Package ‘TDboost’

March 30, 2016

Title  A Boosted Tweedie Compound Poisson Model
Version  1.2
Date  2016-03-29
Author
   Yi Yang <yi.yang6@mcgill.ca>, Wei Qian <wxqsm@rit.edu>, Hui Zou <hzou@stat.umn.edu>
Maintainer  Yi Yang <yi.yang6@mcgill.ca>
Depends  R (>= 2.12.0), lattice
Description  A boosted Tweedie compound Poisson model using the gradient boosting. It is capable of fitting a flexible nonlinear Tweedie compound Poisson model (or a gamma model) and capturing interactions among predictors.

Index  15
Simulation data generated based from the FHT model used in Yang, Y., Qian, W. and Zou, H. (2013).

Description

There are two data sets, one for training and the other for testing. The training data set has \( n = 200 \) observations and \( p = 6 \) predictors. The testing data set has \( n = 20 \) observations and \( p = 6 \) predictors. See details in Friedman et al. (2010).

Usage

data(FHT)

Format

Two data frames both contain the following columns:

- \( X1-X6 \): predictor columns
- \( Y \): response variable

References

Examples

data(FHT)

Marginal plots of fitted TDboost objects

Description

Plots the marginal effect of the selected variables by "integrating" out the other variables.

Usage

```r
## S3 method for class 'TDboost'
plot(x,
i.var = 1,
n.trees = x$n.trees,
continuous.resolution = 100,
return.grid = FALSE,
...)
```
plot.TDboost

Arguments

- `x` a `TDboost.object` fitted using a call to `TDboost`
- `i.var` a vector of indices or the names of the variables to plot. If using indices, the variables are indexed in the same order that they appear in the initial `TDboost` formula. If `length(i.var)` is between 1 and 3 then `plot.TDboost` produces the plots. Otherwise, `plot.TDboost` returns only the grid of evaluation points and their average predictions
- `n.trees` the number of trees used to generate the plot. Only the first `n.trees` trees will be used
- `continuous.resolution` The number of equally space points at which to evaluate continuous predictors
- `return.grid` if `TRUE` then `plot.TDboost` produces no graphics and only returns the grid of evaluation points and their average predictions. This is useful for customizing the graphics for special variable types or for dimensions greater than 3
- `...` other arguments passed to the plot function

Details

`plot.TDboost` produces low dimensional projections of the `TDboost.object` by integrating out the variables not included in the `i.var` argument. The function selects a grid of points and uses the weighted tree traversal method described in Friedman (2001) to do the integration. Based on the variable types included in the projection, `plot.TDboost` selects an appropriate display choosing amongst line plots, contour plots, and `lattice` plots. If the default graphics are not sufficient the user may set `return.grid=TRUE`, store the result of the function, and develop another graphic display more appropriate to the particular example.

Value

Nothing unless `return.grid` is true then `plot.TDboost` produces no graphics and only returns the grid of evaluation points and their average predictions.

predict.TDboost

Predict method for TDboost Model Fits

Description

Predicted values based on an TDboost Tweedie regression model object

Usage

```r
## S3 method for class 'TDboost'
predict(object, newdata, n.trees, single.tree=FALSE, type=c("response","link"), ...)
```

Arguments

- `object` Object of class inheriting from `TDboost.object`
- `newdata` Data frame of observations for which to make predictions
- `n.trees` Number of trees used in the prediction. `n.trees` may be a vector in which case predictions are returned for each iteration specified
- `single.tree` If `single.tree=TRUE` then `predict.TDboost` returns only the predictions from tree(s) `n.trees`
- `type` type of prediction required.
  - Type "response" gives predicted response \( \mu(x) = E(Y|X=x) \) for the regression problems. It is the default.
  - Type "link" gives the linear predictors \( x^*b = \log(\mu(x)) = \log(E(Y|X=x)) \) for the regression problems.
- `...` further arguments passed to or from other methods

Details

`predict.TDboost` produces predicted values for each observation in `newdata` using the the first `n.trees` iterations of the boosting sequence. If `n.trees` is a vector than the result is a matrix with each column representing the predictions from TDboost models with `n.trees[1]` iterations, `n.trees[2]` iterations, and so on.

The predictions from TDboost do not include the offset term. The user may add the value of the offset to the predicted value if desired.

If `object` was fit using `TDboost.fit` there will be no Terms component. Therefore, the user has greater responsibility to make sure that `newdata` is of the same format (order and number of variables) as the one originally used to fit the model.
relative.influence

Value

Returns a vector of predictions. By default the predictions are on the scale of f(x).

Author(s)

Yi Yang <yi.yang6@mcgill.ca>, Wei Qian <wxqsma@rit.edu> and Hui Zou <hzou@stat.umn.edu>

See Also

TDboost, TDboost.object

Description

Helper functions for computing the relative influence of each variable in the TDboost object.

Usage

relative.influence(object, n.trees)
permutation.test.TDboost(object, n.trees)
TDboost.loss(y, f, w, offset, dist, baseline)

Arguments

object a TDboost object created from an initial call to TDboost.
n.trees the number of trees to use for computations.
y, f, w, offset, dist, baseline
For TDboost.loss: These components are the outcome, predicted value, observation weight, offset, distribution, and comparison loss function, respectively.

Details

This is not intended for end-user use. These functions offer the different methods for computing the relative influence in summary.TDboost. TDboost.loss is a helper function for permutation.test.TDboost.

Value

Returns an unprocessed vector of estimated relative influences.

Author(s)

Yi Yang <yi.yang6@mcgill.ca>, Wei Qian <wxqsma@rit.edu> and Hui Zou <hzou@stat.umn.edu>
References

`summary.TDboost`

summary.TDboost | Summary of a TDboost object

Description

Computes the relative influence of each variable in the TDboost object.

Usage

```r
## S3 method for class 'TDboost'
summary(object, 
  cBars=length(object$var.names),
  n.trees=object$n.trees,
  plotit=TRUE,
  order=TRUE,
  method=relative.influence,
  normalize=TRUE,
  ...)
```

Arguments

- **object**: a TDboost object created from an initial call to `TDboost`.
- **cBars**: the number of bars to plot. If `order=TRUE` the only the variables with the `cBars` largest relative influence will appear in the barplot. If `order=FALSE` then the first `cBars` variables will appear in the plot. In either case, the function will return the relative influence of all of the variables.
- **n.trees**: the number of trees used to generate the plot. Only the first `n.trees` trees will be used.
- **plotit**: an indicator as to whether the plot is generated.
- **order**: an indicator as to whether the plotted and/or returned relative influences are sorted.
method

The function used to compute the relative influence. `relative.influence` is the default and is the same as that described in Friedman (2001). The other current (and experimental) choice is `permutation.test.TDboost`. This method randomly permutes each predictor variable at a time and computes the associated reduction in predictive performance. This is similar to the variable importance measures Breiman uses for random forests, but TDboost currently computes using the entire training dataset (not the out-of-bag observations).

normalize

if FALSE then `summary.TDboost` returns the unnormalized influence.

... other arguments passed to the plot function.

Details

This returns the reduction attributable to each variable in sum of squared error in predicting the gradient on each iteration. It describes the relative influence of each variable in reducing the loss function. See the references below for exact details on the computation.

Value

Returns a data frame where the first component is the variable name and the second is the computed relative influence, normalized to sum to 100.

**TDboost**

*TDboost Tweedie Regression Modeling*

Description

Fits TDboost Tweedie Regression models.
Usage

TDboost(formula = formula(data),
    distribution = list(name="EDM",alpha=1.5),
    data = list(),
    weights,
    var.monotone = NULL,
    n.trees = 100,
    interaction.depth = 1,
    n.minobsinnode = 10,
    shrinkage = 0.001,
    bag.fraction = 0.5,
    train.fraction = 1.0,
    cv.folds=0,
    keep.data = TRUE,
    verbose = TRUE)

TDboost.fit(x,y,
    offset = NULL,
    misc = NULL,
    distribution = list(name="EDM",alpha=1.5),
    w = NULL,
    var.monotone = NULL,
    n.trees = 100,
    interaction.depth = 1,
    n.minobsinnode = 10,
    shrinkage = 0.001,
    bag.fraction = 0.5,
    train.fraction = 1.0,
    keep.data = TRUE,
    verbose = TRUE,
    var.names = NULL,
    response.name = NULL)

TDboost.more(object,
    n.new.trees = 100,
    data = NULL,
    weights = NULL,
    offset = NULL,
    verbose = NULL)

Arguments

formula a symbolic description of the model to be fit. The formula may include an offset term (e.g. y~offset(n)+x). If keep.data=FALSE in the initial call to TDboost then it is the user’s responsibility to resupply the offset to TDboost.more.

distribution a list with a component name specifying the distribution and any additional parameters needed. Tweedie regression is available and distribution must a list of the form list(name="EDM",alpha=1.5) where alpha is the index param-
eter that must be in (1,2]. When alpha=2, the distribution reduces to gamma. The current version’s Tweedie regression methods do not handle non-constant weights and will stop.

data
an optional data frame containing the variables in the model. By default the variables are taken from environment(formula), typically the environment from which TDboost is called. If keep.data=TRUE in the initial call to TDboost then TDboost stores a copy with the object. If keep.data=FALSE then subsequent calls to TDboost.more must resupply the same dataset. It becomes the user’s responsibility to resupply the same data at this point.

weights
an optional vector of weights to be used in the fitting process. Must be positive but do not need to be normalized. If keep.data=FALSE in the initial call to TDboost then it is the user’s responsibility to resupply the weights to TDboost.more.

var.monotone
an optional vector, the same length as the number of predictors, indicating which variables have a monotone increasing (+1), decreasing (-1), or arbitrary (0) relationship with the outcome.

n.trees
the total number of trees to fit. This is equivalent to the number of iterations and the number of basis functions in the additive expansion.

cv.folds
Number of cross-validation folds to perform. If cv.folds>1 then TDboost, in addition to the usual fit, will perform a cross-validation, calculate an estimate of generalization error returned in cv.error.

interaction.depth
The maximum depth of variable interactions. 1 implies an additive model, 2 implies a model with up to 2-way interactions, etc.

n.minobsinnode
minimum number of observations in the trees terminal nodes. Note that this is the actual number of observations not the total weight.

shrinkage
a shrinkage parameter applied to each tree in the expansion. Also known as the learning rate or step-size reduction.

bag.fraction
the fraction of the training set observations randomly selected to propose the next tree in the expansion. This introduces randomnesses into the model fit. If bag.fraction<1 then running the same model twice will result in similar but different fits. TDboost uses the R random number generator so set.seed can ensure that the model can be reconstructed. Preferably, the user can save the returned TDboost.object using save.

train.fraction
The first train.fraction * nrows(data) observations are used to fit the TDboost and the remainder are used for computing out-of-sample estimates of the loss function.

keep.data
a logical variable indicating whether to keep the data and an index of the data stored with the object. Keeping the data and index makes subsequent calls to TDboost.more faster at the cost of storing an extra copy of the dataset.

object
a TDboost object created from an initial call to TDboost.

n.new.trees
the number of additional trees to add to object.

verbose
If TRUE, TDboost will print out progress and performance indicators. If this option is left unspecified for TDboost.more then it uses verbose from object.
TDboost

x, y
For TDboost.fit: x is a data frame or data matrix containing the predictor variables and y is the vector of outcomes. The number of rows in x must be the same as the length of y.

offset
a vector of values for the offset

misc
For TDboost.fit: misc is an R object that is simply passed on to the TDboost engine.

w
For TDboost.fit: w is a vector of weights of the same length as the y.

var.names
For TDboost.fit: A vector of strings of length equal to the number of columns of x containing the names of the predictor variables.

response.name
For TDboost.fit: A character string label for the response variable.

Details
This package implements a regression tree based gradient boosting estimator for nonparametric multiple Tweedie regression. The code is a modified version of gbm library originally written by Greg Ridgeway.

Boosting is the process of iteratively adding basis functions in a greedy fashion so that each additional basis function further reduces the selected loss function. This implementation closely follows Friedman’s Gradient Boosting Machine (Friedman, 2001).

In addition to many of the features documented in the Gradient Boosting Machine, TDboost offers additional features including the out-of-bag estimator for the optimal number of iterations, the ability to store and manipulate the resulting TDboost object.

TDboost.fit provides the link between R and the C++ TDboost engine. TDboost is a front-end to TDboost.fit that uses the familiar R modeling formulas. However, model.frame is very slow if there are many predictor variables. For power-users with many variables use TDboost.fit. For general practice TDboost is preferable.

Value
TDboost, TDboost.fit, and TDboost.more return a TDboost.object.

TDboost.object  TDboost Tweedie Regression Model Object

Description

These are objects representing fitted TDboosts.

Value

- `initF` the "intercept" term, the initial predicted value to which trees make adjustments
- `fit` a vector containing the fitted values on the scale of regression function
- `train.error` a vector of length equal to the number of fitted trees containing the value of the loss function for each boosting iteration evaluated on the training data
- `valid.error` a vector of length equal to the number of fitted trees containing the value of the loss function for each boosting iteration evaluated on the validation data
- `cv.error` if `cv.folds<2` this component is NULL. Otherwise, this component is a vector of length equal to the number of fitted trees containing a cross-validated estimate of the loss function for each boosting iteration
- `oobag.improve` a vector of length equal to the number of fitted trees containing an out-of-bag estimate of the marginal reduction in the expected value of the loss function. The out-of-bag estimate uses only the training data and is useful for estimating the optimal number of boosting iterations. See `TDboost.perf`
- `trees` a list containing the tree structures.
- `c.splits` a list of all the categorical splits in the collection of trees. If the `trees[[i]]` component of a TDboost object describes a categorical split then the splitting value will refer to a component of `c.splits`. That component of `c.splits` will be a vector of length equal to the number of levels in the categorical split variable. -1 indicates left, +1 indicates right, and 0 indicates that the level was not present in the training data

Structure

The following components must be included in a legitimate TDboost object.

TDboost

---

**TDboost.perf**

**TDboost performance**

**Description**

Estimates the optimal number of boosting iterations for a TDboost object and optionally plots various performance measures.

**Usage**

```
TDboost.perf(object,
 plot.it = TRUE,
 oobag.curve = FALSE,
 overlay = TRUE,
 method)
```

**Arguments**

- `object`: a TDboost.object created from an initial call to TDboost.
- `plot.it`: an indicator of whether or not to plot the performance measures. Setting plot.it=TRUE creates two plots. The first plot plots object$train.error (in black) and object$valid.error (in red) versus the iteration number. The scale of the error measurement, shown on the left vertical axis, depends on the distribution argument used in the initial call to TDboost.
- `oobag.curve`: indicates whether to plot the out-of-bag performance measures in a second plot.
- `overlay`: if TRUE and oobag.curve=TRUE then a right y-axis is added to the training and test error plot and the estimated cumulative improvement in the loss function is plotted versus the iteration number.
- `method`: indicate the method used to estimate the optimal number of boosting iterations. method="OOB" computes the out-of-bag estimate and method="test" uses the test (or validation) dataset to compute an out-of-sample estimate. method="cv" extracts the optimal number of iterations using cross-validation if TDboost was called with cv.folds>1

**Value**

TDboost.perf returns the estimated optimal number of iterations. The method of computation depends on the method argument.
