Package ‘RQuantLib’

August 7, 2019

Title R Interface to the ‘QuantLib’ Library
Version 0.4.10
Date 2019-08-07
Maintainer Dirk Eddelbuettel <edd@debian.org>
Author Dirk Eddelbuettel, Khanh Nguyen (2009-2010), Terry Leitch (since 2016)
Description The 'RQuantLib' package makes parts of 'QuantLib' accessible from R
The 'QuantLib' project aims to provide a comprehensive software framework for quantitative finance. The goal is to provide a standard open source library for quantitative analysis, modeling, trading, and risk management of financial assets.
Depends R (>= 2.10.0)
Suggests rgl, RUnit, shiny
LazyLoad true
Imports methods, Rcpp (>= 0.11.0), stats, graphics, zoo
LinkingTo Rcpp
SystemRequirements QuantLib library (>= 1.14) from http://quantlib.org, Boost library from http://www.boost.org
License GPL (>= 2)
URL http://dirk.eddelbuettel.com/code/rquantlib.html
BugReports https://github.com/eddelbuettel/rquantlib/issues
RoxygenNote 6.0.1
NeedsCompilation yes
Repository CRAN
Date/Publication 2019-08-07 13:00:02 UTC

R topics documented:

AffineSwaption .................................................. 2
AmericanOption .................................................. 5
**AffineSwaption**

AffineSwaption prices a swaption with specified strike and maturity (in years), after calibrating the selected affine short-rate model to an input swaption volatility matrix. Swaption maturities are in years down the rows, and swap tenors are in years along the columns, in the usual fashion. It is assumed that the swaption is exercisable at the start of the swap if params$european flag is set to TRUE or on each reset date (Bermudan) of the underlying swap if params$european flag is set to FALSE.

**Usage**

```r
AffineSwaption(params, ts, swaptionMaturities, swapTenors, volMatrix, legparams)
```
Arguments

params A list specifying the tradeDate (month/day/year), settlementDate, logical flags payFixed & european (european=FALSE generates Bermudan value), strike, pricing method, and curve construction options (see Examples section below). Curve construction options are interpWhat (possible values are discount, forward, and zero) and interpHow (possible values are linear, loglinear, and spline). Both interpWhat and interpHow are ignored when a flat yield curve is requested, but they must be present nevertheless. The pricing method can be one of the following (all short-rate models):

<table>
<thead>
<tr>
<th>Pricing Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>G2Analytic</td>
<td>G2 2-factor Gaussian model using analytic formulas.</td>
</tr>
<tr>
<td>HWAnalytic</td>
<td>Hull-White model using analytic formulas.</td>
</tr>
<tr>
<td>HWTree</td>
<td>Hull-White model using a tree.</td>
</tr>
<tr>
<td>BKTree</td>
<td>Black-Karasinski model using a tree.</td>
</tr>
</tbody>
</table>

ts A term structure built with DiscountCurve is required. See the help page for DiscountCurve and example below for details.

swaptionMaturities A vector containing the swaption maturities associated with the rows of the swaption volatility matrix.

swapTenors A vector containing the underlying swap tenors associated with the columns of the swaption volatility matrix.

volMatrix The swaption volatility matrix. Must be a 2D matrix stored by rows. See the example below.

legparams A list specifying the dayCounter the day count convention for the fixed leg (default is Thirty360), and fixFreq, fixed coupon frequency (default is Annual), floatFreq, floating leg reset frequency (default is Semiannual).

Details

This function is based on QuantLib Version 0.3.10. It introduces support for fixed-income instruments in RQuantLib.

At present only a small number of the many parameters that can be set in QuantLib are exposed by this function. Some of the hard-coded parameters that apply to the current version include: day-count conventions, fixing days (2), index (Euribor), fixed leg frequency (annual), and floating leg frequency (semi-annual). Also, it is assumed that the swaption volatility matrix corresponds to expiration dates and tenors that are measured in years (a 6-month expiration date is not currently supported, for example).

Given the number of parameters that must be specified and the care with which they must be specified (with no defaults), it is not practical to use this function in the usual interactive fashion.

The simplest approach is simply to save the example below to a file, edit as desired, and source the result. Alternatively, the input commands can be kept in a script file (under Windows) or an Emacs/ESS session (under Linux), and selected parts of the script can be executed in the usual way.

Fortunately, the C++ exception mechanism seems to work well with the R interface, and QuantLib exceptions are propagated back to the R user, usually with a message that indicates what went wrong. (The first part of the message contains technical information about the precise location of
AffineSwaption

the problem in the QuantLib code. Scroll to the end to find information that is meaningful to the R user.)

Value

AffineSwaption returns a list containing calibrated model parameters (what parameters are returned depends on the model selected) along with:

NPV  NPV of swaption in basis points (actual price equals price times notional divided by 10,000)
ATMStrike  At-the-money strike
params  Input parameter list

Examples

```r
if (.Platform$OS.type != "windows" && .Platform$r_arch != "i386") {

# This data was generated to match the original quantlib example for Bermudan Swaption
params <- list(tradeDate=as.Date('2016-2-15'),
settleDate=as.Date('2016-2-17'),
startDate=as.Date('2017-2-17'),
maturity=as.Date('2022-2-17'),
payFixed=TRUE,
european=FALSE,
dt=.25,
strike=.06,
method="G2Analytic",
interpWhat="discount",
interpHow="loglinear")

# Market data used to construct the term structure of interest rates
tsQuotes <- list(d1w =0.0382,
d1m =0.0372,
fut1=96.2875,
fut2=96.7875,
```
AmericanOption

American Option evaluation using Finite Differences

Description
This function evaluations an American-style option on a common stock using finite differences. The option value as well as the common first derivatives ("Greeks") are returned.

Usage

## Default S3 method:

```r
fut3=96.9875,
fut4=96.6875,
fut5=96.4875,
fut6=96.3875,
fut7=96.2875,
fut8=96.0875,
s3y =0.0398,
s5y =0.0443,
s10y =0.05165,
s15y =0.055175)

# Swaption volatility matrix with corresponding maturities and tenors
swaptionMaturities <- c(1,2,3,4,5)

swapTenors <- c(1,2,3,4,5)

volMatrix <- matrix(
  c(0.1490, 0.1340, 0.1228, 0.1189, 0.1148,
   0.1290, 0.1201, 0.1146, 0.1108, 0.1040,
   0.1149, 0.1112, 0.1070, 0.1010, 0.0957,
   0.1047, 0.1021, 0.0980, 0.0951, 0.1270,
   0.1000, 0.0950, 0.0900, 0.1230, 0.1160),
  ncol=5, byrow=TRUE)

legparams=list(dayCounter="Thirty360",
    fixFreq="Annual",
    floatFreq="Semiannual")

setEvaluationDate(as.Date("2016-2-16"))
times<-times <- seq(0,14.75,.25)
dcurve <- DiscountCurve(params, tsQuotes, times=times,legparams)

# Price the Bermudan swaption
pricing <- AffineSwaption(params, dcurve,swaptionMaturities, swapTenors, volMatrix,legparams)
summary(pricing)

```
AmericanOption(type, underlying, strike,
dividendYield, riskFreeRate, maturity, volatility,
timeSteps=150, gridPoints=149, engine="BaroneAdesiWhaley",
discreteDividends, discreteDividendsTimeUntil)

Arguments

type A string with one of the values call or put
underlying Current price of the underlying stock
strike Strike price of the option
dividendYield Continuous dividend yield (as a fraction) of the stock
riskFreeRate Risk-free rate
maturity Time to maturity (in fractional years)
volatility Volatility of the underlying stock
timeSteps Time steps for the “CrankNicolson” finite differences method engine, default value is 150
gridPoints Grid points for the “CrankNicolson” finite differences method, default value is 149
engine String selecting pricing engine, currently supported are “BaroneAdesiWhaley” and “CrankNicolson”
discreteDividends Vector of discrete dividends (optional)
discreteDividendsTimeUntil Vector of times to discrete dividends (in fractional years, optional)

Details

The Finite Differences method is used to value the American Option.

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value

An object of class AmericanOption (which inherits from class Option) is returned. It contains a list with the following components:

value Value of option
delta Sensitivity of the option value for a change in the underlying
gamma Sensitivity of the option delta for a change in the underlying
vega Sensitivity of the option value for a change in the underlying’s volatility
theta Sensitivity of the option value for a change in t, the remaining time to maturity
rho Sensitivity of the option value for a change in the risk-free interest rate
dividendRho Sensitivity of the option value for a change in the dividend yield
AmericanOptionImpliedVolatility

Note that under the new pricing framework used in QuantLib, pricers do not provide analytics for all 'Greeks'. When “CrankNicolson” is selected, then at least delta, gamma and vega are available. With the default pricing engine of “BaroneAdesiWhaley”, no greeks are returned. The “CrankNicolson” engine needs to be used when setting discrete dividends.

Note

The interface might change in future release as QuantLib stabilises its own API.

EuropeanOption

Examples

# simple call with unnamed parameters
AmericanOption("call", 100, 100, 0.02, 0.03, 0.5, 0.4)
# simple call with some explicit parameters
AmericanOption("put", strike=100, volatility=0.4, 100, 0.02, 0.03, 0.5)
# simple call with unnamed parameters, using Crank-Nicolons
AmericanOption("put", strike=100, volatility=0.4, 100, 0.02, 0.03, 0.5, engine="CrankNicolson")

AmericanOptionImpliedVolatility

Implied Volatility calculation for American Option

Description

The AmericanOptionImpliedVolatility function solves for the (unobservable) implied volatility, given an option price as well as the other required parameters to value an option.

Usage

```r
## Default S3 method:
AmericanOptionImpliedVolatility(type, value,
underlying, strike,dividendYield, riskFreeRate, maturity, volatility,
timeSteps=150, gridPoints=151)
```
Arguments

type A string with one of the values call or put
value Value of the option (used only for ImpliedVolatility calculation)
derived Value of the derived option (used only for ImpliedVolatility calculation)
derivedUnderlying Value of the derived underlying (used only for ImpliedVolatility calculation)
derivedStrike Strike price of the derived option (used only for ImpliedVolatility calculation)
derivedDividendYield Continuous dividend yield (as a fraction) of the derived stock
riskFreeRate Risk-free rate
maturity Time to maturity (in fractional years)
volatility Initial guess for the volatility of the underlying stock
timeSteps Time steps for the Finite Differences method, default value is 150
gridPoints Grid points for the Finite Differences method, default value is 151

details
The Finite Differences method is used to value the American Option. Implied volatilities are then calculated numerically.
Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value

The AmericanOptionImpliedVolatility function returns an numeric variable with volatility implied by the given market prices and given parameters.

Note

The interface might change in future release as QuantLib stabilises its own API.

Author(s)

EuropeanOption, AmericanOption, BinaryOption

Examples

AmericanOptionImpliedVolatility(type="call", value=11.10, underlying=100, strike=100, dividendYield=0.01, riskFreeRate=0.03, maturity=0.5, volatility=0.4)
**AsianOption**

**Asian Option evaluation using Closed-Form solution**

**Description**

The `AsianOption` function evaluates an Asian-style option on a common stock using an analytic solution for continuous geometric average price. The option value, the common first derivatives ("Greeks") as well as the calling parameters are returned.

**Usage**

```r
## Default S3 method:
AsianOption(averageType, type, underlying, strike,
            dividendYield, riskFreeRate, maturity,
            volatility, first=0, length=11.0/12.0, fixings=26)
```

**Arguments**

- `averageType`: Specify averaging type, either “geometric” or “arithmetic”
- `type`: A string with one of the values `call` or `put`
- `underlying`: Current price of the underlying stock
- `strike`: Strike price of the option
- `dividendYield`: Continuous dividend yield (as a fraction) of the stock
- `riskFreeRate`: Risk-free rate
- `maturity`: Time to maturity (in fractional years)
- `volatility`: Volatility of the underlying stock
- `first`: (Only for arithmetic averaging) Time step to first average, can be zero
- `length`: (Only for arithmetic averaging) Total time length for averaging period
- `fixings`: (Only for arithmetic averaging) Total number of averaging fixings

**Details**

When "arithmetic" evaluation is used, only the NPV() is returned.

The well-known closed-form solution derived by Black, Scholes and Merton is used for valuation. Implied volatilities are calculated numerically.

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.
**Value**

The AsianOption function returns an object of class AsianOption (which inherits from class Option). It contains a list with the following components:

- **value**: Value of option
- **delta**: Sensitivity of the option value for a change in the underlying
- **gamma**: Sensitivity of the option delta for a change in the underlying
- **vega**: Sensitivity of the option value for a change in the underlying’s volatility
- **theta**: Sensitivity of the option value for a change in t, the remaining time to maturity
- **rho**: Sensitivity of the option value for a change in the risk-free interest rate
- **dividendRho**: Sensitivity of the option value for a change in the dividend yield

**Note**

The interface might change in future release as QuantLib stabilises its own API.

**Author(s)**

Dirk Eddelbuettel <edd@debian.org> for the R interface; the QuantLib Group for QuantLib

**References**

[http://quantlib.org](http://quantlib.org) for details on QuantLib.

**Examples**

```r
# simple call with some explicit parameters, and slightly increased vol:
AsianOption("geometric", "put", underlying=80, strike=85, div=-0.03,
            riskFree=0.05, maturity=0.25, vol=0.2)
```

---

**BarrierOption**

**Barrier Option evaluation using Closed-Form solution**

**Description**

This function evaluations an Barrier option on a common stock using a closed-form solution. The option value as well as the common first derivatives ("Greeks") are returned.

**Usage**

```r
## Default S3 method:
BarrierOption(barrType, type, underlying, strike,
              dividendYield, riskFreeRate, maturity,
              volatility, barrier, rebate=0.0)
```
**BarrierOption**

**Arguments**

- `barrType` A string with one of the values `downin`, `downout`, `upin` or `upout`
- `type` A string with one of the values `call` or `put`
- `underlying` Current price of the underlying stock
- `strike` Strike price of the option
- `dividendYield` Continuous dividend yield (as a fraction) of the stock
- `riskFreeRate` Risk-free rate
- `maturity` Time to maturity (in fractional years)
- `volatility` Volatility of the underlying stock
- `barrier` Option barrier value
- `rebate` Optional option rebate, defaults to 0.0

**Details**

A closed-form solution is used to value the Barrier Option. In the case of Barrier options, the calculations are from Haug's "Option pricing formulas" book (McGraw-Hill).

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

**Value**

An object of class `BarrierOption` (which inherits from class `Option`) is returned. It contains a list with the following components:

- `value` Value of option
- `delta` Sensitivity of the option value for a change in the underlying
- `gamma` Sensitivity of the option delta for a change in the underlying
- `vega` Sensitivity of the option value for a change in the underlying’s volatility
- `theta` Sensitivity of the option value for a change in t, the remaining time to maturity
- `rho` Sensitivity of the option value for a change in the risk-free interest rate
- `dividendRho` Sensitivity of the option value for a change in the dividend yield

Note that under the new pricing framework used in QuantLib, binary pricers do not provide analytics for ‘Greeks’. This is expected to be addressed in future releases of QuantLib.

**Note**

The interface might change in future release as QuantLib stabilises its own API.

AmericanOption, EuropeanOption

Examples

BarrierOption(barrType="downin", type="call", underlying=100, strike=100, dividendYield=0.02, riskFreeRate=0.03, maturity=0.5, volatility=0.4, barrier=90)

BermudanSwaption

Bermudan swaption valuation using several short-rate models

Description

BermudanSwaption prices a Bermudan swaption with specified strike and maturity (in years), after calibrating the selected short-rate model to an input swaption volatility matrix. Swaption maturities are in years down the rows, and swap tenors are in years along the columns, in the usual fashion. It is assumed that the Bermudan swaption is exercisable on each reset date of the underlying swaps.

Usage

BermudanSwaption(params, ts, swaptionMaturities, swapTenors, volMatrix)

Arguments

params \hspace{1cm} A list specifying the tradeDate (month/day/year), settlementDate, startDate, maturity, payFixed flag, strike, pricing method, and curve construction options (see Examples section below). Curve construction options are interpWhat (possible values are discount, forward, and zero) and interpHow (possible values are linear, loglinear, and spline). Both interpWhat and interpHow are ignored when a flat yield curve is requested, but they must be present nevertheless. The pricing method can be one of the following (all short-rate models):

G2Analytic \hspace{1cm} G2 2-factor Gaussian model using analytic formulas.
HWAnalytic \hspace{1cm} Hull-White model using analytic formulas.
HWTree \hspace{1cm} Hull-White model using a tree.
BKTTree \hspace{1cm} Black-Karasinski model using a tree.

ts \hspace{1cm} A term structure built with DiscountCurve or market observables needed to construct the spot term structure of interest rates. A list of name/value pairs. See the help page for DiscountCurve for details.
BermudanSwaption

swaptionMaturities
A vector containing the swaption maturities associated with the rows of the swaption volatility matrix.

swapTenors
A vector containing the underlying swap tenors associated with the columns of the swaption volatility matrix.

volMatrix
The swaption volatility matrix. Must be a 2D matrix stored by rows. See the example below.

Details
This function was updated for QuantLib Version 1.7.1 or later. It introduces support for fixed-income instruments in RQuantLib. It implements the full function and should work in most cases as long as there are sufficient swaption vol data points to fit the affine model. At least 5 unique points are required. The data point search attempts to find 5 or more points with one being the closest match in terms of expiration and maturity.

See the SabrSwaption function for an alternative.

Value
BermudanSwaption, if there are sufficient swaption vols to fit an affine model, returns a list containing calibrated model parameters (what parameters are returned depends on the model selected) along with:

price
Price of swaption in basis points (actual price equals price times notional divided by 10,000)

ATMStrike
At-the-money strike

params
Input parameter list

If there are insufficient swaption vols to calibrate it throws a warning and returns NULL

BinaryOption

*Binary Option evaluation using Closed-Form solution*

**Description**

This function evaluates an Binary option on a common stock using a closed-form solution. The option value as well as the common first derivatives ("Greeks") are returned.

**Usage**

```r
## Default S3 method:
BinaryOption(binType, type, excType, underlying,  
strike, dividendYield,  
riskFreeRate, maturity, volatility, cashPayoff)
```

**Arguments**

- **binType**: A string with one of the values `cash`, `asset` or `gap` to select `CashOrNothing`, `AssetOrNothing` or `Gap` payoff profiles
- **type**: A string with one of the values `call` or `put`
- **excType**: A string with one of the values `european` or `american` to denote the exercise type
- **underlying**: Current price of the underlying stock
- **strike**: Strike price of the option
- **dividendYield**: Continuous dividend yield (as a fraction) of the stock
- **riskFreeRate**: Risk-free rate
- **maturity**: Time to maturity (in fractional years)
- **volatility**: Volatility of the underlying stock
- **cashPayoff**: Payout amount

**Details**

A closed-form solution is used to value the Binary Option.

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.
**Value**

An object of class `BinaryOption` (which inherits from class `Option`) is returned. It contains a list with the following components:

- **value**: Value of option
- **delta**: Sensitivity of the option value for a change in the underlying
- **gamma**: Sensitivity of the option delta for a change in the underlying
- **vega**: Sensitivity of the option value for a change in the underlying’s volatility
- **theta**: Sensitivity of the option value for a change in \( t \), the remaining time to maturity
- **rho**: Sensitivity of the option value for a change in the risk-free interest rate
- **dividendRho**: Sensitivity of the option value for a change in the dividend yield

**Note**

The interface might change in future release as QuantLib stabilises its own API.

**Author(s)**

Dirk Eddelbuettel <edd@debian.org> for the R interface; the QuantLib Group for QuantLib

**References**

[http://quantlib.org](http://quantlib.org) for details on QuantLib.

**See Also**

`AmericanOption`, `EuropeanOption`

**Examples**

```r
BinaryOption(binType="asset", type="call", excType="european",
underlying=100, strike=100, dividendYield=0.02,
riskFreeRate=0.03, maturity=0.5, volatility=0.4, cashPayoff=10)
```

**Description**

The `BinaryOptionImpliedVolatility` function solves for the (unobservable) implied volatility, given an option price as well as the other required parameters to value an option.
Usage

```r
## Default S3 method:
BinaryOptionImpliedVolatility(type, value, underlying, 
strike, dividendYield, riskFreeRate, maturity, volatility, 
cashPayoff=1)
```

Arguments

- `type`: A string with one of the values `call`, `put` or `straddle`
- `value`: Value of the option (used only for ImpliedVolatility calculation)
- `underlying`: Current price of the underlying stock
- `strike`: Strike price of the option
- `dividendYield`: Continuous dividend yield (as a fraction) of the stock
- `riskFreeRate`: Risk-free rate
- `maturity`: Time to maturity (in fractional years)
- `volatility`: Initial guess for the volatility of the underlying stock
- `cashPayoff`: Binary payout if options is exercised, default is 1

Details

The Finite Differences method is used to value the Binary Option. Implied volatilities are then calculated numerically.

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value

The `BinaryOptionImpliedVolatility` function returns a numeric variable with volatility implied by the given market prices.

Note

The interface might change in future release as QuantLib stabilises its own API.

Author(s)

Dirk Eddelbuettel <edd@debian.org> for the R interface; the QuantLib Group for QuantLib

- `EuropeanOption`, `AmericanOption`, `BinaryOption`
Examples

BinaryOptionImpliedVolatility("call", value=4.50, strike=100, 100, 0.02, 0.03, 0.5, 0.4, 10)

Description

This class forms the basis from which the more specific classes are derived.

Usage

```r
## S3 method for class 'Bond'
print(x, digits=5, ...)
## S3 method for class 'FixedRateBond'
print(x, digits=5, ...)
## S3 method for class 'Bond'
plot(x, ...)
## S3 method for class 'Bond'
summary(object, digits=5, ...)
```

Arguments

- `x`       Any Bond object derived from this base class
- `object`  Any Bond object derived from this base class
- `digits`  Number of digits of precision shown
- `...`     Further arguments

Details

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value

None, but side effects of displaying content.

Note

The interface might change in future release as QuantLib stabilises its own API.

## BondUtilities

### Bond parameter conversion utilities

**Description**

These functions are using internally to convert from the characters at the R level to the enum types used at the C++ level. They are documented here mostly to provide a means to look up some of the possible values—the user is not expected to call these functions directly.
Usage

matchBDC(bdc = c("Following", "ModifiedFollowing", "Preceding", "ModifiedPreceding", "Unadjusted", "HalfMonthModifiedFollowing", "Nearest"))
matchCompounding(cp = c("Simple", "Compounded", "Continuous", "SimpleThenCompounded"))
matchDateGen(dg = c("Backward", "Forward", "Zero", "ThirdWednesday", "Twentieth", "TwentiethIMM", "OldCDS", "CDS"))
matchParams(params)

Arguments

bdc       A string identifying one of the possible business day convention values.
cp        A string identifying one of the possible compounding frequency values.
daycounter A string identifying one of the possible day counter scheme values.
dg        A string identifying one of the possible date generation scheme values.
freq      A string identifying one of the possible (dividend) frequency values.
params    A named vector containing the other parameters as components.

Details

The QuantLib documentation should be consulted for details.

Note that Actual365NoLeap is deprecated as of QuantLib 1.11 and no longer supported by default. It can be reinstated by defining RQUANTLIB_USE_ACTUAL365NOLEAP.

Value

Each function converts the given character value into a corresponding numeric entry. For matchParams, an named vector of strings is converted into a named vector of numerics.

Note

The interface might change in future release as QuantLib stabilises its own API.

Author(s)

Khanh Nguyen <knguyen@cs.umb.edu> for the R interface; the QuantLib Group for QuantLib
Description

The isBusinessDay function evaluates the given dates in the context of the given calendar, and returns a vector of booleans indicating business day status. BusinessDay is also recognised (but may be deprecated one day).

The isHoliday function evaluates the given dates in the context of the given calendar, and returns a vector of booleans indicating holiday day status.

The isWeekend function evaluates the given dates in the context of the given calendar, and returns a vector of booleans indicating weekend status.

The isEndOfMonth function evaluates the given dates in the context of the given calendar, and returns a vector of booleans indicating end of month status.

The getEndOfMonth function evaluates the given dates in the context of the given calendar, and returns a vector that corresponds to the end of month. endOfMonth is a deprecated form for this function.

The getHolidayList function returns the holidays between the given dates, with an option to exclude weekends. holidayList is a deprecated form for this function.

The adjust function evaluates the given dates in the context of the given calendar, and returns a vector that adjusts each input dates to the appropriate near business day with respect to the given convention.

The advance function evaluates the given dates in the context of the given calendar, and returns a vector that advances the given dates of the given number of business days and returns the result. This functions gets called either with both argument n and timeUnit, or with argument period.

The businessDaysBetween function evaluates two given dates in the context of the given calendar, and returns a vector that gives the number of business day between.

The dayCount function returns the number of day between two dates given a day counter, see Enum.

The yearFraction function returns year fraction between two dates given a day counter, see Enum.

The setCalendarContext function sets three values to a singleton instance at the C++ layer.

The setEvaluationDate function sets the evaluation date used by the QuantLib pricing engines.

The advanceDate function advances the given date by the given number of days in the current calendar instance.

The addHolidays and removeHolidays add (and remove) holidays to (from) the given calendar. Note that this change is transitory and does not persist the session as all actual calendar information comes from the QuantLib library that this package is linked against.

References

http://quantlib.org for details on QuantLib.
Usage

```r
isBusinessDay(calendar, dates)
businessDay(calendar="TARGET", dates=Sys.Date()) # deprecated form
isHoliday(calendar, dates)
isWeekend(calendar, dates)
isEndOfMonth(calendar, dates)
getEndOfMonth(calendar, dates)
endOfMonth(calendar="TARGET", dates=Sys.Date())
getHolidayList(calendar, from, to, includeWeekends=FALSE)
holidayList(calendar="TARGET", from=Sys.Date(), to = Sys.Date() + 5,
includeWeekends = FALSE)
adjust(calendar="TARGET", dates, bdc = 0L)
advance(calendar="TARGET", dates=Sys.Date(), n, timeUnit, period, bdc = 0, emr =0)

businessDaysBetween(calendar, from, to, includeFirst = TRUE, includeLast = FALSE)
dayCount(startDates, endDates, dayCounters)
yearFraction(startDates, endDates, dayCounters)
setCalendarContext(calendar, fixingDays, settleDate)
setEvaluationDate(evalDate)
addHolidays(calendar, dates)
removeHolidays(calendar, dates)
```

Arguments

calendar  A string identifying one of the supported QuantLib calendars, see Details for more
dates     A vector (or scalar) of Date types.
from      A vector (or scalar) of Date types.
to        A vector (or scalar) of Date types.
includeWeekends  boolean that indicates whether the calculation should include the weekends. Default = false
fixingDays An integer for the fixing day period, defaults to 2.
settleDate A date on which trades settles, defaults to two days after the current day.
n          an integer number
timeUnit   A value of 0,1,2,3 that corresponds to Days, Weeks, Months, and Year; for more detail, see the QuantLib documentation at http://quantlib.org/reference/group__datetime.html
period     See Enum
bdc        Business day convention. By default, this value is 0 and correspond to Following convention
emr        End Of Month rule, default is false
includeFirst  boolean that indicates whether the calculation should include the first day. Default = true
includeLast Default = false
startDates A vector of Date type.
endDates A vector of Date type.
dayCounters A vector of numeric type. See Enum
evalDate A single date used for the pricing valuations.

Details
The calendars are coming from QuantLib, and the QuantLib documentation should be consulted for
details.
Currently, the following strings are recognised: TARGET (a default calendar), Argentina, Aus-
tralia, Brazil, Canada and Canada/Settlement, Canada/TSX, China, CzechRepublic, Denmark, Fin-
land, Germany and Germany/FrankfurtStockExchange, Germany/Settlement, Germany/Xetra, Ger-
many/Eurex, Hong Kong, Hungary, Iceland, India, Indonesia, Italy and Italy/Settlement, Italy/Exchange,
Japan, Mexico, New Zealand, Norway, Poland, Russia, Saudi Arabia, Singapore, Slovakia, South Africa,
South Korea, South Korea/KRX, Sweden, Switzerland, Taiwan, Turkey, Ukraine, United Kingdom
and United Kingdom/Settlement, United Kingdom/Exchange, United Kingdom/Metals, United States
and United States/Settlement, United States/NYSE, United States/GovernmentBond, United States/NERC
and WeekendsOnly.
(In case of multiples entries per country, the country default is listed right after the country itself.
Using the shorter form is equivalent.)

Value
A named vector of booleans each of which is true if the corresponding date is a business day (or
holiday or weekend) in the given calendar. The element names are the dates (formatted as text in
yyyy-mm-dd format).
For setCalendarContext, a boolean or NULL in case of error.

Note
The interface might change in future release as QuantLib stabilises its own API.

CallableBond

**CallableBond evaluation**

**Description**

The CallableBond function sets up and evaluates a callable fixed rate bond using Hull-White model and a TreeCallableFixedBondEngine pricing engine. For more detail, see the source codes in quantlib's example folder, Examples/CallableBond/CallableBond.cpp

**Usage**

```r
## Default S3 method:
CallableBond(bondparams, hullWhite, coupon, dateparams)
```

**Arguments**

- **bondparams**: a named list whose elements are:
  - **issueDate**: a Date, the bond's issue date
  - **maturityDate**: a Date, the bond's maturity date
  - **faceAmount**: (Optional) a double, face amount of the bond. Default value is 100.
  - **redemption**: (Optional) a double, percentage of the initial face amount that will be returned at maturity date. Default value is 100.
  - **callSch**: (Optional) a data frame whose columns are "Price", "Type" and "Date" corresponding to QuantLib's CallabilitySchedule. Default is an empty frame, or no callability.

- **hullWhite**: a named list whose elements are parameters needed to set up a HullWhite pricing engine in QuantLib:
  - **term**: a double, to set up a flat rate yield term structure
  - **alpha**: a double, Hull-White model's alpha value
  - **sigma**: a double, Hull-White model's sigma value
  - **gridIntervals**: a double, time intervals parameter to set up the TreeCallableFixedBondEngine

Currently, the codes only support a flat rate yield term structure. For more detail, see QuantLib's doc on HullWhite and TreeCallableFixedBondEngine.

- **coupon**: a numeric vector of coupon rates
- **dateparams**: (Optional) a named list, QuantLib's date parameters of the bond.

```r
dayCount(startDates, endDates, dayCounters)
yearFraction(startDates, endDates, dayCounters)
```
CallableBond

settlementDays
(Optional) a double, settlement days.
Default value is 1.
calendar
(Optional) a string, either 'us' or 'uk'
corresponding to US Government Bond
calendar and UK Exchange calendar.
Default value is 'us'.
dayCounter
(Optional) a number or string,
day counter convention.
See Enum. Default value is 'Thirty360'
period
(Optional) a number or string,
interest compounding interval. See Enum.
Default value is 'Semiannual'.
businessDayConvention
(Optional) a number or string,
business day convention.
See Enum. Default value is 'Following'.
terminationDateConvention
(Optional) a number or string
termination day convention.
See Enum. Default value is 'Following'.

See example below.

Details

Please see any decent Finance textbook for background reading, and the QuantLib documentation
for details on the QuantLib implementation.

Value

The CallableBond function returns an object of class CallableBond (which inherits from class
Bond). It contains a list with the following components:

NPV net present value of the bond
cleanPrice price price of the bond
dirtyPrice dirty price of the bond
accruedAmount accrued amount of the bond
yield yield of the bond
cashFlows cash flows of the bond

Note

The interface might change in future release as QuantLib stabilises its own API.

Author(s)

Khanh Nguyen <knguyen@cs.umb.edu> for the implementation; Dirk Eddelbuettel <edd@debian.org>

http://quantlib.org for details on QuantLib.

Examples

#set-up a HullWhite according to example from QuantLib
HullWhite <- list(term = 0.055, alpha = 0.03, sigma = 0.01, gridIntervals = 40)

#callability schedule dataframe
Price <- rep(as.double(100),24)
Type <- rep(as.character("C"), 24)
Date <- seq(as.Date("2006-09-15"), by = "3 months", length = 24)
callSch <- data.frame(Price, Type, Date)
callSch$Type <- as.character(callSch$Type)

bondparams <- list(faceAmount=100, issueDate = as.Date("2004-09-16"),
    maturityDate=as.Date("2012-09-16"), redemption=100,
    callSch = callSch)
dateparams <- list(settlementDays=3, calendar="UnitedStates/GovernmentBond",
    dayCounter = "ActualActual",
    period="Quarterly",
    businessDayConvention = "Unadjusted",
    terminationDateConvention= "Unadjusted")
coupon <- c(0.0465)
setEvaluationDate(as.Date("2004-11-22"))

CallableBond(bondparams, HullWhite, coupon, dateparams)
#examples using default values
CallableBond(bondparams, HullWhite, coupon)
dateparams <- list(period="Quarterly",
    businessDayConvention = "Unadjusted",
    terminationDateConvention= "Unadjusted")
CallableBond(bondparams, HullWhite, coupon, dateparams)

bondparams <- list(issueDate = as.Date("2004-09-16"),
    maturityDate=as.Date("2012-09-16"))
CallableBond(bondparams, HullWhite, coupon, dateparams)

ConvertibleBond

Convertible Bond evaluation for Fixed, Floating and Zero Coupon

Description

The ConvertibleFixedCouponBond function setups and evaluates a ConvertibleFixedCouponBond using QuantLib's BinomialConvertibleEngine and BlackScholesMertonProcess

The NPV, clean price, dirty price, accrued interest, yield and cash flows of the bond is returned. For detail, see test-suite/convertiblebond.cpp
The ConvertibleFloatingCouponBond function setups and evaluates a ConvertibleFixedCouponBond using QuantLib's BinomialConvertibleEngine and BlackScholesMertonProcess.

The NPV, clean price, dirty price, accrued interest, yield and cash flows of the bond is returned. For detail, see test-suite/convertiblebond.cpp.

The ConvertibleZeroCouponBond function setups and evaluates a ConvertibleFixedCouponBond using QuantLib's BinomialConvertibleEngine and BlackScholesMertonProcess.

The NPV, clean price, dirty price, accrued interest, yield and cash flows of the bond is returned. For detail, see test-suite/convertiblebond.cpp.

Usage

## Default S3 method:
ConvertibleFloatingCouponBond(bondparams, liborindex, spread, process, dateparams)

## Default S3 method:
ConvertibleFixedCouponBond(bondparams, coupon, process, dateparams)

## Default S3 method:
ConvertibleZeroCouponBond(bondparams, process, dateparams)

Arguments

bondparams: bond parameters, a named list whose elements are:

- **issueDate**: a Date, the bond’s issue date
- **maturityDate**: a Date, the bond’s maturity date
- **creditSpread**: a double, credit spread parameter in the constructor of the bond.
- **conversionRatio**: a double, conversion ratio parameter in the constructor of the bond.
- **exercise**: (Optional) a string, either "eu" for European option, or "am" for American option. Default value is ‘am’.
- **faceAmount**: (Optional) a double, face amount of the bond. Default value is 100.
- **redemption**: (Optional) a double, percentage of the initial face amount that will be returned at maturity date. Default value is 100.
- **divSch**: (Optional) a data frame whose columns are "Type", "Amount", "Rate", and "Date" corresponding to QuantLib’s DividendSchedule. Default value is an empty frame, or no dividend.
- **callSch**: (Optional) a data frame whose columns are "Price", "Type" and "Date" corresponding to QuantLib’s CallabilitySchedule. Default value is an empty frame, or no callability.
iborindex    a DiscountCurve object, represents an IborIndex
spread      a double vector, represents parameter ‘spreads’ in ConvertibleFloatingBond’s
coupon      constructor.
process      arguments to construct a BlackScholes process and set up the binomial pricing
underlying  engine for this bond.
volatility   a double, flat volatility term structure
dividendYield a DiscountCurve object
riskFreeRate a DiscountCurve object
dateparams  (Optional) a named list, QuantLib’s date parameters of the bond.
settlementDays (Optional) a double, settlement days. Default value is 1.
calendar    (Optional) a string, either ‘us’ or ‘uk’ corresponding to US Government Bond
calendar and UK Exchange calendar. Default value is ‘us’.
dayCounter  (Optional) a number or string, day counter convention. See Enum. Default value is ‘Thirty360’
period      (Optional) a number or string, interest compounding interval. See Enum. Default value is ‘Semiannual’.
businessDayConvention (Optional) a number or string, business day convention. See Enum. Default value is ‘Following’.

See the examples below.

Details

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value

The ConvertibleFloatingCouponBond function returns an object of class ConvertibleFloatingCouponBond (which inherits from class Bond). It contains a list with the following components:

NPV          net present value of the bond
cleanPrice   price price of the bond
dirtyPrice   dirty price of the bond
accruedAmount accrued amount of the bond
yield yield of the bond
cashFlows cash flows of the bond

The ConvertibleFixedCouponBond function returns an object of class ConvertibleFixedCouponBond (which inherits from class Bond). It contains a list with the following components:

NPV net present value of the bond
cleanPrice price price of the bond
dirtyPrice dirty price of the bond
accruedAmount accrued amount of the bond
yield yield of the bond
cashFlows cash flows of the bond

The ConvertibleZeroCouponBond function returns an object of class ConvertibleZeroCouponBond (which inherits from class Bond). It contains a list with the following components:

NPV net present value of the bond
cleanPrice price price of the bond
dirtyPrice dirty price of the bond
accruedAmount accrued amount of the bond
yield yield of the bond
cashFlows cash flows of the bond

---

**DiscountCurve**

Returns the discount curve (with zero rates and forwards) given times.
DiscountCurve

Description

DiscountCurve constructs the spot term structure of interest rates based on input market data including the settlement date, deposit rates, futures prices, FRA rates, or swap rates, in various combinations. It returns the corresponding discount factors, zero rates, and forward rates for a vector of times that is specified as input.

Usage

DiscountCurve(params, tsQuotes, times, legparams)

Arguments

params A list specifying the tradeDate (month/day/year), settleDate, forward rate time span dt, and two curve construction options: interpWhat (with possible values discount, forward, and zero) and interpHow (with possible values linear, loglinear, and spline). spline here means cubic spline interpolation of the interpWhat value.

tsQuotes Market quotes used to construct the spot term structure of interest rates. Must be a list of name/value pairs, where the currently recognized names are:

- flat rate for a flat yield curve
- d1w 1-week deposit rate
- d1m 1-month deposit rate
- d3m 3-month deposit rate
- d6m 6-month deposit rate
- d9m 9-month deposit rate
- d1y 1-year deposit rate
- s2y 2-year swap rate
- s3y 3-year swap rate
- s4y 4-year swap rate
- s5y 5-year swap rate
- s6y 6-year swap rate
- s7y 7-year swap rate
- s8y 8-year swap rate
- s9y 9-year swap rate
- s10y 10-year swap rate
- s12y 12-year swap rate
- s15y 15-year swap rate
- s20y 20-year swap rate
- s25y 25-year swap rate
- s30y 30-year swap rate
- s40y 40-year swap rate
- s50y 50-year swap rate
- s60y 60-year swap rate
- s70y 70-year swap rate
- s80y 80-year swap rate
- s90y 90-year swap rate
- s100y 100-year swap rate
DiscountCurve

fut1–fut8  3-month futures contracts  
fra3x6   3x6 FRA  
fra6x9   6x9 FRA  
fra6x12  6x12 FRA  

Here rates are expected as fractions (so 5% means .05). If flat is specified it must be the first and only item in the list. The eight futures correspond to the first eight IMM dates. The maturity dates of the instruments specified need not be ordered, but they must be distinct.

times A vector of times at which to return the discount factors, forward rates, and zero rates. Times must be specified such that the largest time plus \( dt \) does not exceed the longest maturity of the instruments used for calibration (no extrapolation).

legparams A list specifying the dayCounter the day count convention for the fixed leg (default is Thirty360), and fixFreq, fixed coupon frequency (default is Annual), floatFreq, floating leg reset frequency (default is Semiannual).

Details

This function is based on QuantLib Version 0.3.10. It introduces support for fixed-income instruments in RQuantLib.

Forward rates and zero rates are computed assuming continuous compounding, so the forward rate \( f \) over the period from \( t_1 \) to \( t_2 \) is determined by the relation

\[
d_1/d_2 = e^{f(t_2-t_1)},
\]

where \( d_1 \) and \( d_2 \) are discount factors corresponding to the two times. In the case of the zero rate \( t_1 \) is the current time (the spot date).

Curve construction can be a delicate problem and the algorithms may fail for some input data sets and/or some combinations of the values for interpWhat and interpHow. Fortunately, the C++ exception mechanism seems to work well with the R interface, and QuantLib exceptions are propagated back to the R user, usually with a message that indicates what went wrong. (The first part of the message contains technical information about the precise location of the problem in the QuantLib code. Scroll to the end to find information that is meaningful to the R user.)

Value

DiscountCurve returns a list containing:

times Vector of input times

discounts Corresponding discount factors

forwards Corresponding forward rates with time span \( dt \)

zerorates Corresponding zero coupon rates

flatQuotes True if a flat quote was used, False otherwise

params The input parameter list

EuropeanOption  European Option evaluation using Closed-Form solution

Description

The EuropeanOption function evaluates an European-style option on a common stock using the Black-Scholes-Merton solution. The option value, the common first derivatives ("Greeks") as well as the calling parameters are returned.

Usage

## Default S3 method:
EuropeanOption(type, underlying, strike,
  dividendYield, riskFreeRate, maturity, volatility,
  discreteDividends, discreteDividendsTimeUntil)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>

</tr>
</tbody>
</table>
Details
The well-known closed-form solution derived by Black, Scholes and Merton is used for valuation. Implied volatilities are calculated numerically.
Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value
The EuropeanOption function returns an object of class EuropeanOption (which inherits from class Option). It contains a list with the following components:

- value: Value of option
- delta: Sensitivity of the option value for a change in the underlying
- gamma: Sensitivity of the option delta for a change in the underlying
- vega: Sensitivity of the option value for a change in the underlying’s volatility
- theta: Sensitivity of the option value for a change in t, the remaining time to maturity
- rho: Sensitivity of the option value for a change in the risk-free interest rate
- dividendRho: Sensitivity of the option value for a change in the dividend yield

Note
The interface might change in future release as QuantLib stabilises its own API.

EuropeanOptionImpliedVolatility, EuropeanOptionArrays, AmericanOption, BinaryOption

Examples
```R
## simple call with unnamed parameters
EuropeanOption("call", 100, 100, 0.01, 0.03, 0.5, 0.4)
## simple call with some explicit parameters, and slightly increased vol:
EuropeanOption(type="call", underlying=100, strike=100, dividendYield=0.01, riskFreeRate=0.03, maturity=0.5, volatility=0.5)
## simple call with slightly shorter maturity: QuantLib 1.7 compiled with
## intra-day time calculation support with create slightly changed values
EuropeanOption(type="call", underlying=100, strike=100, dividendYield=0.01, riskFreeRate=0.03, maturity=0.499, volatility=0.5)
```
EuropeanOptionArrays  European Option evaluation using Closed-Form solution

Description

The EuropeanOptionArrays function allows any two of the numerical input parameters to be a vector, and a list of matrices is returned for the option value as well as each of the 'greeks'. For each of the returned matrices, each element corresponds to an evaluation under the given set of parameters.

Usage

EuropeanOptionArrays(type, underlying, strike, dividendYield, riskFreeRate, maturity, volatility)
oldEuropeanOptionArrays(type, underlying, strike, dividendYield, riskFreeRate, maturity, volatility)
plotOptionSurface(EOres, ylabel="", xlabel="", zlabel="", fov=60)

Arguments

type A string with one of the values call or put
underlying (Scalar or list) current price(s) of the underlying stock
strike (Scalar or list) strike price(s) of the option
dividendYield (Scalar or list) continuous dividend yield(s) (as a fraction) of the stock
riskFreeRate (Scalar or list) risk-free rate(s)
maturity (Scalar or list) time(s) to maturity (in fractional years)
volatility (Scalar or list) volatility(ies) of the underlying stock
EOres result matrix produced by EuropeanOptionArrays
ylabel label for y-axis
xlabel label for x-axis
zlabel label for z-axis
fov viewpoint for 3d rendering

Details

The well-known closed-form solution derived by Black, Scholes and Merton is used for valuation. Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.
Value

The EuropeanOptionArrays function allows any two of the numerical input parameters to be a vector or sequence. A list of two-dimensional matrices is returned. Each cell corresponds to an evaluation under the given set of parameters.

For these functions, the following components are returned:

- **value** (matrix) value of option
- **delta** (matrix) change in value for a change in the underlying
- **gamma** (matrix) change in value for a change in delta
- **vega** (matrix) change in value for a change in the underlying’s volatility
- **theta** (matrix) change in value for a change in delta
- **rho** (matrix) change in value for a change in time to maturity
- **dividendRho** (matrix) change in value for a change in delta
- **parameters** List with parameters with which object was created

The oldEuropeanOptionArrays function is an older implementation which vectorises this at the R level instead but allows more general multidimensional arrays.

Note

The interface might change in future release as QuantLib stabilises its own API.

plot(EOarr$parameters.underlying, EOarr$value[,1], type='n',
```
EuropeanOptionImpliedVolatility

Implied Volatility calculation for European Option

Description

The EuropeanOptionImpliedVolatility function solves for the (unobservable) implied volatility, given an option price as well as the other required parameters to value an option.

Usage

## Default S3 method:
EuropeanOptionImpliedVolatility(type, value, underlying, strike, dividendYield, riskFreeRate, maturity, volatility)

Arguments

type A string with one of the values call or put
value Value of the option (used only for ImpliedVolatility calculation)
underlying Current price of the underlying stock
strike Strike price of the option
dividendYield Continuous dividend yield (as a fraction) of the stock
riskFreeRate Risk-free rate
maturity Time to maturity (in fractional years)
volatility Initial guess for the volatility of the underlying stock
**Details**

The well-known closed-form solution derived by Black, Scholes and Merton is used for valuation. Implied volatilities are then calculated numerically. Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

**Value**

The `EuropeanOptionImpliedVolatility` function returns an numeric variable with volatility implied by the given market prices and given parameters.

**Note**

The interface might change in future release as QuantLib stabilises its own API.

<table>
<thead>
<tr>
<th>FittedBondCurve</th>
<th>Returns the discount curve (with zero rates and forwards) given set of bonds</th>
</tr>
</thead>
</table>

**Description**

`FittedBondCurve` fits a term structure to a set of bonds using three different fitting methodologies. For more detail, see QuantLib/Example/FittedBondCurve.

**Usage**

`FittedBondCurve(curveparams, lengths, coupons, marketQuotes, dateparams)`

**Arguments**

- `curveparams` curve parameters
method: a string, fitting methods: "ExponentialSplinesFitting",
   "SimplePolynomialFitting", "NelsonSiegelFitting"
origDate: a Date, starting date of the curve

lengths: an numeric vector, length of the bonds in year
coupons: a numeric vector, coupon rate of the bonds
marketQuotes: a numeric vector, market price of the bonds
dateparams: (Optional) a named list, QuantLib’s date parameters of the bond.

settlementDays: (Optional) a double, settlement days. Default value is 1.
dayCounter: (Optional) a number or string, day counter convention. See Enum. Default value is 'Thirty360'
period: (Optional) a number or string, interest compounding interval. See Enum. Default value is 'Semiannual'.
businessDayConvention: (Optional) a number or string, business day convention. See Enum. Default value is 'Following'.

See example below.

Details

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value

table, a three columns "date - zeroRate - discount" data frame

Examples

coupons <- c(0.0200, 0.0225, 0.0250, 0.0275, 0.0300, 0.0325, 0.0350, 0.0375, 0.0400, 0.0425,
FixedRateBond

0.0450, 0.0475, 0.0500, 0.0525, 0.0550
marketQuotes <- rep(100, length(lengths))
dateparams <- list(settlementDays=0, period="Annual",
dayCounter="ActualActual",
businessDayConvention ="Unadjusted")
curveparams <- list(method="ExponentialSplinesFitting",
origDate = Sys.Date())
curve <- FittedBondCurve(curveparams, lengths, coupons, marketQuotes, dateparams)
z <- zoo::zoo(curve$table$zeroRates, order.by=curve$table$date)
plot(z)

Description

The FixedRateBond function evaluates a fixed rate bond using discount curve, the yield or the clean price. More specifically, when a discount curve is provided the calculation is done by DiscountingBondEngine from QuantLib. The NPV, clean price, dirty price, accrued interest, yield, duration, actual settlement date and cash flows of the bond is returned. When a yield is provided instead, no engine is provided to the bond class and prices are computed from yield. In the latter case, NPV is set to NA. Same situation when the clean price is given instead of discount curve or yield. For more detail, see the source codes in QuantLib’s file test-suite/bond.cpp.

The FixedRateBondPriceByYield function calculates the theoretical price of a fixed rate bond from its yield.

The FixedRateBondYield function calculates the theoretical yield of a fixed rate bond from its price.

Usage

## Default S3 method:
FixedRateBond(bond, rates, schedule,
calc=list(dayCounter='ActualActual.ISMA',
compounding='Compounded',
freq='Annual',
durationType='Modified'),
discountCurve = NULL, yield = NA, price = NA)

## Default S3 method:
FixedRateBondPriceByYield( settlementDays=1, yield, faceAmount=100,
effectiveDate, maturityDate,
period, calendar="UnitedStates/GovernmentBond",
rates, dayCounter=2,
businessDayConvention=0, compound = 0, redemption=100,
issueDate)
## Default S3 method:

`FixedRateBondYield(settlementDays=1, price, faceAmount=100,`  
`    effectiveDate, maturityDate,`  
`    period, calendar="UnitedStates/GovernmentBond",`  
`    rates, dayCounter=2,`  
`    businessDayConvention=0,`  
`    compound = 0, redemption=100,`  
`    issueDate)`

### Arguments

- **bond** (Optional) bond parameters, a named list whose elements are:
  - **settlementDays** (Optional) a double, settlement days. Default value is 1.
  - **faceAmount** (Optional) a double, face amount of the bond. Default value is 100.
  - **dayCounter** (Optional) a number or string, day counter convention. Defaults to 'Thirty360'
  - **issueDate** (Optional) a Date, the bond’s issue date. Defaults to QuantLib default.
  - **paymentConvention** (Optional) a number or string, the bond payment convention. Defaults to QuantLib default.
  - **redemption** (Optional) a double, the redemption amount. Defaults to QuantLib default (100).
  - **paymentCalendar** (Optional) a string, the name of the calendar. Defaults to QuantLib default.
  - **exCouponPeriod** (Optional) a number, the number of days when the coupon goes ex relative to the coupon date. Defaults to QuantLib default.
  - **exCouponCalendar** (Optional) a string, the name of the ex-coupon calendar. Defaults to QuantLib default.
  - **exCouponConvention** (Optional) a number or string, the coupon payment convention. Defaults to QuantLib default.
  - **exCouponEndOfMonth** (Optional) 1 or 0, use End of Month rule for ex-coupon dates. Defaults to 0 (false).

- **rates** a numeric vector, bond’s coupon rates

- **schedule** (Optional) a named list, QuantLib’s parameters of the bond’s schedule.
  - **effectiveDate** a Date, when the schedule becomes effective.
  - **maturityDate** a Date, when the schedule matures.
  - **period** (Optional) a number or string, the frequency of the schedule. Default value is 'Semiannual'.
  - **calendar** (Optional) a string, the calendar name. Defaults to 'TARGET'

<tr>
<td>businessDayConvention</td>
<td>(Optional) a number or string, the day convention to use. Defaults to 'Following'.</td>
</tr>
<tr>
<td>terminationDateConvention</td>
<td>(Optional) a number or string, the day convention to use for the terminal date. Defaults to 'Following'.</td>
</tr>
<tr>
<td>dateGeneration</td>
<td>(Optional) a number or string, the date generation rule. Defaults to 'Backward'.</td>
</tr>
<tr>
<td>endOfMonth</td>
<td>(Optional) 1 or 0, use End of Month rule for schedule dates. Defaults to 0 (false).</td>
</tr>
</tbody>
</table>

See example below.

calc  (Optional) a named list, QuantLib’s parameters for calculations.

dayCounter  (Optional) a number or string, day counter convention. Defaults to 'ActualActual.ISMA'

compounding  a string, what kind of compounding to use. Defaults to 'Compounded'

dur  (Optional) a number or string, the frequency to use. Default value is 'Annual'.

durationType  (Optional) a number or string, the type of duration to calculate. Defaults to 'Simple'

accuracy  (Optional) a number, the accuracy required. Defaults to 1.0e-8.

maxEvaluations  (Optional) a number, max number of iterations. Defaults to 100.

discountCurve  Can be one of the following:

- a DiscountCurve  a object of DiscountCurve class For more detail, see example or the discountCurve function

- A 2 items list  specifies a flat curve in two values "todayDate" and "rate"

- A 3 items list  specifies three values to construct a DiscountCurve object, "params", "tsQuotes", "times". For more detail, see example or the discountCurve function

yield  yield of the bond

price  clean price of the bond

settlementDays  an integer, 1 for T+1, 2 for T+2, etc...

effectiveDate  bond’s effective date

maturityDate  bond’s maturity date
**FixedRateBond**

**Details**

A discount curve is built to calculate the bond value.

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

**Value**

The `FixedRateBond` function returns an object of class `FixedRateBond` (which inherits from class `Bond`). It contains a list with the following components:

- **NPV** net present value of the bond
- **cleanPrice** clean price of the bond
- **dirtyPrice** dirty price of the bond
- **accruedAmount** accrued amount of the bond
- **yield** yield of the bond
- **duration** the duration of the bond
- **settlementDate** the actual settlement date used for the bond
- **cashFlows** cash flows of the bond

The `FixedRateBondPriceByYield` function returns an object of class `FixedRateBondPriceByYield` (which inherits from class `Bond`). It contains a list with the following components:

- **price** price of the bond

The `FixedRateBondYield` function returns an object of class `FixedRateBondYield` (which inherits from class `Bond`). It contains a list with the following components:

- **yield** yield of the bond
Note

The interface might change in future release as QuantLib stabilises its own API.

Author(s)

Khanh Nguyen <knguyen@cs.umb.edu> for the implementation; Dirk Eddelbuettel <edd@debian.org> for the R interface; the QuantLib Group for QuantLib

FloatingRateBond Floating rate bond pricing

Description
The FloatingRateBond function evaluates a floating rate bond using discount curve. More specifically, the calculation is done by DiscountingBondEngine from QuantLib. The NPV, clean price, dirty price, accrued interest, yield and cash flows of the bond is returned. For more detail, see the source codes in quantlib's test-suite. test-suite/bond.cpp

Usage
## Default S3 method:
FloatingRateBond(bond, gearings, spreads,
    caps, floors, index,
    curve, dateparams )

Arguments
bond bond parameters, a named list whose elements are:

issueDate a Date, the bond’s issue date
maturityDate a Date, the bond’s maturity date
faceAmount (Optional) a double, face amount of the bond. Default value is 100.
redemption (Optional) a double, percentage of the initial face amount that will be returned at maturity date. Default value is 100.
effectiveDate (Optional) a Date, the bond’s effective date. Default value is issueDate

gearings (Optional) a numeric vector, bond’s gearings. See quantlib’s doc on FloatingRateBond for more detail. Default value is an empty vector c().

spreads (Optional) a numeric vector, bond’s spreads. See quantlib’s doc on Floating-
FloatingRateBond for more detail. Default value is an empty vector c()

caps (Optional) a numeric vector, bond’s caps. See quantlib’s doc on FloatingRateBond for more detail. Default value is an empty vector c()
floors (Optional) a numeric vector, bond’s floors. See quantlib’s doc on FloatingRateBond for more detail. Default value is an empty vector c()
curve Can be one of the following:
    a DiscountCurve a object of DiscountCurve class
    For more detail, see example or the discountCurve function
    A 2 items list specifies a flat curve in two values "todayDate" and "rate"
    A 3 items list specifies three values to construct a DiscountCurve object, "params", "tsQuotes", "times".
    For more detail, see example or the discountCurve function

index a named list whose elements are parameters of an IborIndex term structure.
    type a string, currently support only "USDLibor"
    length an integer, length of the index
    inTermOf a string, period unit, currently support only 'Month'
    term a DiscountCurve object, the term structure of the index

dateparams (Optional) a named list, QuantLib’s date parameters of the bond.
    settlementDays (Optional) a double, settlement days. Default value is 1.
    calendar (Optional) a string, either 'us' or 'uk' corresponding to US Goverment Bond calendar and UK Exchange calendar. Default value is 'us'.
    dayCounter (Optional) a number or string, day counter convention. See Enum. Default value is 'Thirty360'
    period (Optional) a number or string, interest compounding interval. See Enum. Default value is 'Semiannual'.
    businessDayConvention (Optional) a number or string, business day convention. See Enum. Default value is 'Following'.
    terminationDateConvention (Optional) a number or string, termination day convention. See Enum. Default value is 'Following'.
    endOfMonth (Optional) a numeric with value 1 or 0.
FloatingRateBond

\[ \text{FloatingRateBond} \]

End of Month rule. Default value is 0.

dateGeneration

(Optional) a numeric, date generation method. See Enum. Default value is 'Backward'

See example below.

Details

A discount curve is built to calculate the bond value.

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value

The `FloatingRateBond` function returns an object of class `FloatingRateBond` (which inherits from class `Bond`). It contains a list with the following components:

- NPV net present value of the bond
- cleanPrice clean price of the bond
- dirtyPrice dirty price of the bond
- accruedAmount accrued amount of the bond
- yield yield of the bond
- cashFlows cash flows of the bond

Note

The interface might change in future release as QuantLib stabilises its own API.

getQuantLibCapabilities

Return configuration options of the QuantLib library
**getQuantLibVersion**

**Description**

This function returns the QuantLib version string as encoded in the header file config.hpp and determined at compilation time of the QuantLib library.

**Usage**

`getQuantLibVersion()`

**Value**

A character variable

**Author(s)**

Dirk Eddelbuettel

**References**

http://quantlib.org for details on QuantLib.

**Examples**

```r
getQuantLibVersion()
```

---

**getQuantLibCapabilities**

**Description**

This function returns a named vector of boolean variables describing several configuration options determined at compilation time of the QuantLib library.

**Usage**

`getQuantLibCapabilities()`

**Details**

Not all of these features are used (yet) by RQuantLib.

**Value**

A named vector of logical variables

**Author(s)**

Dirk Eddelbuettel

**References**

http://quantlib.org for details on QuantLib.

**Examples**

```r
getQuantLibCapabilities()
```
ImpliedVolatility

References

http://quantlib.org for details on QuantLib.

Examples

getQuantLibVersion()

ImpliedVolatility Base class for option-price implied volatility evaluation

Description

This class forms the basis from which the more specific classes are derived.

Usage

## S3 method for class 'ImpliedVolatility'
print(x, digits=3, ...)
## S3 method for class 'ImpliedVolatility'
summary(object, digits=3, ...)

Arguments

x Any option-price implied volatility object derived from this base class
object Any option-price implied volatility object derived from this base class
digits Number of digits of precision shown
... Further arguments

Details

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value

None, but side effects of displaying content.

Note

The interface might change in future release as QuantLib stabilises its own API.

print(impVol)
summary(impVol)

Option

Base class for option price evaluation

Description
This class forms the basis from which the more specific classes are derived.

Usage
## S3 method for class 'Option'
print(x, digits=4, ...)
## S3 method for class 'Option'
plot(x, ...)
## S3 method for class 'Option'
summary(object, digits=4, ...)

Arguments
x  Any option object derived from this base class
object  Any option object derived from this base class
digits  Number of digits of precision shown
...  Further arguments

Details
Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value
None, but side effects of displaying content.

Note
The interface might change in future release as QuantLib stabilises its own API.
SabrSwaption

print(EO)
summary(EO)

SabrSwaption

SABR swaption using vol cube data with bermudan alternative using markovfunctional

Description
SabrSwaption prices a swaption with specified expiration or time range if Bermudan, strike, and maturity, using quantlibs SABR model for europeans and quantlib’s markovfunctional for Bermudans. Currently the input is a zero offset log-normal vol surface. An example of a dataset can be found in the dataset rqlib included with Rquantlib. It is assumed that the swaption is exercisable at the start of a forward start swap if params$european flag is set to TRUE or starting immediately on each reset date (Bermudan) of an existing underlying swap or spot start swap if params$european flag is set to FALSE.

Usage
SabrSwaption(params, ts, volCubeDF,
legparams = list(dayCounter = "Thirty360", fixFreq = "Annual", floatFreq = "Semiannual"),
    tsUp01 = NA, tsDn01 = NA, vega = FALSE)

Arguments
params A list specifying the tradeDate (month/day/year), settlementDate, logical flags payFixed & european (european=FALSE generates Bermudan vlaue), strike, pricing method, and curve construction options (see Examples section below). Curve construction options are interpWhat (possible values are discount, forward, and zero) and interpHow (possible values are linear, loglinear, and spline). Both interpWhat and interpHow are ignored when a flat yield curve is requested, but they must be present nevertheless.
SabrSwaption

**ts**
A term structure built with DiscountCurve is required. See the help page for `DiscountCurve` and example below for details.

**volCubeDF**
The swaption volatility cube in dataframe format with columns Expiry, Tenor, Spread, and LogNormalVol stored by rows. See the example below.

**legparams**
A list specifying the `dayCounter` the day count convention for the fixed leg (default is Thirty360), and `fixFreq`, fixed coupon frequency (default is Annual), `floatFreq`, floating leg reset frequency (default is Semiannual).

**tsUp01**
Discount for a user specified up move in rates.

**tsDn01**
Discount for a user specified down move in rates.

**vega**
Discount for a user specified up move.

**Details**
This function is based on QuantLib Version 1.64. It introduces support for fixed-income instruments in RQuantLib.

**Value**
`SabrSwaption` returns a list containing the value of the payer and receiver swaptions at the strike specified in `params`.

**NPV**
NPV of swaption in basis points (actual price equals price times notional divided by 10,000)

**strike**
swaption strike

**params**
Input parameter list

**atmRate**
fair rate for swap at swap start date for european or fair swap rate for swap at expiration for bermudan

**vol**
vol for swaption at swap start date and rate strike for european or vol for swaption for given expiration and strike for bermudan

**rcvDv01**
receiver value for a change in rates defined by dv01Up

**payDv01**
payer value for a change in rates defined by dv01Up

**rcvCnvx**
receiver second order value change for a change in rates defined by dv01Up & dv01Dn

**payCnvx**
payer second order value for a change in rates defined by dv01Up & dv01Dn

**strike**
swaption strike

**Author(s)**
Terry Leitch

### Schedule

**Schedule generation**

The Schedule function generates a schedule of dates conformant to a given convention in a given calendar.

**Usage**

```r
## Default S3 method:
Schedule(params)
```
Arguments

params a named list, QuantLib’s parameters of the schedule.

effectiveDate a Date, when the schedule becomes effective.
maturityDate a Date, when the schedule matures.
period (Optional) a number or string, the frequency of the schedule. Default value is ‘Semiannual’.
calendar (Optional) a string, the calendar name. Defaults to ‘TARGET’
businessDayConvention (Optional) a number or string, the day convention to use. Defaults to ‘Following’.
terminationDateConvention (Optional) a number or string, the day convention to use for the terminal date. Defaults to ‘Following’.
dateGeneration (Optional) a number or string, the date generation rule. Defaults to ‘Backward’.
endOfMonth (Optional) 1 or 0, use End of Month rule for schedule dates. Defaults to 0 (false).

See example below.

Details

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value

The Schedule function returns an object of class Schedule. It contains the list of dates in the schedule.

Author(s)

ZeroCouponBond

---

ZeroCouponBond  Zero-Coupon bond pricing

---

**Description**

The ZeroCouponBond function evaluates a zero-coupon plainly using discount curve. More specifically, the calculation is done by DiscountingBondEngine from QuantLib. The NPV, clean price, dirty price, accrued interest, yield and cash flows of the bond is returned. For more detail, see the source code in the QuantLib file test-suite/bond.cpp.

The ZeroPriceYield function evaluates a zero-coupon clean price based on its yield.

The ZeroYield function evaluations a zero-coupon yield based. See also http://www.mathworks.com/access/helpdesk/help/toolbox/finfixed/zeroyield.html

**Usage**

```r
## Default S3 method:
ZeroCouponBond(bond, discountCurve, dateparams)

## Default S3 method:
ZeroPriceByYield(yield, faceAmount,
                  issueDate, maturityDate,
                  dayCounter=2, frequency=2,
                  compound=0, businessDayConvention=4)

## Default S3 method:
ZeroYield(price, faceAmount,
          issueDate, maturityDate,
          dayCounter=2, frequency=2,
          compound=0, businessDayConvention=4)
```

**Arguments**

- `bond`  
  bond parameters, a named list whose elements are:
  - `issueDate`  a Date, the bond’s issue date
  - `maturityDate`  a Date, the bond’s maturity date
  - `faceAmount`  (Optional) a double, face amount of the bond. Default value is 100.
  - `redemption`  (Optional) a double, percentage of the initial face amount that will be returned at maturity date. Default value is 100.

- `discountCurve`  
  Can be one of the following:
  - a DiscountCurve  a object of DiscountCurve class
```
For more detail, see example or
A 2 items list specifies a flat curve in two values "todayDate" and "rate"
A 3 items list specifies three values to construct a DiscountCurve object, "params", "tsQuotes", "times".
For more detail, see example or the discountCurve function

dateparams (Optional) a named list, QuantLib’s date parameters of the bond.

settlementDays (Optional) a double, settlement days.
Default value is 1.
calendar (Optional) a string, either 'us' or 'uk' corresponding to US Government Bond calendar and UK Exchange calendar.
Default value is 'us'.
businessDayConvention (Optional) a number or string, business day convention.
See Enum. Default value is 'Following'.

See example below.
yield yield of the bond
price price of the bond
faceAmount face amount of the bond
issueDate date the bond is issued
maturityDate maturity date, an R’s date type
dayCounter day count convention. 0 = Actual360(), 1 = Actual365Fixed(), 2 = ActualActual(), 3 = Business252(), 4 = OneDayCounter(), 5 = SimpleDayCounter(), all other = Thirty360(). For more information, see QuantLib’s DayCounter class
frequency frequency of events, 0 = NoFrequency, 1 = Once, 2 = Annual, 3 = Semiannual, 4 = EveryFourthMonth, 5 = Quarterly, 6 = Bimonthly, 7 = Monthly, 8 = EveryFourthWeekly, 9 = Biweekly, 10 = Weekly, 11 = Daily. For more information, see QuantLib’s Frequency class
compound compounding type. 0 = Simple, 1 = Compounded, 2 = Continuous, all other = SimpleThenCompounded. See QuantLib’s Compound class
businessDayConvention convention used to adjust a date in case it is not a valid business day. See quantlib for more detail. 0 = Following, 1 = ModifiedFollowing, 2 = Preceding, 3 = ModifiedPreceding, other = Unadjusted

Details

A discount curve is built to calculate the bond value.

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.
**Value**

The ZeroCouponBond function returns an object of class ZeroCouponBond (which inherits from class Bond). It contains a list with the following components:

- **NPV**: net present value of the bond
- **cleanPrice**: clean price of the bond
- **dirtyPrice**: dirty price of the bond
- **accruedAmount**: accrued amount of the bond
- **yield**: yield of the bond
- **cashFlows**: cash flows of the bond

The ZeroPriceByYield function returns an object of class ZeroPriceByYield (which inherits from class Bond). It contains a list with the following components:

- **price**: price of the bond

The ZeroYield function returns an object of class ZeroYield (which inherits from class Bond). It contains a list with the following components:

- **yield**: yield of the bond

**Note**

The interface might change in future release as QuantLib stabilises its own API.

**Author(s)**

Khanh Nguyen <knguyen@cs.umb.edu> for the implementation; Dirk Eddelbuettel <edd@debian.org> for the R interface; the QuantLib Group for QuantLib

**References**

http://quantlib.org for details on QuantLib.

**Examples**

```r
# Simple call with all parameter and a flat curve
bond <- list(faceAmount=100, issueDate=as.Date("2004-11-30"),
             maturityDate=as.Date("2008-11-30"), redemption=100 )
dateparams <- list(settlementDays=1, calendar="UnitedStates/GovernmentBond",
                   businessDayConvention='Unadjusted')
discountCurve.param <- list(tradeDate=as.Date('2002-2-15'),
                             settleDate=as.Date('2002-2-15'),
                             dt=0.25,
                             interpWhat='discount', interpHow='loglinear')
discountCurve.flat <- DiscountCurve(discountCurve.param, list(flat=0.05))
```
ZeroCouponBond(bond, discountCurve.flat, dateparams)

# The same bond with a discount curve constructed from market quotes
tsQuotes <- list(d1w =0.0382,
                 d1m =0.0372,
                 fut1=96.2875,
                 fut2=96.7875,
                 fut3=96.9875,
                 fut4=96.6875,
                 fut5=96.4875,
                 fut6=96.3875,
                 fut7=96.2875,
                 fut8=96.0875,
                 s3y =0.0398,
                 s5y =0.0443,
                 s10y =0.05165,
                 s15y =0.055175)
tsQuotes <- list("flat" = 0.02) ## While discount curve code is buggy
discountCurve <- DiscountCurve(discountCurve.param, tsQuotes)
ZeroCouponBond(bond, discountCurve, dateparams)

#examples with default arguments
ZeroCouponBond(bond, discountCurve)

bond <- list(issueDate=as.Date("2004-11-30"),
              maturityDate=as.Date("2008-11-30"))
dateparams <-list(settlementDays=1)
ZeroCouponBond(bond, discountCurve, dateparams)

ZeroPriceByYield(0.1478, 100, as.Date("1993-6-24"), as.Date("1993-11-1"))

ZeroYield(90, 100, as.Date("1993-6-24"), as.Date("1993-11-1"))
