Package ‘RQuantLib’

December 3, 2015

Title R Interface to the ‘QuantLib’ Library
Version 0.4.2
Date 2015-12-03
Maintainer Dirk Eddelbuettel <edd@debian.org>
Author Dirk Eddelbuettel, Khanh Nguyen (during 2009-2010)
Description The ‘RQuantLib’ package makes parts of ‘QuantLib’ accessible from R
The ‘QuantLib’ project aims to provide a comprehensive software framework
for quantitative finance. The goal is to provide a standard open source library
for quantitative analysis, modeling, trading, and risk management of financial
assets.
Depends R (>= 2.10.0)
Suggests rgl, zoo, RUnit, shiny
Imports methods, Rcpp (>= 0.11.0), stats, graphics
LinkingTo Rcpp
SystemRequirements QuantLib library (>= 1.4.0) from
License GPL (>= 2)
URL http://quantlib.org
http://dirk.eddelbuettel.com/code/rquantlib.html
RoxygenNote 5.0.1
NeedsCompilation yes
Repository CRAN
Date/Publication 2015-12-03 16:24:34

R topics documented:

AmericanOption

American Option evaluation using Finite Differences

Description
This function evaluations an American-style option on a common stock using finite differences.
The option value as well as the common first derivatives ("Greeks") are returned.

Usage

```
# Default S3 method:
AmericanOption(type, underlying, strike,
              dividendYield, riskFreeRate, maturity, volatility,
              timeSteps=150, gridPoints=149, engine="BaroneAdesiWhaley")
```

Arguments

- **type** A string with one of the values call or put
- **underlying** Current price of the underlying stock
- **strike** Strike price of the option
- **dividendYield** Continuous dividend yield (as a fraction) of the stock
- **riskFreeRate** Risk-free rate
AmericanOption

- **maturity**: Time to maturity (in fractional years)
- **volatility**: Volatility of the underlying stock
- **timeSteps**: Time steps for the “CrankNicolson” finite differences method engine, default value is 150
- **gridPoints**: Grid points for the “CrankNicolson” finite differences method, default value is 149
- **engine**: String selecting pricing engine, currently supported are “BaroneAdesiWhaley” and “CrankNicolson”

**Details**

The Finite Differences method is used to value the American Option. Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

**Value**

An object of class AmericanOption (which inherits from class Option) is returned. It contains a list with the following components:

- **value**: Value of option
- **delta**: Sensitivity of the option value for a change in the underlying
- **gamma**: Sensitivity of the option delta for a change in the underlying
- **vega**: Sensitivity of the option value for a change in the underlying’s volatility
- **theta**: Sensitivity of the option value for a change in t, the remaining time to maturity
- **rho**: Sensitivity of the option value for a change in the risk-free interest rate
- **dividendRho**: Sensitivity of the option value for a change in the dividend yield

Note that under the new pricing framework used in QuantLib, pricers do not provide analytics for all ‘Greeks’. When “CrankNicolson” is selected, then at least delta, gamma and vega are available. With the default pricing engine of “BaroneAdesiWhaley”, no greeks are returned.

**Note**

The interface might change in future release as QuantLib stabilises its own API.

**Author(s)**

Dirk Eddelbuettel <edd@debian.org> for the R interface; the QuantLib Group for QuantLib

**References**

http://quantlib.org for details on QuantLib.

**See Also**

EuropeanOption
Examples

# simple call with unnamed parameters
AmericanOption("call", 100, 100, 0.02, 0.03, 0.5, 0.4)
# simple call with some explicit parameters
AmericanOption("put", strike=100, volatility=0.4, 100, 0.02, 0.03, 0.5)
# simple call with unnamed parameters, using Crank-Nicolons
AmericanOption("put", strike=100, volatility=0.4, 100, 0.02, 0.03, 0.5, engine="CrankNicolson")

AmericanOptionImpliedVolatility
Implied Volatility calculation for American Option

Description

The AmericanOptionImpliedVolatility function solves for the (unobservable) implied volatility, given an option price as well as the other required parameters to value an option.

Usage

## Default S3 method:
AmericanOptionImpliedVolatility(type, value, 
underlying, strike,dividendYield, riskFreeRate, maturity, volatility, 
timeSteps=150, gridPoints=151)

Arguments

type A string with one of the values call or put
value Value of the option (used only for ImpliedVolatility calculation)
underlying Current price of the underlying stock
strike Strike price of the option
dividendYield Continuous dividend yield (as a fraction) of the stock
riskFreeRate Risk-free rate
maturity Time to maturity (in fractional years)
volatility Initial guess for the volatility of the underlying stock
timeSteps Time steps for the Finite Differences method, default value is 150
gridPoints Grid points for the Finite Differences method, default value is 151

Details

The Finite Differences method is used to value the American Option. Implied volatilities are then calculated numerically.

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.
AsianOption

Value

The `AmericanOptionImpliedVolatility` function returns a numeric variable with volatility implied by the given market prices and given parameters.

Note

The interface might change in future release as QuantLib stabilises its own API.

Author(s)

Dirk Eddelbuettel <edd@debian.org> for the R interface; the QuantLib Group for QuantLib

http://quantlib.org for details on QuantLib.

See Also

`EuropeanOption`, `AmericanOption`, `BinaryOption`

Examples

```r
AmericanOptionImpliedVolatility(type="call", value=11.10, underlying=100, strike=100, dividendYield=0.01, riskFreeRate=0.03,
maturity=0.5, volatility=0.4)
```

---

**AsianOption**

*Asian Option evaluation using Closed-Form solution*

Description

The `AsianOption` function evaluates an Asian-style option on a common stock using an analytic solution for continuous geometric average price. The option value, the common first derivatives ("Greeks") as well as the calling parameters are returned.

Usage

```r
## Default S3 method:
AsianOption(averageType, type, underlying, strike,
            dividendYield, riskFreeRate, maturity,
            volatility, first=0, length=11.0/12.0, fixings=26)
```
AsianOption

Arguments

averageType Specify averaging type, either “geometric” or “arithmetic”
type A string with one of the values call or put
underlying Current price of the underlying stock
strike Strike price of the option
dividendYield Continuous dividend yield (as a fraction) of the stock
riskFreeRate Risk-free rate
maturity Time to maturity (in fractional years)
volatility Volatility of the underlying stock
first (Only for arithmetic averaging) Time step to first average, can be zero
length (Only for arithmetic averaging) Total time length for averaging period
fixings (Only for arithmetic averaging) Total number of averaging fixings

details
When "arithmetic" evaluation is used, only the NPV() is returned.
The well-known closed-form solution derived by Black, Scholes and Merton is used for valuation. Implied volatilities are calculated numerically.
Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value

The AsianOption function returns an object of class AsianOption (which inherits from class Option). It contains a list with the following components:

value Value of option
delta Sensitivity of the option value for a change in the underlying
gamma Sensitivity of the option delta for a change in the underlying
vega Sensitivity of the option value for a change in the underlying’s volatility
theta Sensitivity of the option value for a change in t, the remaining time to maturity
rho Sensitivity of the option value for a change in the risk-free interest rate
dividendRho Sensitivity of the option value for a change in the dividend yield

Note

The interface might change in future release as QuantLib stabilises its own API.

Author(s)

Dirk Eddelbuettel <edd@debian.org> for the R interface; the QuantLib Group for QuantLib
BarrierOption

References

http://quantlib.org for details on QuantLib.

Examples

# simple call with some explicit parameters, and slightly increased vol:
AsianOption("geometric", "put", underlying=80, strike=85, div=-0.03,
            riskFree=0.05, maturity=0.25, vol=0.2)

Description

This function evaluates an Barrier option on a common stock using a closed-form solution. The
option value as well as the common first derivatives ("Greeks") are returned.

Usage

## Default S3 method:
BarrierOption(barrType, type, underlying, strike,
              dividendYield, riskFreeRate, maturity,
              volatility, barrier, rebate=0.0)

Arguments

- **barrType**: A string with one of the values downin, downout, upin or upout
- **type**: A string with one of the values call or put
- **underlying**: Current price of the underlying stock
- **strike**: Strike price of the option
- **dividendYield**: Continuous dividend yield (as a fraction) of the stock
- **riskFreeRate**: Risk-free rate
- **maturity**: Time to maturity (in fractional years)
- **volatility**: Volatility of the underlying stock
- **barrier**: Option barrier value
- **rebate**: Optional option rebate, defaults to 0.0

Details

A closed-form solution is used to value the Barrier Option. In the case of Barrier options, the
calculations are from Haug’s "Option pricing formulas" book (McGraw-Hill).

Please see any decent Finance textbook for background reading, and the QuantLib documentation
for details on the QuantLib implementation.
Value

An object of class `BarrierOption` (which inherits from class `Option`) is returned. It contains a list with the following components:

- **value**: Value of option
- **delta**: Sensitivity of the option value for a change in the underlying
- **gamma**: Sensitivity of the option delta for a change in the underlying
- **vega**: Sensitivity of the option value for a change in the underlying’s volatility
- **theta**: Sensitivity of the option value for a change in \( t \), the remaining time to maturity
- **rho**: Sensitivity of the option value for a change in the risk-free interest rate
- **dividendRho**: Sensitivity of the option value for a change in the dividend yield

Note that under the new pricing framework used in QuantLib, binary pricers do not provide analytics for ‘Greeks’. This is expected to be addressed in future releases of QuantLib.

Note

The interface might change in future release as QuantLib stabilises its own API.

`AmericanOption`, `EuropeanOption`

Examples

```r
BarrierOption(barrType="downin", type="call", underlying=100, strike=100, dividendYield=0.02, riskFreeRate=0.03, maturity=0.5, volatility=0.4, barrier=90)
```
BermudanSwaption

Bermudan swaption valuation using several short-rate models

Description

BermudanSwaption prices a Bermudan swaption with specified strike and maturity (in years), after calibrating the selected short-rate model to an input swaption volatility matrix. Swaption maturities are in years down the rows, and swap tenors are in years along the columns, in the usual fashion. It is assumed that the Bermudan swaption is exercisable on each reset date of the underlying swaps.

Usage

BermudanSwaption(params, tsQuotes, swaptionMaturities, swapTenors, volMatrix)

Arguments

- **params**
  - A list specifying the **tradeDate** (month/day/year), **settlementDate**, **payFixed** flag, **strike**, **pricing** method, and curve construction options (see Examples section below). Curve construction options are **interpWhat** (possible values are **discount**, **forward**, and **zero**) and **interpHow** (possible values are **linear**, **loglinear**, and **spline**). Both **interpWhat** and **interpHow** are ignored when a flat yield curve is requested, but they must be present nevertheless. The pricing method can be one of the following (all short-rate models):
    - **G2Analytic** G2 2-factor Gaussian model using analytic formulas.
    - **HWAnalytic** Hull-White model using analytic formulas.
    - **HWTREE** Hull-White model using a tree.
    - **BKTree** Black-Karasinski model using a tree.

- **tsQuotes**
  - Market observables needed to construct the spot term structure of interest rates. A list of name/value pairs. See the help page for **DiscountCurve** for details.

- **swaptionMaturities**
  - A vector containing the swaption maturities associated with the rows of the swaption volatility matrix.

- **swapTenors**
  - A vector containing the underlying swap tenors associated with the columns of the swaption volatility matrix.

- **volMatrix**
  - The swaption volatility matrix. Must be a 2D matrix stored by rows. See the example below.

Details

This function is based on QuantLib Version 0.3.10. It introduces support for fixed-income instruments in RQuantLib.

At present only a small number of the many parameters that can be set in QuantLib are exposed by this function. Some of the hard-coded parameters that apply to the current version include:
day-count conventions, fixing days (2), index (Euribor), fixed leg frequency (annual), and floating leg frequency (semi-annual). Also, it is assumed that the swaption volatility matrix corresponds to expiration dates and tenors that are measured in years (a 6-month expiration date is not currently supported, for example).

Given the number of parameters that must be specified and the care with which they must be specified (with no defaults), it is not practical to use this function in the usual interactive fashion.

The simplest approach is simply to save the example below to a file, edit as desired, and source the result. Alternatively, the input commands can be kept in a script file (under Windows) or an Emacs/ESS session (under Linux), and selected parts of the script can be executed in the usual way.

Fortunately, the C++ exception mechanism seems to work well with the R interface, and QuantLib exceptions are propagated back to the R user, usually with a message that indicates what went wrong. (The first part of the message contains technical information about the precise location of the problem in the QuantLib code. Scroll to the end to find information that is meaningful to the R user.)

Value

BermudanSwaption returns a list containing calibrated model parameters (what parameters are returned depends on the model selected) along with:

- price: Price of swaption in basis points (actual price equals price times notional divided by 10,000)
- ATMStrike: At-the-money strike
- params: Input parameter list

Author(s)

Dominick Samperi

References

For information about QuantLib see [http://quantlib.org](http://quantlib.org).

See Also

- DiscountCurve

Examples

```r
# This data is taken from sample code shipped with QuantLib 0.3.10.
params <- list(tradeDate=as.Date('2002-2-15'),
               settleDate=as.Date('2002-2-19'),
               payFixed=TRUE,
               strike=.06,
               ...),
```
Description

This function evaluates an Binary option on a common stock using a closed-form solution. The option value as well as the common first derivatives ("Greeks") are returned.
Usage

```r
## Default S3 method:
BinaryOption(binType, type, excType, underlying, 
  strike, dividendYield, 
  riskFreeRate, maturity, volatility, cashPayoff)
```

Arguments

- **binType** A string with one of the values `cash`, `asset` or `gap` to select CashOrNothing, AssetOrNothing or Gap payoff profiles
- **type** A string with one of the values `call` or `put`
- **excType** A string with one of the values `european` or `american` to denote the exercise type
- **underlying** Current price of the underlying stock
- **strike** Strike price of the option
- **dividendYield** Continuous dividend yield (as a fraction) of the stock
- **riskFreeRate** Risk-free rate
- **maturity** Time to maturity (in fractional years)
- **volatility** Volatility of the underlying stock
- **cashPayoff** Payout amount

Details

A closed-form solution is used to value the Binary Option.

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value

An object of class `BinaryOption` (which inherits from class `Option`) is returned. It contains a list with the following components:

- **value** Value of option
- **delta** Sensitivity of the option value for a change in the underlying
- **gamma** Sensitivity of the option delta for a change in the underlying
- **vega** Sensitivity of the option value for a change in the underlying’s volatility
- **theta** Sensitivity of the option value for a change in t, the remaining time to maturity
- **rho** Sensitivity of the option value for a change in the risk-free interest rate
- **dividendRho** Sensitivity of the option value for a change in the dividend yield

Note

The interface might change in future release as QuantLib stabilises its own API.

Bond

Base class for Bond price evaluation

Description
This class forms the basis from which the more specific classes are derived.

Usage
## S3 method for class 'Bond'
print(x, digits=5, ...)
## S3 method for class 'FixedRateBond'
print(x, digits=5, ...)
## S3 method for class 'Bond'
plot(x, ...)
## S3 method for class 'Bond'
summary(object, digits=5, ...)
Arguments

x   Any Bond object derived from this base class
object   Any Bond object derived from this base class
digits   Number of digits of precision shown
...   Further arguments

Details

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value

None, but side effects of displaying content.

Note

The interface might change in future release as QuantLib stabilises its own API.

Description

These functions are using internally to convert from the characters at the R level to the enum types used at the C++ level. They are documented here mostly to provide a means to look up some of the possible values—the user is not expected to call these functions directly.

Usage

matchBDC(bdc = c("Following", "ModifiedFollowing", "Preceding", "ModifiedPreceding", "Unadjusted"))
matchCompounding(cp = c("Simple", "Compounded", "Continuous", "SimpleThenCompounded"))
matchDateGen(dg = c("Backward", "Forward", "Zero", "ThirdWednesday", "Twentieth", "TwentiethIMM"))
matchParams(params)

Arguments

bdc A string identifying one of the possible business day convention values.
cp A string identifying one of the possible compounding frequency values.
daycounter A string identifying one of the possible day counter scheme values.
Calendars

dg  A string identifying one of the possible date generation scheme values.

freq A string identifying one of the possible (dividend) frequency values.

params A named vector containing the other parameters as components.

Details

The QuantLib documentation should be consulted for details.

Value

Each function converts the given character value into a corresponding numeric entry. For `matchParams`, an named vector of strings is converted into a named vector of numerics.

Note

The interface might change in future release as QuantLib stabilises its own API.

Author(s)

____________

Calendars  Calendar functions from QuantLib
____________

Description

The `isBusinessDay` function evaluates the given dates in the context of the given calendar, and returns a vector of booleans indicating business day status. `BusinessDay` is also recognised (but may be deprecated one day).

The `isHoliday` function evaluates the given dates in the context of the given calendar, and returns a vector of booleans indicating holiday day status.

The `isWeekend` function evaluates the given dates in the context of the given calendar, and returns a vector of booleans indicating weekend status.

The `isEndOfMonth` function evaluates the given dates in the context of the given calendar, and returns a vector of booleans indicating end of month status.

The `getEndOfMonth` function evaluates the given dates in the context of the given calendar, and returns a vector that corresponds to the end of month. `endOfMonth` is a deprecated form for this function.

The `getHolidayList` function returns the holidays between the given dates, with an option to exclude weekends. `holidayList` is a deprecated form for this function.
The `adjust` function evaluates the given dates in the context of the given calendar, and returns a vector that adjusts each input date to the appropriate near business day with respect to the given convention.

The `advance` function evaluates the given dates in the context of the given calendar, and returns a vector that advances the given dates of the given number of business days and returns the result. This function gets called either with both argument `n` and `timeUnit`, or with argument `period`.

The `businessDaysBetween` function evaluates two given dates in the context of the given calendar, and returns a vector that gives the number of business days between.

The `dayCount` function returns the number of day between two dates given a day counter, see `Enum`.

The `yearFraction` function returns year fraction between two dates given a day counter, see `Enum`.

The `setCalendarContext` function sets three values to a singleton instance at the C++ layer.

The `setEvaluationDate` function sets the evaluation date used by the QuantLib pricing engines.

The `advanceDate` function advances the given date by the given number of days in the current calendar instance.

**Usage**

```c
isBusinessDay(calendar, dates)
businessDay(calendar="TARGET", dates=Sys.Date())  # deprecated form
isholiday(calendar, dates)
isWeekend(calendar, dates)
isEndOfMonth(calendar, dates)
getEndOfMonth(calendar, dates)
endOfMonth(calendar="TARGET", dates=Sys.Date())
getHolidayList(calendar, from, to, includeWeekends=FALSE)
holidayList(calendar="TARGET", from=Sys.Date(), to = Sys.Date() + 5,
includeWeekends = FALSE)
adjust(calendar, dates, bdc = 0L)
advance(calendar="TARGET", dates=Sys.Date(), n, timeUnit, period, bdc = 0, emr =0)

businessDaysBetween(calendar, from, to, includeFirst = TRUE, includeLast = FALSE)
dayCount(startDates, endDates, dayCounters)
yearFraction(startDates, endDates, dayCounters)
setCalendarContext(calendar, fixingDays, settleDate)
setEvaluationDate(evalDate)
```

**Arguments**

- `calendar` A string identifying one of the supported QuantLib calendars, see Details for more.
- `dates` A vector (or scalar) of Date types.
- `from` A vector (or scalar) of Date types.
- `to` A vector (or scalar) of Date types.
- `includeWeekends` boolean that indicates whether the calculation should include the weekends. Default = false
**fixingDays**  
An integer for the fixing day period, defaults to 2.

**settleDate**  
A date on which trades settles, defaults to two days after the current day.

**n**  
an integer number

**timeUnit**  
A value of 0,1,2,3 that corresponds to Days, Weeks, Months, and Year; for more detail, see the QuantLib documentation at [http://quantlib.org/reference/group__datetime.html](http://quantlib.org/reference/group__datetime.html)

**period**  
See Enum

**bdc**  
Business day convention. By default, this value is 0 and correspond to Following convention

**emr**  
End Of Month rule, default is false

**includeFirst**  
boolean that indicates whether the calculation should include the first day. Default = true

**includeLast**  
Default = false

**startDates**  
A vector of Date type.

**endDates**  
A vector of Date type.

**dayCounters**  
A vector of numeric type. See Enum

**evalDate**  
A single date used for the pricing valuations.

### Details

The calendars are coming from QuantLib, and the QuantLib documentation should be consulted for details.

Currently, the following strings are recognised: TARGET (a default calendar), Argentina, Australia, Brazil, Canada and Canada/Settlement, Canada/TSX, China, CzechRepublic, Denmark, Finland, Germany and Germany/FrankfurtStockExchange, Germany/Settlement, Germany/Xetra, Germany/Eurex, HongKong, Hungary, Iceland, India, Indonesia, Italy and Italy/Settlement, Italy/Exchange, Japan, Mexico, NewZealand, Norway, Poland, Russia, SaudiArabia, Singapore, Slovakia, SouthAfrica, SouthKorea, SouthKorea/KRX, Sweden, Switzerland, Taiwan, Turkey, Ukraine, UnitedKingdom and UnitedKingdom/Settlement, UnitedKingdom/Exchange, UnitedKingdom/Metals, UnitedStates and UnitedStates/Settlement, UnitedStates/NYSE, UnitedStates/GovernmentBond, UnitedStates/NERC and WeekendsOnly.

(In case of multiples entries per country, the country default is listed right after the country itself. Using the shorter form is equivalent.)

### Value

A named vector of booleans each of which is true if the corresponding date is a business day (or holiday or weekend) in the given calendar. The element names are the dates (formatted as text in yyyy-mm-dd format).

For `setCalendarContext`, a boolean or NULL in case of error.

### Note

The interface might change in future release as QuantLib stabilises its own API.

CallableBond

CallableBond evaluation

Description

The CallableBond function sets up and evaluates a callable fixed rate bond using Hull-White model and a TreeCallableFixedBondEngine pricing engine. For more detail, see the source codes in quantlib's example folder, Examples/CallableBond/CallableBond.cpp

Usage

## Default S3 method:
CallableBond(bondparams, hullWhite, coupon, dateparams)

Arguments

bondparams a named list whose elements are:

- **issueDate** a Date, the bond's issue date
- **maturityDate** a Date, the bond's maturity date
- **faceAmount** (Optional) a double, face amount of the bond. Default value is 100.
- **redemption** (Optional) a double, percentage of the initial face amount that will be returned at maturity date. Default value is 100.
- **callSch** (Optional) a data frame whose columns are "Price", "Type" and "Date" corresponding to QuantLib's CallabilitySchedule. Default is an empty frame, or no callability.

hullWhite a named list whose elements are parameters needed to set up a HullWhite pricing
CallableBond

engine in QuantLib:

term a double, to set up a flat rate yield term structure
alpha a double, Hull-White model’s alpha value
sigma a double, Hull-White model’s sigma value
gridIntervals a double, time intervals parameter to set up the TreeCallableFixedBondEngine

currently, the codes only support a flat rate yield term structure. For more detail, see QuantLib’s doc on HullWhite and TreeCallableFixedBondEngine.

coupon a numeric vector of coupon rates
dateparams (Optional) a named list, QuantLib’s date parameters of the bond.

settlementDays (Optional) a double, settlement days. Default value is 1.
calendar (Optional) a string, either ‘us’ or ‘uk’ corresponding to US Goverment Bond calendar and UK Exchange calendar. Default value is ‘us’.
dayCounter (Optional) a number or string, day counter convention. See Enum. Default value is ‘Thirty360’
period (Optional) a number or string, interest compounding interval. See Enum. Default value is ‘Semiannual’.
businessDayConvention (Optional) a number or string, business day convention. See Enum. Default value is ‘Following’.
terminationDateConvention (Optional) a number or string termination day convention. See Enum. Default value is ‘Following’.

see example below.

Details

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value

The CallableBond function returns an object of class CallableBond (which inherits from class Bond). It contains a list with the following components:

NPV net present value of the bond
cleanPrice price price of the bond
CallableBond

dirtyPrice   dirty price of the bond
accruedAmount accrued amount of the bond
yield       yield of the bond
cashFlows   cash flows of the bond

Note
The interface might change in future release as QuantLib stabilises its own API.

Examples

# set-up a HullWhite according to example from QuantLib
HullWhite <- list(term = 0.055, alpha = 0.03, sigma = 0.01,
                   gridIntervals = 40)

# callability schedule dataframe
Price <- rep(as.double(100), 24)
Type <- rep(as.character("C"), 24)
Date <- seq(as.Date("2006-09-15"), by = '3 months', length = 24)
callSch <- data.frame(Price, Type, Date)
callSch$Type <- as.character(callSch$Type)

bondparams <- list(faceAmount=100, issueDate = as.Date("2004-09-16"),
                    maturityDate=as.Date("2012-09-16"), redemption=100,
                    callSch = callSch)

dateparams <- list(settlementDays=3, calendar="UnitedStates/GovernmentBond",
                   dayCounter = "ActualActual",
                   period="Quarterly",
                   businessDayConvention = "Unadjusted",
                   terminationDateConvention= "Unadjusted")
coupon <- c(0.0465)

CallableBond(bondparams, HullWhite, coupon, dateparams)
# examples using default values
CallableBond(bondparams, HullWhite, coupon)
dateparams <- list(
                   period="Quarterly",
                   businessDayConvention = "Unadjusted",
                   terminationDateConvention= "Unadjusted")
CallableBond(bondparams, HullWhite, coupon, dateparams)
ConvertibleBond

convertiblebond <- list(issueDate = as.Date("2004-09-16"),
maturityDate = as.Date("2012-09-16")
)
CallableBond(bondparams, HullWhite, coupon, dateparams)

---

**Description**

The `ConvertibleFixedCouponBond` function setups and evaluates a ConvertibleFixedCouponBond using QuantLib’s BinomialConvertibleEngine and BlackScholesMertonProcess. The NPV, clean price, dirty price, accrued interest, yield and cash flows of the bond is returned. For detail, see `test-suite/convertiblebond.cpp`

The `ConvertibleFloatingCouponBond` function setups and evaluates a ConvertibleFixedCouponBond using QuantLib’s BinomialConvertibleEngine and BlackScholesMertonProcess. The NPV, clean price, dirty price, accrued interest, yield and cash flows of the bond is returned. For detail, see `test-suite/convertiblebond.cpp`

The `ConvertibleZeroCouponBond` function setups and evaluates a ConvertibleFixedCouponBond using QuantLib’s BinomialConvertibleEngine and BlackScholesMertonProcess. The NPV, clean price, dirty price, accrued interest, yield and cash flows of the bond is returned. For detail, see `test-suite/convertiblebond.cpp`

**Usage**

```r
## Default S3 method:
ConvertibleFloatingCouponBond(bondparams, iborindex, spread, process, dateparams)
## Default S3 method:
ConvertibleFixedCouponBond(bondparams, coupon, process, dateparams)
## Default S3 method:
ConvertibleZeroCouponBond(bondparams, process, dateparams)
```

**Arguments**

`bondparams`  
- bond parameters, a named list whose elements are:
  - `issueDate` a Date, the bond’s issue date
  - `maturityDate` a Date, the bond’s maturity date
  - `creditSpread` a double, credit spread parameter in the constructor of the bond.
  - `conversionRatio` a double, conversion ratio parameter in the constructor of the bond.
ConvertibleBond

exercise  (Optional) a string, either "eu" for European option, or "am" for American option. Default value is 'am'.

faceAmount (Optional) a double, face amount of the bond. Default value is 100.

redemption (Optional) a double, percentage of the initial face amount that will be returned at maturity date. Default value is 100.

divSch  (Optional) a data frame whose columns are "Type", "Amount", "Rate", and "Date" corresponding to QuantLib’s DividendSchedule. Default value is an empty frame, or no dividend.

callSch  (Optional) a data frame whose columns are "Price", "Type" and "Date" corresponding to QuantLib’s CallabilitySchedule. Default value is an empty frame, or no callability.

iborindex a DiscountCurve object, represents an IborIndex

spread a double vector, represents parameter 'spreads' in ConvertibleFloatingBond’s constructor.

coupon a double vector of coupon rate

process arguments to construct a BlackScholes process and set up the binomial pricing engine for this bond.

underlying a double, flat underlying term structure

volatility a double, flat volatility term structure

dividendYield a DiscountCurve object

riskFreeRate a DiscountCurve object

dateparams (Optional) a named list, QuantLib’s date parameters of the bond.

settlementDays (Optional) a double, settlement days. Default value is 1.

calendar (Optional) a string, either 'us' or 'uk' corresponding to US Goverment Bond calendar and UK Exchange calendar. Default value is 'us'.

dayCounter (Optional) a number or string, day counter convention. See Enum. Default value is 'Thirty360'

period (Optional) a number or string, interest compounding interval. See Enum. Default value is 'Semiannual'.

businessDayConvention (Optional) a number or string, business day convention. See Enum. Default value is 'Following'.
See the examples below.

Details

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value

The ConvertibleFloatingCouponBond function returns an object of class ConvertibleFloatingCouponBond (which inherits from class Bond). It contains a list with the following components:

- **NPV** net present value of the bond
- **cleanPrice** price price of the bond
- **dirtyPrice** dirty price of the bond
- **accruedAmount** accrued amount of the bond
- **yield** yield of the bond
- **cashFlows** cash flows of the bond

The ConvertibleFixedCouponBond function returns an object of class ConvertibleFixedCouponBond (which inherits from class Bond). It contains a list with the following components:

- **NPV** net present value of the bond
- **cleanPrice** price price of the bond
- **dirtyPrice** dirty price of the bond
- **accruedAmount** accrued amount of the bond
- **yield** yield of the bond
- **cashFlows** cash flows of the bond

The ConvertibleZeroCouponBond function returns an object of class ConvertibleZeroCouponBond (which inherits from class Bond). It contains a list with the following components:

- **NPV** net present value of the bond
- **cleanPrice** price price of the bond
- **dirtyPrice** dirty price of the bond
- **accruedAmount** accrued amount of the bond
- **yield** yield of the bond
- **cashFlows** cash flows of the bond

ConvertibleZeroCouponBond(bondparams, process, dateparams)

#example with default values
ConvertibleZeroCouponBond(bondparams, process)
DiscountCurve

Returns the discount curve (with zero rates and forwards) given times

Description

DiscountCurve constructs the spot term structure of interest rates based on input market data including the settlement date, deposit rates, futures prices, FRA rates, or swap rates, in various combinations. It returns the corresponding discount factors, zero rates, and forward rates for a vector of times that is specified as input.

Usage

DiscountCurve(params, tsQuotes, times)

Arguments

params A list specifying the tradeDate (month/day/year), settleDate, forward rate time span dt, and two curve construction options: interpWhat (with possible values discount, forward, and zero) and interpHow (with possible values linear, loglinear, and spline). spline here means cubic spline interpolation of the interpWhat value.

tsQuotes Market quotes used to construct the spot term structure of interest rates. Must be a list of name/value pairs, where the currently recognized names are:

- flat rate for a flat yield curve
- d1w 1-week deposit rate
- d1m 1-month deposit rate
- d3m 3-month deposit rate
- d6m 6-month deposit rate
- d9m 9-month deposit rate
- d1y 1-year deposit rate
- s2y 2-year swap rate
- s3y 3-year swap rate
- s5y 5-year swap rate
- s10y 10-year swap rate
- s15y 15-year swap rate
- s20y 20-year swap rate
DiscountCurve

s30y 30-year swap rate
fut1–fut8 3-month futures contracts
fra3x6 3x6 FRA
fra6x9 6x9 FRA
fra6x12 6x12 FRA

Here rates are expected as fractions (so 5% means .05). If flat is specified it
must be the first and only item in the list. The eight futures correspond to the
first eight IMM dates. The maturity dates of the instruments specified need not
be ordered, but they must be distinct.

times A vector of times at which to return the discount factors, forward rates, and zero
rates. Times must be specified such that the largest time plus \( dt \) does not exceed
the longest maturity of the instruments used for calibration (no extrapolation).

Details

This function is based on QuantLib Version 0.3.10. It introduces support for fixed-income instru-
ments in RQuantLib.

Forward rates and zero rates are computed assuming continuous compounding, so the forward rate
\( f \) over the period from \( t_1 \) to \( t_2 \) is determined by the relation

\[
d_1/d_2 = e^{f(t_2 - t_1)},
\]

where \( d_1 \) and \( d_2 \) are discount factors corresponding to the two times. In the case of the zero rate \( t_1 \)
is the current time (the spot date).

Curve construction can be a delicate problem and the algorithms may fail for some input data
sets and/or some combinations of the values for interpwhat and interphow. Fortunately, the
C++ exception mechanism seems to work well with the R interface, and QuantLib exceptions are
propagated back to the R user, usually with a message that indicates what went wrong. (The first
part of the message contains technical information about the precise location of the problem in the
QuantLib code. Scroll to the end to find information that is meaningful to the R user.)

Value

DiscountCurve returns a list containing:

times Vector of input times
discounts Corresponding discount factors
forwards Corresponding forward rates with time span \( dt \)
zerorates Corresponding zero coupon rates
flatQuotes True if a flat quote was used, False otherwise
params The input parameter list

EuropeanOption

European Option evaluation using Closed-Form solution

Description
The EuropeanOption function evaluates an European-style option on a common stock using the Black-Scholes-Merton solution. The option value, the common first derivatives ("Greeks") as well as the calling parameters are returned.

Usage

## Default S3 method:
EuropeanOption(type, underlying, strike, dividendYield, riskFreeRate, maturity, volatility)

Arguments

type A string with one of the values call or put
underlying Current price of the underlying stock
strike Strike price of the option
dividendYield Continuous dividend yield (as a fraction) of the stock
riskFreeRate Risk-free rate
maturity Time to maturity (in fractional years)
volatility Volatility of the underlying stock

Details
The well-known closed-form solution derived by Black, Scholes and Merton is used for valuation. Implied volatilities are calculated numerically.

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.
Value

The `EuropeanOption` function returns an object of class `EuropeanOption` (which inherits from class `Option`). It contains a list with the following components:

- **value**: Value of option
- **delta**: Sensitivity of the option value for a change in the underlying
- **gamma**: Sensitivity of the option delta for a change in the underlying
- **vega**: Sensitivity of the option value for a change in the underlying’s volatility
- **theta**: Sensitivity of the option value for a change in \( t \), the remaining time to maturity
- **rho**: Sensitivity of the option value for a change in the risk-free interest rate
- **dividendRho**: Sensitivity of the option value for a change in the dividend yield

Note

The interface might change in future release as QuantLib stabilises its own API.

Author(s)

Dirk Eddelbuettel <edd@debian.org> for the R interface; the QuantLib Group for QuantLib

References

[http://quantlib.org](http://quantlib.org) for details on QuantLib.

See Also

`EuropeanOptionImpliedVolatility`, `EuropeanOptionArrays`, `AmericanOption`, `BinaryOption`

Examples

```r
## simple call with unnamed parameters
EuropeanOption("call", 100, 100, 0.01, 0.03, 0.5, 0.4)
## simple call with some explicit parameters, and slightly increased vol:
EuropeanOption(type="call", underlying=100, strike=100, dividendYield=0.01, riskFreeRate=0.03, maturity=0.5, volatility=0.5)
## simple call with slightly shorter maturity: QuantLib 1.7 compiled with
## intra-day time calculation support with create slightly changed values
EuropeanOption(type="call", underlying=100, strike=100, dividendYield=0.01, riskFreeRate=0.03, maturity=0.499, volatility=0.5)
```
EuropeanOptionArrays  European Option evaluation using Closed-Form solution

Description

The EuropeanOptionArrays function allows any two of the numerical input parameters to be a vector, and a list of matrices is returned for the option value as well as each of the 'greeks'. For each of the returned matrices, each element corresponds to an evaluation under the given set of parameters.

Usage

EuropeanOptionArrays(type, underlying, strike, dividendYield, riskFreeRate, maturity, volatility)  
oldEuropeanOptionArrays(type, underlying, strike, dividendYield, riskFreeRate, maturity, volatility)  
plotOptionSurface(EOres, ylabel='', xlabel='', zlabel='', fov=60)

Arguments

- type : A string with one of the values call or put
- underlying : (Scalar or list) current price(s) of the underlying stock
- strike : (Scalar or list) strike price(s) of the option
- dividendYield : (Scalar or list) continuous dividend yield(s) (as a fraction) of the stock
- riskFreeRate : (Scalar or list) risk-free rate(s)
- maturity : (Scalar or list) time(s) to maturity (in fractional years)
- volatility : (Scalar or list) volatility(ies) of the underlying stock
- EOres : result matrix produced by EuropeanOptionArrays
- ylabel : label for y-axis
- xlabel : label for x-axis
- zlabel : label for z-axis
- fov : viewpoint for 3d rendering

Details

The well-known closed-form solution derived by Black, Scholes and Merton is used for valuation. Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.
The EuropeanOptionArrays function allows any two of the numerical input parameters to be a vector or sequence. A list of two-dimensional matrices is returned. Each cell corresponds to an evaluation under the given set of parameters.

For these functions, the following components are returned:

- **value** (matrix) value of option
- **delta** (matrix) change in value for a change in the underlying
- **gamma** (matrix) change in value for a change in delta
- **vega** (matrix) change in value for a change in the underlying's volatility
- **theta** (matrix) change in value for a change in delta
- **rho** (matrix) change in value for a change in time to maturity
- **dividendRho** (matrix) change in value for a change in delta
- **parameters** List with parameters with which object was created

The oldEuropeanOptionArrays function is an older implementation which vectorises this at the R level instead but allows more general multidimensional arrays.

**Note**

The interface might change in future release as QuantLib stabilises its own API.

  side=1, font=1, outer=TRUE, line=3)
par(old.par)

EuropeanOptionImpliedVolatility

Implied Volatility calculation for European Option

Description

The EuropeanOptionImpliedVolatility function solves for the (unobservable) implied volatility, given an option price as well as the other required parameters to value an option.

Usage

## Default S3 method:
EuropeanOptionImpliedVolatility(type, value,
  underlying, strike, dividendYield, riskFreeRate, maturity, volatility)

Arguments

type | A string with one of the values call or put
value | Value of the option (used only for ImpliedVolatility calculation)
underlying | Current price of the underlying stock
strike | Strike price of the option
dividendYield | Continuous dividend yield (as a fraction) of the stock
riskFreeRate | Risk-free rate
maturity | Time to maturity (in fractional years)
volatility | Initial guess for the volatility of the underlying stock
Details

The well-known closed-form solution derived by Black, Scholes and Merton is used for valuation. Implied volatilities are then calculated numerically. Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value

The EuropeanOptionImpliedVolatility function returns an numeric variable with volatility implied by the given market prices and given parameters.

Note

The interface might change in future release as QuantLib stabilises its own API.

Author(s)

Dirk Eddelbuettel <edd@debian.org> for the R interface; the QuantLib Group for QuantLib

FittedBondCurve

Returns the discount curve (with zero rates and forwards) given set of bonds

Description

FittedBondCurve fits a term structure to a set of bonds using three different fitting methodologies. For more detail, see QuantLib/Example/FittedBondCurve.

Usage

FittedBondCurve(curveparams, lengths, coupons, marketQuotes, dateparams)

Arguments

curveparams          curve parameters
method a string, fitting methods: "ExponentialSplinesFitting", "SimplePolynomialFitting", "NelsonSiegelFitting"
origDate a Date, starting date of the curve

lengths an numeric vector, length of the bonds in year
coupons a numeric vector, coupon rate of the bonds
marketQuotes a numeric vector, market price of the bonds
dateparams (Optional) a named list, QuantLib’s date parameters of the bond.

settlementDays (Optional) a double, settlement days. Default value is 1.
dayCounter (Optional) a number or string, day counter convention. See Enum. Default value is ‘Thirty360’
period (Optional) a number or string, interest compounding interval. See Enum. Default value is ‘Semiannual’.
businessDayConvention (Optional) a number or string, business day convention. See Enum. Default value is ‘Following’.

See example below.

Details
Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value
table, a three columns "date - zeroRate - discount" data frame

Author(s)
Khanh Nguyen <knguyen@cs.umb.edu> for the implementation; Dirk Eddelbuettel <edd@debian.org> for the R interface; the QuantLib Group for QuantLib

References

Examples

lengths <- c(2,4,6,8,10,12,14,16,18,20,22,24,26,28,30)
coupons <- c( 0.0200, 0.0225, 0.0250, 0.0275, 0.0300, 0.0325, 0.0350, 0.0375, 0.0400, 0.0425,
FixedRateBond

Fixed-Rate bond pricing

Description

The FixedRateBond function evaluates a fixed rate bond using discount curve, the yield or the clean price. More specifically, when a discount curve is provided the calculation is done by DiscountingBondEngine from QuantLib. The NPV, clean price, dirty price, accrued interest, yield, duration, actual settlement date and cash flows of the bond is returned. When a yield is provided instead, no engine is provided to the bond class and prices are computed from yield. In the latter case, NPV is set to NA. Same situation when the clean price is given instead of discount curve or yield. For more detail, see the source codes in QuantLib’s file test-suite/bond.cpp.

The FixedRateBondPriceByYield function calculates the theoretical price of a fixed rate bond from its yield.

The FixedRateBondYield function calculates the theoretical yield of a fixed rate bond from its price.

Usage

## Default S3 method:
FixedRateBond(bond, rates, schedule,  
calc=list(dayCounter='ActualActual.ISMA',  
    compounding='Compounded',  
    freq='Annual',  
    durationType='Modified'),  
    discountCurve = NULL, yield = NA, price = NA)

## Default S3 method:
FixedRateBondPriceByYield(  
    settlementDays=1, yield, faceAmount=100,  
    effectiveDate, maturityDate,  
    period, calendar="UnitedStates/GovernmentBond",  
    rates, dayCounter=2,  
    businessDayConvention=0, compound = 0, redemption=100,
FixedRateBond

issueDate)

## Default S3 method:

FixedRateBondYield(settlementDays = 1, price, faceAmount = 100,
effectiveDate, maturityDate,
period, calendar = "UnitedStates/GovernmentBond",
rates, dayCounter = 2,
businessDayConvention = 0,
compound = 0, redemption = 100,
issueDate)

### Arguments

<table>
<thead>
<tr>
<th>bond</th>
<th>(Optional) bond parameters, a named list whose elements are:</th>
</tr>
</thead>
</table>
| settlementDays | (Optional) a double, settlement days.  
  Default value is 1. |
| faceAmount | (Optional) a double, face amount of the bond.  
  Default value is 100. |
| dayCounter | (Optional) a number or string,  
  day counter convention. Defaults to 'Thirty360' |
| issueDate | (Optional) a Date, the bond’s issue date  
  Defaults to QuantLib default. |
| paymentConvention | (Optional) a number or string, the bond  
  payment convention.  
  Defaults to QuantLib default. |
| redemption | (Optional) a double, the redemption amount.  
  Defaults to QuantLib default (100). |
| paymentCalendar | (Optional) a string, the name of the calendar.  
  Defaults to QuantLib default. |
| exCouponPeriod | (Optional) a number, the number of days when  
  the coupon goes ex relative to the coupon date.  
  Defaults to QuantLib default. |
| exCouponCalendar | (Optional) a string, the name of the  
  ex-coupon calendar.  
  Defaults to QuantLib default. |
| exCouponConvention | (Optional) a number or string, the coupon  
  payment convention.  
  Defaults to QuantLib default. |
| exCouponEndOfMonth | (Optional) 1 or 0, use End of Month rule for  
  ex-coupon dates. Defaults to 0 (false). |

<table>
<thead>
<tr>
<th>rates</th>
<th>a numeric vector, bond’s coupon rates</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>schedule</th>
<th>(Optional) a named list, QuantLib’s parameters of the bond’s schedule.</th>
</tr>
</thead>
</table>
| effectiveDate | a Date, when the schedule becomes effective.  
  a Date, when the schedule matures. |
| maturityDate | (Optional) a number or string, the frequency of  
  the schedule. Default value is 'Semiannual'. |
| period | |

calendar (Optional) a string, the calendar name. Defaults to 'TARGET'.

businessDayConvention (Optional) a number or string, the day convention to use. Defaults to 'Following'.

terminationDateConvention (Optional) a number or string, the day convention to use for the terminal date. Defaults to 'Following'.

dateGeneration (Optional) a number or string, the date generation rule. Defaults to 'Backward'.

endOfMonth (Optional) 1 or 0, use End of Month rule for schedule dates. Defaults to 0 (false).

See example below.

calc (Optional) a named list, QuantLib’s parameters for calculations.

dayCounter (Optional) a number or string, day counter convention. Defaults to 'ActualActual.ISMA'.

compounding a string, what kind of compounding to use. Defaults to 'Compounded'.

freq (Optional) a number or string, the frequency to use. Default value is 'Annual'.

durationType (Optional) a number or string, the type of duration to calculate. Defaults to 'Simple'.

accuracy (Optional) a number, the accuracy required. Defaults to 1.0e-8.

maxEvaluations (Optional) a number, max number of iterations. Defaults to 100.

discountCurve Can be one of the following:

  a DiscountCurve a object of DiscountCurve class For more detail, see example or the discountCurve function
  A 2 items list specifies a flat curve in two values "todayDate" and "rate"
  A 3 items list specifies three values to construct a DiscountCurve object, "params", "tsQuotes", "times". For more detail, see example or the discountCurve function

yield yield of the bond

price clean price of the bond

settlementDays an integer, 1 for T+1, 2 for T+2, etc...

effectiveDate bond’s effective date
FixedRateBond

maturityDate  bond’s maturity date
period frequency of events. 0=NoFrequency, 1=Once, 2=Annual, 3=Semiannual, 4=EveryFourthMonth, 5=Quarterly, 6=Bimonthly, 7=Monthly, 8=EveryFourthWeekly, 9=Biweekly, 10=Weekly, 11=Daily. For more information, see QuantLib’s Frequency class

calendar Business Calendar. Either US or UK

faceAmount face amount of the bond

businessDayConvention

convention used to adjust a date in case it is not a valid business day. See quantlib for more detail. 0 = Following, 1 = ModifiedFollowing, 2 = Preceding, 3 = ModifiedPreceding, other = Unadjusted

dayCounter day count convention. 0 = Actual360(), 1 = Actual365Fixed(), 2 = ActualActual(), 3 = Business252(), 4 = OneDayCounter(), 5 = SimpleDayCounter(), all other = Thirty360(). For more information, see QuantLib’s DayCounter class

compound compounding type. 0 = Simple, 1 = Compounded, 2 = Continuous, all other = SimpleThenCompounded. See QuantLib’s Compound class

redemption redemption when the bond expires

issueDate date the bond is issued

Details
A discount curve is built to calculate the bond value.

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value

The FixedRateBond function returns an object of class FixedRateBond (which inherits from class Bond). It contains a list with the following components:

NPV net present value of the bond
cleanPrice clean price of the bond
dirtyPrice dirty price of the bond
accruedAmount accrued amount of the bond
yield yield of the bond
duration the duration of the bond
settlementDate the actual settlement date used for the bond
cashFlows cash flows of the bond

The FixedRateBondPriceByYield function returns an object of class FixedRateBondPriceByYield (which inherits from class Bond). It contains a list with the following components:

price price of the bond

The FixedRateBondYield function returns an object of class FixedRateBondYield (which inherits from class Bond). It contains a list with the following components:

yield yield of the bond
Note

The interface might change in future release as QuantLib stabilises its own API.

FloatingRateBond漂浮利率债券定价

Description

The FloatingRateBond function evaluates a floating rate bond using discount curve. More specifically, the calculation is done by DiscountingBondEngine from QuantLib. The NPV, clean price, dirty price, accrued interest, yield and cash flows of the bond is returned. For more detail, see the source codes in quantlib's test-suite. test-suite/bond.cpp

Usage

## Default S3 method:
FloatingRateBond(bond, gearings, spreads,
        caps, floors, index,
        curve, dateparams)

Arguments

bond bond parameters, a named list whose elements are:

issueDate a Date, the bond’s issue date
maturityDate a Date, the bond’s maturity date
faceAmount (Optional) a double, face amount of the bond. Default value is 100.
redemption (Optional) a double, percentage of the initial face amount that will be returned at maturity date. Default value is 100.
effectiveDate (Optional) a Date, the bond’s effective date. Default value is issueDate

gearings (Optional) a numeric vector, bond’s gearings. See quantlib’s doc on FloatingRateBond for more detail. Default value is an empty vector c().

spreads (Optional) a numeric vector, bond’s spreads. See quantlib’s doc on FloatingRateBond for more detail. Default value is an empty vector c()
FloatingRateBond

caps (Optional) a numeric vector, bond’s caps. See quantlib’s doc on FloatingRateBond for more detail. Default value is an empty vector c()
floors (Optional) a numeric vector, bond’s floors. See quantlib’s doc on FloatingRateBond for more detail. Default value is an empty vector c()
curve Can be one of the following:

- a DiscountCurve a object of DiscountCurve class
  For more detail, see example or the discountCurve function
- A 2 items list specifies a flat curve in two values "todayDate" and "rate"
- A 3 items list specifies three values to construct a DiscountCurve object, "params", "tsQuotes", "times".
  For more detail, see example or the discountCurve function

index a named list whose elements are parameters of an IborIndex term structure.

type a string, currently support only "USDLibor"
length an integer, length of the index
inTermOf a string, period unit, currently support only 'Month'
term a DiscountCurve object, the term structure of the index
dateparams (Optional) a named list, QuantLib’s date parameters of the bond.

settlementDays (Optional) a double, settlement days. Default value is 1.
calendar (Optional) a string, either ‘us’ or ‘uk’ corresponding to US Government Bond calendar and UK Exchange calendar. Default value is ‘us’.
dayCounter (Optional) a number or string, day counter convention. See Enum. Default value is 'Thirty360'
period (Optional) a number or string, interest compounding interval. See Enum. Default value is 'Semiannual'.
businessDayConvention (Optional) a number or string, business day convention. See Enum. Default value is 'Following'.
terminationDateConvention (Optional) a number or string, termination day convention. See Enum. Default value is 'Following'.
endOfMonth (Optional) a numeric with value 1 or 0. End of Month rule. Default value is 0.
dateGeneration (Optional) a numeric, date generation method. See Enum. Default value is 'Backward'

See example below.

Details

A discount curve is built to calculate the bond value.

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value

The FloatingRateBond function returns an object of class FloatingRateBond (which inherits from class Bond). It contains a list with the following components:

- `NPV`: net present value of the bond
- `cleanPrice`: clean price of the bond
- `dirtyPrice`: dirty price of the bond
- `accruedAmount`: accrued amount of the bond
- `yield`: yield of the bond
- `cashFlows`: cash flows of the bond

Note

The interface might change in future release as QuantLib stabilises its own API.

Author(s)

Khanh Nguyen <knguyen@cs.umb.no> for the implementation; Dirk Eddelbuettel <edd@debian.org> for the R interface; the QuantLib Group for QuantLib

Examples

```r
bond <- list(faceAmount=100, issueDate=as.Date("2004-11-30"),
maturityDate=as.Date("2008-11-30"), redemption=100,
   effectiveDate=as.Date("2004-11-30"))
dateparams <- list(settlementDays=1, calendar="UnitedStates/GovernmentBond",
   dayCounter = 'ActualActual', period=2,
   businessDayConvention = 1, terminationDateConvention=1,
   dateGeneration=0, endOfMonth=0, fixingDays = 1)

gearings <- spreads <- caps <- floors <- vector()
```
getQuantLibCapabilities

Return configuration options of the QuantLib library

```r
params <- list(tradeDate=as.Date('2002-2-15'),
    settleDate=as.Date('2002-2-19'),
    dt=.25,
    interpWhat="discount",
    interpHow="loglinear")
setEvaluationDate(as.Date('2004-11-22'))

tsQuotes <- list(dow =0.0382,
    dlm =0.0372,
    fut1=96.2875,
    fut2=96.7875,
    fut3=96.9875,
    fut4=96.6875,
    fut5=96.4875,
    fut6=96.3875,
    fut7=96.2875,
    fut8=96.0875,
    s3y =0.0398,
    s5y =0.0443,
    s10y =0.05165,
    s15y =0.055175)
tsQuotes <- list("flat" = 0.02) ## While discount curve code is buggy

## when both discount and libor curves are flat.

discountCurve.flat <- DiscountCurve(params, list(flat=0.05))
termstructure <- DiscountCurve(params, list(flat=0.03))
iborIndex.params <- list(type="USDLibor", length=6,
    inTermOf="Month", term=termstructure)
FloatingRateBond(bond, gearings, spreads, caps, floors,
    iborIndex.params, discountCurve.flat, dateparams)

## discount curve is constructed from market quotes
## and a flat libor curve

discountCurve <- DiscountCurve(params, tsQuotes)
termstructure <- DiscountCurve(params, list(flat=0.03))
iborIndex.params <- list(type="USDLibor", length=6,
    inTermOf="Month", term = termstructure)
FloatingRateBond(bond, gearings, spreads, caps, floors,
    iborIndex.params, discountCurve, dateparams)

#example using default values
FloatingRateBond(bond=bond, index=iborIndex.params, curve=discountCurve)
```
**getQuantLibVersion**

**Description**
This function returns a named vector of boolean variables describing several configuration options determined at compilation time of the QuantLib library.

**Usage**
getQuantLibCapabilities()

**Details**
Not all of these features are used (yet) by RQuantLib.

**Value**
A named vector of logical variables

**Author(s)**
Dirk Eddelbuettel

**References**
http://quantlib.org for details on QuantLib.

**Examples**
getQuantLibCapabilities()

---

**getQuantLibVersion**  
*Return the QuantLib version number*

**Description**
This function returns the QuantLib version string as encoded in the header file config.hpp and determined at compilation time of the QuantLib library.

**Usage**
getQuantLibVersion()

**Value**
A character variable

**Author(s)**
Dirk Eddelbuettel
References

http://quantlib.org for details on QuantLib.

Examples

getQuantLibVersion()

ImpliedVolatility Base class for option-price implied volatility evaluation

Description
This class forms the basis from which the more specific classes are derived.

Usage

```r
## S3 method for class 'ImpliedVolatility'
print(x, digits=3, ...)
## S3 method for class 'ImpliedVolatility'
summary(object, digits=3, ...)
```

Arguments

- `x` Any option-price implied volatility object derived from this base class
- `object` Any option-price implied volatility object derived from this base class
- `digits` Number of digits of precision shown
- `...` Further arguments

Details
Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value
None, but side effects of displaying content.

Note
The interface might change in future release as QuantLib stabilises its own API.

print(impVol)
summary(impVol)

Option

Base class for option price evaluation

Description

This class forms the basis from which the more specific classes are derived.

Usage

## S3 method for class 'Option'
print(x, digits=4, ...)

## S3 method for class 'Option'
plot(x, ...)

## S3 method for class 'Option'
summary(object, digits=4, ...)

Arguments

x
object
digits
...  Any option object derived from this base class
Any option object derived from this base class
Number of digits of precision shown
Further arguments

Details

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

Value

None, but side effects of displaying content.

summary(EO)

Schedule generation

Description

The Schedule function generates a schedule of dates conformant to a given convention in a given calendar.

Usage

## Default S3 method:
Schedule(params)

Arguments

params a named list, QuantLib’s parameters of the schedule.

effectiveDate a Date, when the schedule becomes effective.
maturityDate a Date, when the schedule matures.
period (Optional) a number or string, the frequency of the schedule. Default value is ‘Semiannual’.
calendar (Optional) a string, the calendar name. Defaults to ‘TARGET’
businessDayConvention (Optional) a number or string, the day convention to use. Defaults to ‘Following’.
terminationDateConvention (Optional) a number or string, the
day convention to use for the terminal date. Defaults to 'Following'.

**dateGeneration**

(Optional) a number or string, the date generation rule. Defaults to 'Backward'.

**endOfMonth**

(Optional) 1 or 0, use End of Month rule for schedule dates. Defaults to 0 (false).

See example below.

**Details**

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.

**Value**

The Schedule function returns an object of class Schedule. It contains the list of dates in the schedule.

**Author(s)**

Michele Salvadore <michele.salvadore@gmail.com> for the implementation; Dirk Eddelbuettel <edd@debian.org> for the R interface; the QuantLib Group for QuantLib

```r
params <- list(effectiveDate=as.Date("2004-11-30"),
maturityDate=as.Date("2008-11-30"),
period='Semiannual',
calendar='UnitedStates/GovernmentBond',
businessDayConvention='Unadjusted',
terminationDateConvention='Unadjusted',
dateGeneration='Forward',
endOfMonth=1)
Schedule(params)
```
ZeroCouponBond

Zero-Coupon bond pricing

Description

The ZeroCouponBond function evaluates a zero-coupon plainly using discount curve. More specifically, the calculation is done by DiscountingBondEngine from QuantLib. The NPV, clean price, dirty price, accrued interest, yield and cash flows of the bond is returned. For more detail, see the source code in the QuantLib file test-suite/bond.cpp.

The ZeroPriceYield function evaluates a zero-coupon clean price based on its yield.

The ZeroYield function evaluates a zero-coupon yield based. See also http://www.mathworks.com/access/helpdesk/help/toolbox/finfixed/zeroyield.html

Usage

```r
## Default S3 method:
ZeroCouponBond(bond, discountCurve, dateparams)

## Default S3 method:
ZeroPriceByYield(yield, faceAmount,
                  issueDate, maturityDate,
                  dayCounter=2, frequency=2,
                  compound=0, businessDayConvention=4)

## Default S3 method:
ZeroYield(price, faceAmount,
          issueDate, maturityDate,
          dayCounter=2, frequency=2,
          compound=0, businessDayConvention=4)
```

Arguments

- **bond**
  - bond parameters, a named list whose elements are:
    - **issueDate**
      - a Date, the bond’s issue date
    - **maturityDate**
      - a Date, the bond’s maturity date
    - **faceAmount**
      - (Optional) a double, face amount of the bond. Default value is 100.
    - **redemption**
      - (Optional) a double, percentage of the initial face amount that will be returned at maturity date. Default value is 100.

- **discountCurve**
  - Can be one of the following:
    - a `DiscountCurve` object of DiscountCurve class
      - For more detail, see example or
A 2 items list specifies a flat curve in two values "todayDate" and "rate"

A 3 items list specifies three values to construct a DiscountCurve object, "params", "tsQuotes", "times". For more detail, see example or the discountCurve function.

dateparams (Optional) a named list, QuantLib’s date parameters of the bond.

settlementDays (Optional) a double, settlement days. Default value is 1.

calendar (Optional) a string, either 'us' or 'uk' corresponding to US Government Bond calendar and UK Exchange calendar. Default value is 'us'.

businessDayConvention (Optional) a number or string, business day convention. See Enum. Default value is 'Following'.

yield yield of the bond
price price of the bond
faceAmount face amount of the bond
issueDate date the bond is issued
maturityDate maturity date, an R’s date type
dayCounter day count convention. 0 = Actual360(), 1 = Actual365Fixed(), 2 = ActualActual(), 3 = Business252(), 4 = OneDayCounter(), 5 = SimpleDayCounter(), all other = Thirty360(). For more information, see QuantLib’s DayCounter class

frequency frequency of events. 0 = NoFrequency, 1 = Once, 2 = Annual, 3 = Semiannual, 4 = EveryFourthMonth, 5 = Quarterly, 6 = Bimonthly, 7 = Monthly, 8 = EveryFourthWeekly, 9 = Biweekly, 10 = Weekly, 11 = Daily. For more information, see QuantLib’s Frequency class

compound compounding type. 0 = Simple, 1 = Compounded, 2 = Continuous, all other = SimpleThenCompounded. See QuantLib’s Compound class

businessDayConvention convention used to adjust a date in case it is not a valid business day. See quantlib for more detail. 0 = Following, 1 = ModifiedFollowing, 2 = Preceding, 3 = ModifiedPreceding, other = Unadjusted

Details

A discount curve is built to calculate the bond value.

Please see any decent Finance textbook for background reading, and the QuantLib documentation for details on the QuantLib implementation.
ZeroCouponBond

Value

The ZeroCouponBond function returns an object of class ZeroCouponBond (which inherits from class Bond). It contains a list with the following components:

- **NPV** net present value of the bond
- **cleanPrice** clean price of the bond
- **dirtyPrice** dirty price of the bond
- **accruedAmount** accrued amount of the bond
- **yield** yield of the bond
- **cashFlows** cash flows of the bond

The ZeroPriceByYield function returns an object of class ZeroPriceByYield (which inherits from class Bond). It contains a list with the following components:

- **price** price of the bond

The ZeroYield function returns an object of class ZeroYield (which inherits from class Bond). It contains a list with the following components:

- **yield** yield of the bond

Note

The interface might change in future release as QuantLib stabilises its own API.
