Description

MixtComp (Mixture Composer, https://github.com/modal-inria/MixtComp) is a model-based clustering package for mixed data.

It has been engineered around the idea of easy and quick integration of all new univariate models, under the conditional independence assumption. Five basic models (Gaussian, Multinomial, Poisson, Weibull, NegativeBinomial) are implemented, as well as two advanced models (Func_CS and Rank_ISR). MixtComp has the ability to natively manage missing data (completely or by interval).

Online SaaS version (not up-to-date): https://massiccc.lille.inria.fr/

Details

Main functions are `mixtCompLearn` for clustering, `mixtCompPredict` for predicting the cluster of new samples with a model learnt with `mixtCompLearn`. `createAlgo` gives you default values for required parameters.

Read the help page of `mixtCompLearn` for available models and data format. A summary of these information can be accessed with the function `availableModels`.

All utility functions (getters, graphical) are in the `RMixtCompUtilities-package` package.

In order to have an overview of the output, you can use `print.MixtCompLearn`, `summary.MixtCompLearn` and `plot.MixtCompLearn` functions.

Getters are available to easily access some results (see `mixtCompLearn` for output format): `getBIC`, `getICL`, `getCompletedData`, `getParam`, `getTik`, `getEmpiricTik`, `getPartition`, `getType`, `getModel`, `getVarNames`.

You can compute discriminative powers and similarities with functions: `computeDiscrimPowerClass`, `computeDiscrimPowerVar`, `computeSimilarityClass`, `computeSimilarityVar`.

# define the algorithm's parameters: you can use createAlgo function
alg <- list(nbBurnInIter = 50,
            nIter = 50,
            nbGibbsBurnInIter = 50,
            nbGibbsIter = 50,
            nInitPerClass = 20,
            nSemTry = 20,
            confidenceLevel = 0.95)

# run RMixtComp for learning using only 3 variables
resLearn <- mixtCompLearn(simData$dataLearn$matrix, simData$model$unsupervised[1:3], alg,
                           nClass = 2:3, nRun = 2, nCore = 1)

summary(resLearn)
plot(resLearn)

# run RMixtComp for predicting
resPred <- mixtCompPredict(simData$dataPredict$matrix, simData$model$unsupervised[1:3], alg,
                           resLearn)

partitionPred <- getPartition(resPred)
print(resPred)

---

CanadianWeather  Canadian average annual weather cycle

Description

Daily temperature and precipitation at 35 different locations in Canada averaged over 1960 to 1994. Data from `fda` package.
Usage

data(CanadianWeather)

Format

A list containing 5 elements:

- tempav: a matrix of dimensions (365, 35) giving the average temperature in degrees Celsius for each day of the year.
- precav: a matrix of dimensions (365, 35) giving the average rainfall in millimeters for each day of the year.
- time: sequence from 1 to 365.
- coordinates: a matrix giving 'N.latitude' and 'W.longitude' for each place.
- region: Which of 4 climate zones contain each place: Atlantic, Pacific, Continental, Arctic.

plot(resLearn)
getPartition(resLearn)
getTik(resLearn, log = FALSE)

extractMixtCompObject  Extract a MixtComp object

Description
Extract a MixtComp object from a MixtCompLearn object

Usage
extractMixtCompObject(object, K)

Arguments
object       mixtCompLearn output
K             number of classes of the model to extract

Value
a MixtComp object containing the clustering model with K classes

Author(s)
Quentin Grimonprez

Examples
# run clustering
resLearn <- mixtCompLearn(data.frame(x = rnorm(500)), nClass = 1:3, criterion = "ICL",
                          nRun = 1, nCore = 1)

# extract the model with 2 classes
clustModel <- extractMixtCompObject(resLearn, K = 2)
mixtCompLearn

Learn and predict using RMixtComp

Description

Estimate the parameter of a mixture model or predict the cluster of new samples. It manages heterogeneous data as well as missing and incomplete data.

Usage

mixtCompLearn(
  data,
  model = NULL,
  algo = createAlgo(),
  nClass,
  criterion = c("BIC", "ICL"),
  hierarchicalMode = c("auto", "yes", "no"),
  nRun = 1,
  nCore = min(max(1, ceiling(detectCores()/2)), nRun),
  verbose = TRUE
)

mixtCompPredict(
  data,
  model = NULL,
  algo = resLearn$algo,
  resLearn,
  nClass = NULL,
  nRun = 1,
  nCore = min(max(1, ceiling(detectCores()/2)), nRun),
  verbose = FALSE
)

Arguments

data a data.frame, a matrix or a named list containing the data (see Details Data format sections).
model a named list containing models and hyperparameters (see Details section).
algo a list containing the parameters of the SEM-Gibbs algorithm (see Details or createAlgo).
nClass the number of class of the mixture model. Can be a vector for mixtCompLearn only.
criterion "BIC" or "ICL". Criterion used for choosing the best model.
hierarchicalMode "auto", "yes" or "no". If "auto", it performs a hierarchical version of MixtComp (clustering in two classes then each classes is split in two ...) when a functional variable is present.
mixtCompLearn

- **nRun**: number of runs for every given number of class. If >1, SEM is run nRun times for every number of class, and the best according to observed likelihood is kept.
- **nCore**: number of cores used for the parallelization of the nRun runs.
- **verbose**: if TRUE, print some informations.
- **resLearn**: output of `mixtCompLearn` (only for `mixtCompPredict` function).

**Details**

The *data* object can be a matrix, a data.frame or a list. In the case of a matrix or data.frame, each column must be names and corresponds to a variable. In the case of a list, each element corresponds to a variable, each element must be named. Missing and incomplete data are managed, see section *Data format* for how to format them.

The *model* object is a named list containing the variables to use in the model. All variables listed in the *model* object must be in the *data* object. *model* can contain less variables than *data*. An element of the list is the model’s name to use (see below for the list of available models). For example, `model <- list(real1 = "Gaussian", counting1 = "Poisson")` indicates a mixture model with 2 variables named real1 and counting1 with Gaussian and Poisson as model. Some models require hyperparameters in this case, the model is described by a list of 2 elements: `type` containing the model name and `paramStr` containing the hyperparameters. For example: `model <- list(func1 = list(type = "Func_CS", paramStr = "nSub: 4, nCoeff: 2"), counting1 = "Poisson")`. If the model is NULL, data are supposed to be provided in data.frame or list with R format (numeric, factor, character, NA as missing value). Models will be imputed as follows: "Gaussian" for numeric variable, "Multinomial" for character or factor variable and "Poisson" for integer variable. A summary of available models (and associated hyperparameters and missing format) can be accessed by calling the `availableModels` function.

Eight models are available in RMixtComp: *Gaussian*, *Multinomial*, *Poisson*, *NegativeBinomial*, *Weibull*, *Func_CS*, *Func_SharedAlpha_CS*, *Rank_ISR*. *Func_CS* and *Func_SharedAlpha_CS* models require hyperparameters: the number of subregressions of functional and the number of coefficients of each subregression. These hyperparameters are specified by: `nSub: i, nCoeff: k` in the `paramStr` field of the *model* object. The *Func_SharedAlpha_CS* is a variant of the *Func_CS* model with the alpha parameter shared between clusters. It means that the start and end of each subregression will be the same across the clusters.

To perform a (semi-)supervised clustering, users can add a variable named `z_class` in the data and model objects with `LatentClass` as model in the model object.

The *algo* object is a list containing the different number of iterations for the algorithm. This list can be generated using the `createAlgo` function. The algorithm is decomposed in a burn-in phase and a normal phase. Estimates from the burn-in phase are not shown in output.

- **nbBurnInIter**: Number of iterations of the burn-in part of the SEM algorithm.
- **nbIter**: Number of iterations of the SEM algorithm.
- **nbGibbsBurnInIter**: Number of iterations of the burn-in part of the Gibbs algorithm.
- **nbGibbsIter**: Number of iterations of the Gibbs algorithm.
- **nInitPerClass**: Number of individuals used to initialize each cluster (default = 10).
- **nSemTry**: Number of try of the algorithm for avoiding an error.
- **confidenceLevel**: confidence level for confidence bounds for parameter estimation.
• ratioStableCriterion: stability partition required to stop earlier the SEM
• nStableCriterion: number of iterations of partition stability to stop earlier the SEM

Value

An object of classes MixtCompLearn and MixtComp for mixtCompLearn function. An object of class MixtComp for mixtCompPredict.

Data format

See https://github.com/modal-inria/MixtComp/blob/master/MixtComp/docs/dataFormat.md.

- Gaussian data: Gaussian data are real values with the dot as decimal separator. Missing data are indicated by a ?. Partial data can be provided through intervals denoted by [a:b] where a (resp. b) is a real or -inf (resp. +inf).
- Categorical Data: Categorical data must be consecutive integer with 1 as minimal value. Missing data are indicated by a ?. For partial data, a list of possible values can be provided by a_1,...,a_j, where a_j denotes a categorical value.
- Poisson and NegativeBinomial Data: Poisson and NegativeBinomial data must be positive integer. Missing data are indicated by a ?. Partial data can be provided through intervals denoted by [a:b] where a and b are positive integers. b can be +inf.
- Weibull Data: Weibull data are real positive values with the dot as decimal separator. Missing data are indicated by a ?. Partial data can be provided through intervals denoted by [a:b] where a and b are positive reals. b can be +inf.
- Rank data: The format of a rank is: o_1,...,o_j where o_1 is an integer corresponding to the number of the object ranked in 1st position. For example: 4,2,1,3 means that the fourth object is ranked first then the second object is in second position and so on. Missing data can be specified by replacing and object by a ? or a list of potential object, for example: 4, {2 3}, {2 1}, ?. means that the object ranked in second position is either the object number 2 or the object number 3, then the object ranked in third position is either the object 2 or 1 and the last one can be anything. A totally missing rank is specified by ?',?,?,?,
- Functional data: The format of a functional data is: time_1:value_1,...,time_j:value_j. Between individuals, functional data can have different length and different time. i is the number of sub-regressions in a functional data and k the number of coefficients of each regression (2 = linear, 3 = quadratic, ...). Missing data are not supported.
- z_class: To perform a (semi-)supervised clustering, user can add a variable named ‘z_class’ (with eventually some missing values) with "LatentClass" as model. Missing data are indicated by a ?. For partial data, a list of possible values can be provided by a_1,...,a_j, where a_j denotes a class number.

MixtComp object

A MixtComp object is a result of a single run of MixtComp algorithm. It is a list containing three elements mixture, variable and algo. If MixtComp fails to run, the list contains a single element: warnLog containing error messages.

The mixture element contains
- BIC: value of BIC
- ICL: value of ICL
- nbFreeParameters: number of free parameters of the mixture
- lnObservedLikelihood: observed loglikelihood
- lnCompletedLikelihood: completed loglikelihood
- IDClass: entropy used to compute the discriminative power (see code of plotDiscrimVar)
- delta: similarities between variables (see heatmapVar)
- completedProbabilityLogBurnIn: evolution of the completed log-probability during the burn-in period (can be used to check the convergence and determine the ideal number of iteration)
- completedProbabilityLogRun: evolution of the completed log-probability after the burn-in period (can be used to check the convergence and determine the ideal number of iteration)
- runTime: list containing the total execution time in seconds and the execution time of some subpart.
- lnProbaGivenClass: log-proportion + log-probability of \( x_i \) for each class

The `algo` list contains a copy of `algo` parameter with extra elements: \( n\text{Ind}, n\text{Class}, \text{mode} \) ("learn" or "predict").

The `variable` list contains 3 lists: `data`, `type` and `param`. Each of these lists contains a list for each variable (the name of each list is the name of the variable) and for the class of samples (\( z_{\text{class}} \)). The `type` list contains the model used for each variable.

Each list of the `data` list contains the completed data in the `completed` element and some statistics about them (\( \text{stat} \)).

The estimated parameter can be found in the `stat` element in the `param` list (see Section View of an output object). For more details about the parameters of each model, you can refer to `rnorm`, `rpois`, `rweibull`, `rmnbinom`, `rmultinom`, or references in the References section.

MixtCompLearn object

The MixtCompLearn object is the result of a run of the `mixtCompLearn` function. It is a list containing `nClass`: the vector of number of classes given by user, `res` a list of MixtComp object (one per element of `nbClass`), `criterion` the criterion used to choose the best model, `crit` a matrix containing BIC and ICL for each run, and finally the elements of the MixtComp object with the best criterion value (`algo`, `mixture`, `variable` or `warnLog`).

**Prostate Cancer Data**

**Description**

This data set was obtained from a randomized clinical trial comparing four treatments for $n = 506$ patients with prostatic cancer grouped on clinical criteria into two Stages 3 and 4 of the disease.

**Usage**

```r
data(prostate)
```

**Format**

A list containing of 2 elements `data` and `model`. `data` contains 506 individuals described by 12 variables:

- Age: Age (Continuous)
- HG: Index of tumour stage and histologic grade (Continuous)
- Wt: Weight (Continuous)
- AP: Serum prostatic acid phosphatase C (Continuous)
- SBP: Systolic blood pressure (Continuous)
- PF: Performance rating (Categorical)
- DBP: Diastolic blood pressure (Continuous)
- HX: Cardiovascular disease history (Categorical)
- SG: Serum haemoglobin (Continuous)
- BM: Bone metastasis (Categorical)
- SZ: Size of primary tumour (Continuous)
- EKG: Electrocardiogram code (Categorical)

simData  
Simulated Heterogeneous data

Description

Simulated Heterogeneous data

Usage

```r
data(simData)
```

Format

A list containing three elements: `dataLearn`, `dataPredict` and `model`.

- `dataLearn` is a list containing the data in the three accepted format (list, data.frame and matrix). Data consists of 200 individuals and 9 variables.
- `dataPredict` is a list containing the data in the three accepted format (list, data.frame and matrix). Data consists of 100 individuals and 8 variables.
- `model` is a list containing the model lists used for clustering `model$unsupervised` and classification `model$supervised`.

```
Description
Criterion to choose the number of clusters

Usage
slopHeuristic(object, K0 = floor(max(object$nClass) * 0.4))

Arguments
object output of mixtCompLearn
K0 number of class for computing the constant value (see details)

Details
The slope heuristic criterion is: LL_k - 2 * C * D_k, with LL_k the loglikelihood for k classes, D_k the number of free parameters for k classes, C is the slope of the linear regression between D_k and LL_k for (k> K0)

Value
the values of the slope heuristic
