Package ‘SparseBiplots’

October 12, 2022

Type Package

Title 'HJ-Biplot' using Different Ways of Penalization Plotting with 'ggplot2'

Version 4.0.1

Author Mitzi Isabel Cubilla-Montilla <mitzi@usal.es>, Carlos Alfredo Torres-Cubilla <carlos_t22@usal.es>, Purificacion Galindo Villardon <pgalindo@usal.es> and Ana Belen Nieto-Librero <ananieto@usal.es>

Maintainer Mitzi Isabel Cubilla-Montilla <mitzi@usal.es>

Description 'HJ-Biplot' is a multivariate method that allow represent multivariate data on a subspace of low dimension, in such a way that most of the variability of the information is captured in a few dimensions. This package implements three new techniques and constructs in each case the 'HJ-Biplot', adapting restrictions to reduce weights and / or produce zero weights in the dimensions, based on the regularization theories. It implements three methods of regularization: Ridge, LASSO and Elastic Net.

HJBiplot ................................................................. 3
Description

This function is a generalization of the Ridge regularization method and the LASSO penalty. Realizes the representation of the SPARSE HJ Biplot through a combination of LASSO and Ridge, on the data matrix. This means that with this function you can eliminate weak variables completely as with the LASSO regularization or contract them to zero as in Ridge.

Usage

ElasticNet_HJBiplot(X, Lambda = 1e-04, Alpha = 1e-04, Transform.Data = 'scale')

Arguments

X
array_like;
A data frame with the information to be analyzed

Lambda
float;
Tuning parameter of the LASSO penalty. Higher values lead to sparser components.

Alpha
float;
Tuning parameter of the Ridge shrinkage

Transform.Data character;
A value indicating whether the columns of X (variables) should be centered or scaled. Options are: "center" that removes the columns means and "scale" that removes the columns means and divide by its standard deviation. Default is "scale".

Details

Algorithm used to perform automatic selection of variables and continuous contraction simultaneously. With this method, the model obtained is simpler and more interpretable. It is a particularly useful method when the number of variables is much greater than the number of observations.

Value

ElasticNet_HJBiplot returns a list containing the following components:

loadings array_like;
penalized loadings, the loadings of the sparse principal components.
HJBiplot

n_ceros
array_like;
number of loadings equal to cero in each component.

coord_ind
array_like;
matrix with the coordinates of individuals.

coord_var
array_like;
matrix with the coordinates of variables.
eigenvalues
array_like;
vector with the eigenvalues penalized.
explvar
array_like;
an vector containing the proportion of variance explained by the first 1, 2,...k sparse principal components obtained.

HJBiplot

HJ Biplot

Description
This function performs the representation of HJ Biplot (Galindo, 1986).

Usage
HJBiplot (X, Transform.Data = 'scale')
Arguments

- **X**: array_like; A data frame which provides the data to be analyzed. All the variables must be numeric.

- **Transform.Data**: character; A value indicating whether the columns of X (variables) should be centered or scaled. Options are: "center" that removes the columns means and "scale" that removes the columns means and divide by its standard deviation. Default is "scale".

Details

Algorithm used to construct the HJ Biplot. The Biplot is obtained as result of the configuration of markers for individuals and markers for variables in a reference system defined by the factorial axes resulting from the Decomposition in Singular Values (DVS).

Value

HJBiplot returns a list containing the following components:

- **eigenvalues**: array_like; vector with the eigenvalues.
- **explvar**: array_like; a vector containing the proportion of variance explained by the first 1, 2,...k principal components obtained.
- **loadings**: array_like; the loadings of the principal components.
- **coord_ind**: array_like; matrix with the coordinates of individuals.
- **coord_var**: array_like; matrix with the coordinates of variables.

**LASSO_HJBiplot**

**Examples**

`HJBiplot(mtcars)`

---

**Description**

This function performs the representation of the SPARSE HJ Biplot applying the LASSO regularization, on the original data matrix, implementing the norm L1.

**Usage**

`LASSO_HJBiplot(X, Lambda, Transform.Data = 'scale', Operator = 'Hard-Thresholding')`

**Arguments**

- **X**: array_like; A data frame which provides the data to be analyzed. All the variables must be numeric.
- **Lambda**: float; Tuning parameter for the LASSO penalty.
- **Transform.Data**: character; A value indicating whether the columns of X (variables) should be centered or scaled. Options are: "center" that removes the columns means and "scale" that removes the columns means and divide by its standard deviation. Default is "scale".
- **Operator**: character; The operator used to solve the norm L1. Allowed values are "Soft-Thresholding" and "Hard-Thresholding".

**Details**

Algorithm that performs a procedure of contraction and selection of variables. LASSO imposes a penalty that causes the charges of some components to be reduced to zero. By producing zero loadings for some components and not zero for others, the Lasso technique performs selection of variables. As the value of the penalty approaches one, the loadings approach zero.

**Value**

`LASSO_HJBiplot` returns a list containing the following components:

- **loadings**: array_like; penalized loadings, the loadings of the sparse principal components.
- **n_ceros**: array_like; number of loadings equal to cero in each component.
coord_ind    array_like; matrix with the coordinates of individuals.
coord_var    array_like; matrix with the coordinates of variables.
eigenvalues array_like; vector with the eigenvalues penalized.
explvar      array_like; an vector containing the proportion of variance explained by the first 1, 2,...k sparse principal components obtained.

Examples
LASSO_HJBiplot(mtcars, Lambda = 0.2, Operator = 'Hard-Thresholding')

Plot_Biplot initializes a ggplot2-based visualization of the characteristics presented in the data analized by the Biplot selected.

Usage
Plot_Biplot(X, axis = c(1,2), hide = "none", labels = "auto", ind.shape = 19,
ind.color = "red", ind.size = 2,
ind.label = FALSE, ind.label.size = 4,
var.color = "black", var.size = 0.5,
var.label = TRUE, var.label.size = 4, var.label.angle = FALSE)
Plot_Biplot

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>List containing the output of one of the functions of the package.</td>
</tr>
<tr>
<td>axis</td>
<td>Vector with length 2 which contains the axis plotted in x and y axis.</td>
</tr>
<tr>
<td>hide</td>
<td>Vector specifying the elements to be hidden on the plot. Default value is “none”. Other allowed values are “ind” and “var”.</td>
</tr>
<tr>
<td>labels</td>
<td>It indicates the label for points. If it is &quot;auto&quot; the labels are the row names of the coordinates of individuals. If it isn’t auto it would be a vector containing the labels.</td>
</tr>
<tr>
<td>ind. shape</td>
<td>Points shape. It can be a number to indicate the shape of all the points or a factor to indicate different shapes.</td>
</tr>
<tr>
<td>ind. color</td>
<td>Points colors. It can be a character indicating the color of all the points or a factor to use different colors.</td>
</tr>
<tr>
<td>ind. size</td>
<td>Size of points.</td>
</tr>
<tr>
<td>ind. label</td>
<td>Logical value, if it is TRUE it prints the name for each row of X. If it is FALSE (default) does not print the names.</td>
</tr>
<tr>
<td>ind. label.size</td>
<td>Numeric value indicating the size of the labels of points.</td>
</tr>
<tr>
<td>var. color</td>
<td>Character indicating the color of the arrows.</td>
</tr>
<tr>
<td>var. size</td>
<td>Size of arrow.</td>
</tr>
<tr>
<td>var. label</td>
<td>Logical value, if it is TRUE (default) it prints the name for each column of X. If it is FALSE does not print the names.</td>
</tr>
<tr>
<td>var. label.size</td>
<td>Numeric value indicating the size of the labels of variables.</td>
</tr>
<tr>
<td>var. label.angle</td>
<td>Logical value, if it is TRUE (default) it print the vector names with orientation of the angle of the vector. If it is FALSE the angle of all tags is 0.</td>
</tr>
</tbody>
</table>

Value

Return a ggplot2 object.

Examples

hj.biplot <- HJBiplot(mtcars)
Plot_Biplot(hj.biplot, ind.label = TRUE)
Ridge_HJBiplot

Description

This function performs the representation of the HJ Biplot applying the Ridge regularization, on the
original data matrix, implementing the norm L2.

Usage

Ridge_HJBiplot (X, Lambda, Transform.Data = 'scale')

Arguments

X array_like;
A data frame which provides the data to be analyzed. All the variables must be numeric.

Lambda float;
Tuning parameter for the Ridge penalty

Transform.Data character;
A value indicating whether the columns of X (variables) should be centered or scaled. Options are: "center" that removes the columns means and "scale" that removes the columns means and divide by its standard deviation. Default is "scale".

Details

Algorithm used to contract the loads of the main components towards zero, but without achieving the nullity of any. If the penalty parameter is less than or equal to 1e-4 the result is like Galindo’s HJ Biplot (1986).

Value

Ridge_HJBiplot returns a list containing the following components:

eigenvalues array_like;
vector with the eigenvalues penalized.

explvar array_like;
an vector containing the proportion of variance explained by the first 1, 2,...k sparse principal components obtained.

loadings array_like;
penalized loadings, the loadings of the sparse principal components.

coord_ind array_like;
matrix with the coordinates of individuals.

coord_var array_like;
matrix with the coordinates of variables.
