Package ‘SDLfilter’

May 4, 2020

Type Package

Title Filtering and Assessing Sample Size of Tracking Data

Version 2.0.0

Date 2020-05-04

Author Takahiro Shimada

Maintainer Takahiro Shimada <taka.shimada@gmail.com>

Description Functions to filter GPS and/or Argos locations, as well as assessing sample sizes for the analysis of animal distributions. The filters remove temporal and spatial duplicates, fixes located at a given height from estimated high tide line, and locations with high error as described in Shimada et al. (2012) <doi:10.3354/meps09747> and Shimada et al. (2016) <doi:10.1007/s00227-015-2771-0>. Sample sizes for the analysis of animal distributions can be assessed by the conventional area-based approach or the alternative probability-based approach as described in Shimada et al. (in prep).

asymptote Horizontal asymptotes of rational functions

Description

Function to find horizontal asymptotes of a rational function.

Usage

asymptote(
  data = NULL,
  x = NULL,
  y = NULL,
  d1 = 1,
  d2 = 1,
  threshold = 0.95,
asymptote

    proportional = TRUE
"

Arguments

data An output object from `boot_overlap` or `boot_area`.
x, y Numeric vectors of independent (x) and dependent (y) variables. These parameters will be ignored if `data` is supplied.
d1, d2 Maximal degrees of numerator (d1) and denominator (d2) of a rational function.
threshold Threshold value for considering an asymptote. Once the y value reaches the threshold, it is considered that an asymptote is reached.
proportional If TRUE (default), a threshold is calculated as `estimated asymptote * threshold`. If FALSE, the value specified in `threshold` is used in the analysis.

Details

This function fits a rational function to the input data. When an output object from `boot_overlap` or `boot_area` is supplied, a rational function is fit to the means of the bootstrap results (e.g. mean overlap probability) as a function of `x` (e.g. sample size). It then estimates horizontal asymptotes and identifies the sample size when an asymptote is considered.

Value

A list containing a data frame (rational function fit associated with x values), an estimated horizontal asymptote, and the minimum sample size if an asymptote is reached.

boot_area

Cumulative analysis of collective areas by bootstrapping

Description

Function to calculate collective areas (merged x\% Utilisation Distributions or UD) of n individuals by bootstrapping.

Usage

```r
boot_area(
  data,
  cell.size = NA,
  R = 1000,
  percent = 50,
  quantiles = c(0.25, 0.5, 0.75)
)
```

Arguments

- **data**: A matrix or list of RasterLayer objects. Each row of the matrix or each RasterLayer object contains a utilisation distribution (or other statistics that sums to 1 - e.g. proportion of time spent). The grid size and geographical extent must be consistent across each row of the matrix or each RasterLayer object. The function assumes that each column of the matrix is associated with a unique geographical location or that each RasterLayer has exactly the same geographical extent and resolution.
- **cell.size**: A numeric value specifying the grid cell size of the input data in metres.
- **R**: An integer specifying the number of iterations.
- **percent**: An integer specifying the percent volume of each UD to be considered in the analysis.
- **quantiles**: A vector or a number to specify the quantiles to be calculated in the summary of the results.

Details

This function calculates collective areas (e.g. 50\% UD) of 1 to n individuals by bootstrapping.

Value

A list containing two data frames - raw results and summary (mean, sd, sem and quantiles at each sample size).

Author(s)

Takahiro Shimada
References

Shimada et al. (in prep)

Examples

```r
## Not run:

#1 Utilisation distributions of flatback turtles.
data(curtis)

#2 Calculate collective areas from 1000 random permutation
area <- boot_area(curtis, R = 1000, percent = 50)

#3 Find the minimum sample size required to estimate the general distribution.
a <- asymptote(area)

#4 Plot the mean collective area and rational function fit relative to the sample sizes.
 ggplot(data = area$summary) +
    geom_point(aes(x = N, y = mu/1e+6), alpha = 0.5) +
    geom_path(data = a$results, aes(x = x, y = ys/1e+6)) +
    labs(x = "N", y = expression(Area~(km^2)))

## End(Not run)
```

---

**boot_overlap**

(*Bootstrap overlaps between Utilisation Distributions (UDs)*)

**Description**

Function to calculate overlaps between UDs relative to sample size by bootstrapping.

**Usage**

```r
boot_overlap(
data,
R = 1000,
method = "PHR",
percent = 100,
quantiles = c(0.25, 0.5, 0.75)
)
```

**Arguments**

- `data`: A matrix or list of RasterLayer objects. Each row of the matrix or each RasterLayer object contains a utilisation distribution (or other statistics that sums to 1 - e.g. proportion of time spent). **The grid size and geographical extent must be consistent across each row of the matrix or each RasterLayer object.** The
function assumes that each column of the matrix is associated with a unique geographical location or that each RasterLayer has exactly the same geographical extent and resolution.

R  An integer specifying the number of iterations.

method The overlap quantification method. "HR" is for the proportion of an individual's home range overlapped by the known habitats of other individuals. "PHR" is for the probability of an individual to be within the known habitats of other individuals. "VI", "BA" and "UDOI" quantify overlap between UD between each additional UD and a collective UD. To generate a collective UD, each UD is overlaid and averaged at each grid cell so the probability density of the collective UD sums up to 1 (Shimada et al. in prep).

percent  An integer specifying the percent volume of each UD to be considered in the analysis.

quantiles  A vector or a number to specify the quantiles to be calculated in the summary of the results.

Details

This function calculates and bootstraps overlap between UD based on the areas ("HR"), areas of collective UD and the probability distribution of each individual ("PHR"), or the probability distribution of an individual and an averaged probability distribution of collective individuals ("VI", "BA", "UDOI").

Value

A list containing two data frames - raw results and summary (mean, sd, sem and quantiles at each sample size).

data(curtis)

#2 Calculate overlap probability from 1000 random permutation.
overlap <- boot_overlap(curtis, R = 1000, method = "PHR")

#3 Find the minimum sample size required to estimate the general distribution.
a <- asymptote(overlap)

#4 Plot the mean probability and rational function fit relative to the sample sizes.
ggplot(data = overlap$summary)+
  geom_point(aes(x = N, y = mu), alpha = 0.5) +
  geom_path(data = a$results, aes(x = x, y = ys)) +
  geom_vline(xintercept = a$min.n, linetype = 2) +
  labs(x = "N", y = "Overlap probability")

## End(Not run)

---

**curtis**

*Flatback turtle utilisation distributions*

**Description**

Inter-nesting utilisation distributions of 29 flatback turtles (*Natator depressus*) that nested in Curtis Island, Australia. As a demonstration, the resolution of the UDs is reduced to 1km grid instead of 50m as used in Shimada et al (in prep).

**Usage**

curtis

**Format**

A list of 29 RasterLayer objects

**Source**

Shimada T et al, (in prep)

---

**ddfilter**

*Filter locations using a data driven filter*

**Description**

Function to remove locations by a data driven filter as described in Shimada et al. (2012).

**Usage**

ddfilter(sdata, vmax = 8.9, vmaxlp = 1.8, qi = 4, ia = 90, method = 1)
Arguments

sdata  A data frame containing columns with the following headers: "id", "DateTime", "lat", "lon", "qi". The function filters the input data by the unique "id". "DateTime" is date & time in class POSIXct. "lat" and "lon" are the latitude and longitude of each location in decimal degrees. "qi" is the numerical quality index associated with each location fix where a greater number indicates a higher accuracy (e.g. number of GPS satellites used for estimation).

vmax  A numeric value specifying a threshold of speed from a previous and/or to a subsequent fix. Default is 8.9km/h. If this value is unknown, it can be estimated from sdata using the function vmax.

vmaxlp  A numeric value specifying a threshold of speed, which is used to evaluate the locations of loop trips. Default is 1.8 km/h. If this value is unknown, it can be estimated from sdata using the function vmaxlp.

qi  An integer specifying a threshold of quality index, which is used to evaluate the locations of loop trips. Default is 4.

ia  An integer specifying a threshold of inner angle, which is used to evaluate the locations of loop trips. Default is 90 degrees.

method  An integer specifying how locations should be filtered with vmax. A location is removed if the speed from a previous and(1)/or(2) to a subsequent location exceeds vmax. Default is 1 (both way).

Details

Locations are removed if the speed from a previous and/or to a subsequent location exceeds vmax, or if all of the following criteria apply: the associated quality index is less than or equal to qi, the inner angle is less than or equal to ia and the speed either from a previous or to a subsequent location exceeds vmaxlp. If vmax and vmaxlp are unknown, they can be estimated using the functions vmax and vmaxlp respectively.

Value

The input data is returned without locations identified by this filter. The following columns are added: "pTime", "sTime", "pDist", "sDist", "pSpeed", "sSpeed", "inAng". "pTime" and "sTime" are hours from a previous and to a subsequent fix respectively. "pDist" and "sDist" are straight distances in kilometres from a previous and to a subsequent fix respectively. "pSpeed" and "sSpeed" are linear speed from a previous and to a subsequent fix respectively. "inAng" is the degree between the bearings of lines joining successive location points.

ggridExtra::marrangeGrob(list(p1, p2), nrow=1, ncol=2)
ddfilter_loop

Description
A partial component of ddfilter, although works as a stand-alone function. This function removes locations by speed, inner angle, and quality index as described in Shimada et al. (2012).

Usage
ddfilter_loop(sdata, qi = 4, ia = 90, vmaxlp = 1.8)

Arguments
- **sdata**: A data frame containing columns with the following headers: "id", "DateTime", "lat", "lon", "qi". The function filters the input data by the unique "id". "DateTime" is date & time in class *POSIXct*. "lat" and "lon" are the latitude and longitude of each location in decimal degrees. "qi" is the numerical quality index associated with each location fix where a greater number indicates a higher accuracy (e.g. number of GPS satellites used for estimation).
- **qi**: An integer specifying a threshold of quality index, which is used to evaluate the locations of loop trips. Default is 4.
- **ia**: An integer specifying a threshold of inner angle, which is used to evaluate the locations of loop trips. Default is 90 degrees.
- **vmaxlp**: A numeric value specifying a threshold of speed, which is used to evaluate the locations of loop trips. Default is 1.8 km/h. If this value is unknown, it can be estimated from *sdata* using the function *vmaxlp*.

Details
This function removes locations if all of the following criteria apply: the number of source satellites are less than or equal to *qi*, the inner angle is less than and equal to *ia* and the speed either from a previous or to a subsequent location exceeds *vmaxlp*. If *vmaxlp* is unknown, it can be estimated using the function *vmaxlp*.

Value
The input data is returned without locations identified by this filter. The following columns are added: "pTime", "sTime", "pDist", "sDist", "pSpeed", "sSpeed", "inAng". "pTime" and "sTime" are hours from a previous and to a subsequent fix respectively. "pDist" and "sDist" are straight distances in kilometres from a previous and to a subsequent fix respectively. "pSpeed" and "sSpeed" are linear speed from a previous and to a subsequent fix respectively. "inAng" is the degree between the bearings of lines joining successive location points.

ddfilter_speed  Filter locations by speed

Description
A partial component of ddfilter, although works as a stand-alone function. This function removes locations by a given threshold speed as described in Shimada et al. (2012).

Usage
```
ddfilter_speed(sdata, vmax = 8.9, method = 1)
```

Arguments

- **sdata** A data frame containing columns with the following headers: "id", "DateTime", "lat", "lon", "qi". The function filters the input data by the unique "id". "DateTime" is date & time in class POSIXct. "lat" and "lon" are the latitude and longitude of each location in decimal degrees. "qi" is the numerical quality index associated with each location fix where a greater number indicates a higher accuracy (e.g. number of GPS satellites used for estimation).
- **vmax** A numeric value specifying a threshold of speed from a previous and/or to a subsequent fix. Default is 8.9km/h. If this value is unknown, it can be estimated from sdata using the function vmax.
- **method** An integer specifying how locations should be filtered with vmax. A location is removed if the speed from a previous and(1)/or(2) to a subsequent location exceeds vmax. Default is 1 (both way).

Details
This function removes locations if the speed from a previous and/or to a subsequent location exceeds a given threshold speed. If vmax is unknown, it can be estimated using the function vmax.

Value
The input data is returned without locations identified by this filter. The following columns are added: "pTime", "sTime", "pDist", "sDist", "pSpeed", "sSpeed". "pTime" and "sTime" are hours from a previous and to a subsequent fix respectively. "pDist" and "sDist" are straight distances in kilometres from a previous and to a subsequent fix respectively. "pSpeed" and "sSpeed" are linear speed from a previous and to a subsequent fix respectively.

depthfilter  Filter locations by water depth

Description
Function to filter locations according to bathymetry and tide.

Usage
depthfilter(
sdata, bathymetry, extract = "bilinear", qi = 4, tide, tidal.plane, type = "HT", height = 0, filter = TRUE
)

Arguments
sdata  A data frame containing columns with the following headers: "id", "DateTime", "lat", "lon", "qi". The function filters the input data by the unique "id". "DateTime" is date & time in class POSIXct. "lat" and "lon" are the latitude and longitude of each location in decimal degrees. "qi" is the numerical quality index associated with each location fix where a greater number indicates a higher accuracy (e.g. number of GPS satellites used for estimation).
bathymetry  A RasterLayer object containing bathymetric data in metres. Negative and positive values indicate below and above the water respectively. Geographic coordinate system is WGS84.
extract  Method to extract cell values from the raster layer as inherited from the extract function of the raster package. Default is bilinear.
qi  An integer specifying a threshold of quality index. depthfilter does not filter a location that is associated with a quality index higher than this threshold. Default is 4.
A data frame containing columns with the following headers: "tideDT", "reading", "standard.port". "tideDT" is date & time in class POSIXct at each observation. "reading" is the observed tidal height in metres. "standard.port" is the identifier of each tidal station.

A data frame containing columns with the following headers: "standard.port", "secondary.port", "lat", "lon", "timeDiff", "datumDiff". "standard.port" is the identifier for a tidal observation station. "secondary.port" is the identifier for a station at which tide is only predicted using tidal records observed at the related standard port. "lat" and "lon" are the latitude and longitude of each secondary port in decimal degrees. "timeDiff" is the time difference between standard port and its associated secondary port. "datumDiff" is the baseline difference in metres if bathymetry and tidal observations/predictions uses different datum (e.g. LAT and MSL).

The type of water depth considered in the filtering process. "exp" is for the water depth experienced by the animal at the time. This option may be applicable to species that remain in water at all times (e.g. dugongs, dolphins, etc). "HT" is for the water depth at the nearest high tide (default). This option is useful for animals that use inter-tidal zones at high tide and may remain there even after the tide drops (e.g. some sea turtles).

A numerical value to adjust the water depth an animal is likely to use. Default is 0 m. This parameter is useful if the minimum water depth used by the animal is known. For example, a dugong is unlikely to use water shallower than its body height (e.g. ~0.5 m) so it may be sensible to consider the fix is an error if the estimated water depth is shallower than its body height. A negative value indicates below the water surface. For the dugong example, to remove locations for which the water depth was <0.5 m, it should be specified as: height = -0.5. By supplying the body height to this argument, all the locations recorded shallower than its body will be removed.

Default is TRUE. If FALSE, the function does not filter locations but it still returns estimates of the water depth experienced by the animal at each location.

The function examines each location according to the water depth experienced by the animal or the water depth at the nearest high tide. The function looks for the closest match between each fix and tidal observations or predictions in temporal and spatial scales. When filter is disabled, the function does not filter locations but returns the estimated water depth of each location with the tide effect considered (bathymetry + tide).

When filter option is enabled, this function filters the input data and returns with two additional columns; "depth.exp", "depth.HT". "depth.exp" is the estimated water depth at each location at the time of location fixing. "depth.HT" is the estimated water depth at the nearest high tide at each location.

The input data must not contain temporal or spatial duplicates.

```
### distfilter

**Filter locations by distance**

**Description**

This function removes locations that are located beyond a specified distance.

**Usage**

```r
distfilter(sdata, max.dist = 100, method = 1)
```

**Arguments**

- `sdata`: A data frame containing columns with the following headers: "id", "DateTime", "lat", "lon". The function filters the input data by the unique "id". "DateTime" is date & time in class `POSIXct". "lat" and "lon" are the latitude and longitude of each location in decimal degrees.
- `max.dist`: A numeric value specifying a threshold of distance between successive locations. Default is 100 km.
- `method`: An integer specifying how locations should be filtered with `max.dist`. A location is removed if the distance from a previous and(1)/or(2) to a subsequent location exceeds `max.dist`. Default is 1 (both way).

**Details**

This function removes locations if the distance from a previous and/or to a subsequent location exceeds `max.dist`.

**Value**

The input data is returned without locations identified by this filter. The following columns are added: "pDist", "sDist". "pDist" and "sDist" are straight distances in kilometres from a previous and to a subsequent fix respectively.

**dupfilter**

**Filter temporal and/or spatial duplicates**

**Description**

Function to filter temporal and spatial duplicates in tracking data and retain only a single fix per time and location.

**Usage**

```r
dupfilter(sdata, step.time = 0, step.dist = 0, conditional = FALSE)
```
Arguments

sdata  A data frame containing columns with the following headers: "id", "DateTime", "lat", "lon", "qi". The function filters the input data by the unique "id". "DateTime" is date & time in class POSIXct. "lat" and "lon" are the latitude and longitude of each location in decimal degrees. "qi" is the numerical quality index associated with each location fix where a greater number indicates a higher accuracy (e.g. the number of GPS satellites involved in estimation).

step.time  Consecutive locations less than or equal to step.time apart are considered temporal duplicates. Default is 0 hours.

step.dist  Consecutive locations less than or equal to step.dist apart are considered spatial duplicates. Default is 0 kilometres.

conditional  If TRUE, spatial duplicates are filtered only if they are less than or equal to step.time apart. Default is FALSE.

Details

This function filters temporal and spatial duplicates in tracking data. It first filters temporally and spatially exact locations. It then looks for temporal duplicates and retains a fix with the highest quality index. When temporal or spatial duplicates are associated with the same quality index, the function retains a location that is nearest from a previous and to a subsequent location.

Value

The input data frame is returned containing only a single fix (latitude/longitude pair) per time and location.

**dupfilter_exact**

Filter temporally and spatially exact duplicates

**Description**

Function to filter temporally and spatially exact locations in tracking data.

**Usage**

`dupfilter_exact(sdata)`

**Arguments**

- **sdata**: A data frame containing columns with the following headers: "id", "DateTime", "lat", "lon", "qi". The function filters the input data by the unique "id". "DateTime" is date & time in class `POSIXct`. "lat" and "lon" are the latitude and longitude of each location in decimal degrees. "qi" is the numerical quality index associated with each location fix where a greater number indicates a higher accuracy (e.g. the number of GPS satellites involved in estimation).

**Details**

This is a partial component of `dupfilter`, although works as a stand-alone function. It looks for temporally and spatially exact locations and retains only a single fix (latitude/longitude pair) per time and location.

**Value**

The input data frame is returned with temporally and spatially exact duplicates removed.

**Author(s)**

Takahiro Shimada

**References**

dupfilter, dupfilter_qi, dupfilter_time, dupfilter_space, track_param
dupfilter_qi  Filter temporal duplicates by quality index

Description

Function to filter temporal duplicates in tracking data by quality index.

Usage

dupfilter_qi(sdata = sdata, step.time = 0)

Arguments

sdata  A data frame containing columns with the following headers: "id", "DateTime", "qi". The function filters the input data by the unique "id". "DateTime" is date & time in class POSIXct. "qi" is the numerical quality index associated with each location fix where a greater number indicates a higher accuracy (e.g. the number of GPS satellites involved in estimation).

step.time  Consecutive locations less than or equal to step.time apart are considered temporal duplicates. Default is 0 hours.

Details

This function is a partial component of dupfilter, although works as a stand-alone function. It looks for temporal duplicates and retains a fix with the highest quality index.

Value

The input data frame is returned with temporal duplicates removed by the quality index.

Author(s)

Takahiro Shimada

dupfilter, dupfilter_exact, dupfilter_time, dupfilter_space, track_param
Description

Function to filter spatial duplicates in tracking data.

Usage

dupfilter_space(sdata, step.time = 0, step.dist = 0, conditional = FALSE)

Arguments

sdata  A data frame containing columns with the following headers: "id", "DateTime", "lat", "lon", "qi". The function filters the input data by the unique "id". "DateTime" is date & time in class POSIXct. "lat" and "lon" are the latitude and longitude of each location in decimal degrees. "qi" is the numerical quality index associated with each location fix where a greater number indicates a higher accuracy (e.g. the number of GPS satellites involved in estimation).

step.time  Consecutive locations less than or equal to step.time apart are considered temporal duplicates. Default is 0 hours.

step.dist  Consecutive locations less than or equal to step.dist apart are considered spatial duplicates. Default is 0 kilometres.

conditional  If TRUE, spatial duplicates are filtered only if they are less than or equal to step.time apart. Default is FALSE.

Details

This function is a partial component of dupfilter, although works as a stand-alone function. First it identifies spatial duplicates by searching for consecutive fixes that were located within step.dist. For each group of spatial duplicates, the function then retains a single fix that is nearest from a previous and to a subsequent location.

Value

The input data frame is returned with spatial duplicates removed.

Note

A minimum of two locations per id is required.

dupfilter_time  Filter temporal duplicates

Description

Function to filter temporal duplicates that are associated with the same quality index.

Usage

dupfilter_time(sdata, step.time = 0)

Arguments

sdata  A data frame containing columns with the following headers: "id", "DateTime", "lat", "lon", "qi". The function filters the input data by the unique "id". "DateTime" is date & time in class POSIXct. "lat" and "lon" are the latitude and longitude of each location in decimal degrees. "qi" is the numerical quality index associated with each location fix where a greater number indicates a higher accuracy (e.g. the number of GPS satellites involved in estimation).

step.time  Consecutive locations less than or equal to step.time apart are considered temporal duplicates. Default is 0 hours.

Details

This is a partial component of dupfilter, although works as a stand-alone function. First it identifies temporal duplicates by searching for consecutive locations that were obtained within step.time. For each group of temporal duplicates, the function then retains a single fix that is nearest from a previous and to a subsequent location.

Value

The input data frame is returned with temporal duplicates removed.

### kml_track

**Generate KML from locations**

**Description**

Function to generate a kml file from tracking data. This is a wrapper of `plotKML` and `kml`, specifically designed to generate a kml file from tracking data.

**Usage**

```r
kml_track(sdata, sdata.CRS = "WGS", output = "open", type = "point", ...)
```

**Arguments**

- `sdata`: A data frame containing location data of one individual, with the following column headers: "id", "DateTime", "lat", "lon". "id" is the identifier of the individual. "DateTime" is date & time in class `POSIXct`. "lat" and "lon" are the latitude and longitude of each location in decimal degrees.
- `sdata.CRS`: Coordinate reference system (CRS) for the input location data. If the input data is not in WGS, the specific CRS needs to be supplied as a PROJ.4 notation or EPSG code. (e.g. "+proj=utm +zone=37 +datum=WGS84 +units=m +no_defs" or "EPSG:32637")
- `output`: A string specifying whether to 'open' or 'save' the output. The output will be saved in the current working directory.
- `type`: Type of the output. 'point' or 'line.'
- `...`: Optional arguments passed to `plotKML` and `kml`.

**Value**

A kml file

**Author(s)**

Takahiro Shimada

**See Also**

`map_track`
Examples

```r
#### Fastloc GPS data obtained from a green turtle
data(turtle)

## Not run:
#### See the data on Google earth
## points with time stamps
kml_track(turtle, output = "open", type = "point",
points_names = turtle$DateTime, colour_scale = "yellow")

## lines
kml_track(turtle, output = "open", type = "line", colour = "red")

#### Save the location points to the current working directory
shape <- "http://maps.google.com/mapfiles/kml/pal2/icon26.png"
kml_track(turtle, output = "save", type = "point", shape = shape, colour = "yellow")

## End(Not run)
```

map_track

Plot location data on a map

Description

Function to plot tracking data on a map or a satellite image.

Usage

```r
map_track(
sdata,
 xlim = NULL,
ylim = NULL,
 margin = 10,
 bgmap = NULL,
google.key = NULL,
 map.bg = "grey",
 map.col = "black",
 zoom = NULL,
 point.bg = "yellow",
 point.col = "black",
 point.symbol = 21,
 point.size = 1,
 line.col = "lightgrey",
 line.type = 1,
 line.size = 0.5,
 sb.distance = NULL,
 sb.lwd = 1,
```

\textit{map\_track}

\begin{verbatim}
  sb.line.col = "black",
  sb.text.size = 4,
  sb.text.col = "black",
  sb.space = 3,
  title = "id",
  title.size = 11,
  axes.text.size = 11,
  axes.lab.size = 11,
  multiplot = TRUE,
  nrow = 1,
  ncol = 1
)

Arguments

\begin{itemize}
  \item \texttt{sdata} \hspace{1cm} A data frame containing columns with the following headers: "id", "DateTime", "lat", "lon". The function creates a map for each unique "id". "DateTime" is date \& time in class \texttt{POSIXct}. "lat" and "lon" are the latitude and longitude of each location in decimal degrees.
  \item \texttt{xlim, ylim} \hspace{1cm} Limits for x and y axes. If not specified, the values are determined as the maximum range of the input data plus an additional margin (see \texttt{margin}).
  \item \texttt{margin} \hspace{1cm} Set the amount of spaces added around the periphery of the plot. The value is scaled to the plot. The smaller value increases the margin.
  \item \texttt{bgmap} \hspace{1cm} A data frame of a background map data, containing the following headers: "long", "lat", "group". If not specified, the \texttt{world} map is used. Google Maps ("terrain", "satellite", "roadmap", "hybrid") can also be queried.
  \item \texttt{google.key} \hspace{1cm} If Google Maps are queried, a valid API key (a string) needs to be specified here. See \texttt{register\_google} for details.
  \item \texttt{map.bg} \hspace{1cm} Background colour of the map. This argument is ignored when any Google Maps is selected.
  \item \texttt{map.col} \hspace{1cm} Outline colour of the map. This argument is ignored when any Google Maps is selected.
  \item \texttt{zoom} \hspace{1cm} Map zoom for Google Maps. Default (NULL) to estimate the zoom from each data set. For other options, see \texttt{get\_map} for details.
  \item \texttt{point.bg} \hspace{1cm} The colour to fill in a symbol.
  \item \texttt{point.col} \hspace{1cm} The colour for the outline of a symbol.
  \item \texttt{point.symbol} \hspace{1cm} An integer or a string to specify the symbol type. See \texttt{shape} for details.
  \item \texttt{point.size} \hspace{1cm} An integer to specify the size of the symbol.
  \item \texttt{line.col} \hspace{1cm} The colour of the line that connects consecutive points.
  \item \texttt{line.type} \hspace{1cm} The type of the line that connects consecutive points. See \texttt{linetype} for details.
  \item \texttt{line.size} \hspace{1cm} An integer to specify the thickness (width) of the line that connects consecutive points.
  \item \texttt{sb.distance} \hspace{1cm} An integer to specify the length of the scale bar. If not specified, approximately a quarter of the plotting range will be used.
\end{itemize}
\end{verbatim}
sb.lwd: An integer to specify the thickness (width) of the scale bar.

sb.line.col: The colour of the scale bar.

sb.text.size: An integer to specify the text size for the scale bar.

sb.text.col: The colour of the text for the scale bar.

sb.space: Set the amount of space between the scale bar and the text. The value is scaled to the plot. The smaller value increases the space.

title: The main title for each plot. If not specified, the "id" will be used.

title.size: An integer to specify the size of the title.

axes.text.size: An integer to specify the size of the axes characters.

axes.lab.size: An integer to specify the size of the axes labels.

multiplot: Logical. If TRUE (default), multiple plots are displayed on the same page.

ncol: An integer to specify the number of columns in the multiple plot page.

nrow: An integer to specify the number of rows in the multiple plot page.

Value
An arrangelist is returned when *multiplot* is TRUE. Otherwise a list is returned.

kml_track, dupfilter, ddfilter, vmax, vmaxlp

Examples

```r
#### Load data sets
## Fastloc GPS data obtained from two green turtles
data(turtle)
data(turtle2)
turtles <- rbind(turtle, turtle2)

#### Filter temporal and/or spatial duplicates
turtle.dup <- dupfilter(turtles, step.time=5/60, step.dist=0.001)

#### ddfilter
V <- vmax(turtle.dup)
VLP <- vmaxlp(turtle.dup)
turtle.dd <- ddfilter(turtle.dup, vmax=V, vmaxlp=VLP)

#### Plot filtered data for each animal
## using the low-resolution world map
map_track(turtle.dd, point.size = 2, line.size = 0.5, axes.lab.size = 0, ncol=2, nrow=1)
```
percent_vol

```r
## Not run:
## using the high-resolution google satellite images
map_track(turtle.dd, bgmap = "satellite", google.key = "key", ncol=2)

## End(Not run)
```

### percent_vol

**UD percent volume**

**Description**

Function to calculate a percent volume on a utilisation distribution (UD)

**Usage**

```r
percent_vol(x, percent = 100)
```

**Arguments**

- `x`: A vector containing the probability density.
- `percent`: An integer specifying the percent volume of a UD to be considered.

**Details**

This function calculates a percent volume on a UD. The probability beyond the specified range will be assigned with a zero value.

**Value**

A vector containing the specified percent volume.

Takahiro Shimada

---

**SandyStrait**

**A map of Sandy Strait, Australia**

**Description**

This map layer outlines the coast around Sandy Strait, Australia.

**Usage**

```r
SandyStrait
```

**Format**

A data.frame
**tidalplane**  
*Tidal plane table for Sandy Strait, Australia*

**Description**
A semidiurnal tidal plane table containing the height of the mean tidal planes and the average time differences of tide at different locations within Sandy Strait.

**Usage**
tidalplane

**Format**
A data frame with 2 rows and 6 variables:
- **standard.port** identifier for a tidal observation station.
- **secondary.port** identifier for a station at which tide is only predicted using the tidal records observed at the related standard port.
- **lat** latitude in decimal degrees.
- **lon** longitude in decimal degrees.
- **timeDiff** time difference between standard port and its associated secondary port.
- **datumDiff** baseline difference in metres between the bathymetry model and tidal observations/predictions, if each data uses different datum (e.g. LAT and MSL).

**Source**
The State of Queensland (Department of Transport and Main Roads), Tidal planes.

---

**tidedata**  
*Tidal data for Sandy Strait, Australia*

**Description**
A dataset containing tidal observations recorded at Bundaberg, Australia

**Usage**
tidedata

**Format**
A data frame with 26351 rows and 3 variables:
- **tideDT** date & time in class POSIXct for each observed tidal height.
- **reading** observed tidal height in metres.
- **standard.port** identifier of the tidal station.
**track_param**

**Source**

The State of Queensland (Department of Transport and Main Roads), Tidal data.

---

**track_param**  
*Calculate parameters between locations*

---

**Description**

Calculate time, distance, speed, and inner angle between successive locations

**Usage**

```r
track_param(
  sdata,
  param = c("time", "distance", "speed", "angle", "mean speed", "mean angle"),
  days = 2
)
```

**Arguments**

- **sdata**: A data frame containing columns with the following headers: "id", "DateTime", "lat", "lon". The function calculates each movement parameter by the unique "id". "DateTime" is date & time in class POSIXct. "lat" and "lon" are the latitude and longitude of each location in decimal degrees.

- **param**: A string or vector specifying movement parameters to be calculated. Options are 'time', 'distance', 'speed', 'angle', 'mean speed' and 'mean angle'. See details.

- **days**: A numeric value specifying the number of days to calculate mean speeds and angles. This argument is only used when 'mean speed' and/or 'mean angle' are selected in param.

**Details**

This function calculates various parameters of tracks. time (h), distance (km), speed (km/h) and inner angle (degrees) are calculated from each pair of successive locations. mean speed (km/h) and angle (degrees) are calculated from locations over a specified number of days.

**Value**

The input data is returned with new columns containing the requested parameters. "pTime" and "sTime" are hours from a previous and to a subsequent fix respectively. "pDist" and "sDist" are straight distances in kilometres from a previous and to a subsequent fix respectively. "pSpeed" and "sSpeed" are linear speed (km/h) from a previous and to a subsequent fix respectively. "inAng" is the degree between the bearings of lines joining successive location points. "meanSpeed" and "meanAngle" are the mean speed and degree over a specified number of days.

Takahiro Shimada

### Examples

```r
#### Load turtle tracking data
data(turtle)

#### Filter temporal and/or spatial duplicates
turtle.dup <- dupfilter(turtle, step.time=5/60, step.dist=0.001)

#### ddfilter
turtle.dd <- ddfilter(turtle.dup, vmax=9.9, qi=4, ia=90, vmaxlp=2.0)

#### Mean speed over 2 days
mean.speed <- track_param(turtle.dd, param = c('speed', 'mean speed'), days=2)

#### Plot data
ggplot(data = mean.speed, aes(x=lon, y=lat)) +
  geom_path(colour = 'grey') +
  geom_point(aes(colour=meanSpeed))
```

---

### Description
A dataset containing Fastloc GPS locations of a green turtle tracked in Sandy Strait, Australia.

### Usage

```r
turtle
```

### Format
A data frame with 429 rows and 5 variables:

- **id**: identifier for each animal.
- **DateTime**: date & time in class POSIXct.
- **lat**: latitude in decimal degrees.
- **lon**: longitude in decimal degrees.
- **qi**: numerical quality index associated with each location fix where a greater number indicates a higher accuracy (e.g. number of GPS satellites used for estimation).
Source

---

**turtle2**

*Green turtle tracking data 2*

---

**Description**
A dataset containing Fastloc GPS locations of a green turtle tracked in Moreton Bay, Australia.

**Usage**
turtle2

**Format**
A data frame with 276 rows and 5 variables:
- **id** identifier for each animal.
- **DateTime** date & time in class *POSIXct*.
- **lat** latitude in decimal degrees.
- **lon** longitude in decimal degrees.
- **qi** numerical quality index associated with each location fix where a greater number indicates a higher accuracy (e.g. number of GPS satellites used for estimation).

Source

---

**vmax**

*Estimate maximum linear speed*

---

**Description**
Function to estimate the maximum linear speed between two consecutive locations.

**Usage**
vmax(sdata, qi = 5, prob = 0.99, ...)

vmaxlp

Arguments

sdata A data frame containing columns with the following headers: "id", "DateTime", "lat", "lon", "qi", "id" is the unique representing an individual. "DateTime" is date & time in class POSIXct. "lat" and "lon" are the latitude and longitude of each location in decimal degrees. "qi" is the numerical quality index associated with each location fix where a greater number indicates a higher accuracy (e.g. the number of GPS satellites involved in estimation).

qi An integer specifying the lowest quality index of a location that is qualified to be used in the estimation. Default is 5 (e.g. 5 GPS satellite or more).

prob A numeric value to specify a sample quantile. Default is 0.99.

... Extra arguments passed to dupfilter.

Details

The function first calculates the linear speed between each pair of two consecutive locations. It then discards extreme values, based on the specified quantile, to exclude potential outliers from the estimation process. The maximum value in the retained dataset (i.e. without outliers) represents the maximum linear speed at which an animal would travel between two consecutive locations.

Value

Maximum linear speed (vmax) estimated from the input data. The unit is km/h.

Author(s)

Takahiro Shimada

References

See Also
ddfilter, ddfilter_speed, track_param, dupfilter

Description

Function to estimate the maximum one-way linear speed of a loop trip as described in Shimada et al. (2012).

Usage

vmaxlp(sdata, qi = 4, prob = 0.99, ...)

Estimate maximum one-way linear speed of a loop trip
vmaxlp

Arguments

sdata   A data frame containing columns with the following headers: "id", "DateTime", "lat", "lon", "qi". "id" is the unique representing an individual. "DateTime" is date & time in class POSIXct. "lat" and "lon" are the recorded latitude and longitude in decimal degrees. "qi" is the numerical quality index associated with each location fix where a greater number indicates a higher accuracy (e.g. the number of GPS satellites involved in estimation).

qi      An integer specifying the minimum quality index associated with a location used for the estimation. Default is 4 (e.g. 4 GPS satellite or more).

prob    A numeric value to specify a sample quantile. Default is 0.99.

...     Extra arguments passed to dupfilter.

Details

The function first detects a "loop trip". Loop trip behaviour is represented by spatial departure and return involving more than 3 consecutive locations (Shimada et al 2012). The function calculates the net (i.e. straight-line) distance between the departure and turning point as well as the turning point and return location of a loop trip. It then calculates the one-way travelling speed to or from each turning point for each loop trip. The function discards extreme values, based on the specified quantile, to exclude potential outliers from the estimation process. The maximum value in the retained dataset (i.e. without outliers) represents the maximum one-way linear speed at which an animal would travel during a loop trip.

Value

Maximum one-way linear speed of a loop trip (vmaxlp) estimated from the input data. The unit km/h.

Note

The input data must not contain temporal or spatial duplicates. A minimum of 8 locations are required.
