Package ‘RSiena’

November 2, 2023

Encoding UTF-8
Type Package
Title Siena - Simulation Investigation for Empirical Network Analysis
Version 1.4.1
Date 2023-11-01
Maintainer Tom A.B. Snijders <tom.snijders@nuffield.ox.ac.uk>
Depends R (>= 3.5.0)
Imports Matrix, lattice, parallel, MASS, methods, xtable
Suggests network, tools, codetools, tcltk
SystemRequirements GNU make
Description The main purpose of this package is to perform simulation-based estimation of stochastic actor-oriented models for longitudinal network data collected as panel data. Dependent variables can be single or multivariate networks, which can be directed, non-directed, or two-mode; and associated actor variables. There are also functions for testing parameters and checking goodness of fit. An overview of these models is given in Snijders (2017), <doi:10.1146/annurev-statistics-060116-054035>.

**RSiena-package**

**Simulation Investigation for Empirical Network Analysis**

**Description**

Fits statistical models to longitudinal sets of networks, and to longitudinal sets of networks and behavioral variables. Not only one-mode networks but also two-mode networks and multivariate networks are allowed. The models are stochastic actor-oriented models, described in Snijders (2017).

Recent versions of the package are distributed through GitHub, see [https://github.com/snlab-nl/rsiena/](https://github.com/snlab-nl/rsiena/).

**Details**

The main flow of operations of this package is as follows.

Data objects can be created from matrices and vectors using `sienaDependent`, `coCovar`, `varCovar`, `coDyadCovar`, etc., and finally `sienaDataCreate`.

Effects are selected using an `sienaEffects` object, which can be created using `getEffects` and may be further specified by `includeEffects`, `setEffect`, and `includeInteraction`. 
Control of the estimation algorithm requires a \texttt{sienaAlgorithm} object that defines the settings (parameters) of the algorithm, and which can be created by \texttt{sienaAlgorithmCreate}.

Function \texttt{siena07} is used to fit a model. Function \texttt{sienaGOF} can be used for studying goodness of fit.

A general introduction to the method is available in the tutorial paper Snijders, van de Bunt, and Steglich (2010). Next to the help pages, more detailed help is available in the manual (see below) and a lot of information is at the website (also see below).

**allEffects** *Internal data frame used to construct effect objects.*

**Description**

This data frame is used internally to construct effect objects.

**Usage**

`data(allEffects)`

**Format**

A data frame with values for the following 23 variables.

- `effectGroup` a character vector
- `effectName` a character vector
- `functionName` a character vector
- `shortName` a character vector
endowment  a logical vector
interaction1  a character vector
interaction2  a character vector
type  a character vector
basicRate  a logical vector
include  a logical vector
randomEffects  a logical vector
fix  a logical vector
test  a logical vector
timeDummy  a character vector, default ","
initialValue  a numeric vector
parm  a numeric vector
functionType  a character vector
period  a character vector
rateType  a character vector
untrimmedValue  a numeric vector
effect1  a logical vector
effect2  a logical vector
effect3  a logical vector
interactionType  a character vector
local  a logical vector
setting  Settings name: " (no settings), 'primary', 'universal' or the name of the defining covariate.

Details

Used to define effects. Not for general user use.

References

See https://www.stats.ox.ac.uk/~snijders/siena/
**coCovar**

*Function to create a constant covariate object*

**Description**

This function creates a constant covariate object from a vector.

**Usage**

```r
coCovar(val, centered=TRUE, nodeSet="Actors", warn=TRUE, imputationValues=NULL)
```

**Arguments**

- `val`: Vector of covariate values
- `centered`: Boolean: if TRUE, then the mean value is subtracted.
- `nodeSet`: Name of node set: character string. If the entire data set contains more than one node set, then the node sets must be specified in all data objects.
- `warn`: Logical: is a warning given if all values are NA, or all non-missing values are the same.
- `imputationValues`: Vector of covariate values of same length as `val`, to be used for imputation of NA values (if any) in `val`. Must not contain any NA.

**Details**

When part of a Siena data object, the covariate is associated with the node set `nodeSet` of the Siena data object. In practice, the node set needs to be specified only in the case of the use of the covariate with a two-mode network.

If there are any NA values in `val`, and `imputationValues` is given, then the corresponding elements of `imputationValues` are used for imputation. If `imputationValues` is NULL, imputation is by the mean value. In both cases, cases with imputed values are not used for calculating target statistics (see the manual).

**Value**

Returns the covariate as an object of class "coCovar", in which form it can be used as an argument to `sienaDataCreate`.

\texttt{sienaDataCreate}, \texttt{varCovar}, \texttt{coDyadCovar}, \texttt{varDyadCovar}, \texttt{sienaNodeSet}

Examples

```r
myconstCovar <- coCovar(s50a[,1])
senders <- sienaNodeSet(50, nodeSetName="senders")
receivers <- sienaNodeSet(30, nodeSetName="receivers")
senders.attribute <- coCovar(rep(1:10, each=5), nodeSet="senders")
receivers.attribute <- coCovar(rep(1:5, each=6), nodeSet="receivers")
```

\texttt{coDyadCovar} \hspace{1cm} \textit{Function to create a constant dyadic covariate object.}

\textbf{Description}

This function creates a constant dyadic covariate object from a matrix.

\textbf{Usage}

\begin{verbatim}
coDyadCovar(val, centered=TRUE, nodeSets=c("Actors", "Actors"),
warn=TRUE, sparse=inherits(val,"TsparseMatrix"), type=c("oneMode", "bipartite"))
\end{verbatim}

\textbf{Arguments}

\begin{itemize}
  \item \textbf{val} \hspace{1cm} Matrix of covariate values. May be sparse, of type "TsparseMatrix".
  \item \textbf{centered} \hspace{1cm} Boolean: if TRUE, then the mean value is subtracted.
  \item \textbf{nodeSets} \hspace{1cm} The name of the node sets with which this covariate is associated. If the entire data set contains more than one node set, then the node sets must be specified in all data objects.
  \item \textbf{warn} \hspace{1cm} Logical: is a warning given if all values are \texttt{NA}, or all non-missing values are the same.
  \item \textbf{sparse} \hspace{1cm} Boolean: whether a sparse matrix or not.
  \item \textbf{type} \hspace{1cm} oneMode or bipartite: whether the matrix refers to a one-mode or a bipartite (two-mode) network.
\end{itemize}

\textbf{Details}

When part of a Siena data object, the covariate is assumed to be associated with the node sets named in nodeSets of the Siena data object. The name of the associated node sets will only be checked when the Siena data object is created.

\textbf{Value}

Returns the covariate as an object of class "coDyadCovar", in which form it can be used as an argument to \texttt{sienaDataCreate}.

Examples
mydyadvar <- coDyadCovar(s503)

edit.sienaEffects  Allow editing of a sienaEffects object if a gui is available.

Description
Interactive editor for an effects object. A wrapper to edit.data.frame.

Usage
## S3 method for class 'sienaEffects'
edit(name, ...)

Arguments
name An object of class sienaEffects
... For extra arguments (none used at present)

Details
Will be invoked by fix(name) for an object of class sienaEffects.

Value
The updated object. There is no backup copy, and the edits cannot be undone.

mydyadcovar <- coDyadCovar(matrix(as.numeric(rnorm(2500) > 2), nrow=50))
mydata <- sienaDataCreate(mynet1, mybeh, mycovar, mydyadcovar)
myeff <- getEffects(mydata)
## Not run:
fix(myeff)
## End(Not run)
```

---

effectsDocumentation  
*Function to create a table of documentation of effect names, short names etc.*

Description

Produces a table of the shortnames and other information for effects, either in html or latex.

Usage

```r
effectsDocumentation(effects = NULL, type = "html", display = (type=="html"),
filename = ifelse(is.null(effects), "effects", deparse(substitute(effects)))
```

Arguments

- **effects**: A Siena effects object, or NULL.
- **type**: Type of output required. Valid options are "html" or "latex".
- **display**: Boolean: should the output be displayed after creation. Only applicable to html output.
- **filename**: Character string denoting file name.

Details

If `effects=NULL`, the `allEffects` object is written to a table, either latex or html. This table presents all the available effects present in this version of RSiena, not delimited by a particular data set. The default file name is "effects.tex" or "effects.html", respectively.

The table lists all effects, with their name, shortName, whether an endowment (and creation) effect exists, the value of an effect parameter - if any - , and the interactionType (which can be empty or: "ego" or "dyadic" for dependent network variables; "OK" for dependent behavior variables). The latter is important for knowing how the effects can be used in interaction effects. (See `includeInteraction`).
If an existing effects object is specified for \textit{effects}, then all available effects in this effects object are listed. This table lists the name (i.e., dependent variable), effect name, \text{shortName}, type (rate/evaluation/endowment/creation), the variables defined as \text{interaction1} and \text{interaction2} (see \texttt{includeEffects}) that specify this effect, the value of an effect parameter - if any -, and the interactionType.

The GMoM effects, which are those with type=gmm, are listed at the end. For these, the distinction between the fields \text{name} and \text{interaction1}, referring to the dependent and the explanatory roles of the variables, has no meaning.

The default root file name is the name of the input effects object.

\textbf{Value}

Nothing returned. Output files are created in the current working directory.

\textbf{Author(s)}

\textbf{Examples}

\begin{verbatim}
## Not run: effectsDocumentation()
\end{verbatim}

---

\texttt{funnelPlot} \hspace{1cm} \textit{Plot function for a list of sienaFit objects}

\textbf{Description}

Draws a funnel plot for a list of sienaFit objects that all have estimated the same parameter.

\textbf{Usage}

\begin{verbatim}
funnelPlot(anslist, k, threshold=NULL, origin=TRUE, plotAboveThreshold=TRUE, verbose=TRUE, ...)
\end{verbatim}
funnelPlot

Arguments

- **anslist**: A list of objects of class `sienaFit`.
- **k**: The number of the parameter to be plotted.
- **threshold**: Threshold for standard errors: all estimations where the standard error for parameter k is larger than this threshold will be disregarded.
- **origin**: Boolean: whether to include the origin in the plot, if all estimates have the same sign.
- **plotAboveThreshold**: Boolean: whether to include the estimates for which the standard error is larger than `threshold`, and plot them with an asterisk at `se=threshold`.
- **verbose**: Boolean: whether to report in the console all estimates omitted, because either their standard error is larger than `threshold`, or they were fixed.
- ... For extra arguments (passed to `plot`).

Details

The function `funnelPlot` plots estimates against standard errors for a given effect k, with red reference lines added at the two-sided significance threshold 0.05. Effects for which a score test was requested are not plotted (and reported to the console if `verbose`). If not all effects with number k are the same in all `sienaFit` objects, a warning is given. The effect name for the first object is used as the plot title.

Another funnel plot is available as `print.sienaMeta`.

Value

The two-column matrix of values of the plotted points is invisibly returned.

`siena08`, `print.sienaMeta`

Examples

# A meta-analysis for three groups does not make much sense.
# But using three groups shows the idea.

Group1 <- sienaDependent(array(c(N3401, HN3401), dim=c(45, 45, 2)))
Group3 <- sienaDependent(array(c(N3403, HN3403), dim=c(37, 37, 2)))
Group4 <- sienaDependent(array(c(N3404, HN3404), dim=c(33, 33, 2)))
dataset.1 <- sienaDataCreate(Friends = Group1)
dataset.3 <- sienaDataCreate(Friends = Group3)
dataset.4 <- sienaDataCreate(Friends = Group4)
OneAlgorithm <- sienaAlgorithmCreate(projname = NULL, nsub=1, n3=50, seed=123)
getEffects <- function(x, nintn = 10, behNintn = 4, getDocumentation = FALSE, onePeriodSde = FALSE)

Description

Creates a basic list of effects for all dependent variables in the input siena object.

Usage

getect(x, nintn = 10, behNintn = 4, getDocumentation = FALSE, onePeriodSde = FALSE)

Arguments

- x: an object of class 'siena' or 'sienaGroup'
- nintn: Number of user-defined network interactions that can later be created.
- behNintn: Number of user-defined behavior interactions that can later be created.
- getDocumentation: Flag to allow documentation of internal functions, not for use by users.
- onePeriodSde: Flag to indicate that the stochastic differential equation (SDE) model \( dZ(t) = [aZ(t) + b] \, dt + g \, dW(t) \) should be used, instead of the regular SDE with a scale parameter. This is only relevant in case the model includes a continuous dependent variable and one period is studied.

Details

Creates a data frame of effects for use in siena model estimation. The regular way of changing this object is by the functions includeEffects, setEffect, and includeInteraction.

Note that the class of the return object may be lost if the data.frame is edited using fix. See fix and edit.data.frame.

Value

An object of class sienaEffects or sienaGroupEffects: this is a data frame of which the rows are the effects available for data set x.

The effects object consists of consecutive parts, each of which relates to one dependent variable in the input object. The columns are:

- name: name of the dependent variable
getEffects

effectName  name of the effect
functionName name of the function
shortName  short name for the effect
interaction1  second variable to define the effect, if any
interaction2  third variable to define the effect, if any
type  "eval", "endow", "creation", "rate", or "gmm"

basicRate  boolean: whether a basic rate parameter
include  boolean: include in the model to be fitted or not
randomEffects  boolean: random or fixed effect. Currently not used.
fix  boolean: fix parameter value or not
test  boolean: test parameter value or not
timeDummy  comma separated list of periods, or "all", or "," for none – which time dummy interacted parameters should be included?

initialValue  starting value for estimation, also used for fix and test.
parm  internal effect parameter values

functionType  "objective" or "rate"

period  period for basic rate parameters

rateType  "Structural", "covariate", "diffusion"

untrimmedValue  Used to store initial values which could be trimmed
effect1  Used to indicate effect number in user-specified interactions
effect2  Used to indicate effect number in user-specified interactions
effect3  Used to indicate effect number in user-specified interactions

interactionType  Defines "dyadic" or "ego" or "OK" effects, used in includeInteraction

local  whether a local effect; used for the option localML in sienaAlgorithmCreate
effectFn  here NULL, but could be replaced by a function later
statisticFn  here NULL, but could be replaced by a function later

netType  Type of dependent variable: "oneMode", "behavior", or "bipartite"
groupName  name of relevant group data object
group  sequential number of relevant group data object in total

effectNumber  a unique identifier of the row

The combination of name, shortName, interaction1, interaction2, and type uniquely identifies any effect other than basic rate effects and user-specified interaction effects. For the latter, effect1, effect2 and effect3 are also required for the identification. The combination name, shortName, period and group uniquely identifies a basic rate effect.

The columns not used for identifying the effect define how the effect is used for the estimation.

The columns initialValue and parm should not be confused: initialValue gives the initial value for the parameter to be estimated, indicated in the manual by theta; parm gives the internal
value of the parameter defining the effect, indicated in the manual (Chapter 12) by $p$, and is fixed during the estimation.

A list of all effects in a given effects object (e.g., `myeff`), including their names of dependent variables, effect names, short names, and values of interaction1 and interaction2 (if any), is obtained by executing `effectsDocumentation(myeff)`. 

As from version 1.3.24, effects object have a "version" attribute. Effects objects including interaction effects created by `includeInteraction` are not necessarily compatible between versions of RSiena. Therefore it is recommended, for effects objects including any interaction effects, to create them again when changing to a new version of RSiena. If an effects object including any interaction effects is used from an old version of RSiena, this will lead to a warning when running `siena07`.

```r
mynet1 <- sienaDependent(array(c(s501, s502, s503), dim=c(50, 50, 3)))
mybeh <- sienaDependent(s50a, type="behavior")
mycovar <- coCovar(rnorm(50))
mydyadcovar <- coDyadCovar(matrix(as.numeric(rnorm(2500) > 2), nrow=50))
mydata <- sienaDataCreate(mynet1, mybeh, mycovar, mydyadcovar)
myeff <- getEffects(mydata)
myeff
```

Description

Matrices N3401, N3403, N3404, N3406, and HN3401, HN3403, HN3404, HN3406 are two waves of networks for four schools (numbered 1, 3, 4, 6).
**includeEffects**

**Format**

Adjacency matrices for the network at two time points. The matrices with name N... are the first wave, those with name HN... are the second wave.

There is a tie from pupil i to pupil j if i says that he/she receives and/or gives emotional support from/to pupil j. The data are part of a larger data set (see source below) and were collected under the direction of Chris Baerveldt.

**Source**

https://www.stats.ox.ac.uk/~snijders/siena/CB_data.zip

**References**

See https://www.stats.ox.ac.uk/~snijders/siena/BaerveldtData.html

**Examples**

mynet <- sienaDependent(array(c(N3401, HN3401), dim=c(45, 45, 2)))
mydata <- sienaDataCreate(mynet)

---

**includeEffects**  
*Function to include effects in a Siena model*

**Description**

This function can be used for model specification by modifying a Siena effects object.

**Usage**

includeEffects(myeff, ..., include = TRUE, name = myeff$name[1], type = "eval", interaction1 = "", interaction2 = "", fix=FALSE, test=FALSE, character=FALSE, verbose = TRUE)

**Arguments**

- **myeff** a Siena effects object as created by `getEffects`
- **...** short names to identify the effects which should be included or excluded.
- **include** Boolean. default TRUE, but can be switched to FALSE to turn off an effect.
- **name** Name of dependent variable (network or behavior) for which effects are being included. Defaults to the first in the effects object.
includeEffects 17

type Type of effects to be included: "eval", "endow", "creation", or "rate".
interaction1 Name of siena object where needed to completely identify the effects e.g. co-
variate name or behavior variable name.
interaction2 Name of siena object where needed to completely identify the effects e.g. co-
variate name or behavior variable name.
fix Boolean. Are the effects to be fixed at the value stored in myeff$initialValue
or not.
test Boolean. Are the effects to be tested or not (requires fix).
character Boolean: are the effect names character strings or not.
verbose Boolean: should the print of altered effects be produced.

Details
Recall from the help page for getEffects that a Siena effects object (class sienaEffects or
sienaGroupEffects) is a data.frame; the rows in the data frame are the effects for this data set;
some of the columns/variables of the data frame are used to identify the effect, other columns/variables
define how this effect is used in the estimation.

The function includeEffects operates as an interface setting the "include" column on selected
rows of the effects object, to the value requested (TRUE or FALSE). The selected effects must be indi-
cated by the arguments ..., type, and (if necessary) interaction1 and interaction2. The names
interaction1 and interaction2 do not refer to interactions between effects, but to dependence
of effects on other variables in the data set. The arguments should identify the effects completely.
The short names must not be set between quotes, unless you use character=TRUE.
Note that the internal effect parameter has a default value which differs between effects. This can
be set by function setEffect. Also the value of myeff$initialValue can be set by this function.
The function setEffect operates on the effects object in a more detailed way, but applies to one
effect at the time.
Further information about Siena effects objects is given in the help page for getEffects.
A list of all effects available in a given effects object (e.g., myeff), including their names of depen-
dent variables, effect names, short names, and values of interaction1 and interaction2 (if any),
is obtained by executing effectsDocumentation(myeff).
The input names interaction1 and interaction2 do not themselves refer to created interactions,
but to dependence of the base effects on other variables in the data set. They are used to completely
identify the effects.

Value
An updated version of the input effects object, with the include, test, and fix columns for one or
more rows updated. Details of the rows altered will be printed.

Author(s)
Ruth Ripley
includeGMoMStatistics

Function to include GMoM statistics in a Siena model

Description
This function can be used for including one or more GMoM statistics by modifying a Siena effects object.

Usage
includeGMoMStatistics(myeff, ..., include=TRUE, name=myeff$name[1],
                       interaction1="", interaction2="",
                       character=FALSE, verbose=TRUE)

Arguments
myeff   a Siena effects object as created by getEffects
...     short names to identify the GMoM statistics which should be included or excluded.
include Boolean; default TRUE, but can be switched to FALSE to turn off an effect.
name    Name of dependent variable (network or behavior) for which statistics are being included. Defaults to the first in the effects object.
interaction1 Name of siena object where needed to completely identify the effects e.g. covariate name or behavior variable name.
interaction2 Name of siena object where needed to completely identify the effects e.g. covariate name or behavior variable name.
character Boolean: are the statistic names character strings or not.
verbose  Boolean: should the print of altered statistic be produced.

Examples
mynet1 <- sienaDependent(array(c(s501, s502, s503), dim=c(50, 50, 3)))
mybeh <- sienaDependent(s50a, type="behavior")
mydata <- sienaDataCreate(mynet1, mybeh)
myeff <- getEffects(mydata)
myeff <- includeEffects(myeff, transTrip, balance)
myeff <- includeEffects(myeff, avAlt, name="mybeh", interaction1="mynet1")
myeff
Details

The names interaction 1 and interaction 2 refer to the dependence of the GMoM statistics on other variables in the data set. The arguments should identify the GMoM statistic completely. The type does not have to be specified, as it is gmm for all GMoM statistics in the effects object. The short names must not be set between quotes, unless you use character=TRUE.

The function includeGMoMStatistics operates as an interface setting the "include" column on selected rows of the effects object, to the value requested (TRUE or FALSE).

Value

An updated version of the input effects object, with the include column for one or more rows updated. Details of the rows altered will be printed.

myeff

includeInteraction Function to create user-specified interactions for a Siena model.

Description

This function allows the user to include or exclude an interaction effect in a Siena effects object.

Usage

includeInteraction(myeff, ..., include = TRUE, name = myeff$name[1],
                   type = "eval", interaction1 = rep("", 3), interaction2 = rep("", 3),
                   fix=FALSE, test=FALSE, random=FALSE,
                   initialValue=0,
                   character = FALSE, verbose = TRUE)
Arguments

myeff  
a Siena effects object as created by getEffects
include  
2 or 3 short names to identify the effects which should be interacted.
name  
Name of dependent variable (network or behavior) for which interactions are being defined. Defaults to the first in the effects object.
type  
Type of effects to be interacted.
interaction1  
Vector of Siena objects where needed to completely identify the effect e.g. covariate name or behavior variable name. Trailing blanks may be omitted.
interaction2  
Vector of siena objects where needed to completely identify the effect e.g. covariate name or behavior variable name. Trailing blanks may be omitted.
fix  
Boolean. Are the effects to be fixed at the value stored in myeff$initialValue or not.
test  
Boolean. Are the effects to be tested or not (requires fix).
random  
For specifying that the interaction effect will vary randomly; not relevant for RSiena at this moment. Boolean required. Default FALSE.
initialValue  
Initial value for estimation. Default 0.
character  
Boolean: are the effect names character strings or not.
verbose  
Boolean: should the print of altered effects be produced.

Details

The details provided should uniquely identify up to three effects. If so, an interaction effect will be created and included or not in the model.
Whether interactions between two or three given effects can be created depends on their interactionType (which can be, for dependent network variables, empty, ego, or dyadic; and for dependent behavioral variables, empty or OK). Consult the section on Interaction Effects in the manual for this. The interactionType is shown in the list of effects obtained from the function effectsDocumentation. The short names must not be set between quotes, unless you use character=TRUE.
From the point of view of model building it is usually advisable, when including an interaction effect in a model, also to include the corresponding main effects. This is however not enforced by includeInteraction().

As from version 1.3.24, effects object have a "version" attribute. Effects objects including interaction effects are not necessarily compatible between versions of RSiena. Therefore it is recommended to create such effects objects again when changing to a new version of RSiena. If an effects object including any interaction effects is used from an old version of RSiena, this will lead to a warning when running siena07.

An interaction effect does not have its own internal effect parameter. The internal effect parameters of the interacting main effects are used, whether or not these are included in the model. This implies that if an interaction effect is included but not the corresponding main effects, or not all of them, then nevertheless the internal effect parameters as specified in the effects object are used for the interaction. These can be set using function setEffect with the desired value of parameter and
includeInteraction

(in this case) include=FALSE.

The values of the internal effect parameters can be checked for a sienaFit object ans produced by siena07 by looking at ans$effects, which is the requested effects object to which the main effects of the user-defined interactions were added, if they were not yet included.

Interaction effects are constructed from effects with shortName unspInt (for networks) and behUnspInt (for behavior) by specifying their elements effect1 and effect2, and possibly effect3. The shortName is not altered by this function.

The number of possible user-specified interaction effects is limited by the parameters nintn (for dependent network variables) and behNintn (for dependent behavior variables) in the call of getEffects, which determine the numbers of effects with shortNames unspInt and behUnspInt.

The input names interaction1 and interaction2 do not themselves refer to created interactions, but to dependence of the base effects on other variables in the data set. They are used to completely identify the effects.

Further information about Siena effects objects is given in the help page for getEffects.

A list of all effects in a given effects object (e.g., myeff), including their names of dependent variables, effect names, short names, and values of interaction1 and interaction2 (if any), is obtained by executing effectsDocumentation(myeff).

Value

An updated version of the input effects object; if include, containing the interaction effect between "effect1" and "effect2" and possibly "effect3"; if not, without this interaction effect. The shortName of the interaction effect is "unspInt" for network effects and "behUnspInt" for behavior effects. If verbose=TRUE, details of the fields altered will be printed.

myeff
includeTimeDummy  
*Function to include time dummy effects in a Siena model*

**Description**

This function specifies time heterogeneity for selected effects in a Siena model, by interacting them with time dummies, without explicitly using time-dependent covariates.

**Usage**

```
includeTimeDummy(myeff, ..., timeDummy="all", name=myeff$name[1], type="eval",
                   interaction1="", interaction2="", include=TRUE, character=FALSE)
```

**Arguments**

- **myeff**: A Siena effects object as created by `getEffects`.
- **...**: Short names to identify the effects for which interactions with time dummies should be included or excluded. This function cannot be used for regular interaction effects.
- **timeDummy**: Character string. Either "all" or the periods for which to create dummies (from 1 to (number of waves - 1)), space delimited.
- **include**: Boolean. default TRUE, but can be switched to FALSE to turn off an effect.
- **name**: Name of dependent network or behavioral variable for which effects are being included. Defaults to the first in the effects object.
- **type**: Type of dummy effects to be interacted.
- **interaction1**: Name of variable where needed to completely identify the effects e.g. covariate name or behavior variable name.
- **interaction2**: Name of variable where needed to completely identify the effects e.g. covariate name or behavior variable name.
- **character**: Boolean: are the effect names character strings or not

**Details**

The arguments (..., name, interaction1, interaction2) should identify the effects completely. See `includeEffects` and `effectsDocumentation` for more information about this.

This function operates by setting the `timeDummy` column on selected rows of a Siena effects object, thereby specifying interactions of the specified effect or effects with dummy variables for the specified periods. The `timeDummy` column of `myeff` will be set to include the values requested if `include=TRUE`, and to exclude them for `include=FALSE`.

For an effects object in which the `timeDummy` column of some of the included effects includes some or all period numbers, interactions of those effects with ego effects of time dummies for the indicated periods will also be estimated by `siena07`. For the outdegree effect this is just the ego effect of the time dummies. If ... does not include the outdegree effect, then still this ego effect will be created, but its parameter will be fixed to 0.
An alternative to the use of `includeTimeDummy` is to define time-dependent actor covariates (dummy variables or other functions of wave number that are the same for all actors), include these in the data set through `sienaDataCreate`, and include interactions of other effects with ego effects of these time-dependent actor covariates by `includeInteraction`. This is illustrated in an example in the help file for `sienaTimeTest`. Using `includeTimeDummy` is easier; on the other hand, using self-defined interactions with time-dependent variables gives more control (e.g., it will allow to specify linear time dependence and test time heterogeneity for interaction effects).

Value

An updated version of `myeff`, with the `timeDummy` column for one or more rows updated. Details of the rows altered will be printed.

iwlsm

Function to fit an iterated weighted least squares model.

**Description**

Fits an iterated weighted least squares model.

**Usage**

iwlsm(x, ...)

## S3 method for class 'formula'

iwlsm(formula, data, weights, ses, ..., subset, na.action,
method = c("M", "MM", "model.frame"),
wt.method = c("inv.var", "case"),
model = TRUE, x.ret = TRUE, y.ret = FALSE, contrasts = NULL)

## Default S3 method:

iwlsm(x, y, weights, ses, ..., w = rep(1/nrow(x), nrow(x)),
init = "ls", psi = psi.iwlsm,
scale.est = c("MAD", "Huber", "proposal 2"), k2 = 1.345,
method = c("M", "MM"), wt.method = c("inv.var", "case"),
maxit = 20, acc = 1e-4, test.vec = "resid", lqs.control = NULL)

psi.iwlsm(u, k, deriv = 0, w, sj2, hh)
Arguments

formula a formula of the form y ~ x1 + x2 + ...
data data frame from which variables specified in formula are preferentially to be taken.
weights a vector of prior weights for each case.
subset An index vector specifying the cases to be used in fitting.
ses Estimated variance of the responses. Will be pased to psi as sj2
na.action A function to specify the action to be taken if NAs are found. The ‘factory-fresh’ default action in R is na.omit, and can be changed by options(na.action=).
x a matrix or data frame containing the explanatory variables.
y the response: a vector of length the number of rows of x.
method Must be "M". (argument not used here).
wt.method are the weights case weights (giving the relative importance of case, so a weight of 2 means there are two of these) or the inverse of the variances, so a weight of two means this error is half as variable? This will not work at present.
model should the model frame be returned in the object?
x.ret should the model matrix be returned in the object?
y.ret should the response be returned in the object?
contrasts optional contrast specifications: see lm.
w (optional) initial down-weighting for each case. Will not work at present.
init (optional) initial values for the coefficients OR a method to find initial values OR the result of a fit with a coef component. Known methods are "ls" (the default) for an initial least-squares fit using weights w*weights, and "lts" for an unweighted least-trimmed squares fit with 200 samples. Probably not functioning.
psi the psi function is specified by this argument. It must give (possibly by name) a function g(x, ..., deriv, w) that for deriv=0 returns psi(x)/x and for deriv=1 returns some value. Extra arguments may be passed in via ... .
scale.est method of scale estimation: re-scaled MAD of the residuals (default) or Huber's proposal 2 (which can be selected by either "Huber" or "proposal 2").
k2 tuning constant used for Huber proposal 2 scale estimation.
maxit the limit on the number of IWLS iterations.
acc the accuracy for the stopping criterion.
test.vec the stopping criterion is based on changes in this vector.
... additional arguments to be passed to iwlsm.default or to the psi function.
lqs.control An optional list of control values for lqs.
u numeric vector of evaluation points.
k tuning constant. Not used.
deriv 0 or 1: compute values of the psi function or of its first derivative. (Latter not used).
sj2 Estimated variance of the responses
hh Diagonal values of the hat matrix
Details

This function is very slightly adapted from rlm in packages MASS. It alternates between weighted least squares and estimation of variance on the basis of a common variance. The function psi.iwlsm calculates the weights for the next iteration. Used by siena08 to combine estimates from different sienaFits.

Value

An object of class "iwlsm" inheriting from "lm". Note that the df.residual component is deliberately set to NA to avoid inappropriate estimation of the residual scale from the residual mean square by "lm" methods.

The additional components not in an lm object are

s the robust scale estimate used
w the weights used in the IWLS process
psi the psi function with parameters substituted
conv the convergence criteria at each iteration
converged did the IWLS converge?
wresid a working residual, weighted for "inv.var" weights only.

Note

The function has been changed as little as possible, but has only been used with default arguments. The other options have been retained just in case they may prove useful.

maxlikefn

A ML version of FRAN

Description

A function to be called as "FRAN". All in R. very slow. work in progress.

Usage

maxlikefn(z, x, INIT = FALSE, TERM = FALSE, data,
effects = NULL, nstart = 1000, pinsdel = 0.6,
pperm = 0.3, prelins = 0.1, multfactor=2, promul = 0.1,
promul0 = 0.5, pdiaginsdel = 0.1, fromFiniteDiff = FALSE,
noSamples = 1, sampInterval = 50, int = 1)

Arguments

- **z**: control object, passed in automatically in siena07
- **x**: model object, passed in automatically in siena07
- **INIT**: if TRUE, do initial processing. May be required to set up z
- **TERM**: if TRUE, do end processing.
- **data**: A siena object
- **effects**: list of data frames as returned by getEffects
- **nstart**: Number of MH steps at the start, after making the chain
- **pinsdel**: Probability of insert/delete step
- **pperm**: Probability of permutation step. (set to zero in startup phase.)
- **prelins**: Insertion probability in InsDelPermute
- **multfactor**: Factor controlling number of MH steps. Will be read from the model in preference, and that is easier to alter! But I don’t want to alter that program yet.
- **promul**: Probability of choosing a random single multiple in InsDelPermute in start up phase.
promul0 Probability of choosing a random single multiple in InsDelPermute not in startup phase
pdiaginsdel Probability of insertion or deletion of a diagonal link.
fromFiniteDiff Should always be FALSE
noSamples Number of chains to be returned
sampInterval If multiple chains are returned, the number of steps between each
int Number of parallel MCMC chains to pursue.

Details
This can be used for the element FRAN of the model object. The arguments with no defaults must be passed in on the call to siena07. Also you must set the option maxlike=TRUE in the call to sienaAlgorithmCreate()

Value
Depends on the call. If INIT or initC or TERM are true, returns z, the control object. Otherwise, returns a list containing:
fra Simulated scores
dff 2nd deriv, not phase 2
OK could be set to FALSE if serious error has occurred

Network data: excerpt from "Dutch Social Behavior Data Set" of Chris Baerveldt.

Description
Matrices N3401, N3403, N3404, N3406, and HN3401, HN3403, HN3404, HN3406 are two waves of networks for four schools (numbered 1, 3, 4, 6).

Format
Adjacency matrices for the network at two time points. The matrices with name N... are the first wave, those with name HN... are the second wave.

There is a tie from pupil i to pupil j if i says that he/she receives and/or gives emotional support from/to pupil j. The data are part of a larger data set (see source below) and were collected under the direction of Chris Baerveldt.

plot.sienaTimeTest
Functions to plot assessment of time heterogeneity of parameters

Description
Plot method for sienaTimeTest objects.
## S3 method for class 'sienaTimeTest'

```r
plot(x, pairwise=FALSE, effects, scale=.2, plevels=c(.1, .05, .025), ...)
```

### Arguments

- **x**
  - A `sienaTimeTest` object returned by `sienaTimeTest`.

- **pairwise**
  - A Boolean value corresponding to whether the user would like a pairwise plot of the simulated statistics to assess correlation among the effects (`pairwise=TRUE`), or a plot of the estimates across waves in order to assess graphically the results of the score type test.

- **effects**
  - A vector of integers corresponding to the indices given in the `sienaTimeTest` output for effects which are to be plotted.

- **scale**
  - A positive number corresponding to the number of standard deviations on one step estimates to use for computing the maximum and minimum of the plotting range. We recommend experimenting with this number when the y-axes of the plots are not satisfactory. Smaller numbers shrink the axes.

- **plevels**
  - A list of three decimals indicating the gradients at which to draw the confidence interval bars.

- **...**
  - For extra arguments. The Lattice parameter `layout` can be used to control the layout of the graphs.

### Details

The `pairwise=TRUE` plot may be used to assess whether effects are highly correlated. This information may be important when considering forward-model selection, since highly correlated effects may have highly correlated one-step estimates, particularly since the individual score type tests are not orthogonalized against the scores and deviations of yet-unestimated dummies. For example, reciprocity and outdegree may have highly correlated statistics as indicated by a strong, positive correlation coefficient. When considering whether to include dummy terms, it may be a good idea to include, e.g., outdegree, estimate the parameter, and see whether reciprocity dummies remain significant after method of moments estimation of the updated model—as opposed to including both outdegree and reciprocity.

The `pairwise=FALSE` plot displays the most of the information garnered from `sienaTimeTest` in a graphical fashion. For each effect, the method of moments parameter estimate for the base period (i.e. wave 1) is given as a blue, horizontal reference line. One step estimates are given for all of the parameters by dots at each wave. The dots are colored black if the parameter has been included in the model already (i.e. has been estimated via method of moments), or red if they have not been included. Confidence intervals are given based on pivots given at `pvalues`. Evidence of time heterogeneity is suggested by points with confidence intervals not overlapping with the base period.

print.sienaEffects  
Print methods for Siena effects objects

Description

Prints the major columns of the effects object. Or all, with any non-atomic columns listed separately.
## Usage

```r
## S3 method for class 'sienaEffects'
print(x, fileName = NULL, includeOnly=TRUE,
      expandDummies = FALSE, includeRandoms = FALSE, dropRates=FALSE, ...)
## S3 method for class 'sienaEffects'
summary(object, fileName = NULL,
        includeOnly=TRUE, expandDummies = FALSE, ...)
## S3 method for class 'summary.sienaEffects'
print(x, fileName = NULL, ...)
```

## Arguments

- `object`: An object of class `sienaEffects`
- `x`: An object of class `sienaEffects` or `summary.sienaEffects` as appropriate.
- `fileName`: Character string denoting file name if file output desired.
- `includeOnly`: Boolean. If TRUE, only effects with the include flag TRUE will be printed.
- `expandDummies`: Interpret the `timeDummy` column and show any effects which would be added by `sienaTimeFix`.
- `includeRandoms`: Boolean. If TRUE, also the `randomEffects` column will be printed.
- `dropRates`: Boolean. If TRUE, do not print the rows for basic rate effects.
- `...`: For extra arguments (none used at present).

## Value

The function `print.sienaEffects` prints details of the main columns of the selected rows of the effects object.

If the effects object includes statistics for the Generalized Method of Moments (GMoM), as included by function `includeGMoMStatistics` and for which `type=gmm`, the print consists of two parts: the first consists of the included effects for the probability model, the second of the statistics used for GMoM estimation.

The function `summary.sienaEffects` checks the rows for valid printing via `print.data.frame` and excludes any that will fail. The OK columns are printed first, followed by any others.

Output from either can be directed to a file by using the argument `filename`.

     useBound=TRUE, layout = c(2,2))

meta.table(x, d=3, option=2,
           filename=paste(deparse(substitute(x)),'_global.tex',sep=""), align=TRUE)

Arguments

object An object of class sienaMeta.
x An object of class sienaMeta, or summary.sienaMeta as appropriate.
file Boolean: if TRUE, sends output to file named x$projname.txt. If FALSE, output is to the terminal.
reportEstimates Boolean: whether to report all estimates and standard errors.
extra Boolean: if TRUE, prints more information.
which Set of effects contained in the plot (given by sequence numbers).
useBound Boolean: whether to restrict plotted symbols to the bound used in the call of sienaMeta.
Value

The function `print.sienaMeta` prints details of the merged estimates of the meta-analysis carried out by `siena08`, with test statistics. See the help page for `siena08` for what is produced by this function.

The function `summary.sienaMeta` prints details as for the `print` method, but also details of the `sienaFit` objects included.

Output from either can be directed to a file by using the argument `file`. It will be appended to any existing file of the same name: `projname.txt` where `projname` is the value of the argument to `siena08`.

The function `meta.table` writes a combined table of results for all parameters to a LaTeX file in (as default) the current working directory. This table is a more compact version of the results presented by `print.sienaMeta`.

The function `plot.sienaMeta` plots estimates against standard errors for each effect, with reference lines added at the two-sided significance threshold 0.05. It returns an object of class `trellis`, of the `lattice` package. Effects for which a score test was requested are not plotted.

Another funnel plot, not using `siena08`, is available as `funnelPlot`.

print.sienaMeta
print.sienaTest                   Print method for Wald and score tests for RSiena results

Description
This method prints Wald-type and score-type tests for results estimated by siena07.

Usage
## S3 method for class 'sienaTest'
print(x, ...)

Arguments
x                  An object of type sienaTest, produced by Wald.RSiena, Multipar.RSiena,
or score.Test.
...
Extra arguments (not used at present).

Details
The functions Wald.RSiena, Multipar.RSiena, and score.Test produce an object of type sienaTest. These can be printed by this method.

Value
An object of type sienaTest.

print(mprs)

print01Report Function to produce the Siena01 report from R objects

Description

Prints a report of a Siena data object and its default effects.

Usage

print01Report(data, modelname = "Siena", getDocumentation=FALSE)

Arguments

data a Siena data object
modelname Character string used to name the output file "modelname.txt"
getDocumentation Flag to allow documentation of internal functions, not for use by users.

Details

First deletes any file of the name "modelname.txt", then prints a new one.

Value

No value returned.

setEffect
Function to set various columns in an effects object in a Siena model.

Description
This function provides an interface to change various columns of a selected row of a Siena effects object.

Usage
setEffect(myeff, shortName, parameter = NULL, fix = FALSE, test = FALSE, random=FALSE, initialValue = 0, timeDummy = ",", include = TRUE, name = myeff$name[1], type = "eval", interaction1 = "", interaction2 = "", effect1=0, effect2=0, effect3=0, period=1, group=1, character=FALSE, verbose = TRUE)

Arguments
myeff a Siena effects object as created by getEffects
shortName A short name (all with or all without quotes) to identify the effect which should be changed.
parameter Value of internal effect parameter. If NULL, no change is made.
fix For fixing effects. Boolean required. Default FALSE.
test For testing effects by score-type tests. Boolean required. Default FALSE.
random For specifying that effects will vary randomly; not relevant for RSiena at this moment. Boolean required. Default FALSE.
initialValue Initial value for estimation. Default 0.
timeDummy string: Comma delimited string of which periods to dummy. Alternatively, use includeTimeDummy.
**setEffect**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>include</td>
<td>Boolean. default TRUE, but can be switched to FALSE to turn off an effect.</td>
</tr>
<tr>
<td>name</td>
<td>Name of dependent variable (network or behavior) for which effects are being modified. Defaults to the first in the effects object.</td>
</tr>
<tr>
<td>type</td>
<td>Character string indicating the type of the effect to be changed: currently &quot;rate&quot;, &quot;eval&quot;, &quot;endow&quot;, or &quot;creation&quot;. Default &quot;eval&quot;.</td>

<td>Only for shortName=unspInt: second component of interaction effect (see effect1).</td>
</tr>
<tr>
<td>effect3</td>
<td>Only for shortName=unspInt: third component of interaction effect, if any (see effect1).</td>
</tr>
<tr>
<td>period</td>
<td>Number of period if basic rate. Use numbering within groups.</td>
</tr>
<tr>
<td>group</td>
<td>Number of group if basic rate. Only relevant for sienaGroup data sets.</td>
</tr>
<tr>
<td>character</td>
<td>Boolean: whether the short name is a character string.</td>
</tr>
<tr>
<td>verbose</td>
<td>Boolean: should the print of altered effects be produced.</td>
</tr>
</tbody>
</table>

**Details**

Recall from the help page for `getEffects` that a Siena effects object (class sienaEffects or sienaGroupEffects) is a data.frame; the rows in the data frame are the effects for this data set; some of the columns/variables of the data frame are used to identify the effect, other columns/variables define how this effect is used in the estimation.

The function `includeEffects` can operate on several effects simultaneously, but in a less detailed way. The main use of `setEffect` is that it can change not only the value of the column include, but also those of initialValue and parm. The arguments shortName, name, type, interaction1, interaction2, effect1, effect2, effect3, period, and group should identify one effect completely. (Not all of them are needed; see `getEffects`.)

The call of `setEffect` will set, for this effect, the column elements of the resulting effects object for parm, fix, test, randomEffects, initialValue, timeDummy, and include to the values requested.

The shortName must not be set between quotes, unless you use character=TRUE.

The input names interaction1 and interaction2 do not themselves refer to created interactions, but to dependence of the base effects on other variables in the data set. They are used to completely identify the effects.

**Value**

An object of class sienaEffects or sienaGroupEffects. This will be an updated version of the input effects object, with one row updated. Details of the row altered will be printed, unless verbose=FALSE.

sienna07

Function to estimate parameters in a Siena model

Description

Estimates parameters in a Siena model using Method of Moments, based on direct simulation, con-
ditional or otherwise; or using Generalized Method of Moments; or using Maximum Likelihood by
MCMC simulation. Estimation is done using a Robbins-Monro algorithm. Note that the data and
particular model to be used must be passed in using named arguments as the \(...\), and the specifi-
cation for the algorithm must be passed on as \(x\), which is a \texttt{siennaAlgorithm} object as produced by
\texttt{sienaAlgorithmCreate} (see examples).

Usage

\[
\text{sienna07}(x, \text{batch}=\text{FALSE}, \text{verbose}=\text{FALSE}, \text{silent}=\text{FALSE},
\text{useCluster}=\text{FALSE}, \text{nbrNodes}=2,
\text{thetaValues}=\text{NULL},
\text{returnThetas}=\text{FALSE},
\text{initC}=\text{TRUE},
\text{clusterString} = \text{rep("localhost", nbrNodes)}, \text{tt}=\text{NULL},
\text{parallelTesting}=\text{FALSE}, \text{clusterIter}=!x$\text{maxlike},
\text{clusterType}=c("PSOCK", "FORK"), \text{cl}=\text{NULL}, \ldots)
\]
Arguments

x  A control object, of class \texttt{sienaAlgorithm}.

batch  Desired interface: \texttt{FALSE} gives a gui (graphical user interface implemented as a tcl/tk screen), \texttt{TRUE} gives a small (if \texttt{verbose=FALSE}) amount of printout to the console.

verbose  Produces various output to the console if \texttt{TRUE}.

silent  Produces no output to the console if \texttt{TRUE}, even if batch mode.

useCluster  Boolean: whether to use a cluster of processes (useful if multiple processors are available).

nbrNodes  Number of processes to use if \texttt{useCluster} is \texttt{TRUE}.

thetaValues  If not \texttt{NULL}, this should be a matrix with parameter values to be used in Phase 3. The number of columns must be equal to the number of estimated parameters in the effects object (if conditional estimation is used, without the rate parameters for the conditioning dependent variable). Can only be used if \texttt{x$simOnly=TRUE}.

returnThetas  Boolean: whether to return theta values and generated estimation statistics of Phase 2 runs.

initC  Boolean: set to \texttt{TRUE} if the simulation will use C routines (currently always needed). Only for use if using multiple processors, to ensure all copies are initialised correctly. Ignored otherwise, so is set to \texttt{TRUE} by default.

clusterString  Definitions of clusters. Default set up to use the local machine only.

tt  A tcltk toplevel window. Used if called from the model options screen.

parallelTesting  Boolean. If \texttt{TRUE}, sets up random numbers to parallel those in Siena 3.

clusterIter  Boolean. If \texttt{TRUE}, multiple processes execute complete iterations at each call. If \texttt{FALSE}, multiple processes execute a single wave at each call.

clusterType  Either "PSOCK" or "FORK". On Windows, must be "PSOCK". On a single non-Windows machine may be "FORK", and subprocesses will be formed by forking. If "PSOCK", subprocesses are formed using \texttt{R} scripts.

cl  An object of class \texttt{c("SOCKcluster","cluster")} (see Details).

...  Arguments for the simulation function, see \texttt{simstats0c}: in any case, data and effects, as in the examples below: possibly also \texttt{prevAns} if a previous reasonable provisional estimate was obtained for a similar model; possibly also \texttt{returnDeps} if the simulated dependent variables (networks, behaviour) should be returned; possibly also \texttt{returnChains} if the simulated sequences (chains) of ministeps should be returned; this may produce a very big file.

Details

This is the main function and workhorse of RSiena.

For use of \texttt{siena07}, it is necessary to specify parameters \texttt{data} (RSiena data set) and \texttt{effects} (effects object), which are required parameters in function \texttt{simstats0c}. (These parameters are inserted through \'\ldots\') See the examples.
siena07 runs a Robbins-Monro algorithm for parameter estimation using the three-phase implementation described in Snijders (2001, 2017), with (if x$findiff=FALSE) derivative estimation as in Schweinberger and Snijders (2007). The default is estimation according to the Method of Moments as in Snijders, Steglich and Schweinberger (2017). If x$gmm=TRUE and myeff contains one or more gmm statistics as included by function includeGMoMStatistics, the algorithm employs the Generalized Method of Moments as defined in Amati, Schoenenberger, and Snijders (2015, 2019).

For continuous behavior variables defined with type="continuous" in sienaDependent, estimation is done as described in Niezink and Snijders (2017).

If x$maxlike=TRUE, estimation is done by Maximum Likelihood implemented as in Snijders, Koskinen and Schweinberger (2010).

Phase 1 does a few iterations to estimate the derivative matrix of the targets with respect to the parameter vector. Phase 2 does the estimation. Phase 3 runs a simulation to estimate standard errors and check convergence of the model. The simulation function is called once for each iteration in these phases and also once to initialise the model fitting and once to complete it. Unless in batch mode, a tcl/tk screen is displayed to allow interruption and to show progress.

It is necessary to check that convergence has been achieved. The rule of thumb is that the all t-ratios for convergence should be in absolute value less than 0.1 and the overall maximum convergence ratio should be less than 0.25. If this was not achieved, the result can be used to start another estimation run from the estimate obtained, using the parameter prevAns as illustrated in the example below. (This parameter is inserted through '...' into the function initializeFRAN.)

For good estimation of standard errors, it is necessary that x$n3 is large enough. More about this is in the manual. The default value x$n3 set in sienaAlgorithmCreate is adequate for most explorative use, but for presentation in publications larger values are necessary, depending on the data set and model; e.g., x$n3=3000 or larger.

Parameters can be tested against zero by dividing the estimate by its standard error and using an approximate standard normal null distribution. Further, functions Wald.RSiena and Multipar.RSiena are available for multi-parameter testing.

Parameters specified in includeEffects or setEffect with fix=TRUE, test=TRUE will not be estimated; score tests of their hypothesized values are reported in the output file specified in the control (algorithm) object. These tests can be obtained also using score.Test.

If x$simOnly is TRUE, which is meant to go together with x$nsub=0, the calculation of the standard errors and covariance matrix at the end of Phase 3 is skipped. No estimation is performed. If thetaValues is not NULL, the parameter values in the rows of this matrix will be used in the consecutive runs of Phase 3. If x$n3 is larger than the number of rows times nbrNodes (see below), the last row of thetaValues will continue to be used. The parameter values actually used will be stored in the output matrix thetaUsed.

Multiple processors are used for estimation by MoM to distribute each iteration in each subphase over the cluster of nodes. The number of iterations accordingly will be divided (approximately) by the number of nodes; for phase 2, unless n2start is specified. This implies that if multiple processors are used, think of dividing n2start by nbrNodes.

For estimation by ML, multiple processing is done per period. Therefore, for one period (two waves) and one group, this will have no effect.

In the case of using multiple processors, there are two options for telling siena07 to use them. By specifying the options useCluster, nbrNodes, clusterString and initC, siena07 will create a cluster object that will be used by the parallel package. After finishing the estimation procedure, siena07 will automatically stop the cluster. Alternatively, instead of having the function to
create a cluster, the user may provide its own by specifying the option `cl`, similar to what the `boot` function does in the `boot` package. By using the option `cl` the user may be able to create more complex clusters (see examples below).

If `thetaValues` is not `NULL` and `nbrNodes >= 2`, parameters in Phase 3 will be constant for each set of `nbrNodes` consecutive simulations. This must be noted in the interpretation, and will be visible in `thetaUsed` (see below).

**Value**

Returns an object of class `sienaFit`, some parts of which are:

- OK: Boolean indicating successful termination
- termination: Character string, values: "OK", "Error", or "UserInterrupt". "UserInterrupt" indicates that the user asked for early termination before phase 3.
- f: Various characteristics of the data and model definition.
- requestedEffects: The included effects in the effects object.
- effects: The included effects in the effects object to which are added the main effects of the requested interaction effects, if any.
- theta: Estimated value of theta, if `x$simOnly=FALSE`.
- thetas: Matrix, returned if `returnThetas` and `x$nsub >= 1`. First column is subphase; further columns are values of theta as generated during this subphase of Phase 2.
- sfs: Matrix, returned if `returnThetas` and `x$nsub >= 1`. First column is subphase; further columns are deviations from targets generated during this subphase of Phase 2.
- covtheta: Estimated covariance matrix of theta; this is not available if `x$simOnly=TRUE`.
- se: Vector of standard errors of estimated theta, if `x$simOnly=FALSE`.
- dfra: Matrix of estimated derivatives.
- sf: Matrix of simulated deviations from targets in phase 3.
- sf2: Array of periodwise deviations from simulations in phase 3. Not included if `x$lessMem=TRUE`.
- tconv: t-statistics for convergence.
- tmax: maximum absolute t-statistic for convergence for non-fixed parameters.
- tconv.max: overall maximum convergence ratio.
- ac3: If `x$maxlike=TRUE`: autocorrelations of statistics in Phase 3.
- targets: Observed statistics; for ML, zero vector.
- targets2: Observed statistics by wave, starting with second wave; for ML, zero matrix.
- ssc: Score function contributions for each wave for each simulation in phase 3. Not included if finite difference method is used or if `x$lessMem=TRUE`.
- scores: Score functions, added over waves, for each simulation in phase 3. Only included if `x$lessMem=FALSE`. 
regrCoef  If x$dolby and not x$maxlike: regression coefficients of estimation statistics on score functions.

regrCor   If x$dolby and not x$maxlike: correlations between estimation statistics and score functions.

estMeans  Estimated means of estimation statistics.

estMeans.sem If x$simOnly: Standard errors of the estimated means of estimation statistics.

sims      If returnDeps=TRUE: list of simulated dependent variables (networks, behaviour). Networks are given as a list of edgelists, one for each period. The structure of sims is a nested list: sims[[run]][[group]][[dependent variable]][[period]]. If x$maxlike=TRUE and there is only one group and one period, the structure is [[run]][[dependent variable]].

chain     If returnChains = TRUE: list, or data frame, of simulated chains of ministeps. The chain has the structure chain[[run]][[depvar]][[period]][[ministep]].

Phase3nits Number of iterations actually performed in phase 3.

thetaUsed If thetaValues is not NULL, the matrix of parameter values actually used in the simulations of Phase 3.

Writes text output to the file named "projname.txt", where projname is defined in the sienaAlgorithm object x.

siena08

Function to perform a meta analysis of a collection of Siena fits.

Description

Estimates a meta analysis based on a collection of Siena fits.

Usage

siena08(...) projname = "sienaMeta", bound = 5, alpha = 0.05, maxit=20)

Arguments

... names of sienaFit objects, returned from siena07. They will be renamed if entered in format newname=oldname. It is also allowed to give for ...a list of sienaFit objects.
projname Base name of report file if required
bound Upper limit of standard error for inclusion in the meta analysis.
alpha 1 minus confidence level of confidence intervals.
maxit Number of iterations of iterated least squares procedure.
Details

A meta analysis is performed as described in the Siena manual, section "Meta-analysis of Siena results". This consists of three parts: an iterated weighted least squares (IWLS) modification of the method described in the reference below; maximum likelihood estimates and confidence intervals based on profile likelihoods under normality assumptions; and Fisher combinations of left-sided and right-sided \( p \)-values. These are produced for all effects separately.

Note that the corresponding effects must have the same effect name in each model fit. This implies that at least covariates and behavior variables must have the same name in each model fit.

Value

An object of class \texttt{sienaMeta}. There are print, summary and plot methods for this class. This object contains at least the following.

\begin{itemize}
\item \texttt{thetadf} Data frame containing the coefficients, standard errors and score test results
\item \texttt{projname} Root name for any output file to be produced by the print method
\item \texttt{bound} Estimates with standard error above this value were excluded from the calculations
\item \texttt{scores} Object of class \texttt{by} indicating, for each effect in the models, whether score test information was present.
\item \texttt{requestedEffects} The \texttt{requestedEffects} component of the first \texttt{sienaFit} object in ...
\item \texttt{muhat} The vector of IWLS estimates.
\item \texttt{se.muhat} The vector of standard errors of the IWLS estimates.
\item \texttt{theta} The vector of ML estimates \texttt{mu.ml} (see below).
\item \texttt{se} The vector of standard errors of the ML estimates \texttt{mu.ml.se} (see below).
\end{itemize}

Then for each effect, there is a list with at least the following.

\begin{itemize}
\item \texttt{cor.est} Spearman rank correlation coefficient between estimates and their standard errors.
\item \texttt{cor.pval} \texttt{p}-value for above
\item \texttt{regfit} Part of the result of the fit of \texttt{iwls.m}.
\item \texttt{regsummary} The summary of the fit, which includes the coefficient table.
\item \texttt{Tsq} test statistic for effect zero in every model
\item \texttt{pTsq} \texttt{p}-value for above
\item \texttt{tratio} test statistics that mean effect is 0
\item \texttt{ptratio} \texttt{p}-value for above
\item \texttt{Qstat} Test statistic for variance of effects is zero
\item \texttt{pttilde} \texttt{p}-value for above
\item \texttt{cjplus} Test statistic for at least one theta strictly greater than 0
\item \texttt{cjminus} Test statistic for at least one theta strictly less than 0
\item \texttt{cjplusp} \texttt{p}-value for \texttt{cjplus}
\end{itemize}
cjminusp  p-value for cjminus
mu.ml    ML estimate of population mean
mu.ml.se  standard error of ML estimate of population mean
sigma.ml  ML estimate of population standard deviation
mu.confint  confidence interval for population mean based on profile likelihood
sigma.confint  confidence interval for population standard deviation based on profile likelihood
n1       Number of fits on which the meta analysis is based
cjplus   Test statistic for combination of right one-sided Fisher combination tests
cjminus  Test statistic for combination of left one-sided Fisher combination tests
cjplusp  p-value for cjplus
cjminusp  p-value for cjminus
scoreplus Test statistic for combination of right one-sided p-values from score tests
scoreminus Test statistic for combination of left one-sided p-values from score tests
scoreplusp p-value for scoreplus
scoreminusp p-value for scoreminus
ns       Number of fits on which the score test analysis is based

sienaAlgorithmCreate  
Function to create an object containing the algorithm specifications for parameter estimation in RSiena

Description

Creates an object with specifications for the algorithm for parameter estimation in RSiena. sienaAlgorithmCreate() and sienaModelCreate() are identical functions; the second name was used from the start of the RSiena package, but the first name indicates more precisely the purpose of this function.

Usage

sienaAlgorithmCreate(fn, projname = "Siena", MaxDegree = NULL, Offset = NULL, useStdInits = FALSE, n3 = 1000, nsub = 4, n2start = NULL, dolby=TRUE, maxlike = FALSE, gmm = FALSE, diagonalize=0.2*!maxlike, condvarno = 0, condname = "", firstg = 0.2, reduceg = 0.5, cond = NA, findiff = FALSE, seed = NULL,
sienaAlgorithmCreate

prML=1,
maximumPermutationLength=40,
minimumPermutationLength=2, initialPermutationLength=20,
modelType=NULL, behModelType=NULL, mult=5, simOnly=FALSE, localML=FALSE,
truncation=5, doubleAveraging=0, standardizeVar=(diagonalize<1),
lessMem=FALSE)

sienaModelCreate(fn, projname = "Siena", MaxDegree = NULL, Offset = NULL,
useStdInits = FALSE, n3 = 1000, nsub = 4, n2start = NULL,
dolby=TRUE, maxlike = FALSE, gmm = FALSE, diagonalize=0.2*!maxlike,
condvarno = 0, condname = "", firstg = 0.2, reduceg = 0.5,
cond = NA, findiff = FALSE, seed = NULL,
prML=1,
maximumPermutationLength=40,
minimumPermutationLength=2, initialPermutationLength=20,
modelType=NULL, behModelType=NULL, mult=5, simOnly=FALSE, localML=FALSE,
truncation=5, doubleAveraging=0, standardizeVar=(diagonalize<1),
lessMem=FALSE)

Arguments

fn Function to do one simulation in the Robbins-Monro algorithm. Not to be
touched.

projname Character string name of project; the output file will be called projname.txt. No
embedded spaces!!!
If projname=NULL, output will be written to a file in the temporary session di-
rectory, created as tempfile(Siena).

MaxDegree Named vector of maximum degree values for corresponding networks. Allows
to restrict the model to networks with degrees not higher than this maximum.
Names should be the names of all dependent network variables, in the same
order as in the Siena data set.
Default as well as value 0 imply no restrictions.
This option is not available for maximum likelihood estimation.

Offset Named vector of offset values for symmetric networks with modelType = 3 (M.1),
and for universal setting in Settings model. Names should be the names of all
dependent network variables, in the same order as in the Siena data set.
Default NULL implies values 0.

useStdInits Boolean. If TRUE, the initial values in the effects object will be ignored and
default values used instead. If FALSE, the initial values in the effects object will
be used.

n3 Number of iterations in phase 3. For regular use with the Method of Moments,
n3=1000 mostly suffices. For use in publications and for Maximum Likelihood,
at least n3=3000 is advised. Sometimes much higher values are required for
stable estimation of standard errors.

nsub Number of subphases in phase 2.

n2start Minimum number of iterations in subphase 1 of phase 2; default is 2.52*(p+7),
where p = number of estimated parameters; if useCluster=TRUE in the call of
sienaAlgorithmCreate

siena07, this is divided by nbrNodes.

dolby
Boolean. Should there be noise reduction by regression on augmented data score. In most cases dolby=TRUE yields better convergence, but takes some extra computing time; if convergence is problematic, however, dolby=FALSE may be tried. Just use whatever works best.

maxlike
Whether to use maximum likelihood method or Method of Moments estimation.

gmm
Whether to use the Generalized Method of Moments or the regular Method of Moments estimation.

diagonalize
Number between 0 and 1 (bounds included), values outside this interval will be truncated; for diagonalize=0 the complete estimated derivative matrix will be used for updates in the Robbins-Monro procedure; for diagonalize=1 only the diagonal entries will be used; for values between 0 and 1, the weighted average will be used with weight diagonalize for the diagonalized matrix. Has no effect for ML estimation. Higher values are more stable, lower values potentially more efficient. Default: for ML estimation, diagonalize=0; for MoM estimation, diagonalize = 0.2.

condvarno
If cond (conditional simulation), the sequential number of the network or behavior variable on which to condition.

condname
If conditional, the name of the dependent variable on which to condition. Use one or other of condname or condvarno to specify the variable.

firstg
Initial value of scaling ("gain") parameter for updates in the Robbins-Monro procedure.

reduceg
Reduction factor for scaling ("gain") parameter for updates in the Robbins-Monro procedure (MoM only).

cond
Boolean. Only relevant for Method of Moments simulation/estimation. If TRUE, use conditional simulation; if FALSE, unconditional simulation. If missing, decision is deferred until siena07, when it is set to TRUE if there is only one dependent variable, FALSE otherwise.

findiff
Boolean: If TRUE, estimate derivatives using finite differences. If FALSE, use scores.

seed
Integer. Starting value of random seed. Not used if parallel testing.

prML
Either one real number, or a vector of 7 numbers. Determines update probabilities used in Metropolis-Hastings routine in ML estimation. Should be nonnegative; if a vector, the sum should be <= 1. See Details.

maximumPermutationLength
Maximum length of permutation in steps in ML estimation.

minimumPermutationLength
Minimum length of permutation in steps in ML estimation.

initialPermutationLength
Initial length of permutation in steps in ML estimation.

modelType
Named vector indicating the type of model to be fitted for dependent network variables. (See the examples below for how to specify a named vector.) Possible values are: I=directed standard,
2:6 for symmetric networks only: 2=dictatorial forcing (D.1), 3=Initiative model with reciprocal confirmation (M.1), 4=Pairwise dictatorial forcing model (D.2), 5=Pairwise mutual model (M.2), 6=Pairwise joint model (C.2), 7:10 for directed one-mode only: 7=Double Step model with double step probability 0.25, 8=Double Step model with double step probability 0.50, 9=Double Step model with double step probability 0.75, 10=Double Step model with double step probability 1.00.

Names should be the names of all dependent network variables, in the same order as in the Siena data set.

See Snijders and Pickup (2016) for the meanings of the various models for symmetric networks.

Default NULL implies 1 for directed or two-mode, 2 for symmetric.

**behModelType**

Named vector indicating the type of model to be fitted for behavioral dependent variables. (See the examples below for how to specify a named vector.) Possible values are: 1=standard (restricted), 2=absorbing.

Names should be the names of all dependent behavioral variables, in the same order as in the Siena data set.

Default NULL implies values 1.

**mult**

Multiplication factor for maximum likelihood and Bayes. Number of steps per iteration is set to this multiple of the total distance between the observations at start and finish of the wave (and rounded). Decreasing mult below a certain value has no further effect. mult can be either a number (which needs to be positive) or a vector of numbers, of length equal to the total number of periods. Note that for multi-group data, the total number of periods is equal to the number of groups times the number of periods per group (if the latter is constant).

**simOnly**

Logical: If TRUE, then the calculation of the covariance matrix and standard errors of the estimates at the end of Phase 3 of the estimation algorithm in function siena07 is skipped. This is suitable if nsub=0 and siena07 is used only for the purpose of simulation.

**localML**

Logical: If TRUE, and maxlike, then calculations are sped up for models with all local effects.

**truncation**

Used for step truncation in the Robbins Monro algorithm (applied to deviate/(standard deviation)).

**doubleAveraging**

Subphase after which double averaging is used in the Robbins Monro algorithm, which probably increases algorithm efficiency.

**standardizeVar**

Logical: whether to limit deviations used in Robbins-Monro updates to unit variances.

**lessMem**

Logical: whether to reduce storage during operation of siena07, and of the object produced, by leaving out arrays by iteration and by period of simulated statistics sf2 and scores ssc. If lessMem=TRUE, it will be impossible to run sienaTimeTest or sienaGOF on the object produced by siena07.
Details

Model specification is done via this object for siena07. This function creates an object with the elements required to control the Robbins-Monro algorithm. Those not available as arguments can be changed manually when desired.

The value prML=1 defines the defaults valid in RSiena up to version 1.3.16. For ML estimation with only one dependent variable, prML=2 may be more efficient.

If prML is given as a vector of 7 probabilities, these are, consecutively: the probabilities of inserting a diagonal step, deleting a diagonal step, permuting, inserting a CCP, deleting a CCP, inserting random missing, deleting random missing; the residual (1 minus the sum) is the probability of a move step.

Further information about the implementation of the algorithm is in https://www.stats.ox.ac.uk/~snijders/siena/Siena_algorithms.pdf.

Some of the examples use projname=NULL; this is just for the sake of checking the examples, not necessarily intended for normal use.

Value

Returns an object of class sienaAlgorithm containing values implied by the parameters.

Author(s)

Ruth Ripley and Tom A.B. Snijders

# where mynet is the name of the network object created by sienaDependent(),
# and mybeh the name of the behavior object created by the same function.
```
sienaCompositionChange

Functions to create a Siena composition change object

Description

Used to create a list of events describing the changes over time of a Siena actor set.

Usage

sienaCompositionChange(changelist, nodeSet = "Actors", option = 1)
sienaCompositionChangeFromFile(filename, nodeSet = "Actors", fileobj=NULL, option = 1)

Arguments

changelist A list with an entry for each actor in the node set. Each entry a vector of numbers (may be as characters) indicating intervals during which the corresponding actor was present. Each entry must have an even number of digits. The actor is assumed to be present from the first to the second, third to fourth, etc., time points.

filename Name of file containing change information. One line per actor, each line a series of space delimited numbers indicating intervals.

fileobj The result of readLines on filename.

nodeSet Character string containing the name of a Siena node set. If the entire data set contains more than one node set, then the node sets must be specified in all data objects.

option Integer controlling the processing of the tie variables for the actors not currently present. Values (default is 1)

1 0 before entry, final value carried forward after leaving, and used for calculating statistics in Method of Moments estimation
2 0 before entry, missing after (final value carried forward, but treated as missing)
3 missing whenever not in the network. Previous values will be used where available, but always treated as missing values.
4 Convert to structural zeros (not available at present).

Details

If there is a composition change object for the first node set in the data object, then this will be used in estimation by the Method of Moments to make actors active (able to send and receive ties) only for the time intervals when this is indicated in the composition change object. This is done according to the procedure of Huisman and Snijders (2003). See the manual for further details. For bipartite networks, composition change objects for the second node set have no effect and will lead to an error message.

For $M$ waves, time starts at 1 and ends at $M$; so all numbers must be between 1 and the number of
waves (bounds included). Intervals are treated as closed at each end. For example, an entry \((2, 4)\) means that the actor corresponding to this entry arrived at wave 2 and left at wave 4, but did give valid data for both of these waves. An entry \((1.01, 2.99)\) means that the actor arrived just after wave 1 and left just before wave 3, and gave valid data only for wave 2. An entry \((1, 2), (3.5, 4)\) means that the actor was there at the start and left at wave 2 (giving valid data for wave 2), came back halfway between waves 3 and 4, and gave valid data still at wave 4; if there would be more than 4 waves in the data set, this entry would also mean that the actor left at wave 4.

For data sets including a composition change object, estimation by Method of Moments is forced to be unconditional, overriding the specification in the \texttt{sienaAlgorithm} object.

**Value**

An object of class "compositionChange", a list of numeric vectors, with attributes:

- **NodeSet**: Name of node set
- **Option**: Option

**Examples**

```r
clist <- list(c(1, 3), c(1.4, 2.5))
# or
clist <- list(c("1", "3"), c("1.4", "2.5"))
compChange <- sienaCompositionChange(clist)

s50net <- sienaDependent(array(c(s501, s502, s503), dim=c(50, 50, 3)))
s50list <- rep(list(c(1,3)), 50)
# This is a trivial composition change: all actors are present in all waves.
compChange <- sienaCompositionChange(s50list)
s50data <- sienaDataCreate(s50net, compChange)
s50data

## Not run:
filedata <- c("1 3", "1.4 2.5")
write.table(filedata, "cc.dat", row.names=FALSE, col.names=FALSE,
```

[100x712]sienaCompositionChange

sienaDataConstraint

Function to change the values of the constraints between networks.

Description

This function allows the user to change the constraints of "higher", "disjoint" and "atLeastOne" for a specified pair of networks in a Siena data object.

Usage

sienaDataConstraint(x, net1, net2, type = c("higher", "disjoint", "atLeastOne"), value = FALSE)

Arguments

x Siena data object; maybe a group object?
net1 name of first network
net2 name of second network
type one of "higher", "disjoint", "atLeastOne". Default is "higher".
value Boolean giving the value.

Details

The value of the appropriate attribute is set to the value requested. Note that, for value=TRUE, the correspondence of this value to the data is not checked.

Value

Updated Siena data object.

Author(s)

Ruth Ripley

References

See https://www.stats.ox.ac.uk/~snijders/siena/
sienaDataCreate

Function to create a Siena data object

Description

Creates a Siena data object from input dependent variables (networks and possibly behavioural variables), covariates, and composition change objects.

Usage

sienaDataCreate(..., nodeSets=NULL, getDocumentation=FALSE)

Arguments

... objects of class sienaDependent, coCovar, varCovar, coDyadCovar, varDyadCovar, and/or sienaCompositionChange; or a list of such objects, of which the first element must not be a sienaCompositionChange object. There should be at least one sienaDependent object.

If there are one-mode as well as two-mode dependent networks, the one-mode networks should be mentioned first.
	nodeSets list of Siena node sets. Default is the single node set named "Actors", length equal to the number of rows in the first object of class "sienaDependent". If the entire data set contains more than one node set, then the node sets must have been specified in the creation of all data objects mentioned in ....

getDocumentation Flag to allow documentation of internal functions, not for use by users.

Examples

nowFriends <- sienaDependent(array(c(s501, s502, s503), dim=c(50, 50, 3)))
ever <- array(c(s501, s502, s503), dim=c(50, 50, 3))
ever[,2] <- pmax(ever[,1], ever[,2])
ever[,3] <- pmax(ever[,2], ever[,3])
everFriends <- sienaDependent(ever)
# Note: this data set serves to illustrate this function,
# but it is not an appropriate data set for estimation by siena07,
# because everFriends (for the three waves together) depends deterministically
# on nowFriends (for the three waves together).
nowOrEver <- sienaDataCreate(nowFriends, everFriends)
attr(nowOrEver, "higher")
nowOrEver
nowOrEver.unconstrained <-
sienaDataConstraint(nowOrEver, everFriends, nowFriends, "higher", FALSE)
nowOrEver.unconstrained
attr(nowOrEver.unconstrained, "higher")

See Also

sienaDataCreate, sienaGroupCreate
Details

The function checks that the objects fit, that there is at least one dependent variable, and adds various attributes to each dependent variable describing the data. If there is more than one nodeSet they must all be specified.

Function `print01Report` will give a basic description of the data object and is a check useful, e.g., for diagnosing problems.

Value

An object of class "siena" which is designed to be used in a siena model fit by `link{siena07}`. The components of the object are:

- `nodeSets` List of node sets involved
- `observations` Integer indicating number of waves of data
- `deppars` List of networks and behavior variables
- `cCovars` List of constant covariates
- `vCovars` List of changing covariates
- `dyCovars` List of constant dyadic covariates
- `dyvCovars` List of changing dyadic covariates
- `compositionChange` List of composition change objects corresponding to the node sets

sienaDependent  
*Function to create a dependent variable for a Siena model*

**Description**

Creates a Siena dependent variable: either a network, created from a matrix or array or list of sparse matrix of triples; or a behavior variable, created from a matrix. 
`sienaDependent()` and `sienaNet()` are identical functions; the second name was used from the start of the RSiena package, but the first name indicates more precisely the purpose of this function.

**Usage**

```r
sienaDependent(netarray, type=c("oneMode", "bipartite", "behavior", "continuous"),
nodeSet="Actors", sparse=is.list(netarray), allowOnly=TRUE, imputationValues=NULL)
```

```r
sienaNet(netarray, type=c("oneMode", "bipartite", "behavior", "continuous"),
nodeSet="Actors", sparse=is.list(netarray), allowOnly=TRUE, imputationValues=NULL)
```

**Arguments**

- `netarray`  
  type="behavior" or "continuous": matrix (actors × waves).  
  type="oneMode" or "bipartite": array of values or list of sparse matrices of type "TsparseMatrix", see the Matrix package; if an array is used, it should have dimensions: for a one-mode network, \( n \times n \times M \), and for a two-mode network \( n \times m \times M \), where \( n \) is the number of actors, \( m \) is the number of nodes in the second mode, and \( M \) is the number of waves.
- `type`  
  type of dependent variable, default oneMode.
- `nodeSet`  
  character string naming the appropriate node set. For a bipartite network, a vector containing 2 character strings: "rows" first, then "columns".
- `sparse`  
  logical: TRUE indicates the data is in sparse matrix format, FALSE otherwise.
- `allowOnly`  
  logical: If TRUE, it will be detected when between any two consecutive waves the changes are non-decreasing or non-increasing, and if this is the case, this will also be a constraint for the simulations between these two waves. This is done by means of the internal parameters `uponly` and `downonly`. If FALSE, the parameters `uponly` and `downonly` always are set to FALSE, and changes in dependent variables will not be constrained to be non-decreasing or non-increasing. This also will imply that some effects are excluded because they are superfluous in such constrained situations. This will be reported in the output of print01Report.
For normal operation when this is the case for all periods, usually TRUE is the appropriate option. When it is only the case for some of the periods, and for data sets that will be part of a multi-group object created by `sienaGroupCreate`, FALSE usually is preferable.

For behavior or continuous dependent variables, a matrix with imputation values can be included that will be used instead of the default imputation values.

### Details
Adds attributes so that the array or list of matrices can be used in a Siena model fit.

### Value
An object of class `sienaDependent`. An array or (networks only) a list of sparse matrices with attributes:

- **netdims**: Dimensions of the network or behavior variable: senders, receivers (1 for behavior), periods
- **type**: oneMode, bipartite or behavior
- **sparse**: Boolean: whether the network is given as a list of sparse matrices or not
- **nodeSet**: Character string with name(s) of node set(s)
- **allowOnly**: The value of the allowOnly parameter

### Author(s)
Ruth Ripley and Tom A.B. Snijders

### References
See [https://www.stats.ox.ac.uk/~snijders/siena/](https://www.stats.ox.ac.uk/~snijders/siena/).

### See Also
`sienaDataCreate, sienaNodeSet, sienaDataConstraint`

### Examples
```r
mynet1 <- sienaDependent(array(c(s501, s502, s503), dim=c(50, 50, 3)))
mybeh <- sienaDependent(s50a, type="behavior")
## note that the following example works although the node sets do not yet exist!
mynet3 <- sienaDependent(array(c(s501, s502, s503), dim=c(50, 50, 3)),
                         type="bipartite", nodeSet=c("senders", "receivers"))
## sparse matrix input
## To show this, we first go back from the adjacency matrices to edgelists.
## The manual shows one way to do this.
## Another way is to use the sparse matrix representation which internally
## indeed is an edge list:
library(Matrix)
sp501 <- as(Matrix(s501), "TsparseMatrix")
```
sp502 <- as(Matrix(s502), "TsparseMatrix")
sp503 <- as(Matrix(s503), "TsparseMatrix")

## If you are interested in the internal structure of these sparse matrices,
## you can request
str(sp501)

## Slot @i is the row, @j is the column, and @x the value;
## here the values all are 1.
## Slots @i and @j do not contain information about the number of nodes,
## so that is supplied additionally by @Dim.

mymatlist <- list(sp501, sp502, sp503)

mynet.sp <- sienaDependent(mymatlist)

---

sienaFit.methods  
Methods for processing sienaFit objects, produced by siena07.

Description

print, summary, and xtable methods for sienaFit objects.

Usage

## S3 method for class 'sienaFit'
print(x, tstat=TRUE, ...)

## S3 method for class 'sienaFit'
summary(object, ...)

## S3 method for class 'summary.sienaFit'
print(x, matrices=TRUE, ...)

## S3 method for class 'sienaFit'
xtable(x, caption = NULL, label = NULL, align = NULL,
digits = NULL, display = NULL, ...)

siena.table(x, type="tex", file=paste(deparse(substitute(x)), ".", type,sep=""),
vertLine=TRUE, tstatPrint=FALSE, sig=FALSE, d=3, nfirst=NULL)

Arguments

object  
An object of class sienaFit, produced by siena07. For siena.table, objects
of class sienaBayes are also permitted.

x  
An object of class sienaFit, or summary.sienaFit as appropriate. For siena.table,
objects of class sienaBayes are also permitted.

matrices  
Boolean: whether also to print in the summary the covariance matrix of the
estimates, the derivative matrix of expected statistics X by parameters, and the
covariance matrix of the statistics.
tstat  Boolean: if this is NULL, the t-statistics for convergence will not be added to the report.
type  Type of output to produce; must be either "tex" or "html".
file  Name of the file; defaults to the name of the sienaFit object. "" indicates output to the console.
vertLine  Boolean: add vertical lines separating the columns in siena.table.
tstatPrint  Boolean: add a column of significance t values (parameter estimate/standard error estimate) to siena.table.
sig  Boolean: adds symbols (daggers and asterisks) indicating significance levels for the parameter estimates to siena.table.
d  The number of decimals places used in siena.table.
caption  See documentation for xtable.
label  See documentation for xtable.
align  See documentation for xtable.
digits  See documentation for xtable.
display  See documentation for xtable
nfirst  Only relevant for the multiSiena package.
...  Add extra parameters for print.xtable here. e.g. type, file.

Value

The function print.sienaFit prints a table containing estimated parameter values, standard errors and (optionally) t-statistics for convergence.

The function summary.sienaFit prints a table containing estimated parameter values, standard errors and t-statistics for convergence together with the covariance matrix of the estimates, the derivative matrix of expected statistics $X$ by parameters, and the covariance matrix of the expected statistics $X$.

The function xtable.sienaFit creates an object of class xtable.sienaFit which inherits from class xtable and passes an extra arguments to the print.xtable.

The function siena.table outputs a latex or html table of the estimates and standards errors of a sienaFit object. The table will be written to a file in the current directory and has a footnote reporting the maximum of the convergence t-ratios. Endowment or creation effects will be denoted, respectively, by 'maintenance' or 'creation'.

See the manual for how to import the html tables easily into MS-Word.

sienaGOF

Functions to assess goodness of fit for SAOMs

Description

The function sienaGOF assesses goodness of fit for a model specification as represented by an estimated sienaFit object created by siena07. This is done by simulations of auxiliary statistics, that differ from the statistics used for estimating the parameters. The auxiliary statistics must be given explicitly.

The fit is good if the average values of the auxiliary statistics over many simulation runs are close to the values observed in the data. A Monte Carlo test based on the Mahalanobis distance is used to calculate frequentist \( p \)-values.

Plotting functions can be used to diagnose bad fit. There are basic functions for calculating auxiliary statistics available out of the box, and the user is invited to create additional ones.

Usage

sienaGOF(sienaFitObject, auxiliaryFunction,

period=NULL, verbose=FALSE, join=TRUE, twoTailed=FALSE,
cluster=NULL, robust=FALSE, packageName="Data1",
varName, tested=NULL, giveNAWarning=TRUE, ...)
## S3 method for class 'sienaGOF'
plot(x, center=FALSE, scale=FALSE, violin=TRUE, key=NULL,
perc=.05, period=1, position=4, fontsize=12, ...) 
descriptives.sienaGOF(x, center=FALSE, scale=FALSE, perc=.05, key=NULL,
period=1, showAll=FALSE)
Arguments

sienaFitObject An object of class sienaFit, produced by a call to siena07 with returnDeps = TRUE and maxlike=FALSE (the latter is the default, the former is not); or a list of such objects; if a list, then the first period of each sienaFit object will be used. If this is a list of sienaFit objects, where sienaFitObject is mentioned below, it refers to the first element of this list.

auxiliaryFunction Function to be used to calculate the auxiliary statistics; this can be a user-defined function, e.g. depending on the sna or igraph packages. See Examples and sienaGOF-auxiliary for more information on the signature of this function. The basic signature is function(index, data, sims, period, groupName, varName, ...), where index is the index of the simulated network, or NULL if the observed variable is needed; data is the observed data object from which the relevant variables are extracted; sims is the list of simulations returned from siena07; period is the index of the period; and ... are further arguments (like levls in the examples below and in sienaGOF-auxiliary).

period Vector of period(s) to be used (may run from 1 to number of waves - 1). Has an effect only if join=FALSE. May be only a single number if sienaFitObject is a list of sienaFit objects.

verbose Whether to print intermediate results. This may give some peace of mind to the user because calculations can take some time.

join Boolean: should sienaGOF do tests on all of the periods individually (FALSE), or sum across periods (TRUE)?

twoTailed Whether to use two tails for calculating p-values on the Monte Carlo test. Recommended for advanced users only, as it is probably only applicable in rare cases.

cluster Optionally, a parallel or snow cluster to execute the auxiliary function calculations on.

robust Whether to use robust estimation of the covariance matrix.

groupName Name of group; relevant for multi-group data sets.

varName Name of dependent variable.

tested A logical vector of length sienaFitObject$pp (number of parameters), indicating a subset of tested parameters; or NULL, indicating all tested parameters (see below); or FALSE, indicating nothing is to be tested.

giveNAWarning If TRUE, a warning is given if any simulated values are missing.

x Result from a call to sienaGOF.

center Whether to center the statistics by median during plotting.

scale Whether to scale the statistics by range during plotting. scale=TRUE makes little sense without also center=TRUE.

violin Use violin plots (vs. box plots only)?

key Keys in the plot for the levels of the auxiliary statistic (as given by parameter levls in the examples).
perc  1 minus confidence level for the confidence bands (two sided).
position  Position where the observed value is plotted: 1=under, 2=to the left, 3=above, 4=to the right of the red dot. Can be a single number from 1 to 4, or a vector with positions for each statistic (possibly recycled).
fontsize  Font size for the observed values plotted.
...  Other arguments; for \texttt{sienaGOF()}, e.g., \texttt{levls} as a parameter for the auxiliary statistic in \texttt{sienaGOF-auxiliary}; for \texttt{plot.sienaGOF()}, e.g., the usual plotting parameters \texttt{main}, \texttt{xlab}, \texttt{ylab}, \texttt{cex}, \texttt{cex.main}, \texttt{cex.lab}, and \texttt{cex.axis}.
showAll  If \texttt{FALSE}, drops statistics with variance 0, like in the plot.

Details

This function is used to assess the goodness of fit of an estimated stochastic actor-oriented model for an arbitrarily defined multidimensional auxiliary statistic. It operates basically by comparing the observed values, at the ends of the periods, with the simulated values for the ends of the periods. The differences are assessed by combining the components of the auxiliary statistic using the Mahalanobis distance.

For \texttt{sienaFitObject}s that were made for a multi-group data set, if you are not sure about the \texttt{groupName}s to use, these can be retrieved by the command \texttt{"names(dataObject)"} (where \texttt{dataObject} is the data used to produce the \texttt{sienaFitObject}). Mostly they are \texttt{"Data1"}, \texttt{"Data2"}, etc.

The function does not work properly for data sets that include a \texttt{sienaCompositionChange} object. If you wish to test the fit for such a data set, you need (for the purpose of fit assessment only) to replace the data set by a data set where absent actors are represented by structural zeros, and estimate the same model for this data set with the corresponding effects object, and use \texttt{sienaGOF} for this \texttt{sienaFit} object.

To achieve comparability between simulated and observed dependent variables, variables that are missing in the data at the start or end of a period are replaced by 0 (for tie variables) or \texttt{NA} (for behavior variables).

If there are any differences between structural values at the beginning and at the end of a period, these are dealt with as follows. For tie variables that have a structural value at the start of the period, this value is used to replace the observed value at the end of the period (for the goodness of fit assessment only). For tie variables that have a structural value at the end of the period but a free value value at the start of the period, the reference value for the simulated values is lacking; therefore, the simulated values at the end of the period then are replaced by the structural value at the end of the period (again, for the goodness of fit assessment only).

The auxiliary statistics documented in \texttt{sienaGOF-auxiliary} are calculated for the simulated dependent variables in Phase 3 of the estimation algorithm, returned in \texttt{sienaFitObject} because of having used \texttt{returnDeps = TRUE} in the call to \texttt{siena07}. These statistics should be chosen to represent features of the network that are not explicitly fit by the estimation procedure but can be considered important properties that the model at hand should represent well. Some examples are:

- Outdegree distribution
- Indegree distribution
- Distribution of the dependent behavior variable (if any).
- Distribution of geodesic distances
The function is written so that the user can easily define other functions to capture some other relevant aspects of the network, behaviors, etc. This is further illustrated in the help page `sienaGOF-auxiliary`.

We recommend the following heuristic approach to model checking:

1. Check convergence of the estimation.
2. Assess goodness of fit (primarily using `join=TRUE`) on auxiliary statistics, and if necessary refine the model.
3. Assess time heterogeneity by `sienaTimeTest` and if there is evidence for time heterogeneity either modify the base effects or include time dummy terms.

No general rules can be given about whether time heterogeneity (`sienaTimeTest`) or goodness of fit using `sienaGOF` have precedence. This is an explorative issue.

The summary function will display some useful information to help with model selection if some effects are set in the effects object to be fixed and tested. In that case, for all parameters indicated in the vector `tested`, a rough estimator is computed for the Mahalanobis distance that would be obtained at each proposed specification. This is then given in the summary. This can help guide model selection. This estimator is called the modified Mahalanobis distance (MMD). See Lospinoso and Snijders (2019) or the manual for more information.

The following functions are pre-fabricated for ease of use, and can be passed in as the `auxiliaryFunction` with no extra effort; see `sienaGOF-auxiliary` and the examples below.

- `IndegreeDistribution`
- `OutdegreeDistribution`
- `BehaviorDistribution`
- `TriadCensus`
- `mixedTriadCensus`
- `dyadicCov`

### Value

`sienaGOF` returns a result of class `sienaGOF`; this is a list of elements of class `sienaGofTest`; if `join=TRUE`, the list has length 1; if `join=FALSE`, each list element corresponds to a period analyzed; the list elements are themselves lists again, including the following elements:

- `sienaFitName` The name of `sienaFitObject`.
- `auxiliaryStatisticName` The name of `auxiliaryFunction`.
- `Observations` The observed values for the auxiliary statistics.
- `Simulations` The simulated auxiliary statistics.
- `ObservedTestStat` The observed Mahalanobis distance in the data.
- **SimulatedTestStat**
  The Mahalanobis distance for the simulations.
- **TwoTailed**
  Whether the p-value corresponds to a one- or two-tailed Monte Carlo test.
- **p**
  The p-value for the observed Mahalanobis distance in the permutation distribution of the simulated Mahalanobis distances.
- **Rank**
  Rank of the covariance matrix of the simulated auxiliary statistics.

In addition there are several attributes which give, for model specifications with fixed-and-tested effects, approximations to the expected Mahalanobis distance for model specifications where each of these effects would be added. This is reported in the summary method.

The plot method makes violin plots or box plots, with superimposed confidence bands, for the simulated distributions of all elements of the auxiliaryFunction, with the observed values indicated by red dots; but statistics with variance 0 are dropped.

descriptives.sienaGOF returns a matrix giving numerical information about what is plotted in the plot method: maximum, upper percentile, mean, median, lower percentile, minimum, and standard deviation of the simulated distributions of the auxiliary statistics, the observed values, and the proportions of simulated values greater and greater-or-equal than the observed values. If center=TRUE the median is subtracted from mean, median, and percentiles; if scale=TRUE these numbers and the standard deviation are divided by (maximum - minimum).
If showAll=FALSE, statistics with variance 0 will be dropped.

Description

The functions given here are auxiliary to function \texttt{sienaGOF} which assesses goodness of fit for actor-oriented models.

The auxiliary functions are, first, some functions of networks or behaviour (i.e., statistics) for which the simulated values for the fitted model are compared to the observed value; second, some extraction functions to extract the observed and simulated networks and/or behaviour from the \texttt{sienaFit} object produced by \texttt{siena07} with \texttt{returnDeps=TRUE}.

These functions are exported here mainly to enable users to write their own versions. At the end of this help page some non-exported functions are listed. These are not exported because they depend on packages that are not in the R base distribution; and to show templates for readers wishing to construct their own functions.

Usage

\begin{verbatim}
OutdegreeDistribution(i, obsData, sims, period, groupName, varName, 
levls=0:8, cumulative=TRUE)

IndegreeDistribution(i, obsData, sims, period, groupName, varName, 
levls=0:8, cumulative=TRUE)

BehaviorDistribution(i, obsData, sims, period, groupName, varName, 
levls=NULL, cumulative=TRUE)

TriadCensus(i, obsData, sims, period, groupName, varName, levls=1:16)
mixedTriadCensus(i, obsData, sims, period, groupName, varName)
dyadicCov(i, obsData, sims, period, groupName, varName, dc)
sparseMatrixExtraction(i, obsData, sims, period, groupName, varName)
networkExtraction(i, obsData, sims, period, groupName, varName)
behaviorExtraction(i, obsData, sims, period, groupName, varName)
\end{verbatim}
Arguments

- **i**: Index number of simulation to be extracted, ranging from 1 to `length(sims)`; if NULL, the data observation will be extracted.
- **obsData**: The observed data set to which the model was fitted; normally this is `x$f` where `x` is the `sienaFit` object for which the fit is being assessed.
- **sims**: The simulated data sets to be compared with the observed data; normally this is `x$sims` where `x` is the `sienaFit` object for which the fit is being assessed.
- **period**: Period for which data and simulations are used (may run from 1 to number of waves - 1).
- **groupName**: Name of group; relevant for multi-group data sets; defaults in `sienaGOF` to "Data1".
- **varName**: Name of dependent variable.
- **levls**: Levels used as values of the auxiliary statistic. For `BehaviorDistribution`, this defaults to the observed range of values.
- **cumulative**: Are the distributions to be considered as raw or cumulative (<=) distributions?
- **dc**: Dyadic covariate: either a matrix with dimensions `n x n`; or, as period-dependent values, an array with dimensions `n x n x (M - 1)`; where `n` is the number of actors and `M` is the number of waves. There may be more time points, but those after `(M - 1)` will not be used.

Details

The statistics should be chosen to represent features of the network that are not explicitly fit by the estimation procedure but can be considered important properties that the model at hand should represent well. The three given here are far from a complete set; they will be supplemented in due time by statistics depending on networks and behavior jointly. The examples below give a number of other statistics, using the packages `sna` and `igraph`.

The `levls` parameter must be adapted to the range of values that is considered important. For indegrees and outdegrees, the whole range should usually be covered. If the range is large, which could be the case, e.g., for indegrees of two-mode networks where the second mode has few nodes, think about the possibility of making a selection such as `levls=5*(0:20)` or `levls=c(0:4,5*(1:20))`; which in most cases will make sense only if `cumulative=TRUE`.

The method signature for the auxiliary statistics generally is `function(i, obsData, sims, period, groupName, varName, ...)`. For constructing new auxiliary statistics, it is helpful to study the code of `OutdegreeDistribution`, `IndegreeDistribution`, and `BehaviorDistribution` and of the example functions below.

`TriadCensus` returns the distribution of the Holland-Leinhardt triad census according to the algorithm by Batagelj and Mrvar (implementation by Parimalarangan Slota, and Madduri). An alternative is the `TriadCensus.sna` function mentioned below, from package `sna`, which gives the same results. Here the `levls` parameter can be used to exclude some triads, e.g., for non-directed networks.

The Batagelj-Mrvar algorithm is optimized for sparse, large graphs and may be much faster than the procedure implemented in `sna`. For dense graphs the `sna` procedure may be faster.

`dyadicCov` assumes that `dc` is a categorical dyadic variable, and returns the frequencies of the non-zero values for realized ties. Since zero values of `dc` are not counted, it may be advisable to code `dc` so that all non-diagonal values are non-zero, and all diagonal values are zero.
Value

OutdegreeDistribution returns a named vector, the distribution of the observed or simulated outdegrees for the values in levls.

IndegreeDistribution returns a named vector, the distribution of the observed or simulated in-degrees for the values in levls.

BehaviorDistribution returns a named vector, the distribution of the observed or simulated behavioral variable for the values in levls.

TriadCensus returns a named vector, the distribution of the Holland-Leinhardt triad census according to the algorithm by Batagelj and Mrvar.

mixedTriadCensus returns a named vector, the distribution of the mixed triad census of Hollway, Lomi, Pallotti, and Stadtfeld (2017). See their Figure 1 for the meaning of the codes. In this figure, ties between the bottom nodes are for the first network, ties from the bottom to the top nodes are for the second network. The mixed triad census can be used for pairs of dependent networks of which the first must be one-mode and the second can be one-mode or two-mode. If the second is one-mode, the set of triads considered is only a subset of all mixed triads, and ties in the figure are directed upward; existence of other ties is not considered.

dyadicCov returns a named vector, the frequencies of the non-missing non-zero values dc(ego,alter) of the observed or simulated (ego,alter) ties.

sparseMatrixExtraction returns the simulated network as a "TsparseMatrix"; this is the virtual class for sparse numeric matrices represented by triplets in the Matrix package.

Tie variables for ordered pairs with a missing value for wave=period or period+1 are zeroed; note that this also is done in RSiena for calculation of target statistics. Tie variables that are structurally determined at the beginning of a period are used to replace observed values at the end of the period; tie variables that are structurally determined at the end, but not the beginning, of a period are used to replace simulated values at the end of the period.

To treat the objects returned by this function as regular matrices, it is necessary to attach the Matrix package in your session.

networkExtraction returns the network as an edge list of class network according to the network package (used for package sna). Missing values and structural values are treated as in sparseMatrixExtraction, see above.

behaviorExtraction returns the dependent behavior variable as an integer vector. Values for actors with a missing value for wave=period or period+1 are transformed to NA.

plot(gof.two, center=TRUE, scale=TRUE)

## Not run:
### Here come some useful functions for building your own auxiliary statistics:
### First an extraction function.

# igraphNetworkExtraction extracts simulated and observed networks
# from the results of a siena07 run.
# It returns the network as an edge list of class "graph"
# according to the igraph package.
# Ties for ordered pairs with a missing value for wave=period or period+1
# are zeroed;
# note that this also is done in RSiena for calculation of target statistics.
# However, changing structurally fixed values are not taken into account.
igraphNetworkExtraction <- function(i, data, sims, period, groupName, varName) {
  require(igraph)
dimsOfDepVar <- attr(data[[groupName]]$depvars[[varName]], "netdims")[1]
misssings <- is.na(data[[groupName]]$depvars[[varName]][,,period]) |
  is.na(data[[groupName]]$depvars[[varName]][,,period+1])
if (is.null(i)) {
  # sienaGOF wants the observation:
  original <- data[[groupName]]$depvars[[varName]][,,period+1]
  original[misssings] <- 0
  returnValue <- graph.adjacency(original)
} else {
  misssings <- graph.adjacency(misssings)
  #sienaGOF wants the i-th simulation:
  returnValue <- graph.difference(
    graph.empty(dimsOfDepVar) +
    edges(t(sims[[i]][[groupName]][[varName]][[period]][,1:2]),
      misssings)
  
}
returnValue
}

### Then some auxiliary statistics.

# GeodesicDistribution calculates the distribution of non-directed
# geodesic distances; see ?sna::geodist
# The default for \code{levls} reflects that geodesic distances larger than 5
# do not differ appreciably with respect to interpretation.
# Note that the levels of the result are named;
# these names are used in the \code{plot} method.

## End(Not run)

sienaGroupCreate  Function to group together several Siena data objects

Description

Creates an object of class "sienaGroup" from a list of Siena data objects.

Usage

sienaGroupCreate(objlist, singleOK = FALSE, getDocumentation=FALSE)

Arguments

  objlist  List of objects of class siena.
  singleOK Boolean: is it OK to only have one object?
  getDocumentation
            Flag to allow documentation of internal functions, not for use by users.

Details

This function creates a Siena group object from several Siena data objects ('groups'), all of which use networks, covariates and actor sets with the same names. The variables must correspond exactly between all data objects; the numbers of waves may differ. It can be used as data input to siena07 for the multigroup option. Also used internally for convenience with a single Siena data object.

Each covariate should either be centered in all groups, or non-centered in all groups. Centered actor covariates are re-centered at the overall mean. This means that the original values are used, and the overall mean of all non-missing observations is subtracted. Note that this implies that group-dependent variables that are constant for all actors in each group, can be used as centered actor covariates.

For combining two-wave with more-wave groups in one group object, covariates that are changing covariates for the more-wave groups have to be specified as changing covariates also for the two-wave groups. This can be done by specifying them with values for the two waves; for actor covariates this will be by using an $n \times 2$ matrix, for dyadic covariates an $n \times n \times 2$ array (or $n \times m \times 2$ for the two-mode case). The values for the second wave should be identical to those for the first wave (they will be used only for centering operations).
For later use in `siena07`, it will often (but not always...) be helpful when creating the Siena data objects in `objlist` to use `allowOnly=FALSE` in the call of `sienaDependent`; see the help page for this function.

If there are multiple dependent networks, it may be necessary to run `sienaDataConstraint` before `sienaGroupCreate` to ensure that these constraints are equal for all groups.

**Value**

An object of class `sienaGroup`; this is a list containing the input objects, with attributes:

- `netnames` names of the dependent variables in each set
- `symmetric` vector of booleans, one for each dependent variable. TRUE if all occurrences of the network are symmetric.
- `structural` vector of booleans, indicating whether structurally fixed values occur in this network
- `allUpOnly` vector of booleans, indicating whether changes are all upwards in all the occurrences of this network
- `allDownOnly` similar to previous, but for downward changes
- `anyUpOnly` vector of booleans, indicating whether changes are all upwards in any of the occurrences of this network
- `anyDownOnly` similar to previous, but for downward changes
- `types` vector of network types of the dependent variables
- `observations` Total number of periods to process
- `periodNos` Sequence of numbers of periods which are not skipped in multigroup processing
- `netnodeSets` list of names of the node sets corresponding to the dependent variables
- `cCovars` names of the constant covariates, if any
- `vCovars` names of the changing covariates, if any
- `dyCovars` names of the constant dyadic covariates, if any
- `dyvCovars` names of the changing dyadic covariates, if any
- `ccnodeSets` list of the names of the node sets corresponding to the constant covariates
- `cvnodeSets` list of the names of the node sets corresponding to the changing covariates
- `dycnodeSets` list of the names of the node sets corresponding to the constant dyadic covariates
- `dyvcnodeSets` list of the names of the node sets corresponding to the changing dyadic covariates
- `compositionChange` boolean: any composition change at all?
- `exooptions` named vector of composition change options for the node sets
- `names` Either from the input objects or "Data1", "Data2" etc
- `class"sienaGroup" inheriting from "siena"
- `balmean` vector of means for balance calculations
- `bRange` vector of difference between maximum and minimum values for behavior variables, NA for other dependent variables
behRange  matrix of maximum and minimum values for behavior variables, NA for other dependent variables
bSim     vector of similarity means for behavior variables, NA for other dependent variables
bPoszvar vector of booleans indicating positive variance for behavior variables. NA for other dependent variables
bMoreThan2 vector of booleans indicating whether the behavior variables take more than 2 distinct values
cCovarPoszvar vector of booleans indicating positive variance for constant covariates
cCovarMoreThan2 vector of booleans indicating whether the constant covariates take more than 2 distinct values
cCovarRange vector of difference between maximum and minimum values for constant covariates
cCovarRange2 matrix of maximum and minimum values for constant covariates
cCovarSim vector of similarity means for constant covariates
cCovarMean vector of means for constant covariates
vCovarRange vector of difference between maximum and minimum values for changing covariates
vCovarSim vector of similarity means for changing covariates
vCovarMoreThan2 vector of booleans indicating whether the changing covariates take more than 2 distinct values
vCovarPoszvar vector of booleans indicating positive variance for changing covariates
vCovarMean vector of means for changing covariates
dycCovarMean vector of means for constant dyadic covariates
dycCovarRange vector of ranges for constant dyadic covariates
dycCovarRange2 matrix of maximum and minimum values for constant dyadic covariates
dyvCovarRange vector of ranges for changing dyadic covariates
dyvCovarMean vector of means for changing dyadic covariates
anyMissing vector of booleans, one for each dependent variable, indicating the presence of any missing values
netRanges matrix of maximum and minimum values for dependent networks, NA for behavior variables

Function to create a node set

Description

Creates a Siena node set which can be used as the nodes in a Siena network.

Usage

sienaNodeSet(n, nodeName="Actors", names=NULL)

Arguments

n

type: integer, size of set.

nodeName

type: character string naming the node set.

names
	optional character string vector of length n of the names of the nodes.

Details

This function is important for data sets having more than one node set, but not otherwise.

Examples

Group1 <- sienaDependent(array(c(N3401, HN3401), dim=c(45, 45, 2)))
Group3 <- sienaDependent(array(c(N3403, HN3403), dim=c(37, 37, 2)))
Group4 <- sienaDependent(array(c(N3404, HN3404), dim=c(33, 33, 2)))
Group6 <- sienaDependent(array(c(N3406, HN3406), dim=c(36, 36, 2)))

# Illustration of the use of group-level variables:
# dum1 is a dummy variable for group 1,
# having constant value 1 in group 1, and constant value 0 in the other groups.
dum1.1 <- coCovar(c(rep(1,45)), warn = FALSE)
dum1.3 <- coCovar(c(rep(0,37)), warn = FALSE)
dum1.4 <- coCovar(c(rep(0,33)), warn = FALSE)
dum1.6 <- coCovar(c(rep(0,36)), warn = FALSE)

# In a similar way, dummies for the other groups can be defined.
dataset.1 <- sienaDataCreate(Friends = Group1, dum1 = dum1.1)
dataset.3 <- sienaDataCreate(Friends = Group3, dum1 = dum1.3)
dataset.4 <- sienaDataCreate(Friends = Group4, dum1 = dum1.4)
dataset.6 <- sienaDataCreate(Friends = Group6, dum1 = dum1.6)

(FourGroups <- sienaGroupCreate(list(dataset.1, dataset.3, dataset.4,
dataset.6)))
class(FourGroups)

# The main effect of the group-level variable is the \code{egoX} effect:
myeff <- getEffects(FourGroups)
(myeff <- includeEffects(myeff, egoX, interaction1 = "dum1"))
Value

Returns a Siena node set, an integer vector, possibly with names, plus the attributes, class equal to "sienaNodeSet", and nodeSetName equal to the argument nodeSetName.

**sienaRI**

*Functions to assess the relative importance of effects at observation moments*

Description

The function `sienaRI` computes various effect sizes for Stochastic Actor-oriented Models. As its value it returns the relative importance of effects of a SAOM according to the measure of relative importance described in Section 3.1 of Indlekofer and Brandes (2013). This is based on the influence of effects on potential tie change or behavior change decisions of individual actors at the given observation moments (waves).

It takes the data as well as the complete model specification into account. Therefore, necessary arguments are the analysed data given as a `siena` data object as well as the complete model specification represented either by an estimated `sienaFit` object or by the triple consisting of a suitable parameter vector `theta` and the corresponding `sienaAlgorithm` and `sienaEffects` objects.

Other measures useful for effect sizes are entropy-based effect sizes as in Snijders (2004) and the within-ego standard deviations of change statistics. If `getChangeStats=TRUE`, the arrays of change statistics are stored in the `sienaRI` object.
Usage

sienaRI(data, ans=NULL, theta=NULL, algorithm=NULL, effects=NULL,
       getChangeStats=FALSE)
## S3 method for class 'sienaRI'
print(x, printSigma=FALSE,...)
## S3 method for class 'sienaRI'
plot(x, actors = NULL, col = NULL, addPieChart = FALSE,
     radius = 1, width = NULL, height = NULL, legend = TRUE,
     legendColumns = NULL, legendHeight = NULL,
     cex.legend = NULL, cex.names = NULL,...)

Arguments

data siena data object representing the analyzed data and resulting from a call to sienaDataCreate.
ans sienaFit object resulting from a call to siena07. The sienaFit object contains all necessary information on the model specification, in particular, the vector of parameter values ans$theta, the used algorithm for estimation ans$x, and information on included model effects ans$effects. If ans is a valid sienaFit object, the calculations of relative importances are based on ans$theta, ans$x, and ans$effects. Alternatively, the necessary information can be given directly as a suitable parameter vector theta, a sienaAlgorithm object, and a sienaEffects object. In this case, ans has to be unspecified (i.e., ans=NULL).
theta Vector of parameter values of effects included in the model. Length of theta has to be equal to the number of included effects.
algorithm sienaAlgorithm object as resulting from a call to sienaAlgorithmCreate. Works only for estimation by Method of Moments (i.e., if maxlike = FALSE).
effects sienaEffects object specifying which effects are included the model. Note that sienaRI does not yet work for endowment or creation effect, i.e., included effects have to be of type eval (or rate).
getChangeStats Boolean: If TRUE, an array of change statistics is added to the sienaRI object.
x sienaRI object resulting from a call to sienaRI.
printSigma Boolean: If TRUE, average within-actor standard deviations of change statistics ('sigma') are included in the print.
actors vector of integers: set of actors to be included in the plot; if NULL, all actors.
col Colors used in the plot. If col=NULL a default color scheme is used.
addPieChart Boolean: If TRUE, pie charts of aggregated relative importances for the complete set of actors will be added to the plot.
radius Radius of pie charts. Only effective if addPieCharts = TRUE.
width Width of the plot. If width=NULL a default value is used.
height Height of the plot. If height=NULL a default value is used.
legend Boolean: if TRUE a legend is added to the plot. x$effectNames are used as labels.
legendColumns Number of columns in legend. If legendColumns=NULL a default value is used. Only effective if legend=TRUE.
legendHeight Height of legend. If legendHeight=NULL a default value is used. Only effective if legend=TRUE.
cex.legend Specifies the relative font size of legend labels.
cex.names Specifies the relative font size of bar graph labels.
... Other arguments.

Details
sienaRI takes the data as well as the complete model specification into account. Therefore, necessary arguments are the analyzed data given as a siena data object as well as the complete model specification represented either by an estimated sienaFit object or by the triple consisting of a suitable parameter vector theta and the corresponding sienaAlgorithm and sienaEffects objects.

A sienaFit object contains all necessary information on the model specification, in particular, the vector of parameter values ans$theta, the used algorithm for estimation ans$x, and information on included model effects ans$effects.

If ans is a valid sienaFit object, the calculations of relative importances are based on ans$theta, ans$x, and ans$effects. Alternatively, the necessary information can be given directly as a suitable parameter vector theta, a sienaAlgorithm object, and a sienaEffects object. In this case, ans has to be unspecified, i.e., ans=NULL.

Note that sienaRI works only with Method of Moments (i.e., for sienaAlgorithm objects with maxlike = FALSE) and that it does not yet work for endowment or creation effects (i.e., included effects have to be of type eval), and also not for models with interaction effects. For two-mode (bipartite) networks as dependent variables, it works only if the number of second-mode nodes is less than the number of actors. If the network is non-directed, the relative importances and entropy-based 'degrees of certainty' are calculated for modelType=2 ('forcing'; see sienaAlgorithmCreate). For dependent behavior variables, behModelType=1 ('standard') is assumed.

If there are any missing tie values in the network data set, they are imputed by initial zeros and Last Observation Carried Forward. Structural zeros and ones are replaced by NA and treated as impossible choices in the probability vectors and ignored in the standard deviations; but the change statistics for these dyads still are given in changeStatistics (if requested).

The averages reported in the components sigmas (average across actors) and meansigmas (average across waves) are obtained by averaging at the variance level and then taking square roots.

Value
If the model contains only one dependent variable, sienaRI returns an object of class sienaRI. Otherwise, it returns a list of objects of class sienaRI, each corresponding to one dependent variable.

A returned sienaRI object stores the expected relative importances of effects of one dependent variable at observation moments as defined in Section 3.1 of Indlekofer and Brandes (2013).

A sienaRI object is a list with the following components. For the components referred to as lists themselves, these are lists corresponding to the observation moments.
- **dependentVariable** the name of the corresponding dependent variable.
- **effectNames** the names of considered effects.
- **RIActors** a list that contains the expected relative importances of effects for each potential actor decision at observation moments. This is equation (3) in Indlekofer and Brandes (2013).
- **expectedRI** a list that contains the expected relative importances of effects aggregated over all actors for each network observation. These are the averages of the actor related values in RIActors. This is equation (4) in Indlekofer and Brandes (2013).
- **IActors** a list that contains the expected importances of effects for each potential actor decision at observation moments. This is the numerator of equation (3) in Indlekofer and Brandes (2013).
- **expectedI** a list that contains the expected importances of effects aggregated over all actors in each observation. More precisely, it contains the averages of the actor related values in IActors.
- **absoluteSumActors** a list that contains the sum of the (unstandardized) L1-differences calculated for each potential actor decision at observation moments. This is the denominator of equation (3) in Indlekofer and Brandes (2013).
- **RHActors** a list that contains the degree of certainty, also called degree of determination, in the potential ministep taken by an actor at the observation moments; this is $R_H(i,x)$ of formula (6) in Snijders (2004). The mean over actors of these degrees of certainty, given by formula (7) in Snijders (2004), is printed by the `print` method for sienaRI objects.
- **sigma** a list of effects by ego matrices of the values of the within-ego standard deviations of the change statistics.
- **sigmas** effects by wave matrices of averages (see above for how this is done; across actors) of sigma. These are printed if `printSigma=TRUE`.
- **meansigmas** average (see above for how this is done) over waves of sigmas.
- **changeStatistics** a list of arrays (effects by choices by egos) containing, for each observation wave, the values of the change statistics for making this choice, where for one-mode networks the choice is defined by the alters with alter=ego referring to 'no change', for two-mode networks the choice is defined in the second-mode nodes with the last choice referring to 'no change', and for behavior the choice is defined as going down, staying constant, or going up; this output is produced only if `getChangeStats=TRUE`.
- **toggleProbabilities** an array (egos by choices by waves), where "choices" are as directly above, giving the choice probabilities of ego in a ministep, when the data are as in this wave.

sienaTimeTest

Functions to assess and account for time heterogeneity of parameters

Description

Takes a sienaFit object estimated by Method of Moments, and tests for time heterogeneity by the addition of interactions with time dummy variables at waves \( m=2 \ldots (M-1) \). The test used is the score-type test of Schweinberger (2012).

Tests for joint significance, parameter-wise significance, period-wise significance, individual significance, and one-step estimates of the unrestricted model parameters are returned in a list.
Usage

sienaTimeTest(sienaFit, effects=NULL, excludedEffects=NULL, condition=FALSE)

Arguments

sienaFit A sienaFit object returned by siena07.
effects Optional vector of effect numbers to test. Use the numbering on the print of the sienaFit object.
excludedEffects Optional vector of effect numbers for which time heterogeneity is not to be tested. Use the numbering on the print of the sienaFit object.
condition Whether to orthogonalize effect-wise score-type tests and individual significance tests against estimated effects and un-estimated dummy terms, or just against estimated effects.

Details

This test follows the score type test of Schweinberger (2012) as elaborated by Lospinoso et al. (2011) by using statistics already calculated at each wave to obtain vectors of partitioned moment functions corresponding to a restricted model (the model in the sienaFit object; used as null hypothesis) and an unrestricted model (which contains dummies for waves \(m=2\ldots(M-1)\); used as alternative hypothesis).

condition=TRUE leads to a rough-and-easy approximation to controlling the mentioned tests also for the unestimated effects.

After assessing time heterogeneity, effects objects can be modified by adding numbers of all or some periods to the timeDummy column. This is facilitated by the includeTimeDummy function. For an effects object in which the timeDummy column of some of the included effects includes some or all period numbers, interactions of those effects with time dummies for the indicated periods will also be estimated.

An alternative to the use of includeTimeDummy is to define time-dependent actor covariates (dummy variables or other functions of wave number that are the same for all actors), include these in the data set through sienaAlgorithmCreate, and include interactions of other effects with ego effects of these time-dependent actor covariates by includeInteraction. This is illustrated in an example below. Using includeTimeDummy is easier; using self-defined interactions with time-dependent variables gives more control.

If you wish to use this function with sienaFit objects that use the finite differences method of derivative estimation, or which use maximum likelihood estimation, you must request the derivatives to be returned by wave using the byWave=TRUE option for siena07.

Effects leading to dummy interactions that are collinear with the model originally fitted, after excluding the effects mentioned, will be automatically excluded from the time heterogeneity testing.

If sienaTimeTest gives errors that there are too many collinear effects, run it with a smaller set of effects as specified by the effects parameter. For example, if the model has 40 effects of which the first 8 are rate parameters and therefore uninteresting, and there is such an error message, try effects=9:30; if that still does not work, decrease the upper limit of 30, if it does work increase it, to find the largest possible set of effects for which heterogeneity assessment still is possible; then as a next step try the remaining effects in a similar way.
Also if the execution is time-consuming, e.g., for a multi-group \texttt{sienaFit} object with many groups and many effects, it can be helpful to carry out the function in smaller subsets of effects.

Value

\texttt{sienaTimeTest} returns a list containing many items, including the following:

- \texttt{JointTest} A chi-squared test for joint significance of the dummies.
- \texttt{EffectTest} A chi-squared test for joint significance across dummies for each separate effect.
- \texttt{GroupTest} A chi-squared test for joint significance across dummies; if \texttt{sienaFit} is a fit for a multi-group object then these refer to each group; else they refer to each period.
- \texttt{IndividualTest} A matrix displaying initial estimates, one-step estimates, and \( p \)-values for the individual interactions.

### simstats0c

#### Versions of FRAN

**Description**

The functions to be called as "FRAN" by `siena07`. They call compiled C++. Not for general users' use.

**Usage**

```r
simstats0c(z, x, data=NULL, effects=NULL, fromFiniteDiff=FALSE, returnDeps=FALSE, returnChains=FALSE, byWave=FALSE, returnDataFrame=FALSE, returnLoglik=FALSE)
maxlikec(z, x, data=NULL, effects=NULL, returnChains=FALSE, byGroup = FALSE, byWave=FALSE, returnDataFrame=FALSE, returnLoglik=FALSE, onlyLoglik=FALSE)
initializeFRAN(z, x, data, effects, prevAns = NULL, initC, profileData = FALSE, returnDeps = FALSE, returnChains = FALSE, byGroup = FALSE, returnDataFrame = FALSE, returnLoglik = FALSE, onlyLoglik = FALSE)
terminateFRAN(z, x)
```

**Arguments**

- `z`  Control object, passed in automatically in `siena07`.
- `x`  A `sienaAlgorithm` object, passed in automatically in `siena07`.

data A sienaData object as returned by \texttt{sienaDataCreate}.
effects A sienaEffects object as returned by \texttt{getEffects}.
fromFiniteDiff Boolean used during calculation of derivatives by finite differences. Not for user use.
returnDeps Boolean. Whether to return the simulated networks in Phase 3.
returnChains Boolean. Whether to return the chains.
byWave Boolean. Whether to return the finite difference or maximum likelihood derivatives by wave (uses a great deal of memory). Only necessary for \texttt{sienaTimeTest}.
byGroup Boolean. For internal use: allows different thetas for each group to be used in \texttt{sienaBayes}.
returnDataFrame Boolean. Whether to return the chains as lists or data frames.
returnLoglik Boolean. Whether to return the log likelihood of the simulated chain.
onlyLoglik Boolean: whether to return just the likelihood for the simulated chain, plus details of steps accepted and rejected.
prevAns An object of class "sienaFit" as returned by \texttt{siena07}, from which scaling information (derivative matrix and standard deviation of the deviations) will be extracted along with the latest version of the parameters which will be used as the initial values, unless the model requests the use of standard initial values. If the previous model is exactly the same as the current one, Phase 1 will be omitted. If not, any parameter estimates for effects which are included in the new model will be used as initial values, but phase 1 will still be carried out. If the results used as prevAns are a reasonable starting point, this will increase the efficiency of the algorithm.

\texttt{initC} If TRUE, call is to setup the data and model in C++. For use with multiple processes only.
profileData Boolean to force dumping of the data for profiling with \texttt{sienaProfile.exe}.

\textbf{Details}

Not for general users’ use.
The name of \texttt{simstats0c} or \texttt{maxlikec} should be used for the element FRAN of the model object, the former when using estimation by forward simulation, the latter for maximum likelihood estimation. The arguments with no defaults must be passed in on the call to \texttt{siena07}. initializeFRAN and terminateFRAN are called in both cases.

\textbf{Value}

\texttt{simstats0c} returns a list containing:

\begin{itemize}
  \item \texttt{fra} Simulated statistics.
  \item \texttt{sc} Scores with which to calculate the derivative (not phase 2 or if using finite differences or maximum likelihood).
  \item \texttt{dff} Contributions to the derivative if finite differences
  \item \texttt{ntim} For conditional processing, time taken.
\end{itemize}
feasible  
Currently set to TRUE.

OK  
Could be set to FALSE if serious error has occurred.

sims  
A list of simulation results, one for each period. Each list consists of a list for each data object, each of which consists of a list for each network, each of which consists of a list for each period, each component of which is an edgelist in matrix form (the columns are from, to, value) (or vector for behavior variables). Only if returnDeps is TRUE.

maxlikec returns a list containing:

fra  
Simulated scores.

dff  
Simulated Hessians: stored as lower triangular matrices

ntim  
NULL, compatibility only

feasible  
Currently set to TRUE.

OK  
Could be set to FALSE if serious error has occurred.

dff  
Simulated Hessian

sims  
NULL, for compatibility only

chain  
A list of sampled chains, one for each period. Each list consists of a list for each data object, each of which consists of a list for each network, each of which consists of a list for each period, each component of which is a list or a data frame depending on the value of returnDataFrame. Only if returnChains is TRUE.

accepts  
Number of accepted MH steps by dependent variable (permute steps are counted under first dependent variable)

rejects  
Number of rejected MH steps by dependent variable (permute steps are counted under first dependent variable)

aborts  
Number of aborted MH steps counted under first dependent variable.

loglik  
Loglikelihood of the simulations. Only if returnLoglik is TRUE. If onlyLoglik is TRUE, only loglik, accepts, rejects and aborts are returned.

initializeFRAN and terminateFRAN return the control object z.

```

## S3 method for class 'iwlsm'

```r
summary(object, method = c("XtX", "XtWX"),
         correlation = FALSE, ...)
```

Arguments

- **object**: the fitted model. This is assumed to be the result of some fit that produces an object inheriting from the class `iwlsm`, in the sense that the components returned by the `iwlsm` function will be available.
- **method**: Should the weighted (by the IWLS weights) or unweighted cross-products matrix be used?
- **correlation**: logical. Should correlations be computed (and printed)?
- **...**: arguments passed to or from other methods.

Details

This function is a method for the generic function `summary()` for class "iwlsm". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.iwlsm(x)` regardless of the class of the object.

Value

If printing takes place, only a null value is returned. Otherwise, a list is returned with the following components. Printing always takes place if this function is invoked automatically as a method for the `summary` function.

- **correlation**: The computed correlation coefficient matrix for the coefficients in the model.
cov.unscaled  The unscaled covariance matrix; i.e, a matrix such that multiplying it by an estimate of the error variance produces an estimated covariance matrix for the coefficients.

sigma  The scale estimate.

stddev  A scale estimate used for the standard errors.

df  The number of degrees of freedom for the model and for residuals.

coefficients  A matrix with three columns, containing the coefficients, their standard errors and the corresponding t statistic.

terms  The terms object used in fitting this model.

tmp3

updateTheta  A function to update the initial values of theta, and a function to update an effects object.

Description
updateTheta copies the final values of any matching selected effects from a sienaFit object to a Siena effects object.
updateSpecification includes in a Siena effects object a set of effects that are included in another effects object.

Usage
updateTheta(effects, prevAns, varName=NULL)
updateSpecification(effects.to, effects.from, name.to=NULL, name.from=NULL)

Arguments
effects Object of class sienaEffects.
prevAns Object of class sienaFit as returned by siena07.
varName Character string or vector of character strings; is this is not NULL, the update will only applied to this dependent variable / these dependent variables.
effects.to Object of class sienaEffects.
effects.from Object of class sienaEffects.
name.to Character string, name of dependent variable in object.to.
name.from Character string, name of dependent variable in object.from.

Details
The initial values of any selected effects in the input effects object which match an effect estimated in prevAns will be updated by updateTheta. If the previous run was conditional, the estimated rate parameters for the dependent variable on which the run was conditioned are added to the final value of theta. If varName is not NULL, this update is restricted to effects for the dependent variable/s specified by varName.
By updateSpecification, the effects included in effects.from are also included in effects.to;
if name.to and/or name.from is specified, this is restricted to effects for those dependent variables. If name.to = "all" (should then not be used as variable name!), the effects for all dependent variables will be updated.

Correspondence between effects is defined by "name", "shortName", "type", "groupName", "interaction1", "interaction2", "period", "effect1", "effect2", and "effect3". This means that inclusion of user-defined interactions will be updated only if they were available (i.e., defined) already in effects.to.

Value

Updated effects object.

Note

Using updateTheta explicitly before calling siena07 rather than using it via the argument prevAns of siena07 will not permit the use of the previous derivative matrix. In most cases, using siena07 with prevAns will be more efficient.

ans <- siena07(myalgorithm, data=mydata, effects=myeff1, batch=TRUE)
ans$theta
(myeff <- updateTheta(myeff1, ans))
##
## For updateSpecification:
myeff2 <- getEffects(mydata)
myeff2 <- includeEffects(myeff2, inPop)
updateSpecification(myeff2, myeff1)
# Create (meaningless) two-dimensional dependent network
mynet1 <- sienaDependent(array(c(s501, s502), dim=c(50, 50, 2)))
mynet2 <- sienaDependent(array(c(s503, s501), dim=c(50, 50, 2)))
mydata12 <- sienaDataCreate(mynet1, mynet2)
myeff12 <- getEffects(mynet1, mynet2)
```
```r
myeff.new <- getEffects(mydata12)
(myeff12 <- includeEffects(myeff12, inPop, outPop, outAct))
# update myeff.new only for mynet1:
updateSpecification(myeff.new, myeff12)
# update myeff.new for all dependent networks:
(myeff.updated <- updateSpecification(myeff.new, myeff12, "all"))
# use multivariate effects object to update univariate effects object:
myeff1 <- getEffects(sienaDataCreate(mynet1))
updateSpecification(myeff1, myeff.updated)
```

**varCovar**

*Function to create a changing covariate object.*

**Description**

This function creates a changing covariate object from a matrix.

**Usage**

```r
varCovar(val, centered=TRUE, nodeSet="Actors", warn=TRUE,
imputationValues=NULL)
```

**Arguments**

- `val`: Matrix of covariate values, one row for each actor, one column for each period.
- `centered`: Boolean: if TRUE, then the overall mean value is subtracted.
- `nodeSet`: Character string containing the name of the associated node set. If the entire data set contains more than one node set, then the node sets must be specified in all data objects.
- `warn`: Logical: is a warning given if all values are `NA`, or all non-missing values are the same.
- `imputationValues`: Matrix of covariate values of same dimensions as `val`, to be used for imputation of `NA` values (if any) in `val`. Must not contain any `NA`.

**Details**

When part of a Siena data object, the covariate is assumed to be associated with node set `nodeSet` of the Siena data object. In practice, the node set needs to be specified only in the case of the use of the covariate with a two-mode network.

If there are any `NA` values in `val`, and `imputationValues` is given, then the corresponding elements of `imputationValues` are used for imputation. If `imputationValues` is `NULL`, imputation is by the overall mean value. In both cases, cases with imputed values are not used for calculating target statistics (see the manual).

The value of the changing covariate for wave `m` is supposed in the simulations to be valid in the whole period from wave `m` to wave `m+1`. If the data set has `M` waves, this means that the values, if any, for wave `M` will not be used. Therefore, the number of columns can be `M` or `M-1`: if the former, the values in the last column will not be used.
Value

Returns the covariate as an object of class "varCovar", in which form it can be used as an argument to sienaDataCreate.

See Also

sienaDataCreate, coCovar, coDyadCovar, varDyadCovar, sienaNodeSet

Examples

myvarCovar <- varCovar(s50a)
senders <- sienaNodeSet(50, nodeSetName="senders")
receivers <- sienaNodeSet(30, nodeSetName="receivers")
senders.covariate <- varCovar(s50a, nodeSet="senders")
receivers.covariate <- varCovar(s50s[1:30,], nodeSet="receivers")

Description

This function creates a changing dyadic covariate object from an array.

Usage

varDyadCovar(val, centered=TRUE, nodeSets=c("Actors", "Actors"),
            warn=TRUE, sparse=is.list(val), type=c("oneMode", "bipartite"))

Arguments

val
  Array of covariate values, third dimension is the time. Alternatively, a list of
  sparse matrices of type "TsparseMatrix".

centered
  Boolean: if TRUE, then the overall mean value is subtracted.

nodeSets
  Names (character string) of the associated node sets. If the entire data set con-
  tains more than one node set, then the node sets must be specified in all data
  objects.

warn
  Logical: is a warning given if all values are NA, or all non-missing values are the
  same.
spare  Boolean: whether sparse matrices or not.

Details

When part of a Siena data object, the covariate is assumed to be associated with the node sets named NodeSets of the Siena data object. The names of the associated node sets will only be checked when the Siena data object is created. In practice, the node set needs to be specified only in the case of the use of the covariate with a two-mode network. The value of the changing covariate for wave m is supposed in the simulations to be valid in the whole period from wave m to wave m+1. If the data set has M waves, this means that the values, if any, for wave M will not be used. Therefore, the number of columns can be M or M-1; if the former, the values in the last column will not be used.

Value

Returns the covariate as an object of class "varDyadCovar", in which form it can be used as an argument to SienaDataCreate.

Wald

Wald and score tests for RSiena results

Description

These functions compute Wald-type and score-type tests for results estimated by siena07.
**Usage**

Wald.RSiena(A, ans)

Multipar.RSiena(ans, ...)

score.Test(ans, test=ans$test)

testSame.RSiena(ans, e1, e2)

**Arguments**

A | A k * p matrix, where p = ans$pp, the number of parameters in ans excluding the basic rate parameters used for conditional estimation.

ans | An object of class sienaFit, resulting from a call to siena07.

... | One or more integer numbers between 1 and p, specifying the tested effects (numbered as in print(ans); if conditional estimation was used, numbered as the 'Other parameters').

test | One or more integer numbers between 1 and p, or a logical vector of length p; these should specify the tested effects (numbered as described for the ...).

e1, e2 | Each an integer number between 1 and p, or a vector of such numbers; the hypothesis tested is that the parameters for effects with number/s e1 are equal to those in e2.

**Details**

The hypothesis tested by Wald.RSiena is $A\theta = 0$, where $\theta$ is the parameter estimated in the process leading to ans.

The hypothesis tested by Multipar.RSiena is that all parameters given in ... are 0. This is a special case of Wald.RSiena.

The hypothesis tested by testSame.RSiena is that all parameters given in e1 are equal to those in e2. This also is a special case of Wald.RSiena.

The tested effects for score.Test should have been specified in includeEffects or setEffect with fix=TRUE, test=TRUE, i.e., they should not have been estimated. The hypothesis tested by score.Test is that the tested parameters have the value indicated in the effects object used for obtaining ans.

These tests should be carried out only when convergence is adequate (overall maximum convergence ratio less than 0.25 and all t-ratios for convergence less than 0.1 in absolute value).

These functions have their own print method, see print.sienaTest.

**Value**

An object of class sienaTest, which is a list with elements:

chisquare: The test statistic, assumed to have a chi-squared null distribution.

df: The degrees of freedom.

pvalue: The associated $p$-value.
onesided: For df=1, the onesided test statistic.

efnames: For Multipar.RSiena and score.Test, the names of the tested effects.

Examples

```r
mynet <- sienaDependent(array(c(s501, s502), dim=c(50, 50, 2)))
mydata <- sienaDataCreate(mynet)
myeff <- getEffects(mydata)
myalgorithm <- sienaAlgorithmCreate(nsub=1, n3=40, seed=1777, projname=NULL)
# nsub=1 and n3=40 is used here for having a brief computation,
# not for practice.
myeff <- includeEffects(myeff, transTrip, transTies)
myeff <- includeEffects(myeff, outAct, outPop, fix=TRUE, test=TRUE)
(ans <- siena07(myalgorithm, data=mydata, effects=myeff, batch=TRUE))
A <- matrix(0, 2, 6)
A[1, 3] <- 1
A[2, 4] <- 1
wa <- Wald.RSiena(A, ans)
wa
# A shortcut for the above is:
Multipar.RSiena(ans, 3, 4)
# The following two are equivalent:
sct <- score.Test(ans, c(FALSE, FALSE, FALSE, FALSE, FALSE, TRUE))
sct <- score.Test(ans, 6)
print(sct)
# Getting all 1-df score tests separately:
for (i in which(ans$test)){
  sc <- score.Test(ans,i)
  print(sc)
}
# Testing that endowment and creation effects are identical:
myeff1 <- getEffects(mydata)
myeff1 <- includeEffects(myeff1, recip, include=FALSE)
myeff1 <- includeEffects(myeff1, recip, type='creation')
(myeff1 <- includeEffects(myeff1, recip, type='endow'))
(ans1 <- siena07(myalgorithm, data=mydata, effects=myeff1, batch=TRUE))
testSame.RSiena(ans1, 2, 3)
```
xtable

Access xtable in package xtable

Description
Dummy function to allow access to xtable in package xtable

Usage
xtable(x, ...)

Arguments
x          sienaFit object
...        Other arguments for \texttt{xtable.sienaFit}

Value
Value returned from \texttt{xtable.sienaFit}
