Package ‘RRF’

January 26, 2017

Title Regularized Random Forest
Version 1.7
Date 2017-1-25
Depends R (>= 2.5.0), stats
Suggests RColorBrewer, MASS
Author Fortran original by Leo Breiman and Adele Cutler, R port by
Andy Liaw and Matthew Wiener, Regularized random forest for classification by
Houtao Deng. Regularized random forest for regression by Xin Guan.
Description Feature Selection with Regularized Random Forest. This
package is based on the ‘randomForest’ package by Andy Liaw.
The key difference is the RRF() function that builds a
regularized random forest.

Prototypes of groups.

Prototypes are ‘representative’ cases of a group of data points, given the similarity matrix among the points. They are very similar to medoids. The function is named ‘classCenter’ to avoid conflict with the function prototype in the methods package.

Usage

classCenter(x, label, prox, nNbr = min(table(label))-1)

Arguments

<table>
<thead>
<tr>
<th>x</th>
<th>a matrix or data frame</th>
</tr>
</thead>
<tbody>
<tr>
<td>label</td>
<td>group labels of the rows in x</td>
</tr>
<tr>
<td>prox</td>
<td>the proximity (or similarity) matrix, assumed to be symmetric with 1 on the diagonal and in [0, 1] off the diagonal (the order of row/column must match that of x)</td>
</tr>
<tr>
<td>nNbr</td>
<td>number of nearest neighbors used to find the prototypes</td>
</tr>
</tbody>
</table>

Details

This version only computes one prototype per class. For each case in x, the nNbr nearest neighbors are found. Then, for each class, the case that has most neighbors of that class is identified. The prototype for that class is then the medoid of these neighbors (coordinate-wise medians for numerical variables and modes for categorical variables).

This version only computes one prototype per class. In the future more prototypes may be computed (by removing the ‘neighbors’ used, then iterate).
Value
A data frame containing one prototype in each row.

Author(s)
Andy Liaw

RRF, MDSplot

Examples
```r
data(iris)
iris.rf <- RRF(iris[-5], iris[,5], prox=TRUE)
iris.p <- classCenter(iris[-5], iris[,5], iris.rf$prox)
plot(iris[,3], iris[,4], pch=21, xlab=names(iris)[3], ylab=names(iris)[4],
     bg=c("red", "blue", "green")[as.numeric(factor(iris$Species))],
     main="Iris Data with Prototypes")
points(iris.p[,3], iris.p[,4], pch=21, cex=2, bg=c("red", "blue", "green"))
```

Description
Combine two more more ensembles of trees into one.

Usage
```r
combine(...)
```

Arguments
...  two or more objects of class RRF, to be combined into one.

Value
An object of class RRF.

Note
The confusion, err.rate, mse and rsq components (as well as the corresponding components in the test component, if exist) of the combined object will be NULL.

Author(s)
Andy Liaw <andy\_liaw@merck.com>
**See Also**

`RRF`, `grow`

**Examples**

```r
data(iris)
rf1 <- RRF(Species ~ ., iris, ntree=50, norm.votes=FALSE)
rf2 <- RRF(Species ~ ., iris, ntree=50, norm.votes=FALSE)
rf3 <- RRF(Species ~ ., iris, ntree=50, norm.votes=FALSE)
rf.all <- combine(rf1, rf2, rf3)
print(rf.all)
```

---

**getTree**

*Extract a single tree from a forest.*

**Description**

This function extracts the structure of a tree from a RRF object.

**Usage**

```r
getTree(rfobj, k=1, labelVar=FALSE)
```

**Arguments**

- `rfobj`: a RRF object.
- `k`: which tree to extract?
- `labelVar`: Should better labels be used for splitting variables and predicted class?

**Details**

For numerical predictors, data with values of the variable less than or equal to the splitting point go to the left daughter node.

For categorical predictors, the splitting point is represented by an integer, whose binary expansion gives the identities of the categories that go to left or right. For example, if a predictor has four categories, and the split point is 13. The binary expansion of 13 is \(1 \times 2^3 + 0 \times 2^2 + 1 \times 2^1 + 1 \times 2^0\), so cases with categories 1, 3, or 4 in this predictor get sent to the left, and the rest to the right.

**Value**

A matrix (or data frame, if `labelVar=TRUE`) with six columns and number of rows equal to total number of nodes in the tree. The six columns are:

- `left daughter`: the row where the left daughter node is; 0 if the node is terminal
- `right daughter`: the row where the right daughter node is; 0 if the node is terminal
- `split var`: which variable was used to split the node; 0 if the node is terminal
split point  where the best split is; see Details for categorical predictor
status  is the node terminal (-1) or not (1)
prediction  the prediction for the node; 0 if the node is not terminal

RRF

Examples
```
data(iris)
## Look at the third trees in the forest.
getTree(RRF(iris[,-5], iris[,5], ntree=10), 3, labelVar=TRUE)
```

Description
Add additional trees to an existing ensemble of trees.

Usage
```
## S3 method for class 'RRF'
grow(x, how.many, ...)
```

Arguments
- `x`  an object of class RRF, which contains a forest component.
- `how.many`  number of trees to add to the RRF object.
- `...`  currently ignored.

Value
An object of class RRF, containing `how.many` additional trees.

Note
The confusion, err.rate, mse and rsq components (as well as the corresponding components in the test component, if exist) of the combined object will be NULL.

data(iris)
iris.rf <- RRF(Species ~ ., iris, ntree=50, norm.votes=FALSE)
iris.rf <- grow(iris.rf, 50)
print(iris.rf)

importance
Extract variable importance measure

Description

This is the extractor function for variable importance measures as produced by RRF.

Usage

## S3 method for class 'RRF'
importance(x, type=NULL, class=NULL, scale=TRUE, ...)

Arguments

x an object of class RRF.

type either 1 or 2, specifying the type of importance measure (1=mean decrease in accuracy, 2=mean decrease in node impurity).

class for classification problem, which class-specific measure to return.

scale For permutation based measures, should the measures be divided their “standard errors”?

... not used.

Details

Here are the definitions of the variable importance measures. The first measure is computed from permuting OOB data: For each tree, the prediction error on the out-of-bag portion of the data is recorded (error rate for classification, MSE for regression). Then the same is done after permuting each predictor variable. The difference between the two are then averaged over all trees, and normalized by the standard deviation of the differences. If the standard deviation of the differences is equal to 0 for a variable, the division is not done (but the average is almost always equal to 0 in that case).

The second measure is the total decrease in node impurities from splitting on the variable, averaged over all trees. For classification, the node impurity is measured by the Gini index. For regression, it is measured by residual sum of squares.
Value

A matrix of importance measure, one row for each predictor variable. The column(s) are different importance measures.

Examples

```r
set.seed(4543)
data(mtcars)
mtcars.rf <- RRF(mpg ~ ., data=mtcars, ntree=1000,
                 keep.forest=FALSE, importance=TRUE)
importance(mtcars.rf)
importance(mtcars.rf, type=1)
```

Description

This is the ‘Automobile’ data from the UCI Machine Learning Repository.

Usage

data(imports85)

Format

`imports85` is a data frame with 205 cases (rows) and 26 variables (columns). This data set consists of three types of entities: (a) the specification of an auto in terms of various characteristics, (b) its assigned insurance risk rating, (c) its normalized losses in use as compared to other cars. The second rating corresponds to the degree to which the auto is more risky than its price indicates. Cars are initially assigned a risk factor symbol associated with its price. Then, if it is more risky (or less), this symbol is adjusted by moving it up (or down) the scale. Actuarians call this process ‘symboling’. A value of +3 indicates that the auto is risky, -3 that it is probably pretty safe.

The third factor is the relative average loss payment per insured vehicle year. This value is normalized for all autos within a particular size classification (two-door small, station wagons, sports/speciality, etc...), and represents the average loss per car per year.

margin

Margins of RRF Classifier

Description

Compute or plot the margin of predictions from a RRF classifier.

Usage

## S3 method for class 'RRF'
margin(x, ...)
## Default S3 method:
margin(x, observed, ...)
## S3 method for class 'margin'
plot(x, sort=TRUE, ...)

---

margin
Arguments

x an object of class \texttt{RRF}, whose type is not regression, or a matrix of predicted probabilities, one column per class and one row per observation. For the \texttt{plot} method, \texttt{x} should be an object returned by \texttt{margin}.

observed the true response corresponding to the data in \texttt{x}.

sort Should the data be sorted by their class labels?

... other graphical parameters to be passed to \texttt{plot.default}.

Value

For \texttt{margin}, the margin of observations from the \texttt{RRF} classifier (or whatever classifier that produced the predicted probability matrix given to \texttt{margin}). The margin of a data point is defined as the proportion of votes for the correct class minus maximum proportion of votes for the other classes. Thus under majority votes, positive margin means correct classification, and vice versa.

**MDSplot**

Multi-dimensional Scaling Plot of Proximity matrix from RRF

Description

Plot the scaling coordinates of the proximity matrix from RRF.

Usage

\texttt{MDSplot}(rf, fac, k=2, palette=NULL, pch=20, ...)}
Arguments

rf an object of class RRF that contains the proximity component.
fac a factor that was used as response to train rf.
k number of dimensions for the scaling coordinates.
palette colors to use to distinguish the classes; length must be the equal to the number of levels.
pch plotting symbols to use.
... other graphical parameters.

Value

The output of cmdscale on 1 - rf$proximity is returned invisibly.

Note

If k > 2, pairs is used to produce the scatterplot matrix of the coordinates.

## Using different symbols for the classes:
MDSplot(iris.rf, iris$Species, palette=rep(1, 3), pch=as.numeric(iris$Species))

na.roughfix Rough Imputation of Missing Values

Description

Impute Missing Values by median/mode.

Usage

na.roughfix(object, ...)

Rough Imputation of Missing Values
outlier

Arguments

  object  a data frame or numeric matrix.
  ...    further arguments special methods could require.

Value

  A completed data matrix or data frame. For numeric variables, NAs are replaced with column medians. For factor variables, NAs are replaced with the most frequent levels (breaking ties at random). If object contains no NAs, it is returned unaltered.

Note

  This is used as a starting point for imputing missing values by random forest.

Author(s)

  Andy Liaw

See Also

  rrfImpute, RRF.

Examples

  data(iris)
  iris.na <- iris
  set.seed(111)
  ## artificially drop some data values.
  for (i in 1:4) iris.na[sample(150, sample(20)), i] <- NA
  iris.roughfix <- na.roughfix(iris.na)
  iris.narf <- RRF(Species ~ ., iris.na, na.action=na.roughfix)
  print(iris.narf)

outlier  Compute outlying measures

Description

  Compute outlying measures based on a proximity matrix.

Usage

  ## Default S3 method:
  outlier(x, cls=NULL, ...)
  ## S3 method for class 'RRF'
  outlier(x, ...)
Arguments

x  
a proximity matrix (a square matrix with 1 on the diagonal and values between 0 and 1 in the off-diagonal positions); or an object of class RRF, whose type is not regression.

cls  
the classes the rows in the proximity matrix belong to. If not given, all data are assumed to come from the same class.

...  
arguments for other methods.

Value

A numeric vector containing the outlying measures. The outlying measure of a case is computed as \( \frac{n}{\text{sum(squared proximity)}} \), normalized by subtracting the median and divided by the MAD, within each class.

See Also

RRF

Examples

```r
set.seed(1)
iris.rf <- RRF(iris[,1:5], iris[,5], proximity=TRUE)
outlier(iris.rf, type="h",
       col=c("red", "green", "blue")[[as.numeric(iris$Species)])
```

partialPlot  
Partial dependence plot

Description

Partial dependence plot gives a graphical depiction of the marginal effect of a variable on the class probability (classification) or response (regression).

Usage

```r
## S3 method for class 'RRF'
partialPlot(x, pred.data, x.var, which.class,
            w, plot = TRUE, add = FALSE,
            n.pt = min(length(unique(pred.data[, xname]))), 51),
            rug = TRUE, xlab=deparse(substitute(x.var)), ylab="",
            main=paste("Partial Dependence on", deparse(substitute(x.var))))
```
Arguments

- **x**: an object of class RRF, which contains a forest component.
- **pred.data**: a data frame used for constructing the plot, usually the training data used to construct the random forest.
- **x.var**: name of the variable for which partial dependence is to be examined.
- **which.class**: For classification data, the class to focus on (default the first class).
- **w**: weights to be used in averaging; if not supplied, mean is not weighted
- **plot**: whether the plot should be shown on the graphic device.
- **add**: whether to add to existing plot (TRUE).
- **n.pt**: if x.var is continuous, the number of points on the grid for evaluating partial dependence.
- **rug**: whether to draw hash marks at the bottom of the plot indicating the deciles of x.var.
- **xlab**: label for the x-axis.
- **ylab**: label for the y-axis.
- **main**: main title for the plot.
- **...**: other graphical parameters to be passed on to plot or lines.

Details

The function being plotted is defined as:

\[
\tilde{f}(x) = \frac{1}{n} \sum_{i=1}^{n} f(x, x_{iC}),
\]

where \(x\) is the variable for which partial dependence is sought, and \(x_{iC}\) is the other variables in the data. The summand is the predicted regression function for regression, and logits (i.e., log of fraction of votes) for which.class for classification:

\[
f(x) = \log p_k(x) - \frac{1}{K} \sum_{j=1}^{K} \log p_j(x),
\]

where \(K\) is the number of classes, \(k\) is which.class, and \(p_j\) is the proportion of votes for class \(j\).

Value

A list with two components: \(x\) and \(y\), which are the values used in the plot.

Note

The RRF object must contain the forest component; i.e., created with RRF(..., keep.forest=TRUE).

This function runs quite slow for large data sets.

`rrf`

Examples

```r
data(airquality)
airquality <- na.omit(airquality)
set.seed(131)
ozone.rf <- RRF(Ozone ~ ., airquality)
partialPlot(ozone.rf, airquality, Temp)

data(iris)
set.seed(543)
iris.rf <- RRF(Species ~ ., iris)
partialPlot(iris.rf, iris, Petal.Width, "versicolor")
```

---

**plot.RRF**  
*Plot method for RRF objects*

**Description**

Plot the error rates or MSE of a RRF object

**Usage**

```r
## S3 method for class 'RRF'
plot(x, type="l", main=deparse(substitute(x)), ...)
```

**Arguments**

- `x`: an object of class RRF.
- `type`: type of plot.
- `main`: main title of the plot.
- `...`: other graphical parameters.

**Value**

Invisibly, the error rates or MSE of the RRF object. If the object has a non-null test component, then the returned object is a matrix where the first column is the out-of-bag estimate of error, and the second column is for the test set.
Note

This function does not work for RRF objects that have type=unsupervised. If the x has a non-null test component, then the test set errors are also plotted.

plot(RRF(mpg ~ ., mtcars, keep.forest=FALSE, ntree=100), log="y")

predict.RRF                  predict method for random forest objects

Description

Prediction of test data using random forest.

Usage

## S3 method for class 'RRF'
predict(object, newdata, type="response",
        norm.votes=TRUE, predict.all=FALSE, proximity=FALSE, nodes=FALSE,
        cutoff, ...)

Arguments

object               an object of class RRF, as that created by the function RRF.
newdata              a data frame or matrix containing new data. (Note: If not given, the out-of-bag prediction in object is returned.
type                 one of response, prob. or votes, indicating the type of output: predicted values, matrix of class probabilities, or matrix of vote counts. class is allowed, but automatically converted to "response", for backward compatibility.
norm.votes           Should the vote counts be normalized (i.e., expressed as fractions)? Ignored if object$type is regression.
predict.all           Should the predictions of all trees be kept?
proximity             Should proximity measures be computed? An error is issued if object$type is regression.
nodes
Should the terminal node indicators (an \( n \) by \( n_{\text{tree}} \) matrix) be return? If so, it is in the “nodes” attribute of the returned object.

cutoff
(Classification only) A vector of length equal to number of classes. The ‘winning’ class for an observation is the one with the maximum ratio of proportion of votes to cutoff. Default is taken from the forest\$cutoff component of object (i.e., the setting used when running RRF).

... not used currently.

Value

If object\$type is regression, a vector of predicted values is returned. If predict.all=TRUE, then the returned object is a list of two components: aggregate, which is the vector of predicted values by the forest, and individual, which is a matrix where each column contains prediction by a tree in the forest.

If object\$type is classification, the object returned depends on the argument type:

- **response**: predicted classes (the classes with majority vote).
- **prob**: matrix of class probabilities (one column for each class and one row for each input).
- **vote**: matrix of vote counts (one column for each class and one row for each new input); either in raw counts or in fractions (if norm.votes=TRUE).

If predict.all=TRUE, then the individual component of the returned object is a character matrix where each column contains the predicted class by a tree in the forest.

If proximity=TRUE, the returned object is a list with two components: pred is the prediction (as described above) and proximity is the proximity matrix. An error is issued if object\$type is regression.

If nodes=TRUE, the returned object has a “nodes” attribute, which is an \( n \) by \( n_{\text{tree}} \) matrix, each column containing the node number that the cases fall in for that tree.

NOTE: If the object inherits from RRF.formula, then any data with NA are silently omitted from the prediction. The returned value will contain NA correspondingly in the aggregated and individual tree predictions (if requested), but not in the proximity or node matrices.

NOTE2: Any ties are broken at random, so if this is undesirable, avoid it by using odd number ntree in RRF().

ind <- sample(2, nrow(iris), replace = TRUE, prob=c(0.8, 0.2))
iris.rf <- RRF(Species ~ ., data=iris[ind == 1,])
iris.pred <- predict(iris.rf, iris[ind == 2,])
table(observed = iris[ind==2, "Species"], predicted = iris.pred)
# Get prediction for all trees.
predict(iris.rf, iris[ind == 2,], predict.all=TRUE)
# Proximities.
predict(iris.rf, iris[ind == 2,], proximity=TRUE)
# Nodes matrix.
str(attr(predict(iris.rf, iris[ind == 2,], nodes=TRUE), "nodes"))

Description

RRF implements the regularized random forest algorithm. It is based on the randomForest R package by Andy Liaw, Matthew Wiener, Leo Breiman and Adele Cutler.

Usage

## S3 method for class 'formula'
RRF(formula, data=NULL, ..., subset, na.action=na.fail)
## Default S3 method:
RRF(x, y=NULL, xtest=NULL, ytest=NULL, ntree=500,
   mtry=if (is.null(y) & & !is.factor(y))
   max(floor(ncol(x)/3), 1) else floor(sqrt(ncol(x))),
   replace=TRUE, classwt=NULL, cutoff, strata,
   sampsize = if (replace) nrow(x) else ceiling(.632*nrow(x)),
   nodesize = if (!is.null(y) & & !is.factor(y)) 5 else 1,
   maxnodes = NULL,
   importance=FALSE, localImp=FALSE, nPerm=1,
   proximity, oob.prox=proximity,
   norm.votes=TRUE, do.trace=FALSE,
   keep.forest=!is.null(y) & & is.null(xtest), corr.bias=FALSE,
   keep.inbag=FALSE, coefReg=NULL, flagReg=1, feaIni=NULL,...)
## S3 method for class 'RRF'
print(x, ...)

Arguments

data an optional data frame containing the variables in the model. By default the variables are taken from the environment which RRF is called from.

subset an index vector indicating which rows should be used. (NOTE: If given, this argument must be named.)
na.action  A function to specify the action to be taken if NAs are found. (NOTE: If given, this argument must be named.)

x, formula a data frame or a matrix of predictors, or a formula describing the model to be fitted (for the print method, an RRF object).

y A response vector. If a factor, classification is assumed, otherwise regression is assumed. If omitted, RRF will run in unsupervised mode.

xtest a data frame or matrix (like x) containing predictors for the test set.

ytest response for the test set.

ntree Number of trees to grow. This should not be set to too small a number, to ensure that every input row gets predicted at least a few times.

mtry Number of variables randomly sampled as candidates at each split. Note that the default values are different for classification (sqrt(p) where p is number of variables in x) and regression (p/3).

replace Should sampling of cases be done with or without replacement?

classwt Priors of the classes. Need not add up to one. Ignored for regression.

cutoff (Classification only) A vector of length equal to number of classes. The ‘winning’ class for an observation is the one with the maximum ratio of proportion of votes to cutoff. Default is 1/k where k is the number of classes (i.e., majority vote wins).

strata A (factor) variable that is used for stratified sampling.

sampsize Size(s) of sample to draw. For classification, if sampsize is a vector of the length the number of strata, then sampling is stratified by strata, and the elements of sampsize indicate the numbers to be drawn from the strata.

nodesize Minimum size of terminal nodes. Setting this number larger causes smaller trees to be grown (and thus take less time). Note that the default values are different for classification (1) and regression (5).

maxnodes Maximum number of terminal nodes trees in the forest can have. If not given, trees are grown to the maximum possible (subject to limits by nodesize). If set larger than maximum possible, a warning is issued.

importance Should importance of predictors be assessed?

localImp Should casewise importance measure be computed? (Setting this to TRUE will override importance.)

nPerm Number of times the OOB data are permuted per tree for assessing variable importance. Number larger than 1 gives slightly more stable estimate, but not very effective. Currently only implemented for regression.

proximity Should proximity measure among the rows be calculated?

oob.prox Should proximity be calculated only on “out-of-bag” data?

norm.votes If TRUE (default), the final result of votes are expressed as fractions. If FALSE, raw vote counts are returned (useful for combining results from different runs). Ignored for regression.

do.trace If set to TRUE, give a more verbose output as RRF is run. If set to some integer, then running output is printed for every do.trace trees.
RRF

keep.forest If set to FALSE, the forest will not be retained in the output object. If xtest is given, defaults to FALSE.
corr.bias perform bias correction for regression? Note: Experimental. Use at your own risk.
keep.inbag Should an n by ntree matrix be returned that keeps track of which samples are “in-bag” in which trees (but not how many times, if sampling with replacement)
coefReg the coefficient(s) of regularization. A smaller coefficient may lead to a smaller feature subset, i.e. there are fewer variables with non-zero importance scores. coefReg must be either a single value (all variables have the same coefficient) or a numeric vector of length equal to the number of predictor variables. default: 0.8
flagReg 1: with regularization; 0: without regularization. default: 1
feaIni initial feature subset, useful only when flagReg = 1
... optional parameters to be passed to the low level function RRF.default.

Value

An object of class RRF, which is a list with the following components:
call the original call to RRF
type one of regression, classification, or unsupervised.
predicted the predicted values of the input data based on out-of-bag samples.importance a matrix with nclass + 2 (for classification) or two (for regression) columns. For classification, the first nclass columns are the class-specific measures computed as mean decrease in accuracy. The nclass + 1st column is the mean decrease in accuracy over all classes. The last column is the mean decrease in Gini index. For Regression, the first column is the mean decrease in accuracy and the second the mean decrease in MSE. If importance=FALSE, the last measure is still returned as a vector.importanceSD The “standard errors” of the permutation-based importance measure. For classification, a p by nclass + 1 matrix corresponding to the first nclass + 1 columns of the importance matrix. For regression, a length p vector.
localImp a p by n matrix containing the casewise importance measures, the [i,j] element of which is the importance of i-th variable on the j-th case. NULL if localImp=FALSE.
ntree number of trees grown.
mtry number of predictors sampled for splitting at each node.
forest (a list that contains the entire forest; NULL if RRF is run in unsupervised mode or if keep. forest=FALSE.
err.rate (classification only) vector error rates of the prediction on the input data, the i-th element being the (OOB) error rate for all trees up to the i-th.
confusion (classification only) the confusion matrix of the prediction (based on OOB data).
votes (classification only) a matrix with one row for each input data point and one column for each class, giving the fraction or number of (OOB) ’votes’ from the random forest.
oob.times number of times cases are ‘out-of-bag’ (and thus used in computing OOB error estimate)

proximity if proximity=TRUE when RRF is called, a matrix of proximity measures among the input (based on the frequency that pairs of data points are in the same terminal nodes).

feaSet features selected

mse (regression only) vector of mean square errors: sum of squared residuals divided by n.

rsq (regression only) “pseudo R-squared”: 1 - mse / Var(y).

test if test set is given (through the xtest or additionally ytest arguments), this component is a list which contains the corresponding predicted, err.rate, confusion, votes (for classification) or predicted, mse and rsq (for regression) for the test set. If proximity=TRUE, there is also a component, proximity, which contains the proximity among the test set as well as proximity between test and training data.

Note

For large data sets, especially those with large number of variables, calling RRF via the formula interface is not advised: There may be too much overhead in handling the formula.

Examples

```r
#-----Example 1-----
library(RRF); set.seed(1)

#only the first feature and last feature are truly useful
X <- matrix(runif(50*50), ncol=50)
class <- (X[,1])^2 + (X[,50])^2
class[class>median(class)] <- 1;
class[class<=median(class)] <- 0

#ordinary random forest.
rf <- RRF(X, as.factor(class), flagReg = 0)
impRF <- rf$importance
```
`rrfcv` - Random Forest Cross-Validation for Feature Selection

**Description**

This function shows the cross-validated prediction performance of models with sequentially reduced number of predictors (ranked by variable importance) via a nested cross-validation procedure.

**Usage**

```r
rrfcv(trainx, trainy, cv.fold=5, scale="log", step=0.5, mtry=function(p) max(1, floor(sqrt(p))), recursive=FALSE, ...)
```

**Arguments**

- `trainx`: matrix or data frame containing columns of predictor variables
- `trainy`: vector of response, must have length equal to the number of rows in `trainx`
- `cv.fold`: number of folds in the cross-validation
- `scale`: if "log", reduce a fixed proportion (step) of variables at each step, otherwise reduce step variables at a time
step if log=TRUE, the fraction of variables to remove at each step, else remove this many variables at a time

mtry a function of number of remaining predictor variables to use as the mtry parameter in the RRF call

recursive whether variable importance is (re-)assessed at each step of variable reduction

other arguments passed on to RRF

Value

A list with the following components:

list(n.var=n.var, error.cv=error.cv, predicted=cv.pred)

n.var vector of number of variables used at each step

error.cv corresponding vector of error rates or MSEs at each step

predicted list of n.var components, each containing the predicted values from the cross-validation

Examples

```r
## The following can take a while to run, so if you really want to try
## it, copy and paste the code into R.

## Not run:
set.seed(647)
myiris <- cbind(iris[1:4], matrix(runif(508 * nrow(iris)), nrow(iris), 508))
result <- rrfcv(myiris, iris$Species)
with(result, plot(n.var, error.cv, log="x", type="o", lwd=2))

result <- replicate(5, rrfcv(myiris, iris$Species), simplify=FALSE)
error.cv <- sapply(result, "[[", "error.cv")
matplot(result[[1]]$n.var, cbind(rowMeans(error.cv), error.cv), type="l",
        lwd=c(2, rep(1, ncol(error.cv))), col=1, lty=1, log="x",
        xlab="Number of variables", ylab="CV Error")
```
## rrfImpute

**Description**

Impute missing values in predictor data using proximity from RRF.

**Usage**

```r
## Default S3 method:
rrfImpute(x, y, iter=5, ntree=300, ...)
## S3 method for class 'formula'
rrfImpute(x, data, ..., subset)
```

**Arguments**

- `x`: A data frame or matrix of predictors, some containing NAs, or a formula.
- `y`: Response vector (NA’s not allowed).
- `data`: A data frame containing the predictors and response.
- `iter`: Number of iterations to run the imputation.
- `ntree`: Number of trees to grow in each iteration of RRF.
- `...`: Other arguments to be passed to `rrf`.
- `subset`: A logical vector indicating which observations to use.

**Details**

The algorithm starts by imputing NAs using `na.roughfix`. Then `RRF` is called with the completed data. The proximity matrix from the RRF is used to update the imputation of the NAs. For continuous predictors, the imputed value is the weighted average of the non-missing observations, where the weights are the proximities. For categorical predictors, the imputed value is the category with the largest average proximity. This process is iterated `iter` times.

Note: Imputation has not (yet) been implemented for the unsupervised case. Also, Breiman (2003) notes that the OOB estimate of error from RRF tend to be optimistic when run on the data matrix with imputed values.

**Value**

A data frame or matrix containing the completed data matrix, where NAs are imputed using proximity from RRF. The first column contains the response.

Examples

data(iris)
iris.na <- iris
set.seed(111)
## artificially drop some data values.
for (i in 1:4) iris.na[sample(150, sample(20)), i] <- NA
set.seed(222)
iris.imputed <- rrfImpute(Species ~ ., iris.na)
set.seed(333)
iris.rf <- RRF(Species ~ ., iris.imputed)
print(iris.rf)

rrfNews

Show the NEWS file

Description

Show the NEWS file of the RRF package.

Usage

rrfNews()

Value

None.

treesize

Size of trees in an ensemble

Description

Size of trees (number of nodes) in and ensemble.

Usage

treesize(x, terminal=TRUE)
Arguments

- `x`: an object of class RRF, which contains a forest component.
- `terminal`: count terminal nodes only (TRUE) or all nodes (FALSE)

Value

A vector containing number of nodes for the trees in the RRF object.

Note

The RRF object must contain the forest component; i.e., created with `RRF(..., keep.forest=TRUE)`.

tuneRRF

**Tune RRF for the optimal mtry parameter**

Description

Starting with the default value of mtry, search for the optimal value (with respect to Out-of-Bag error estimate) of mtry for RRF.

Usage

tuneRRF(x, y, mtryStart, ntreeTry=50, stepFactor=2, improve=0.05, trace=TRUE, plot=TRUE, doBest=FALSE, ...)

Arguments

- `x`: matrix or data frame of predictor variables
- `y`: response vector (factor for classification, numeric for regression)
- `mtryStart`: starting value of mtry; default is the same as in RRF
- `ntreeTry`: number of trees used at the tuning step
- `stepFactor`: at each iteration, mtry is inflated (or deflated) by this value
improve  the (relative) improvement in OOB error must be by this much for the search to continue
trace   whether to print the progress of the search
plot    whether to plot the OOB error as function of mtry
doBest whether to run a forest using the optimal mtry found
...     options to be given to \texttt{RRF}

\textbf{Value}

If \texttt{doBest}=FALSE (default), it returns a matrix whose first column contains the mtry values searched, and the second column the corresponding OOB error.

If \texttt{doBest}=TRUE, it returns the \texttt{RRF} object produced with the optimal mtry.

\textbf{See Also}

\texttt{RRF}

\textbf{Examples}

\begin{verbatim}
data(fgl, package="MASS")
g1.res <- tuneRRF(fgl[,10], fgl[,10], stepFactor=1.5)
\end{verbatim}

\begin{verbatim}
varImpPlot(x = tuneRRF(fgl[,10], fgl[,10], stepFactor=1.5),
           sort = TRUE)
\end{verbatim}

\textbf{Description}

Dotchart of variable importance as measured by a Random Forest

\textbf{Usage}

\begin{verbatim}
varImpPlot(x, sort=TRUE, n.var=min(30, nrow(x$importance)),
           type=\texttt{NULL}, class=\texttt{NULL}, scale=\texttt{TRUE},
           main=deparse(substitute(x)), ...)
\end{verbatim}

\textbf{Arguments}

\begin{description}
\item{x} An object of class \texttt{RRF}.
\item{sort} Should the variables be sorted in decreasing order of importance?
\item{n.var} How many variables to show? (Ignored if \texttt{sort}=FALSE.)
\item{type, class, scale} arguments to be passed on to \texttt{importance}
\item{main} plot title.
\item{...} Other graphical parameters to be passed on to \texttt{dotchart}.\end{description}
Value

Invisibly, the importance of the variables that were plotted.

RRF, importance

Examples

```r
set.seed(4543)
data(mtcars)
mtcars.rf <- RRF(mpg ~ ., data=mtcars, ntree=1000, keep.forest=FALSE,
                  importance=TRUE)
varImpPlot(mtcars.rf)
```

---

varUsed

Variables used in a random forest

Description

Find out which predictor variables are actually used in the random forest.

Usage

```r
varUsed(x, by.tree=FALSE, count=TRUE)
```

Arguments

- `x` An object of class RRF.
- `by.tree` Should the list of variables used be broken down by trees in the forest?
- `count` Should the frequencies that variables appear in trees be returned?

Value

If `count=TRUE` and `by.tree=FALSE`, an integer vector containing frequencies that variables are used in the forest. If `by.tree=TRUE`, a matrix is returned, breaking down the counts by tree (each column corresponding to one tree and each row to a variable).

If `count=FALSE` and `by.tree=TRUE`, a list of integer indices is returned giving the variables used in the trees, else if `by.tree=FALSE`, a vector of integer indices giving the variables used in the entire forest.
