1 Introduction

This vignette documents the beta-binomial distribution, which is included in the TailRank package

> library(TailRank)

Mathematically, the beta-binomial distribution has parameters $N$, $u$, and $v$ that determine the density function

$$\binom{N}{x} \frac{\text{Beta}(x + u, N - x + v)}{\text{Beta}(u, v)}.$$

Statistically, one can think of this distribution as a hierarchical model, starting with a binomial distribution $\text{Binom}(x, N, \theta)$ whose success parameter $\theta$ comes from a beta distribution, $\theta \sim \text{Beta}(x, u, v)$. This distribution has a larger variance than the binomial distribution with a fixed (known) parameter $\theta$.

We provide the usual set of functions to implement a distribution:

- $\text{dbb}$ is the distribution function.
- $\text{pbb}$ is the cumulative distribution function.
- $\text{qbb}$ is the quantile function.
- $\text{rbb}$ is the random-sample function.

We start by comparing the distributions of a binomial distribution and a beta-binomial distribution.

> N <- 20
> u <- 3
> v <- 10
> p <- u/(u+v)
> x <- 0:N
> y <- dbinom(x, N, p)
> yy <- dbb(x, N, u, v)
>
> barplot(t(matrix(c(y, yy), ncol=2)), beside=TRUE, col=c("blue", "red"))
> legend("topright", c("Binomial", "Beta-Binomial"), col=c("blue", "red"), pch=15)

Now we sample data from each of these distributions.

> set.seed(561662)
> r <- rbinom(1000, N, p)
> rr <- rbb(1000, N, u, v)
> mean(r)

[1] 4.599

> mean(rr)

[1] 4.482

> var(r)

[1] 3.345545
> var(rr)
[1] 7.741417
> sd(r)
[1] 1.829083
> sd(rr)
[1] 2.78234
