Exposing C++ functions and classes with Rcpp modules

Dirk Eddelbuettel\textsuperscript{a} and Romain François\textsuperscript{b}

\textsuperscript{a}http://dirk.eddelbuettel.com; \textsuperscript{b}https://romain.bind.io/

This note discusses \texttt{Rcpp modules}. \texttt{Rcpp modules} allow programmers to expose C++ functions and classes to \texttt{R} with relative ease. \texttt{Rcpp modules} are inspired from the Boost.Python C++ library (Abrahams and Grosse-Kunstleve, 2003) which provides similar features for Python.

\texttt{Rcpp \& modules | R \& C++}

1. Motivation

Exposing C++ functionality to \texttt{R} is greatly facilitated by the \texttt{Rcpp} package and its underlying C++ library (Eddelbuettel et al., 2019; Eddelbuettel and François, 2011). \texttt{Rcpp} smoothes many of the rough edges in \texttt{R} and C++ integration by replacing the traditional \texttt{R} Application Programming Interface (API) described in ‘Writing \texttt{R} Extensions’ (R Core Team, 2018) with a consistent set of C++ classes. The ‘Rcpp-jss-2011’ vignette (Eddelbuettel et al., 2019; Eddelbuettel and François, 2011) describes the API and provides an introduction to using \texttt{Rcpp}.

These \texttt{Rcpp} facilities offer a lot of assistance to the programmer wishing to interface \texttt{R} and C++. At the same time, these facilities are limited as they operate on a function-by-function basis. The programmer has to implement a \texttt{.Call} compatible function (to conform to the \texttt{R} API) using classes of the \texttt{Rcpp} API as described in the next section.

1.1. Exposing functions using \texttt{Rcpp}. Exposing existing C++ functions to \texttt{R} through \texttt{Rcpp} usually involves several steps. One approach is to write an additional wrapper function that is responsible for converting input objects to the appropriate types, calling the actual worker function and converting the results back to a suitable type that can be returned to \texttt{R} (SEXP). Consider the \texttt{norm} function below:

```cpp
double norm(double x, double y) {
    return sqrt(x*x + y*y);
}
```

This simple function does not meet the requirements set by the \texttt{.Call} convention, so it cannot be called directly by \texttt{R}. Exposing the function involves writing a simple wrapper function that does match the \texttt{.Call} requirements. \texttt{Rcpp} makes this easy.

```cpp
using namespace Rcpp;
RcppExport SEXP norm_wrapper(SEXP x_, SEXP y_) {
    double x = as<double>(x_);
    double y = as<double>(y_);

    // step 1: call the underlying C++ function
    double res = norm(x, y);

    // step 2: return the result as a SEXP
    return wrap(res);
}
```

Here we use the (templated) \texttt{Rcpp} converter \texttt{as()} which can transform from a SEXP to a number of different C++ and \texttt{Rcpp} types. The \texttt{Rcpp} function \texttt{wrap()} offers the opposite functionality and converts many known types to a SEXP.

This process is simple enough, and is used by a number of CRAN packages. However, it requires direct involvement from the programmer, which quickly becomes tiresome when many functions are involved. \texttt{Rcpp modules} provides a much more elegant and unintrusive way to expose C++ functions such as the \texttt{norm} function shown above to \texttt{R}.

We should note that \texttt{Rcpp} now has \texttt{Rcpp attributes} which extends certain aspect of \texttt{Rcpp modules} and makes binding to simple functions such as this one even easier. With \texttt{Rcpp attributes} we can just write

```cpp
#include <Rcpp.h>

// [[Rcpp::export]]
double norm(double x, double y) {
    return sqrt(x*x + y*y);
}
```

See the corresponding vignette (Allaire et al., 2018) for details, but read on for \texttt{Rcpp modules} which contains to provide features not covered by \texttt{Rcpp attributes}, particularly when it comes to binding entire C++ classes and more.

1.2. Exposing classes using \texttt{Rcpp}. Exposing C++ classes or structs is even more of a challenge because it requires writing glue code for each member function that is to be exposed.

Consider the simple Uniform class below:

```cpp
class Uniform {
public:
    Uniform(double min_, double max_) : 
        min(min_), max(max_) {}

    NumericVector draw(int n) {
        RNGScope scope;
        return runif(n, min, max);
    }

private:
    double min, max;
};
```

To use this class from \texttt{R}, we at least need to expose the constructor and the \texttt{draw} method. External pointers (R Core Team, 2018) are the perfect vessel for this, and using the \texttt{Rcpp:::XPtr} template from \texttt{Rcpp} we can expose the class with these two functions:
using namespace Rcpp;

/// create external pointer to a Uniform object
RcppExport SEXP Uniform__new(SEXP min_, SEXP max_) {
  // convert inputs to appropriate C++ types
double min = as<double>(min_),
  max = as<double>(max_);

  // create pointer to an Uniform object and
  // wrap it as an external pointer
  Rcpp::XPtr<Uniform> ptr(
    new Uniform( min, max ),
    true);

  // return the external pointer to the R side
  return ptr;
}

/// invoke the draw method
RcppExport SEXP Uniform__draw(SEXP xp, SEXP n_) {
  // grab the object as a XPtr (smart pointer)
  // to Uniform
  Rcpp::XPtr<Uniform> ptr(xp);

  // convert the parameter to int
  int n = as<int>(n_);

  // invoke the function
  NumericVector res = ptr->draw( n );

  // return the result to R
  return res;
}

As it is generally a bad idea to expose external pointers `as is`,
they usually get wrapped as a slot of an S4 class.

Using `cxxfunction()` from the `inline` package, we can build
this example on the fly. Suppose the previous example code
assigned to a text variable `unifModCode`, we could then do

```r
f1 <- cxxfunction( , "", includes = unifModCode,
  plugin = "Rcpp" )
getDynLib(f1) # will display info about 'f1'
```

The following listing shows some manual wrapping to access
the code, we will see later how this can be automated:

```r
using namespace Rcpp;

// helper
Uniform_method < function(name) {
  paste("Uniform", name, sep = "_")
}

# syntactic sugar to allow object$method( ... )
setMethod("$", "Uniform", function(x, name) {
  function(...) .Call(Uniform_method(name) ,
    x@pointer, ...)})
```

Rcpp considerably simplifies the code that would be involved
for using external pointers with the traditional R API. Yet this still
involves a lot of mechanical code that quickly becomes hard to
maintain and error prone. Rcpp modules offer an elegant way to
expose the Uniform class in a way that makes both the internal
C++ code and the R code easier.

2. Rcpp modules

The design of Rcpp modules has been influenced by Python modules
which are generated by the Boost.Python library (Abrahams and
Grosse-Kunstleve, 2003). Rcpp modules provide a convenient and
easy-to-use way to expose C++ functions and classes to R, grouped
together in a single entity.

A Rcpp module is created in a cpp file using the `RCPP_MODULE`
macro, which then provides declarative code of what the module
exposes to R.

2.1. Exposing C++ functions using Rcpp modules. Consider the
`norm` function from the previous section. We can expose it to R:

```r
using namespace Rcpp;

double norm(double x, double y) {
  return sqrt(x*x + y*y);
}

RCPP_MODULE(mod) {
  function("norm", &norm);
}
```

The code creates an Rcpp module called `mod` that exposes the
`norm` function. Rcpp automatically deduces the conversions that
are needed for input and output. This alleviates the need for a
wrapper function using either Rcpp or the R API.

On the R side, the module is retrieved by using the `Module`
function from Rcpp

```r
inc <-`
using namespace Rcpp;

double norm( double x, double y ) {
  return sqrt(x*x + y*y);
}

RCPP_MODULE(mod) {
  function("norm", &norm);
}
'
fx <- cxxfunction(signature(),
  plugin="Rcpp", include=inc)

```
mod <- Module("mod", getDynLib(fx))

Note that this example assumed that the previous code segment defining the module was returned by the cxxfunction() (from the inline package) as callable R function fx from which we can extract the relevant pointer using getDynLib(). In the case of using Rcpp modules via a package (which is detailed in Section 3 below), modules are actually loaded differently and we would have used

```r
require(nameOfMyModulePackage)
mod <- new(mod)
mod$norm(3, 4)
```

where the module is loaded upon startup and we use the constructor directly. More details on this aspect follow below.

A module can contain any number of calls to function to register many internal functions to R. For example, these 6 functions:

```cpp
std::string hello() {
    return "hello";
}
int bar(int x) {
    return x*2;
}
double foo(int x, double y) {
    return x * y;
}
void bla() {
    Rprintf("hello\n");
}
void bla1(int x) {
    Rprintf("hello (x = %d)\n", x);
}
void bla2(int x, double y) {
    Rprintf("hello (x = %d, y = %.5f)\n", x, y);
}
```

can be exposed with the following minimal code:

```r
cpp_module(yada) {
    using namespace Rcpp;
    double norm(double x, double y) {
        return sqrt(x*x + y*y);
    }
}
```

The requirements for a function to be exposed to R via Rcpp modules are:

- The function takes between 0 and 65 parameters.
- The type of each input parameter must be manageable by the Rcpp::as template.
- The return type of the function must be either void or any type that can be managed by the Rcpp::wrap template.
- The function name itself has to be unique in the module. In other words, no two functions with the same name but different signatures are allowed. C++ allows overloading functions. This might be added in future versions of modules.

2.1.1. Documentation for exposed functions using Rcpp modules. In addition to the name of the function and the function pointer, it is possible to pass a short description of the function as the third parameter of function.

```r
cpp_module(mod) {
    function("norm", &norm, 
        "Provides a simple vector norm")
}
```

The description is used when displaying the function to the R prompt:

```r
mod <- Module("mod", getDynLib(fx))
show(mod$norm)
```

2.1.2. Formal arguments specification. function also gives the possibility to specify the formal arguments of the R function that encapsulates the C++ function, by passing a Rcpp::List after the function pointer.

```r
cpp_module(mod) {
    function("norm", &norm, 
        "Provides a simple vector norm")
}
```

The description is used when displaying the function to the R prompt:

```r
mod <- Module("mod", getDynLib(fx))
show(mod$norm)
```

2.1.2. Formal arguments specification. function also gives the possibility to specify the formal arguments of the R function that encapsulates the C++ function, by passing a Rcpp::List after the function pointer.
A simple usage example is provided below:

```r
norm <- mod$norm
norm()
norm(y = 2)
norm(x = 2, y = 3)
args(norm)
```

To set formal arguments without default values, simply omit the rhs.

```cpp
class Uniform {
public:
Uniform(double min_, double max_) :
  min(min_), max(max_) {}

NumericVector draw(int n) const {
  RNGScope scope;
  return runif(n, min, max);
}

double min, max;
}
```

This can be used as follows:

```r
norm <- mod$norm
args(norm)
```

The ellipsis (…) can be used to denote that additional arguments are optional; it does not take a default value.

```cpp
class Uniform {
public:
Uniform(double min_, double max_) :
  min(min_), max(max_) {}

NumericVector draw(int n) const {
  RNGScope scope;
  return runif(n, min, max);
}

double min, max;
}
```

## assumes fx_unif <- cxxfunction(...) ran
```
unif_module <- Module("unif_module",
  getDynLib(fx_unif))
```

```
Uniform <- unif_module$Uniform
u <- new(Uniform, 0, 10)
u$draw(10L)
u$range()
u$max <- 1
u$range()
u$draw(10)
```

2.2. Exposing C++ classes using Rcpp modules. Rcpp modules also provide a mechanism for exposing C++ classes, based on the reference classes introduced in R 2.12.0.

2.2.1. Initial example. A class is exposed using the class_ keyword. The Uniform class may be exposed to R as follows:

```cpp
class Uniform {
public:
Uniform(double min_, double max_) :
  min(min_), max(max_) {}

NumericVector draw(int n) const {
  RNGScope scope;
  return runif(n, min, max);
}

double min, max;
}
```

```r
## assumes fx_unif <- cxxfunction(...) ran
unif_module <- Module("unif_module",
  getDynLib(fx_unif))
```

```r
Uniform <- unif_module$Uniform
u <- new(Uniform, 0, 10)
u$draw(10L)
u$range()
u$max <- 1
u$range()
u$draw(10)
```

class_ is templated by the C++ class or struct that is to be exposed to R. The parameter of the class_<Uniform> constructor is the name we will use on the R side. It usually makes sense to use the same name as the class name. While this is not enforced, it might be useful when exposing a class generated from a template.

Then constructors, fields and methods are exposed.

2.2.2. Exposing constructors using Rcpp modules. Public constructors that take from 0 and 6 parameters can be exposed to the R level using the .constructor template method of .class_.

Optionally, .constructor can take a description as the first argument.

```cpp
class Uniform {
public:
Uniform(double min_, double max_) :
  min(min_), max(max_) {}

NumericVector draw(int n) const {
  RNGScope scope;
  return runif(n, min, max);
}

double min, max;
}
```

```r
## assumes fx_unif <- cxxfunction(...) ran
unif_module <- Module("unif_module",
  getDynLib(fx_unif))
```

```r
Uniform <- unif_module$Uniform
u <- new(Uniform, 0, 10)
u$draw(10L)
u$range()
u$max <- 1
u$range()
u$draw(10)
```

Also, the second argument can be a function pointer (called validator) matching the following type:

```cpp
class Uniform {
public:
Uniform(double min_, double max_) :
  min(min_), max(max_) {}

NumericVector draw(int n) const {
  RNGScope scope;
  return runif(n, min, max);
}

double min, max;
}
```
typedef bool (*ValidConstructor)(SEXP*, int);

The validator can be used to implement dispatch to the appropriate constructor, when multiple constructors taking the same number of arguments are exposed. The default validator always accepts the constructor as valid if it is passed the appropriate number of arguments. For example, with the call above, the default validator accepts any call from R with two `double` arguments (or arguments that can be cast to `double`).

TODO: include validator example here

### 2.2.3. Exposing fields and properties.

`class_` has three ways to expose fields and properties, as illustrated in the example below:

```cpp
using namespace Rcpp;

class Foo {
public:
  Foo(double x_, double y_, double z_): x(x_), y(y_), z(z_) {}

  double x;
  double y;

  double get_z() { return z; }
  void set_z(double z_) { z = z_; }

private:
  double z;
};

RCPP_MODULE(mod_foo) {
  class_<Foo>("Foo")
    .constructor<double, double, double>()
    .field("x", &Foo::x)
    .field_readonly("y", &Foo::y)
    .property("z", &Foo::get_z, &Foo::set_z);
}
```

The `.field` method exposes a public field with read/write access from R. `.field` accepts an extra parameter to give a short description of the field:

```cpp
.field("x", &Foo::x, "documentation for x")
```

The `.field_readonly` exposes a public field with read-only access from R. It also accepts the description of the field.

```cpp
.field_readonly("y", &Foo::y,
  "documentation for y")
```

The `.property` method allows indirect access to fields through a getter and a setter. The setter is optional, and the property is considered read-only if the setter is not supplied. A description of the property is also allowed:

```cpp
// with getter and setter
.property("z", &Foo::get_z, &Foo::set_z, "Documentation for z")
```

The type of the field (T) is deduced from the return type of the getter, and if a setter is given its unique parameter should be of the same type.

Getters can be member functions taking no parameter and returning a T (for example `get_z` above), or a free function taking a pointer to the exposed class and returning a T, for example:

```cpp
void z_get(Foo* foo) { return foo->get_z(); }
```

Setters can be either a member function taking a T and returning void, such as `set_z` above, or a free function taking a pointer to the target class and a T:

```cpp
void z_set(Foo* foo, double z) { foo->set_z(z); }
```

Using properties gives more flexibility in case field access has to be tracked or has impact on other fields. For example, this class keeps track of how many times the x field is read and written.

```cpp
class Bar {
public:
  Bar(double x_) : x(x_), nread(0), nwrite(0) {}

  double get_x() {
    nread++;
    return x;
  }

  void set_x(double x_) {
    nwrite++;
    x = x_;}

  IntegerVector stats() const {
    return IntegerVector::create(_["read"] = nread,
      _["write"] = nwrite);
  }

private:
  double x;
  int nread, nwrite;
};

RCPP_MODULE(mod_bar) {
  class_<Bar>("Bar")
    .constructor<double>()
    .property("x", &Bar::get_x, &Bar::set_x)
    .method("stats", &Bar::stats);
}
```

Here is a simple usage example:
Bar <- mod_bar
b <- new(Bar, 10)
b$x + b$x
b$stats()
b$x <- 10
b$stats()

2.2.4. Exposing methods using Rcpp modules. `class_` has several overloaded and templated `.method` functions allowing the programmer to expose a method associated with the class.

A legitimate method to be exposed by `.method` can be:

- A public member function of the class, either const or non const, that returns void or any type that can be handled by `Rcpp::wrap`, and that takes between 0 and 65 parameters whose types can be handled by `Rcpp::as`.
- A free function that takes a pointer to the target class as its first parameter, followed by 0 or more (up to 65) parameters that can be handled by `Rcpp::as` and returning a type that can be handled by `Rcpp::wrap` or void.

2.2.5. Documenting methods. `.method` can also include a short documentation of the method, after the method (or free function) pointer.

```
.method("stats", &Bar::stats,
  "vector indicating the number of "
  "times x has been read and written")
```

TODO: mention overloading, need good example.

2.2.6. Const and non-const member functions. `.method` is able to expose both `const` and `non const` member functions of a class. There are however situations where a class defines two versions of the same method, differing only in their signature by the `const`-ness. It is for example the case of the member functions back of the `std::vector` template from the STL.

```
reference back ( );
const_reference back ( ) const;
```

To resolve the ambiguity, it is possible to use `const_method` or `nonconst_method` instead of `.method` in order to restrict the candidate methods.

2.2.7. Special methods. `Rcpp` considers the methods `[[` and `[[<-` special, and promotes them to indexing methods on the R side.

2.2.8. Object finalizers. The `.finalizer` member function of `class_` can be used to register a finalizer. A finalizer is a free function that takes a pointer to the target class and return void. The finalizer is called before the destructor and so operates on a valid object of the target class.

It can be used to perform operations, releasing resources, etc...

The finalizer is called automatically when the R object that encapsulates the C++ object is garbage collected.

2.2.9. Object factories. The `.factory` member function of `class_` can be used to register a `factory` that can be used as alternative to a constructor. A factory can be a static member function or a free function that returns a pointer to the target class. Typical use-cases include creating objects in a hierarchy:

```
#include <Rcpp.h>
using namespace Rcpp;

// abstract class
class Base {
  public:
    virtual ~Base() {}
    virtual std::string name() const = 0;
  
  // first derived class
  class Derived1: public Base {
    public:
      Derived1() : Base() {}
      virtual std::string name() const {
        return "Derived1";
      }
  }

  // second derived class
  class Derived2: public Base {
    public:
      Derived2() : Base() {}
      virtual std::string name() const {
        return "Derived2";
      }
  }

  Base *newBase( const std::string &name ) {
    if (name == "d1"){
      return new Derived1;
    } else if (name == "d2"){
      return new Derived2;
    } else {
      return 0;
    }
  }

  RCPP_MODULE(mod) {
    Rcpp::class_< Base >("Base")
      .factory<const std::string&>(newBase)
      .method("name", &Base::name);
  }
```

The `newBase` method returns a pointer to a `Base` object. Since that class is an abstract class, the objects are actually instances of `Derived1` or `Derived2`. The same behavior is now available in R:

```
dv1 <- new(Base, "d1")
dv1$name() # returns "Derived1"
dv2 <- new(Base, "d2")
dv2$name() # returns "Derived2"
```

2.2.10. S4 dispatch. When a C++ class is exposed by the `class_` template, a new S4 class is registered as well. The name of the S4 class is obfuscated in order to avoid name clashes (i.e. two modules exposing the same class).

This allows implementation of R-level (S4) dispatch. For example, one might implement the `show` method for `C++ World` objects:
```r
setMethod("show", yada$World, function(object) {
  msg <- paste("World object with message : ", object$greet())
  writeLines(msg)
})
```

Todo: mention R inheritance (John ?)

### 2.2.11. Full example

The following example illustrates how to use Rcpp modules to expose the class `std::vector<double>` from the STL.

```r
typedef std::vector<double> vec;
void vec_assign(vec* obj, 
Rcpp::NumericVector data) {
  obj->assign(data.begin(), data.end());
}
void vec_insert(vec* obj, int position, 
Rcpp::NumericVector data) {
  vec::iterator it = obj->begin() + position;
  obj->insert(it, data.begin(), data.end());
}
Rcpp::NumericVector vec_asR( vec* obj ) {
  return Rcpp::wrap( *obj );
}
void vec_set(vec* obj, int i, double value) {
  obj->at( i ) = value;
}

RCPP_MODULE(mod_vec) {
  using namespace Rcpp;
  // we expose class std::vector<double>
  // as "vec" on the R side
  class_<vec>("vec")
    // exposing constructors
    .constructor()
    .constructor<int>()
    // exposing member functions
    .method("size", &vec::size)
    .method("max_size", &vec::max_size)
    .method("resize", &vec::resize)
    .method("capacity", &vec::capacity)
    .method("empty", &vec::empty)
    .method("reserve", &vec::reserve)
    .method("push_back", &vec::push_back)
    .method("pop_back", &vec::pop_back)
    .method("clear", &vec::clear)
    // exposing const member functions
    .const_method("back", &vec::back)
    .const_method("front", &vec::front)
    .const_method("at", &vec::at )
    // exposing free functions taking a
    // std::vector<double>* as their first
    // argument
    .method("assign", &vec_assign)
    .method("insert", &vec_insert)
}
```

```r
# for code compiled on the fly using # cxxfunction() into 'fx_vec', we use mod_vec <- Module("mod_vec",
getDynLib(fx_vec),
  mustStart = TRUE)
vec <- mod_vec$vec
# and that is not needed in a package
# setup as e.g. one created
# via Rcpp.package.skeleton(..., module=TRUE)
v <- new(vec)
v$reserve(50L)
v$assign(1:10)
v$push_back(10)
v$size()
v$capacity()
v[[1L]]
v$as.vector()
```

### 3. Using modules in other packages

#### 3.1. Namespace import/export

##### 3.1.1. Import all functions and classes

When using Rcpp modules in a packages, the client package needs to import Rcpp's namespace. This is achieved by adding the following line to the NAMESPACE file.

```r
import(Rcpp)
```

In some case we have found that explicitly naming a symbol can be preferable:

```r
import(Rcpp, evalCpp)
```

#### 3.2. Load the module

##### 3.2.1. Deprecated older method using loadRcppModules

Note: This approach is deprecated as of Rcpp 0.12.5, and now triggers a warning message. Eventually this function will be withdrawn.

The simplest way to load all functions and classes from a module directly into a package namespace used to be to use the loadRcppModules function within the .onLoad body.

```r
.onLoad <- function(libname, pkgname) {
  loadRcppModules()
}
```

This will look in the package's DESCRIPTION file for the RcppModules field, load each declared module and populate their contents into the package's namespace. For example, both the testRcppModule package (which is part of large unit test suite for Rcpp) and the package created via Rcpp.package.skeleton("somename", module=TRUE) have this declaration:
RcppModules: yada, stdVector, NumEx

The loadRcppModules function has a single argument direct with a default value of TRUE. With this default value, all content from the module is exposed directly in the package namespace. If set to FALSE, all content is exposed as components of the module.

3.2.2. Preferred current method using loadModule. Starting with release 0.9.11, an alternative is provided by the loadModule() function which takes the module name as an argument. It can be placed in any .R file in the package. This is useful as it allows to load the module from the same file as some auxiliary R functions using the module. For the example module, the equivalent code to the .onLoad() use shown above then becomes

```r
loadModule("yada")
loadModule("stdVector")
loadModule("NumEx")
```

This feature is also used in the new Rcpp Classes introduced with Rcpp 0.9.11.

3.2.3. Just expose the module. Alternatively, it is possible to just expose the module to the user of the package, and let them extract the functions and classes as needed. This uses lazy loading so that the module is only loaded the first time the user attempts to extract a function or a class with the dollar extractor.

```r
yada <- Module("yada")
.onLoad <- function(libname, pkgname) {
  # placeholder
}
```

3.3. Support for modules in skeleton generator. The Rcpp.package.skeleton function has been improved to help Rcpp modules. When the module argument is set to TRUE, the skeleton generator installs code that uses a simple module.

```r
Rcpp.package.skeleton("testmod", module = TRUE)
```

Creating a new package using Rcpp modules is easiest via the call to Rcpp.package.skeleton() with argument module=TRUE as a working package with three example Modules results.

3.4. Module documentation. Rcpp defines a prompt method for the Module class, allowing generation of a skeleton of an Rd file containing some information about the module.

```r
yada <- Module("yada")
prompt(yada, "yada-module.Rd")
```

We strongly recommend using a package when working with Modules. But in case a manually compiled shared library has to loaded, the return argument of the getDynLib() function can be supplied as the PACKAGE argument to the Module() function as well.

4. Future extensions

Boost.Python has many more features that we would like to port to Rcpp modules: class inheritance, default arguments, enum types,…

5. Known shortcomings

There are some things Rcpp modules is not good at:

- serialization and deserialization of objects: modules are implemented via an external pointer using a memory location, which is non-constant and varies between session. Objects have to be re-created, which is different from the (de)serialization that R offers. So these objects cannot be saved from session to session.
- multiple inheritance: currently, only simple class structures are representable via Rcpp modules.

6. Summary

This note introduced Rcpp modules and illustrated how to expose C++ function and classes more easily to R. We hope that R and C++ programmers find Rcpp modules useful.
