.slide  This argument determines how often you test markers. If window.slide = 1, every marker will be tested. If you want to perform SNP set by bins, please set window.slide = 2 * window.size.half + 1.

chi0.mixture  RAINBOWR assumes the test statistic $l_1'F{l_1}$ is considered to follow a $a \times \text{chisq}(df = 0) + (1 - a) \times \text{chisq}(df = r)$, where $l_1$ is the first derivative of the log-likelihood and $F$ is the Fisher information. And $r$ is the degree of freedom. The argument chi0.mixture is a (0 <= a < 1), and default is 0.5.

weighting.center  In kernel-based GWAS, weights according to the Gaussian distribution (centered on the tested SNP) are taken into account when calculating the kernel if Rainbow = TRUE. If weighting.center = FALSE, weights are not taken into account.

weighting.other  You can set other weights in addition to weighting.center. The length of this argument should be equal to the number of SNPs. For example, you can assign SNP effects from the information of gene annotation.

gene.set  If you have information of gene, you can use it to perform kernel-based GWAS. You should assign your gene information to gene.set in the form of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.

min.MAF  Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.

count  When count is TRUE, you can know how far RGWAS has ended with percent display.
**Value**

\(-\log_{10}(p)\) for each SNP-set

**References**

------

**score.calc.score.MC**

*Calculate \(-\log_{10}(p)\) of each SNP-set by the score test (multi-cores)*

**Description**

This function calculates \(-\log_{10}(p)\) of each SNP-set by the score test. First, the function calculates the score statistic without solving the multi-kernel mixed model for each SNP-set. Then it performs the score test by using the fact that the score statistic follows the chi-square distribution.

**Usage**

```r
score.calc.score.MC(M.now, y, X.now, ZETA.now, LL0, Gu, Ge, P0, 
n.core = 2, map, kernel.method = "linear", kernel.h = "tuned", 
haplotype = TRUE, num.hap = NULL, test.effect = "additive", 
window.size.half = 5, window.slide = 1, chi0.mixture = 0.5, 
weighting.center = TRUE, weighting.other = NULL, gene.set = NULL, 
min.MAF = 0.02, count = TRUE)
```

**Arguments**

- `M.now`: A n.sample x n.mark genotype matrix where n.sample is sample size and n.mark is the number of markers.
- `y`: A n x 1 vector. A vector of phenotypic values should be used. NA is allowed.
- `X.now`: A n x p matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.
- `ZETA.now`: A list of variance (relationship) matrix (K; m x m) and its design matrix (Z; n x m) of random effects. You can use only one kernel matrix. For example, ZETA = list(A = list(Z = Z, K = K)) Please set names of list "Z" and "K"!

- `Ge`: A n x n matrix. You should assign identity matrix I (diag(n)).
- `P0`: A n x n matrix. The Moore-Penrose generalized inverse of \(SV'0S\), where \(S = X(X'X)^{-1}X'\) and \(V0 = \sigma_u^2Gu + \sigma_e^2Ge\). \(\sigma_u^2\) and \(\sigma_e^2\) are estimators of the null model.
Setting n.core > 1 will enable parallel execution on a machine with multiple cores.

Data frame of map information where the first column is the marker names, the second and third column is the chromosome and map position, and the forth column is -log10(p) for each marker.

It determines how to calculate kernel. There are three methods.

"gaussian" It is the default method. Gaussian kernel is calculated by distance matrix.

"exponential" When this method is selected, exponential kernel is calculated by distance matrix.

"linear" When this method is selected, linear kernel is calculated by A.mat.

The hyper parameter for gaussian or exponential kernel. If kernel.h = "tuned", this hyper parameter is calculated as the median of off-diagonals of distance matrix of genotype data.

If the number of lines of your data is large (maybe > 100), you should set haplotype = TRUE. When haplotype = TRUE, haplotype-based kernel will be used for calculating -log10(p). (So the dimension of this gram matrix will be smaller.) The result won’t be changed, but the time for the calculation will be shorter.

When haplotype = TRUE, you can set the number of haplotypes which you expect. Then similar arrays are considered as the same haplotype, and then make kernel(K.SNP) whose dimension is num.hap x num.hap. When num.hap = NULL (default), num.hap will be set as the maximum number which reflects the difference between lines.

Effect of each marker to test. You can choose "test.effect" from "additive", "dominance" and "additive+dominance". You also can choose more than one effect, for example, test.effect = c("additive", "additive+dominance")

This argument decides how many SNPs (around the SNP you want to test) are used to calculated K.SNP. More precisely, the number of SNPs will be 2 * window.size.half + 1.

This argument determines how often you test markers. If window.slide = 1, every marker will be tested. If you want to perform SNP set by bins, please set window.slide = 2 * window.size.half + 1.

RAINBOWR assumes the test statistic \( l_1 F l_1 \) is considered to follow a \( \chi^2(df = 0) + (1 - a) \chi^2(df = r) \). where \( l_1 \) is the first derivative of the log-likelihood and \( F \) is the Fisher information. And \( r \) is the degree of freedom. The argument chi0.mixture is a \( (0 <= a < 1) \), and default is 0.5.

In kernel-based GWAS, weights according to the Gaussian distribution (centered on the tested SNP) are taken into account when calculating the kernel if Rainbow = TRUE. If weighting.center = FALSE, weights are not taken into account.

You can set other weights in addition to weighting.center. The length of this argument should be equal to the number of SNPs. For example, you can assign SNP effects from the information of gene annotation.
gene.set

If you have information of gene, you can use it to perform kernel-based GWAS. You should assign your gene information to gene.set in the form of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.

min.MAF

Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.

count

When count is TRUE, you can know how far RGWAS has ended with percent display.

Value

-log10(p) for each SNP-set

References

score.cpp

Calculte -log10(p) by score test (slow, for general cases)

Description

Calculte -log10(p) by score test (slow, for general cases)

Usage

score.cpp(y, Gs, Gu, Ge, P0, chi0.mixture = 0.5)

Arguments

- **y**: A n x 1 vector. A vector of phenotypic values should be used. NA is allowed.
- **Gs**: A list of kernel matrices you want to test. For example, Gs = list(A.part = K.A.part, D.part = K.D.part)
- **Gu**: A n x n matrix. You should assign \(ZKZ'\), where K is covariance (relationship) matrix and Z is its design matrix.
- **Ge**: A n x n matrix. You should assign identity matrix I (diag(n)).
- **P0**: A n x n matrix. The Moore-Penrose generalized inverse of \(SV0S\), where \(S = X(X'X)^{-1}X'\) and \(V0 = \sigma_u^2 Gu + \sigma_e^2 Ge\). \(\sigma_u^2\) and \(\sigma_e^2\) are estimators of the null model.
- **chi0.mixture**: RAINBOW assumes the test statistic \(l1'Fl1\) is considered to follow a x chisq(df = 0) + (1 - a) x chisq(df = r), where l1 is the first derivative of the log-likelihood and F is the Fisher information. And r is the degree of freedom. The argument chi0.mixture is a (0 <= a < 1), and default is 0.5.
-log10(p) calculated by score test

\[ \text{Value} \]

- \(-\log_{10}(p)\) calculated by score test

---

\[ \text{score.linker.cpp} \quad \text{Calculate -log10(p) by score test (fast, for limited cases)} \]

---

\[ \text{Description} \]

Calculate -log10(p) by score test (fast, for limited cases)

\[ \text{Usage} \]

\[
\text{score.linker.cpp}(y, Ws, Gammas, gammas.diag = TRUE, Gu, Ge, P0,
\text{chi0.mixture} = 0.5)
\]

\[ \text{Arguments} \]

- **y**: A \(n \times 1\) vector. A vector of phenotypic values should be used. NA is allowed.
- **Ws**: A list of low rank matrices (\(ZW; n \times k\) matrix). This forms linear kernel \(ZKZ' = ZWT(ZW)'\). For example, \(Ws = \text{list}(A.part = ZW.A, D.part = ZW.D)\)
- **Gammas**: A list of matrices for weighting SNPs (\(Gamma; k \times k\) matrix). This forms linear kernel \(ZKZ' = ZWT(ZW)'\). For example, if there is no weighting, \(\text{Gammas} = \text{lapply}(Ws, \text{function}(x) \text{diag}(\text{ncol}(x)))\)
- **gammas.diag**: If each Gamma is the diagonal matrix, please set this argument TRUE. The calculation time can be saved.
- **Gu**: A \(n \times n\) matrix. You should assign \(ZKZ'\), where \(K\) is covariance (relationship) matrix and \(Z\) is its design matrix.
- **Ge**: A \(n \times n\) matrix. You should assign identity matrix I (\text{diag}(n)).
- **P0**: A \(n \times n\) matrix. The Moore-Penrose generalized inverse of \(SV0S\), where \(S = X(X'X)^{-1}X'\) and \(V0 = \sigma_u^2 Gu + \sigma_e^2 Ge\). \(\sigma_u^2\) and \(\sigma_e^2\) are estimators of the null model.
- **chi0.mixture**: RAINBOW assumes the statistic \(l1'F11\) follows the mixture of \(\chi_0^2\) and \(\chi_r^2\), where \(l1\) is the first derivative of the log-likelihood and \(F\) is the Fisher information. And \(r\) is the degree of freedom. \text{chi0.mixture} determines the proportion of \(\chi_0^2\)

\[ \text{Value} \]

- \(-\log_{10}(p)\) calculated by score test
See Function to view the first part of data (like head(), tail())

Description

Function to view the first part of data (like head(), tail())

Usage

See(data, fh = TRUE, fl = TRUE, rown = 6, coln = 6, rowst = 1, colst = 1, narray = 2, drop = FALSE, save.variable = FALSE, verbose = TRUE)

Arguments

- **data**: Your data. 'vector', 'matrix', 'array' (whose dimensions <= 4), 'data.frame' are supported format. If other formatted data is assigned, str(data) will be returned.
- **fh**: From head. If this argument is TRUE, first part (row) of data will be shown (like head() function). If FALSE, last part (row) of your data will be shown (like tail() function).
- **fl**: From left. If this argument is TRUE, first part (column) of data will be shown (like head() function). If FALSE, last part (column) of your data will be shown (like tail() function).
- **rown**: The number of rows shown in console.
- **coln**: The number of columns shown in console.
- **rowst**: The start point for the direction of row.
- **colst**: The start point for the direction of column.
- **narray**: The number of dimensions other than row and column shown in console. This argument is effective only your data is array (whose dimensions >= 3).
- **drop**: When rown = 1 or coln = 1, the dimension will be reduced if this argument is TRUE.
- **save.variable**: If you want to assign the result to a variable, please set this argument TRUE.
- **verbose**: If TRUE, print the first part of data.

Value

If save.variable is FALSE, NULL. If TRUE, the first part of your data will be returned.
Perform spectral decomposition (implemented by Rcpp)

**Description**

Perform spectral decomposition for $G = ZKZ'$ or SGS where $S = I - X(X'X)^{-1}X$.

**Usage**

```r
spectralG.cpp(ZETA, ZWs = NULL, X = NULL, weights = 1,
               return.G = TRUE, return.SGS = FALSE, spectral.method = NULL,
               tol = NULL, df.H = NULL)
```

**Arguments**

- **ZETA**
  A list of variance (relationship) matrix ($K; m \times m$) and its design matrix ($Z; n \times m$) of random effects. You can use only one kernel matrix. For example, ZETA = list(A = list(Z = Z, K = K)) Please set names of list "Z" and "K"!

- **ZWs**
  A list of additional linear kernels other than genetic relationship matrix. We utilize this argument in RGWAS.multisnp function, so you can ignore this.

- **X**
  $n \times p$ matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.

- **weights**
  If the length of ZETA >= 2, you should assign the ratio of variance components to this argument.

- **return.G**
  If this argument is TRUE, spectral decomposition results of $G$ will be returned. ($G = ZKZ'$)

- **return.SGS**
  If this argument is TRUE, spectral decomposition results of SGS will be returned. ($S = I - X(X'X)^{-1}X, G = ZKZ'$)

- **spectral.method**
  The method of spectral decomposition. In this function, "eigen" : eigen decomposition and "cholesky" : cholesky and singular value decomposition are offered. If this argument is NULL, either method will be chosen according to the dimension of $Z$ and $X$.

- **tol**
  The tolerance for detecting linear dependencies in the columns of $G = ZKZ'$. Eigen vectors whose eigen values are less than "tol" argument will be omitted from results. If tol is NULL, top 'n' eigen values will be effective.

- **df.H**
  The degree of freedom of $K$ matrix. If this argument is NULL, min(n, sum(nrow(K1), nrow(K2), ...)) will be assigned.

**Value**

- **$U** Eigen vectors of $G$.
- **$delta** Eigen values of $G$. 
$\text{SS\_gwas}$ Estimator for $\sigma_e^2$

$\text{SQ}$ Eigen vectors of SGS.

$\theta$ Eigen values of SGS.

---

**SS\_gwas**

*Calculate some summary statistics of GWAS (genome-wide association studies) for simulation study*

---

**Description**

Calculate some summary statistics of GWAS (genome-wide association studies) for simulation study

**Usage**

```r
SS_gwas(res, x, map.x, qtn.candidate, gene.set = NULL, 
n.top.false.block = 10, sig.level = c(0.05, 0.01),
method.thres = "BH", inflator.plus = 2, LD_length = 150000,
cor.thres = 0.35, window.size = 0, saveName = NULL,
plot.ROC = TRUE)
```

**Arguments**

- **res**: Data frame of GWAS results where the first column is the marker names, the second and third column is the chromosome and map position, and the forth column is -$\log_{10}(p)$ for each marker.
- **x**: A N (lines) x M (markers) marker genotype data (matrix), coded as -1, 0, 1 = aa, Aa, AA.
- **map.x**: Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position.
- **qtn.candidate**: A vector of causal markers. You should assign where those causal markers are positioned in our marker genotype, rather than physical position of those causal markers.
- **gene.set**: If you have information of gene (or haplotype block), and if you used it to perform kernel-based GWAS, you should assign your gene information to gene.set in the form of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "x" argument.
- **n.top.false.block**: We will calculate the mean of -$\log_{10}(p)$ values of top 'n.top.false.block’ blocks to evaluate the inflation level of results. The default is 10.
- **sig.level**: Significance level for the threshold. The default is 0.05.
- **method.thres**: Method for determining threshold of significance. "BH" and "Bonferroni" are offered.
If the \(-\log_{10}(p)\) value for each marker exceeds (the inflation level + inflator.plus), that marker is regarded as significant.

SNPs within the extent of LD are regarded as one set. This LD_length determines the size of LD block, and \(2 \times LD_{\text{length}}\) (b.p.) will be the size of LD block.

SNPs within the extent of LD are regarded as one set. This cor.thres also determines the size of LD block, and the region with square of correlation coefficients \(\geq cor.thres\) is regarded as one LD block. More precisely, the regions which satisfies both LD_length and cor.thres condition is regarded as one LD block.

If you perform SNP-set analysis with sliding window, we can consider the effect of window size by this argument.

When drawing any plot, you can save plots in png format. In saveName, you should substitute the name you want to save. When saveName = NULL, the plot is not saved.

If this argument is TRUE, ROC (Receiver Operating Characteristic) curve will be drawn with AUC (Area Under the Curve).

\begin{itemize}
  \item \texttt{log.p} -log_{10}(p)) values of the causals.
  \item \texttt{qtn.logp.order} The rank of -log_{10}(p) of causals.
  \item \texttt{thres} A vector which contains the information of threshold.
  \item \texttt{overthres} The number of markers which exceed the threshold.
  \item \texttt{AUC} Area under the curve.
  \item \texttt{AUC.relax} Area under the curve calculated with LD block units.
  \item \texttt{FDR} False discovery rate. 1 - Precision.
  \item \texttt{FPR} False positive rate.
  \item \texttt{FNR} False negative rate. 1 - Recall.
  \item \texttt{Recall} The proportion of the number of causals detected by GWAS to the number of causals you set.
  \item \texttt{Precision} The proportion of the number of causals detected by GWAS to the number of markers detected by GWAS.
  \item \texttt{Accuracy} The accuracy of GWAS results.
  \item \texttt{Hm} Harmonic mean of Recall and Precision.
  \item \texttt{haplo.name} The haplotype block name which correspond to causals.
  \item \texttt{mean.false} The mean of -log_{10}(p) values of top \(\text{n.top.false.block}\) blocks.
  \item \texttt{max.trues} Maximum of the -log_{10}(p) values of the region near causals.
\end{itemize}
