Package ‘WebPower’

October 13, 2023

Title Basic and Advanced Statistical Power Analysis
Version 0.9.4
Date 2023-10-13
Author Zhiyong Zhang [aut, cre],
       Yujiao Mai [aut],
       Miao Yang [ctb],
       Ziqian Xu [ctb],
       Conor McNamara [ctb]
Maintainer Zhiyong Zhang <johnnyzhz@gmail.com>
Depends R (>= 3.2.5), MASS, grDevices, graphics, lme4, lavaan,
       parallel, PearsonDS
Imports dplyr, stats
License GPL (>= 3)
Description This is a collection of tools for conducting both basic and advanced statistical power analysis including correlation, proportion, t-test, one-way ANOVA, two-way ANOVA, linear regression, logistic regression, Poisson regression, mediation analysis, longitudinal data analysis, structural equation modeling and multilevel modeling. It also serves as the engine for conducting power analysis online at <https://webpower.psychstat.org>.

**WebPower-package**

**Basic and Advanced Statistical Power Analysis**

**Description**

This is a collection of tools for conducting both basic and advanced statistical power analysis including correlation, proportion, t-test, one-way ANOVA, two-way ANOVA, linear regression, logistic regression, Poisson regression, mediation analysis, longitudinal data analysis, structural equation modeling and multilevel modeling. It also serves as the engineer for conducting power analysis online at https://webpower.psychstat.org.

**Details**

This is a collection of tools for conducting both basic and advanced statistical power analysis including correlation, proportion, t-test, one-way ANOVA, two-way ANOVA, linear regression, logistic regression, Poisson regression, mediation analysis, longitudinal data analysis, structural equation modeling and multilevel modeling. It also serves as the engineer for conducting power analysis online at https://webpower.psychstat.org.

**References**

---

**CRT2**

**Example Data For CRT With 2 Arms**

**Description**

- ID. The identification number of the subjects.
- cluster. The cluster number.
- score. The score of the subject.
- group. The group number.

**Usage**

CRT2

**Format**

An object of class `data.frame` with 8 rows and 4 columns.
Examples

# ID cluster score group
# 1 1 6 0
# 2 1 2 0
# 3 2 6 1
# 4 2 5 1
# 5 3 1 0
# 6 3 4 0
# 7 4 6 1
# 8 4 4 1

Example Data For CRT With 3 Arms

Description

- ID. The identification number of the subjects.
- cluster. The cluster number.
- score. The score of the subject.
- group. The group number.

Usage

CRT3

Format

An object of class data.frame with 30 rows and 4 columns.

Examples

# id cluster score group
# 1 1 1.93 0
# 2 1 1.51 0
# 3 1 2.13 0
# 4 1 2.96 0
# 5 1 3.84 0
# 6 2 3.36 1
# 7 2 3.13 1
# 8 2 1.71 1
# 9 2 3.1 1
# 10 2 2.53 1
# 11 3 2.01 2
# 12 3 4.73 2
# 13 3 3.34 2
# 14 3 0.11 2
# 15 3 3.6 2
# 16 4 2 0
estCRT2arm

Estimate multilevel effect size from data

Description

Estimate multilevel effect size from data

Usage

estCRT2arm(file)
estCRT3arm(file)
estMRT2arm(file)
estMRT3arm(file)

Arguments

file a data file

MRT2

Example Data For MRT With 2 Arms

Description

- ID. The identification number of the subjects.
- cluster. The cluster number.
- score. The score of the subject.
- group. The group number.

Usage

MRT2
Format

An object of class `data.frame` with 16 rows and 4 columns.

Examples

```r
# Example data for MRT with 3 arms
ID cluster score group
1 1 6 0
2 1 2 0
3 1 3 1
4 1 3 1
5 2 6 0
6 2 10 0
7 2 7 1
8 2 6 1
9 3 6 0
10 3 5 0
11 3 4 1
12 3 4 1
13 4 1 0
14 4 8 0
15 4 10 1
16 4 -2 1
```

Description

- ID. The identification number of the subjects.
- cluster. The cluster number.
- score. The score of the subject.
- group. The group number.

Usage

MRT3

Format

An object of class `data.frame` with 24 rows and 4 columns.
nuniroot

Examples

```
# id cluster score group
#  1  1   2  0
#  2  1   3  0
#  3  1   2  1
#  4  1   0  1
#  5  1   3  2
#  6  1   2  2
#  7  2   1  0
#  8  2   4  0
#  9  2   2  1
# 10 2   3  1
# 11 2   3  2
# 12 2   1  2
# 13 3   1  0
# 14 3   4  0
# 15 3   1  1
# 16 3   1  1
# 17 3   2  2
# 18 3   0  2
# 19 4   4  0
# 20 4   3  0
# 21 4   1  1
# 22 4   3  1
# 23 4   3  2
# 24 4   3  2
```

nuniroot

**Solve A Single Equation**

Description

The function searches in an interval for a root (i.e., zero) of the function f with respect to its first argument. The argument interval is for the input of x, the corresponding outcome interval will be used as the interval to be searched in.

Usage

```
nuniroot(f, interval, maxlength = 100)
```

Arguments

- **f**
  - Function for which the root is sought.
- **interval**
  - A vector containing the end-points of the interval to be searched for the root.
- **maxlength**
  - The number of value points in the interval to be searched. It is 100 by default.
Value

A list with at least four components: root and f.root give the location of the root and the value of the function evaluated at that point. iter and estim.prec give the number of iterations used and an approximate estimated precision for root. (If the root occurs at one of the endpoints, the estimated precision is NA.)

Examples

```r
f <- function(x) 1+x-0.5*x^2
interval <- c(-3,6)
uniroot(f, interval)
```

---

**plot.lcs.power**

Plot the power curve for Latent Change Score Models

Description

This function is used to plot the power analysis results for Latent Change Score Models.

Usage

```r
## S3 method for class 'lcs.power'
plot(x, parameter, ...)
```

Arguments

- `x`: Data to plot.
- `parameter`: Parameters for features of the plot.
- `...`: Extra arguments. It is not required.

References

**plot.webpower**

To plot Statistical Power Curve

### Description

This function is used to plot the power curves generated by `webpower`.

### Usage

```r
## S3 method for class 'webpower'
plot(x, xvar = NULL, yvar = NULL, xlab = NULL, ylab = NULL, ...)
```

### Arguments

- `x`: Objects of power analysis.
- `xvar`: The variable name used as the x (horizontal) axis. It is not required.
- `yvar`: The variable name used as the y (vertical) axis. It is not required.
- `xlab`: The label for the x axis. It is not required.
- `ylab`: The label for the y axis. It is not required.
- `...`: Extra arguments. It is not required.

### Value

The plot.

### Examples

```r
res <- wp.correlation(n=seq(50,100,10),r=0.3, alternative="two.sided")
plot(res)
```

**print.webpower**

To Print Statistical Power Analysis Results

### Description

This function is used to summary the power analysis results.

### Usage

```r
## S3 method for class 'webpower'
print(x, ...)
```

### Examples

```r
res <- wp.correlation(n=seq(50,100,10),r=0.3, alternative="two.sided")
print(res)
```
Arguments

x Object of power analysis. It is an object returned by a webpower function such as `wp.anova()`.

... Extra arguments. It is not required.

Value

The printing of the input object of power analysis.

Examples

```r
res <- wp.correlation(n=50, r=0.3, alternative="two.sided")
print(res)
```

---

**sem.effect.size**  
*Calculate the Effect Size for SEM*

Description

This function is for calculating SEM effect size.

Usage

```r
sem.effect.size(full.model.pop, reduced.model)
```

Arguments

full.model.pop Full model (under the alternative hypothesis) with population parameters.

reduced.model Reduced model (under the null hypothesis) lavaan specification.

Value

An object of the power analysis.

delta Effect size.

df Degrees of freedom

RMSEA RMSEA

References

Examples

```r
full.model.pop <-
  y1 ~ 0.4*x
  y2 ~ 0.5*x + 0.2*y1
  y3 ~ 0.4*x
  y4 ~ 0.4*y1 + 0.4*y2 + 0.4*y3
  y1 ~~ 0.84*y1
  y2 ~~ 0.61*y2
  y3 ~~ 0.84*y3
  y4 ~~ 0.27*y4
```

```r
reduced.model <-
  y1 ~ x
  y2 ~ x
  y3 ~ x
  y4 ~ y1 + y3
```

```r
sem.effect.size(full.model.pop, reduced.model)
```

---

Summary Statistical Power Analysis Results

Description

This function is used to summary the power analysis results.

Usage

```r
## S3 method for class 'power'
summary(object, ...)
```

Arguments

- `object` Object of power analysis. It is an object returned by a webpower function for SEM based on Monte Carlo methods with class = 'power'.
- `...` Extra arguments. It is not required.

Value

The summary of the input object of power analysis.
### Description

One-way analysis of variance (one-way ANOVA) is a technique used to compare means of two or more groups (e.g., Maxwell & Delaney, 2003). The ANOVA tests the null hypothesis that samples in two or more groups are drawn from populations with the same mean values. The ANOVA analysis typically produces an F-statistic, the ratio of the between-group variance to the within-group variance.

### Usage

```r
wp.anova(k = NULL, n = NULL, f = NULL, alpha = 0.05, power = NULL, type = c("overall", "two.sided", "greater", "less"))
```

### Arguments

- **k**: Number of groups.
- **n**: Sample size.
- **f**: Effect size. We use the statistic $f$ as the measure of effect size for one-way ANOVA as in Cohen (1988). Cohen defined the size of effect as: small $0.1$, medium $0.25$, and large $0.4$.
- **alpha**: Significance level chosen for the test. It equals 0.05 by default.
- **power**: Statistical power.
- **type**: Type of test ("overall" or "two.sided" or "greater" or "less"). The default is "two.sided". The option "overall" is for the overall test of anova; "two.sided" is for a contrast anova; "greater" is testing the between-group variance greater than the within-group, while "less" is vice versa.

### Value

An object of the power analysis.

### References

Examples

**wp.anova.binary**  
**Statistical Power Analysis for One-way ANOVA with Binary Data**

**Description**

The power analysis procedure for one-way ANOVA with binary data is introduced by Mai and Zhang (2017). One-way ANOVA with binary data is used for comparing means of three or more groups of binary data. Its outcome variable is supposed to follow Bernoulli distribution. And its overall test uses a likelihood ratio test statistics.

**Usage**

```r
wp.anova.binary(k = NULL, n = NULL, V = NULL, alpha = 0.05, power = NULL)
```

**Arguments**

- **k**: Number of groups.
wp.anova.binary

n: Sample size.
V: Effect size. See the research by Mai and Zhang (2017) for details.
alpha: Significance level chose for the test. It equals 0.05 by default.
power: Statistical power.

Value
An object of the power analysis.

References

**wp.anova.count**

*Statistical Power Analysis for One-way ANOVA with Count Data*

**Description**

The power analysis procedure for one-way ANOVA with count data is introduced by *Mai and Zhang* (2017). One-way ANOVA with count data is used for comparing means of three or more groups of binary data. Its outcome variable is supposed to follow Poisson distribution. And its overall test uses a likelihood ratio test statistics.
Usage

```r
wp.anova.count(k = NULL, n = NULL, V = NULL, alpha = 0.05,
               power = NULL)
```

Arguments

- `k`: Number of groups.
- `n`: Sample size.
- `V`: Effect size. See the research by *Mai and Zhang (2017)* for details.
- `alpha`: Significance level chosen for the test. It equals 0.05 by default.
- `power`: Statistical power.

Value

An object of the power analysis.

References

Examples

```r
#To calculate the statistical power for one-way ANOVA (overall test) with count data:

Description

A longitudinal design often involves data collection on multiple variables from multiple participants at multiple times. Growth curve models (GCM) are structural equation models for longitudinal data analysis (McArdle & Epstein, 1987; McArdle & Nesselroade, 2014). Latent change score models (LCSM) combine difference equations with growth curves to investigate change in longitudinal studies. LCSM provided an efficient way to model nonlinear trajectory (e.g., McArdle, 2000; McArdle & Hamagami, 2001; Hamagami et al., 2010). This function is used to conduct power analysis for bivariate LCSMs based on a Monte Carlo method (a method also used by Muthén & Muthén, 2002; Thoemmes et al., 2010; Zhang & Wang, 2009; Zhang, 2014). For each Monte Carlo replication, the Maximum likelihood ratio test is used for the model, while the Wald test is used for the parameter test. The method can obtain the power for testing each individual parameter of the models such as the change rate and coupling parameters.

Usage

\[
\text{wp.blcsm}(N = 100, T = 5, R = 1000, \text{betay} = 0, \text{my0} = 0, \text{mys} = 0, \\
\text{varey} = 1, \text{vary0} = 1, \text{varys} = 1, \text{vary0ys} = 0, \alpha = 0.05, \\
\text{betax} = 0, \text{mx0} = 0, \text{mxs} = 0, \text{varex} = 1, \text{varx0} = 1, \text{varxs} = 1, \\
\text{varx0xs} = 0, \text{varx0y0} = 0, \text{varx0ys} = 0, \text{vary0xs} = 0, \text{varxsys} = 0, \\
\text{gammx} = 0, \text{gammay} = 0, \ldots)
\]

Arguments

- **N**: Sample size. It is 100 by default.
- **T**: Number of measurement occasions. It is 5 by default.
- **R**: Number of replications for the Monte Carlo simulation. It is 1000 by default.
- **betay**: Parameter in the model: The compound rate of change for variable y. Its default value is 0.
- **my0**: Parameter in the model: Mean of the initial latent score for variable y. Its default value is 0.
- **mys**: Parameter in the model: Mean of the linear constant effect for variable y. Its default value is 0.
- **varey**: Parameter in the model: Variance of the measurement error/uniqueness score for variable y. Its default value is 1.
- **vary0**: Parameter in the model: Variance of the initial latent score for variable y. Its default value is 1.
- **varys**: Parameter in the model: Variance of the linear constant effect for variable y. Its default value is 0.
- **vary0ys**: Parameter in the model: Covariance of the initial latent score and the linear constant effect for variable y. Its default value is 0.
alpha  significance level chosen for the test. It equals 0.05 by default.
betax  Parameter in the model: The compound rate of change for variable x. Its default value is 0.
mx0   Parameter in the model: Mean of the initial latent score for variable x. Its default value is 0.
mxs   Parameter in the model: Mean of the linear constant effect for variable x. Its default value is 0.
varex Parameter in the model: Variance of the measurement error/uniqueness score for variable x. Its default value is 1.
varx0 Parameter in the model: Variance of the initial latent score for variable x. Its default value is 1.
varxs Parameter in the model: Variance of the linear constant effect for variable x. Its default value is 0.
varx0xs Parameter in the model: Covariance of the initial latent score and the linear constant effect for variable x. Its default value is 0.
varx0y0 Parameter in the model: Covariance of the initial latent scores for y and x. Its default value is 0.
varx0ys Parameter in the model: Covariance of the initial latent score for x and the linear constant effect for y. Its default value is 0.
vary0xs Parameter in the model: Covariance of the initial latent score for y and the linear constant effect for x. Its default value is 0.
vary0ys Parameter in the model: Covariance of the linear constant effects for y and x. Its default value is 0.
gammax Coupling parameter in the model: The effect of variable x on the change score of variable y. Its default value is 0.
gammay Coupling parameter in the model: The effect of variable y on the change score of variable x. Its default value is 0.

Extra arguments. It is not required.

Value

An object of the power analysis. The output of the R function includes 4 main pieces of information for each parameter in the model. The first is the Monte Carlo estimate (mc.est). It is calculated as the mean of the R sets of parameter estimates from the simulated data. Note that the Monte Carlo estimates should be close to the population parameter values used in the model. The second is the Monte Carlo standard deviation (mc.sd), which is calculated as the standard deviation of the R sets of parameter estimates. The third is the Monte Carlo standard error (mc.se), which is obtained as the average of the R sets of standard error estimates of the parameter estimates. Lastly, mc.power is the statistical power for each parameter.

wp.correlation

Statistical Power Analysis for Correlation

Description

This function is for power analysis for correlation. Correlation measures whether and how a pair
of variables are related. The Pearson Product Moment correlation coefficient (r) is adopted here.
The power calculation for correlation is conducted based on Fisher's z transformation of Pearson
correlation coefficient (Fisher, 1915, 1921).

Usage

wp.correlation(n = NULL, r = NULL, power = NULL, p = 0, rho0 = 0,
alpha = 0.05, alternative = c("two.sided", "less", "greater"))

Arguments

n
Sample size.

r
Effect size or correlation. According to Cohen (1988), a correlation coefficient
of 0.10, 0.30, and 0.50 are considered as an effect size of "small", "medium",
and "large", respectively.

power
Statistical power.

p
Number of variables to partial out.

rho0
Null correlation coefficient.

alpha
Significance level chose for the test. It equals 0.05 by default.

alternative
Direction of the alternative hypothesis ("two.sided" or "less" or "greater").
The default is "two.sided".

Value

An object of the power analysis.
References

Examples

```r

# To estimate the minimum detectable effect size with a given power:
wp.correlation(n=NULL, r=0.3, power=0.8, alternative="two.sided")
# Power for correlation
```
wp.crt2arm

Statistical Power Analysis for Cluster Randomized Trials with 2 Arms

Description

Cluster randomized trials (CRT) are a type of multilevel design for the situation when the entire cluster is randomly assigned to either a treatment arm or a control arm (Liu, 2013). The data from CRT can be analyzed in a two-level hierarchical linear model, where the indicator variable for treatment assignment is included in second level. If a study contains multiple treatments, then multiple indicators will be used. This function is for designs with 2 arms (i.e., a treatment and a control). Details leading to power calculation can be found in Raudenbush (1997) and Liu (2013).

Usage

```r
wp.crt2arm(n = NULL, f = NULL, J = NULL, icc = NULL, power = NULL, alpha = 0.05, alternative = c("two.sided", "one.sided"), interval = NULL)
```
Arguments

n  Sample size. It is the number of individuals within each cluster.
f  Effect size. It specifies either the main effect of treatment, or the mean difference between the treatment clusters and the control clusters.
J  Number of clusters / sides. It tells how many clusters are considered in the study design. At least two clusters are required.
icc  Intra-class correlation. ICC is calculated as the ratio of between-cluster variance to the total variance. It quantifies the degree to which two randomly drawn observations within a cluster are correlated.
power  Statistical power.
alpha  significance level chose for the test. It equals 0.05 by default.
alternative  Type of the alternative hypothesis ("two.sided" or "one.sided"). The default is "two.sided". The option "one.sided" can be either "less" or "greater".
interval  A vector containing the end-points of the interval to be searched for the root.

Value
An object of the power analysis.

wp.crt3arm

Statistical Power Analysis for Cluster Randomized Trials with 3 Arms

### Description

Cluster randomized trials (CRT) are a type of multilevel design for the situation when the entire cluster is randomly assigned to either a treatment arm or a control arm (Liu, 2013). The data from CRT can be analyzed in a two-level hierarchical linear model, where the indicator variable for treatment assignment is included in second level. If a study contains multiple treatments, then multiple indicators will be used. This function is for designs with 3 arms (i.e., two treatments and a control). Details leading to power calculation can be found in Raudenbush (1997) and Liu (2013).

### Usage

```r
wp.crt3arm(n = NULL, f = NULL, J = NULL, icc = NULL, power = NULL,
    alpha = 0.05, alternative = c("two.sided", "one.sided"),
    type = c("main", "treatment", "omnibus"), interval = NULL)
```

### Arguments

- **n**: Sample size. It is the number of individuals within each cluster.
Effect size. It specifies one of the three types of effects: the main effect of treatment, the mean difference between the treatment clusters, and the control clusters.

Number of clusters/sides. It tells how many clusters are considered in the study design. At least two clusters are required.

Intra-class correlation. ICC is calculated as the ratio of between-cluster variance to the total variance. It quantifies the degree to which two randomly drawn observations within a cluster are correlated.

Statistical power.

significance level chosen for the test. It equals 0.05 by default.

Type of the alternative hypothesis ("two.sided" or "one.sided"). The default is "two.sided". The option "one.sided" can be either "less" or "greater".

Type of effect ("main" or "treatment" or "omnibus") with "main" as default. The type "main" tests the difference between the average treatment arms and the control arm; Type "treatment" tests the difference between the two treatment arms; and Type "omnibus" tests whether the tree arms are all equivalent.

A vector containing the end-points of the interval to be searched for the root.

An object of the power analysis.

# To calculate the statistical power given sample size and effect size:
wp.crt3arm(f = 0.5, n = 20, J = 10, icc = 0.1, alpha = 0.05, power = NULL)

Effect size calculation based on raw data for Cluster Randomized Trials with 2 Arms

Description

This function is for effect size and ICC calculation for CRT with 2 arms based on empirical data. Cluster randomized trials (CRT) are a type of multilevel design for the situation when the entire cluster is randomly assigned to either a treatment arm or a control arm (Liu, 2013). The data from CRT can be analyzed in a two-level hierarchical linear model, where the indicator variable for treatment assignment is included in second level. If a study contains multiple treatments, then multiple indicators will be used. This function is for designs with 3 arms (i.e., two treatments and a control). Details leading to power calculation can be found in Raudenbush (1997) and Liu (2013). The Effect size f specifies the main effect of treatment, the mean difference between the treatment clusters and the control clusters. This function is used to calculate the effect size with a input data set.

Usage

wp.effect.CRT2arm(file)
Arguments

file The input data set. The first column of the data is the ID variable, the second column represents cluster, the third column is the outcome variable, and the fourth column is the condition variable (0 for control, 1 for condition).

Value

A list including effect size f and ICC.

Effect size calculator based on raw data for Multisite Randomized Trials with 2 Arms

Description

This function is for effect size calculation for Multisite randomized trials (MRT) with 2 arms based on empirical data. MRTs are a type of multilevel design for the situation when the entire cluster is randomly assigned to either a treatment arm or a control arm (Liu, 2013). The data from MRT can be analyzed in a two-level hierarchical linear model, where the indicator variable for treatment assignment is included in first level. If a study contains multiple treatments, then multiple indicators will be used. Three types of tests are considered in the function: (1) The "main" type tests treatment main effect; (2) The "site" type tests the variance of cluster/site means; and (3) The "variance" type tests variance of treatment effects. Details leading to power calculation can be found in Raudenbush (1997) and Liu (2013). This function is used to calculate the effect size with an input data set.

Usage

wp.effect.MRT2arm(file)

Arguments

file The input data set. The first column of the data is the ID variable, the second column represents cluster, the third column is the outcome variable, and the fourth column is the condition variable (0 for control, 1 for condition).

Value

A list including effect size f.

MRTs are a type of multilevel design for the situation when the entire cluster is randomly assigned to either a treatment arm or a control arm (Liu, 2013). The data from MRT can be analyzed in a two-level hierarchical linear model, where the indicator variable for treatment assignment is included in first level. If a study contains multiple treatments, then multiple indicators will be used. This function is for designs with 3 arms (i.e., two treatments and a control). Three types of tests are considered in the function: (1) The "main" type tests treatment main effect; (2) The "treatment" type tests the difference between the two treatments; and (3) The "omnibus" type tests whether the three arms are all equivalent. Details leading to power calculation can be found in Raudenbush (1997) and Liu (2013). This function is used to calculate the effect size with a input data set.

**Usage**

```r
wp.effect.MRT3arm(file)
```

**Arguments**

- `file` The input data set. The first column of the data is the ID variable, the second column represents cluster, the third column is the outcome variable, and the fourth column is the condition variable (0 for control, 1 for treatment1, 2 for treatment2).

**Value**

A list including effect size f.

**References**

**Examples**

```r
# To calculate the effect size and ICC based on empirical data
# wp.effect.MRT3arm(MRT3)
# Effect size for MRT3arm
#
# f1 f2
# -0.6214215 -0.355098
```
# NOTE: f1 for treatment main effect;
f2 for comparing the two treatments.

**wp.kanova**

*Power analysis for two-way, three-way and k-way ANOVA*

### Description

Power analysis for two-way, three-way and k-way ANOVA

### Usage

```r
wp.kanova(n = NULL, ndf = NULL, f = NULL, ng = NULL, alpha = 0.05, power = NULL)
```

### Arguments

- `n` : Sample size
- `ndf` : Numerator degrees of freedom
- `f` : Effect size
- `ng` : Number of groups
- `alpha` : Significance level
- `power` : Statistical power

### References

### Examples

```
Description

A longitudinal design often involves data collection on multiple variables from multiple participants at multiple times. Growth curve models (GCM) are structural equation models for longitudinal data analysis (McArdle & Epstein, 1987; McArdle & Nesselroade, 2014). Latent change score models (LCSM) combine difference equations with growth curves to investigate change in longitudinal studies. LCSM provided an efficient way to model nonlinear trajectory (e.g., McArdle, 2000; McArdle & Hamagami, 2001; Hamagami et al., 2010). This function is used to conduct power analysis for univariate LCSMs based on a Monte Carlo method (a method also used by Muthén & Muthén, 2002; Thoemmes et al., 2010; Zhang & Wang, 2009; Zhang, 2014). For each Monte Carlo replication, the Maximum likelihood ratio test is used for the model, while the Wald test is used for the parameter test. The method can obtain the power for testing each individual parameter of the models such as the change rate and coupling parameters.

Usage

\[
\text{wp.lcsm}(N = 100, T = 5, R = 1000, \text{betay} = 0, \text{my0} = 0, \text{mys} = 0, \\
\text{varey} = 1, \text{vary0} = 1, \text{varys} = 1, \text{vary0ys} = 0, \text{alpha} = 0.05, \ldots)
\]

Arguments

- **N** Sample size. It is 100 by default.
- **T** Number of measurement occasions. It is 5 by default.
- **R** Number of replications for the Monte Carlo simulation. It is 1000 by default.
- **betay** Parameter in the model: The compound rate of change. Its default value is 0.
- **my0** Parameter in the model: Mean of the initial latent score. Its default value is 0.
- **mys** Parameter in the model: Mean of the linear constant effect. Its default value is 0.
- **varey** Parameter in the model: Variance of the measurement error/uniqueness score. Its default value is 1.
- **vary0** Parameter in the model: Variance of the initial latent score. Its default value is 1.
- **varys** Parameter in the model: Variance of the linear constant effect. Its default value is 0.
- **vary0ys** Parameter in the model: Covariance of the initial latent score and the linear constant effect. Its default value is 0.
- **alpha** Significance level chosen for the test. It equals 0.05 by default.
- **...** Extra arguments. It is not required.
Value

An object of the power analysis. The output of the R function includes 4 main pieces of information for each parameter in the model. The first is the Monte Carlo estimate (mc.est). It is calculated as the mean of the R sets of parameter estimates from the simulated data. Note that the Monte Carlo estimates should be close to the population parameter values used in the model. The second is the Monte Carlo standard deviation (mc.sd), which is calculated as the standard deviation of the R sets of parameter estimates. The third is the Monte Carlo standard error (mc.se), which is obtained as the average of the R sets of standard error estimates of the parameter estimates. Lastly, mc.power is the statistical power for each parameter.

**wp.logistic**

*Statistical Power Analysis for Logistic Regression*

**Description**

This function is for Logistic regression models. Logistic regression is a type of generalized linear models where the outcome variable follows Bernoulli distribution. Here, Maximum likelihood methods is used to estimate the model parameters. The estimated regression coefficient is assumed to follow a normal distribution. A Wald test is use to test the mean difference between the estimated parameter and the null parameter (tiopically the null hypothesis assumes it equals 0). The procedure introduced by Demidenko (2007) is adopted here for computing the statistical power.

**Usage**

```r
wp.logistic(n = NULL, p0 = NULL, p1 = NULL, alpha = 0.05,
             power = NULL, alternative = c("two.sided", "less", "greater"),
             family = c("Bernoulli", "exponential", "lognormal", "normal", "Poisson",
                        "uniform"), parameter = NULL)
```

**Arguments**

- **n**
  - Sample size.

- **p0**
  - \(\text{Prob}(Y=1|X=0)\): the probability of observing 1 for the outcome variable \(Y\) when the predictor \(X\) equals 0.

- **p1**
  - \(\text{Prob}(Y=1|X=1)\): the probability of observing 1 for the outcome variable \(Y\) when the predictor \(X\) equals 1.

- **alpha**
  - Significance level chosen for the test. It equals 0.05 by default.

- **power**
  - Statistical power.

- **alternative**
  - Direction of the alternative hypothesis ("two.sided" or "less" or "greater"). The default is "two.sided".

- **family**
  - Distribution of the predictor ("Bernoulli", "exponential", "lognormal", "normal", "Poisson", "uniform"). The default is "Bernoulli".

- **parameter**
  - Corresponding parameter for the predictor's distribution. The default is 0.5 for "Bernoulli", 1 for "exponential", (0,1) for "lognormal" or "normal", 1 for "Poisson", and (0,1) for "uniform".
Value

An object of the power analysis.

wp.mc.chisq.diff

### Statistical Power Analysis for SEM Based on Chi-square Difference Test

**Description**

This function is for SEM power analysis based on the chi-square difference test.

**Usage**

```r
wp.mc.chisq.diff(full.model.pop, full.model, reduced.model, N=100, R=1000, alpha=0.05)
```

**Arguments**

- `full.model.pop`: Full model (under the alternative hypothesis) with population parameters.
- `full.model`: Full model (under the alternative hypothesis) lavaan specification.
- `reduced.model`: Reduced model (under the null hypothesis) lavaan specification.
- `N`: Sample size.
- `R`: Number of Monte Carlo replications.
- `alpha`: significance level chose for the test. It equals 0.05 by default.

**Value**

An object of the power analysis.

- `power`: Statistical power.
- `df`: Degrees of freedom
- `chi.diff`: Chi-square differences between the reduced model and the full model

**References**

Examples

```r
set.seed(20220722)

full.model.pop <-
  y1 ~ 0.4*x
  y2 ~ 0.5*x + 0.2*y1
  y3 ~ 0.4*x
  y4 ~ 0.4*y1 + 0.4*y2 + 0.4*y3
  y1 ~~ 0.84*y1
  y2 ~~ 0.61*y2
  y3 ~~ 0.84*y3
  y4 ~~ 0.27*y4
`

full.model <-
  y1 ~ x
  y2 ~ x + y1
  y3 ~ x
  y4 ~ y1 + y2 + y3
`

reduced.model <-
  y1 ~ x
  y2 ~ x
  y3 ~ x
  y4 ~ y1 + y3
`

wp.mc.chisq.diff(full.model.pop, full.model, reduced.model)
```

Description

Structural equation modeling (SEM) is a multivariate technique used to analyze relationships among observed and latent variables. It can be viewed as a combination of factor analysis and multivariate regression analysis. A mediation model can be viewed as a SEM model. Functions `wp.sem.chisq` and `wp.sem.rmsea` provide analytical solutions of power analysis for SEM. Function `wp.mediation` provides analytical solutions of power analysis for a simple mediation model. This function provides a solution based on Monte Carlo simulation (see Zhang, 2014). If the model is a mediation, Sobel test is used for the mediation / indirect effects. The solution is extended from the general framework for power analysis for complex mediation models using Monte Carlo simulation in Mplus (Muthén & Muthén, 2011) proposed by Thoemmes et al. (2010). We extended the framework in two ways. First, the method allows the specification of nonnormal data in the Monte Carlo simulation and can
thereby reflect more closely practical data collection. Second, the function `wp.mc.sem.basic` of a free, open-source R package, WebPower, is developed to ease power analysis for mediation models using the proposed method.

Usage

```r
wp.mc.sem.basic(model, indirect = NULL, nobs = 100, nrep = 1000, alpha = 0.95, skewness = NULL, kurtosis = NULL, ovnames = NULL, se = "default", estimator = "default", parallel = "no", ncore = Sys.getenv("NUMBER_OF_PROCESSORS"), cl = NULL, ...)
```

Arguments

- **model**: Model specified using lavaan syntax. More about model specification can be found in Rosseel (2012).
- **indirect**: Indirect effect defined using lavaan syntax.
- **nobs**: Sample size.
- **nrep**: Number of replications for the Monte Carlo simulation.
- **alpha**: Significance level chosen for the test. It equals 0.05 by default.
- **skewness**: A sequence of skewnesses of the observed variables.
- **kurtosis**: A sequence of kurtosises of the observed variables.
- **ovnames**: Names of the observed variables in the model.
- **se**: The method for calculating the standard errors. Its default method "default" is regular standard errors. More about methods specification standard errors calculation can be found in Rosseel (2012).
- **estimator**: Estimator. It is Maximum likelihood estimator by default. More about estimator specification can be found in Rosseel (2012).
- **parallel**: Parallel computing ("no" or "parallel" or "snow"). It is "no" by default, which means it will not use parallel computing. The option "parallel" is to use multiple cores in a computer for parallel computing. It is used with the number of cores (ncore). The option "snow" is to use clusters for parallel computing. It is used with the number of clusters (cl).
- **ncore**: Number of processors used for parallel computing. By default, ncore = Sys.getenv('NUMBER_OF_PROCESSORS').
- **cl**: Number of clusters. It is NULL by default. When it is NULL, the program will detect the number of clusters automatically.
- **...**: Extra arguments. It is not required.

Value

An object of the power analysis. The power for all parameters in the model as well as the indirect effects if specified.

Description

Structural equation modeling (SEM) is a multivariate technique used to analyze relationships among observed and latent variables. It can be viewed as a combination of factor analysis and multivariate regression analysis. A mediation model can be viewed as a SEM model. Functions `wp.sem.chisq` and `wp.sem.rmsea` provide analytical solutions of power analysis for SEM. Function `wp.mediation` provides analytical solutions of power analysis for a simple mediation model. This function provides a solution based on Monte Carlo simulation (see Zhang, 2014) and a bootstrap method for testing the indirect/mediation effects. The solution is extended from the general framework for power analysis for complex mediation models using Monte Carlo simulation in Mplus (Muthén & Muthén, 2011) proposed by Thoemmes et al. (2010). We extended the framework in three ways. First, we propose a general method to conduct power analysis for mediation models based on the bootstrap method. The method is still based on Monte Carlo simulation but uses the bootstrap method to test mediation effects. Second, the method allows the specification of nonnormal data in the Monte Carlo simulation and can thereby reflect more closely practical data collection. Third, the function `wp.mc.sem.boot` of a free, open-source R package, WebPower, is developed to ease power analysis for mediation models using the proposed method.

Usage

```r
wp.mc.sem.boot(model, indirect = NULL, nobs = 100, nrep = 1000, 
nboot = 1000, alpha = 0.95, skewness = NULL, kurtosis = NULL, 
ovnames = NULL, se = "default", estimator = "default", 
parallel = "no", ncore = Sys.getenv("NUMBER_OF_PROCESSORS"), cl = NULL, 
...)
```

Arguments

- `model`: Model specified using lavaan syntax. More about model specification can be found in Rosseel (2012).
- `indirect`: Indirect effect defined using lavaan syntax.
- `nobs`: Sample size. It is 100 by default.
- `nrep`: Number of replications for the Monte Carlo simulation. It is 1000 by default.
- `nboot`: Number of replications for the bootstrap to test the specified parameter (e.g., mediation). It is 1000 by default.
- `alpha`: Significance level chosen for the test. It equals 0.05 by default.
- `skewness`: A sequence of skewnesses of the observed variables. It is not required.
- `kurtosis`: A sequence of kurtoses of the observed variables. It is not required.
- `ovnames`: Names of the observed variables in the model. It is not required.
The method for calculating the standard errors. Its default method "default" is regular standard errors. More about methods specification standard errors calculation can be found in Rosseel (2012).

Estimator. It is Maximum likelihood estimator by default. More about estimator specification can be found in Rosseel (2012).

Parallel computing ("no" or "parallel" or "snow"). It is "no" by default, which means it will not use parallel computing. The option "parallel" is to use multiple cores in a computer for parallel computing. It is used with the number of cores (ncore). The option "snow" is to use clusters for parallel computing. It is used with the number of clusters (cl).

Number of processors used for parallel computing. By default, ncore = Sys.getenv('NUMBER_OF_PROCESSORS').

Number of clusters. It is NULL by default. When it is NULL, the program will detect the number of clusters automatically.

Extra arguments. It is not required.

An object of the power analysis. The power for all parameters in the model as well as the indirect effects if specified.

### wp.mc.sem.power.curve

**Statistical Power Curve for Structural Equation Modeling / Mediation based on Monte Carlo Simulation**

**Description**

A power curve is useful to graphically display how power changes with sample size (e.g., Zhang & Wang). This function is to generate a power curve for SEM based on Monte Carlo simulation, either using Sobel test or bootstrap method to test the indirect / mediation effects if applicable.

**Usage**

```r
wp.mc.sem.power.curve(model, indirect = NULL, nobs = 100, type = "basic",
                      nrep = 1000, nboot = 1000, alpha = 0.95, skewness = NULL,
                      kurtosis = NULL, ovnames = NULL, se = "default",
                      estimator = "default", parallel = "no",
                      ncore = Sys.getenv("NUMBER_OF_PROCESSORS"), cl = NULL, ...)
```

**Arguments**

- `model`: Model specified using lavaan syntax. More about model specification can be found in Rosseel (2012).
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>indirect</td>
<td>Indirect effect defined using lavaan syntax.</td>
</tr>
<tr>
<td>nobs</td>
<td>Sample size. It is 100 by default.</td>
</tr>
<tr>
<td>type</td>
<td>The method used to test the indirect effects ('basic' or 'boot'). By default type='basic'. The type 'basic' is to use Sobel test (see also \texttt{wp.mc.sem.basic}), while 'boot' is to use bootstrap method (see also \texttt{wp.mc.sem.boot}).</td>
</tr>
<tr>
<td>nrep</td>
<td>Number of replications for the Monte Carlo simulation. It is 1000 by default.</td>
</tr>
<tr>
<td>nboot</td>
<td>Number of replications for the bootstrap to test the specified parameter (e.g., mediation). It is 1000 by default.</td>
</tr>
<tr>
<td>alpha</td>
<td>Significance level chosen for the test. It equals 0.05 by default.</td>
</tr>
<tr>
<td>skewness</td>
<td>A sequence of skewnesses of the observed variables. It is not required.</td>
</tr>
<tr>
<td>kurtosis</td>
<td>A sequence of kurtosises of the observed variables. It is not required.</td>
</tr>
<tr>
<td>ovnames</td>
<td>Names of the observed variables in the model. It is not required.</td>
</tr>
<tr>
<td>se</td>
<td>The method for calculating the standard errors. Its default method &quot;default&quot; is regular standard errors. More about methods specification standard errors calculation can be found in Rosseel (2012).</td>
</tr>
<tr>
<td>estimator</td>
<td>Estimator. It is Maximum likelihood estimator by default. More about estimator specification can be found in Rosseel (2012).</td>
</tr>
<tr>
<td>parallel</td>
<td>Parallel computing (&quot;no&quot; or &quot;parallel&quot; or &quot;snow&quot;). It is &quot;no&quot; by default, which means it will not use parallel computing. The option &quot;parallel&quot; is to use multiple cores in a computer for parallel computing. It is used with the number of cores (ncore). The option &quot;snow&quot; is to use clusters for parallel computing. It is used with the number of clusters (cl).</td>
</tr>
<tr>
<td>ncore</td>
<td>Number of processors used for parallel computing. By default, ncore = Sys.getenv('NUMBER_OF_PROCESSORS').</td>
</tr>
<tr>
<td>cl</td>
<td>Number of clusters. It is NULL by default. When it is NULL, the program will detect the number of clusters automatically.</td>
</tr>
<tr>
<td>...</td>
<td>Extra arguments. It is not required.</td>
</tr>
</tbody>
</table>

**Value**

An object of the power analysis. The power for all parameters in the model as well as the indirect effects if specified.

**wp.mc.t**

*Power analysis for t-test based on Monte Carlo simulation*

**Description**

Power analysis for t-test based on Monte Carlo simulation

**Usage**

```r
wp.mc.t(n = NULL, R0 = 1e+05, R1 = 1000, mu0 = 0, mu1 = 0, sd = 1, skewness = 0, kurtosis = 3, alpha = 0.05, type = c("two.sample", "one.sample", "paired"), alternative = c("two.sided", "less", "greater"))
```

**Arguments**

- **n**  
  Sample size
- **R0**  
  Number of replications under the null
R1 Number of replications
mu0 Population mean under the null
mu1 Population mean under the alternative
sd Standard deviation
skewness Skewness
kurtosis Kurtosis
alpha Significance level
type Type of analysis
alternative Alternative hypothesis

########## Chapter 16. Monte Carlo t-test #############
wp.mc.t(n=20, mu0=0, mu1=0.5, sd=1, skewness=0,
kurtosis=3, type=c("one.sample"), alternative=c("two.sided"))

wp.mc.t(n=40, mu0=0, mu1=0.3, sd=1, skewness=1,
kurtosis=6, type=c("paired"), alternative=c("greater"))

wp.mc.t(n=c(15, 15), mu1=c(0.2, 0.5), sd=c(0.2, 0.5),
skewness=c(1, 2), kurtosis=c(4, 6), type=c("two.sample"), alternative=c("less"))

Description
This function is for mediation models. Mediation models can be used to investigate the underlying mechanisms related to why an input variable x influences an output variable y (e.g., Hayes, 2013; MacKinnon, 2008). The mediation effect is calculated as $a \times b$, where $a$ is the path coefficient from the predictor x to the mediator m, and $b$ is the path coefficient from the mediator m to the outcome variable y. Sobel test statistic (Sobel, 1982) is used to test whether the mediation effect is significantly different from zero.

Usage
wp.mediation(n = NULL, power = NULL, a = 0.5, b = 0.5, varx = 1,
 vary = 1, varm = 1, alpha = 0.05, interval = NULL)
Arguments

- `n`: Sample size.
- `power`: Statistical power.
- `a`: Coefficient from x to m. The default value is 0.5.
- `b`: Coefficient from m to y. The default value is 0.5.
- `varx`: Variance of x. The default value is 1.
- `vary`: Variance of y. The default value is 1.
- `varm`: Variance of m. The default value is 1.
- `alpha`: Significance level chosen for the test. It equals 0.05 by default.
- `interval`: A vector containing the end-points of the interval to be searched for the root.

Value

An object of the power analysis.

# Power for simple mediation

# n power a b varx vary varm alpha
# 100 0.9337271 0.5 0.5 1 1 1 0.05

# URL: http://psychstat.org/mediation

# To generate a power curve given a sequence of sample sizes:
res <- wp.mediation(n = seq(50,100,5), power = NULL, a = 0.5, b = 0.5,
                     varx = 1, vary = 1, varm = 1, alpha = 0.05)
res
# Power for simple mediation

# n power a b varx vary varm alpha
# 50 0.6877704 0.5 0.5 1 1 1 0.05
# 55 0.7287681 0.5 0.5 1 1 1 0.05
# 60 0.7652593 0.5 0.5 1 1 1 0.05
```
# Power analysis for longitudinal data analysis

## Description

The two functions are adapted from the R package longpower by Michael C. Donohue. More will be added later.

## Usage

```r
wp.mmrm(N = NULL, Ra = NULL, ra = NULL, sigmaa = NULL, Rb = NULL, rb = NULL, sigmab = NULL, lambda = 1, delta = NULL, alpha = 0.05, power = NULL, alternative = c("two.sided", "one.sided"))
```
rb = NULL, sigmab = NULL, lambda = 1, times = 1:length(ra),
delta = NULL, alpha = 0.05, power = NULL,
alternative = c("two.sided", "one.sided"))

Arguments

N N
Ra Ra
ra ra
sigmaa sigmaa
Rb Rb
rb rb
sigmab sigmab
lambda lambda
delta delta
alpha Significance level
power Statistical power
alternative alternative hypothesis
rho rho
times times

wp.modmed.m14  model14

Description

power analysis of model 14 in Introduction to Mediation, Moderation, and Conditional Process Analysis

Usage

wp.modmed.m14(
  a1,
  cp,
  b1,
  d1,
  b2,
  sige12,
sige22, n, sigx_w, sigx2 = 1, sigw2 = 1, nrep = 1000, alpha = 0.05, b = 1000, nb = n, MCrep = 1000, w_value = 0, power_method = "product", simulation_method = "percentile", ncore = 1, pop.cov = NULL, mu = NULL, varnames = c("y", "x", "w", "m", "mw")
)

Arguments

- a1: regression coefficient of mediator (m) on predictor (x)
- cp: regression coefficient of outcome (y) on predictor (x)
- b1: regression coefficient of outcome (y) on mediator (m)
- d1: regression coefficient of outcome (y) on moderator (w)
- b2: regression coefficient of outcome (y) on the product (mw)
- sige12: variance of error in the first regression equation
- sige22: variance of error in the second regression equation
- n: sample size
- sigx_w: covariance between predictor (x) and moderator (w)
- sigx2: variance of predictor (x)
- sigw2: variance of moderator (w)
- nrep: number of replications for finding power
- alpha: type 1 error rate
- b: number of bootstrap iterations used when simulation method is "percentile"
- nb: bootstrap sample size, default to n, used when simulation method is "percentile"
- MCrep: number of repetitions used for finding distribution when simulation method is "MC"
- w_value: moderator level
- power_method: "product" for using the indirect effect value in power calculation, or "joint" for using joint significance in power calculation
- simulation_method: "percentile" for using percentile bootstrap CI in finding significance of mediation, or "MC" for using Monte Carlo CI in finding significance of mediation
ncore  number of cores to use, default is 1, when ncore > 1, parallel is used
pop.cov  covariance matrix, default to NULL if using the regression coefficient approach
mu  mean vector, default to NULL if using the regression coefficient approach
varnames  name of variables for the covariance matrix

Value
power of indirect effect, direct effect, and moderation

References

Examples

```r
test = wp.modmed.m14(a1 = 0.2, cp = 0.2, b1 = 0.5, d1 = 0.5, b2 = 0.2, sigx2 = 1,

w_value moderator level  

drollable for using the indirect effect value in power calculation, or "joint" for using joint significance in power calculation  
simulation_method "percentile" for using percentile bootstrap CI in finding significance of mediation, or "MC" for using Monte Carlo CI in finding significance of mediation  
ncore number of cores to use, default is 1, when ncore > 1, parallel is used  
MCrep number of repetitions used for finding distribution when simulation method is "MC"  
pop.cov covariance matrix, default to NULL if using the regression coefficient approach  
mu mean vector, default to NULL if using the regression coefficient approach  
varnames name of variables for the covariance matrix  

Value  

power of indirect effect, direct effect, and moderation

Statistical Power Analysis for Multisite Randomized Trials with 2 Arms

Description

Multisite randomized trials (MRT) are a type of multilevel design for the situation when the entire cluster is randomly assigned to either a treatment arm or a control arm (Liu, 2013). The data from MRT can be analyzed in a two-level hierarchical linear model, where the indicator variable for treatment assignment is included in first level. If a study contains multiple treatments, then multiple indicators will be used. This function is for designs with 2 arms (i.e., a treatment and a control). Three types of tests are considered in the function: (1) The "main" type tests treatment main effect; (2) The "site" type tests the variance of cluster/site means; and (3) The "variance" type tests variance of treatment effects. Details leading to power calculation can be found in Raudenbush (1997) and Liu (2013).

Usage

wp.mrt2arm(n = NULL, f = NULL, J = NULL, tau00 = NULL, tau11 = NULL,
sg2 = NULL, power = NULL, alpha = 0.05, alternative = c("two.sided",
"one.sided"), type = c("main", "site", "variance"), interval = NULL)

Arguments

n Sample size. It is the number of individuals within each cluster.
f Effect size. It specifies the main effect of treatment, the mean difference between the treatment clusters/sites and the control clusters/sites. Effect size must be positive.
J Number of clusters / sites. It tells how many clusters are considered in the study design. At least two clusters are required.
tau00  Variance of cluster/site means. It is one of the residual variances in the second level. Its value must be positive.

tau11  Variance of treatment effects across sites. It is one of the residual variances in the second level. Its value must be positive.

sg2  Level-one error Variance. The residual variance in the first level.

power  Statistical power.

alpha  significance level choses for the test. It equals 0.05 by default.

alternative  Type of the alternative hypothesis ("two.sided" or "one.sided"). The default is "two.sided". The option "one.sided" can be either "less" or "greater".

type  Type of effect ("main" or "site" or "variance") with "main" as default. The type "main" tests treatment main effect, no tau00 needed; Type "site" tests the variance of cluster/site means, no tau11 or f needed; and Type "variance" tests variance of treatment effects, no tau00 or f needed.

interval  A vector containing the end-points of the interval to be searched for the root.

Value

An object of the power analysis.

**wp.mrt3arm**

*Statistical Power Analysis for Multisite Randomized Trials with 3 Arms*
Description

Multisite randomized trials (MRT) are a type of multilevel design for the situation when the entire cluster is randomly assigned to either a treatment arm or a control arm (Liu, 2013). The data from MRT can be analyzed in a two-level hierarchical linear model, where the indicator variable for treatment assignment is included in first level. If a study contains multiple treatments, then multiple indicators will be used. This function is for designs with 3 arms (i.e., two treatments and a control). Three types of tests are considered in the function: (1) The "main" type tests treatment main effect; (2) The "treatment" type tests the difference between the two treatments; and (3) The "omnibus" type tests whether the three arms are all equivalent. Details leading to power calculation can be found in Raudenbush (1997) and Liu (2013).

Usage

wp.mrt3arm(n = NULL, f1 = NULL, f2 = NULL, J = NULL, tau = NULL, sg2 = NULL, power = NULL, alpha = 0.05, alternative = c("two.sided", "one.sided"), type = c("main", "treatment", "omnibus"), interval = NULL)

Arguments

n Sample size. It is the number of individuals within each cluster.
f1 Effect size for treatment main effect. Effect size must be positive.
f2 Effect size for the difference between two treatments. Effect size must be positive.
J Number of clusters / sites. It tells how many clusters are considered in the study design. At least two clusters are required.
tau Variance of treatment effects across sites/clusters.
sg2 Level-one error Variance. The residual variance in the first level.
power Statistical power.
alpha significance level chose for the test. It equals 0.05 by default.
alternative Type of the alternative hypothesis ("two.sided" or "one.sided"). The default is "two.sided". The option "one.sided" can be either "less" or "greater".
type Type of effect ("main" or "treatment" or "omnibus") with "main" as default. The type "main" tests the difference between the average treatment arms and the control arm; Type "treatment" tests the difference between the two treatment arms; and Type "omnibus" tests whether the three arms are all equivalent.
interval A vector containing the end-points of the interval to be searched for the root.

Value

An object of the power analysis.

#  50  30 0.2 0.4  2.25 0.4603091  0.05
Description

This function is for Poisson regression models. Poisson regression is a type of generalized linear models where the outcomes are usually count data. Here, Maximum likelihood methods is used to estimate the model parameters. The estimated regression coefficient is assumed to follow a normal distribution. A Wald test is used to test the mean difference between the estimated parameter and the null parameter (typically the null hypothesis assumes it equals 0). The procedure introduced by Demidenko (2007) is adopted here for computing the statistical power.

Usage

wp.poisson(n = NULL, exp0 = NULL, exp1 = NULL, alpha = 0.05, power = NULL, alternative = c("two.sided", "less", "greater"), family = c("Bernoulli", "exponential", "lognormal", "normal", "Poisson", "uniform"), parameter = NULL, subdivisions=200L, i.method=c("numerical", "MC"), mc.iter=20000)

Arguments

n Sample size.
exp0 The base rate under the null hypothesis. It always takes positive value. See the article by Demidenko (2007) for details.

exp1 The relative increase of the event rate. It is used for calculation of the effect size. See the article by Demidenko (2007) for details.

alpha significance level chosen for the test. It equals 0.05 by default.

power Statistical power.

alternative Direction of the alternative hypothesis ("two.sided" or "less" or "greater"). The default is "two.sided".

family Distribution of the predictor ("Bernoulli", "exponential", "lognormal", "normal", "Poisson", "uniform"). The default is "Bernoulli".

parameter Corresponding parameter for the predictor’s distribution. The default is 0.5 for "Bernoulli", 1 for "exponential", (0,1) for "lognormal" or "normal", 1 for "Poisson", and (0,1) for "uniform".

subdivisions Number of divisions for integration

i.method Integration method

mc.iter Number of iterations for Monte Carlo integration

Value
An object of the power analysis.

**wp.popPar**

### Extract Population Value Table

**Description**

This function is used to extract population value table for parameters from an power analysis object for SEM based on Monte Carlo methods (class = 'power').

**Usage**

wp.popPar(object)

**Arguments**

- **object** Object of power analysis. It is an object returned by a webpower function for SEM based on Monte Carlo methods with class = 'power'.

**Value**

Population value table of parameters from the input object of power analysis.
Description

Tests of proportions are a technique used to compare proportions of success or agreement in one or two samples. The one-sample test of proportion tests the null proportion of success, usually 0.5. The two-sample test of proportions tests the null hypothesis that the two samples are drawn from populations with the same proportion of success. A z-test is used to evaluate whether the given difference in proportions is statistically significantly different from the null hypothesis. The power calculation is based on the arcsine transformation of the proportion (see Cohen, 1988, p.548).

Usage

```r
wp.prop(h = NULL, n1 = NULL, n2 = NULL, alpha = 0.05, power = NULL, type = c("1p", "2p", "2p2n"), alternative = c("two.sided", "less", "greater"))
```

Arguments

- `h`: Effect size of the proportion comparison. Cohen (1992) suggested that effect size values of 0.2, 0.5, and 0.8 represent "small", "medium", and "large" effect sizes, respectively.
- `n1`: Sample size of the first group.
- `n2`: Sample size of the second group if applicable.
- `alpha`: Significance level chosen for the test. It equals 0.05 by default.
- `power`: Statistical power.
- `type`: Type of comparison ("1p" or "2p" or "2p2n"). The default is "1p". 1p: one sample; 2p: two sample with equal sample size; 2p2n: two sample with unequal sample size.
- `alternative`: Direction of the alternative hypothesis ("two.sided" or "less" or "greater"). The default is "two.sided".

Value

An object of the power analysis.

References

wp.regression

Description

This function is for power analysis for regression models. Regression is a statistical technique for examining the relationship between one or more independent variables (or predictors) and one dependent variable (or the outcome). Regression provides an F-statistic that can be formulated using the ratio between variation in the outcome variable that is explained by the predictors and the unexplained variation (Cohen, 1988). The test statistic can also be expressed in terms of the comparison between Full and Reduced models (Maxwell & Delaney, 2003).

Usage

wp.regression(n = NULL, p1 = NULL, p2 = 0, f2 = NULL, alpha = 0.05, power = NULL, type = c("regular", "Cohen"))

Arguments

n
Sample size.
p1
Number of predictors in the full model.
p2
Number of predictors in the reduced model, it is 0 by default. See the book by Maxwell and Delaney (2003) for the definition of the reduced model.
f2
Effect size. We use the statistic f2 as the measure of effect size for linear regression proposed by Cohen (1988, p.410). Cohen discussed the effect size in three different cases. The calculation of f2 can be generalized using the idea of a full model and a reduced model by Maxwell and Delaney (2003).

alpha
significance level chosen for the test. It equals 0.05 by default.
power
Statistical power.
type
If set to "Cohen", the formula used in the Cohen’s book will be used (not recommended).
Value

An object of the power analysis

wp.rmanova

Statistical Power Analysis for Repeated Measures ANOVA

Description

Repeated-measures ANOVA can be used to compare the means of a sequence of measurements (e.g., O’Brien & Kaiser, 1985). In a repeated-measures design, every subject is exposed to all different treatments, or more commonly measured across different time points. Power analysis for (1) the within-effect test about the mean difference among measurements by default. If the subjects are from more than one group, the power analysis is also available for (2) the between-effect test about mean difference among groups and (3) the interaction effect test of the measurements and groups.

Usage

wp.rmanova(n = NULL, ng = NULL, nm = NULL, f = NULL, nscor = 1,
alpha = 0.05, power = NULL, type = 0)
Arguments

- **n**: Sample size.
- **ng**: Number of groups.
- **nm**: Number of measurements.
- **f**: Effect size. We use the statistic f as the measure of effect size for repeated-measures ANOVA as in Cohen (1988, p.275).
- **nscor**: Nonsphericity correction coefficient. The nonsphericity correction coefficient is a measure of the degree of sphericity in the population. A coefficient of 1 means sphericity is met, while a coefficient less than 1 means not met. The smaller value of the coefficient means the further departure from sphericity. The lowest value of the coefficient is 1/(nm-1) where nm is the total number of measurements. Two viable approaches for computing the empirical nonsphericity correction coefficient are suggested. One is by Greenhouse and Geisser (1959), the other is by Huynh and Feldt (1976).
- **alpha**: Significance level chosen for the test. It equals 0.05 by default.
- **power**: Statistical power.
- **type**: Type of analysis (0 or 1 or 2). The value "0" is for between-effect; "1" is for within-effect; and "2" is for interaction effect.

Value

An object of the power analysis

Description

Structural equation modeling (SEM) is a multivariate technique used to analyze relationships among observed and latent variables. It can be viewed as a combination of factor analysis and multivariate regression analysis. Two methods are widely used in power analysis for SEM. One is based on the likelihood ratio test proposed by Satorra and Saris (1985). The other is based on RMSEA proposed by MacCallum et al. (1996). This function is for SEM power analysis based on the likelihood ratio test.

Usage

wp.sem.chisq(n = NULL, df = NULL, effect = NULL, power = NULL, alpha = 0.05)

Arguments

n Sample size.

df Degrees of freedom. The degrees of freedom of the chi-squared test.

effect Effect size. It specifies the population misfit of a SEM model, which is the difference between two SEM models: a full model (Mf) and a reduced model (Mr). A convenient way to get the effect size is to fit the reduced model using SEM software such R package ‘lavaan’ (Rossel, 2012). Then the effect size is calculated as the chi-squared statistics dividing by the sample size.

power Statistical power.

alpha significance level chosen for the test. It equals 0.05 by default.

Value

An object of the power analysis.

Statistical Power Analysis for Structural Equation Modeling based on RMSEA

Description

Structural equation modeling (SEM) is a multivariate technique used to analyze relationships among observed and latent variables. It can be viewed as a combination of factor analysis and multivariate regression analysis. Two methods are widely used in power analysis for SEM. One is based on the likelihood ratio test proposed by Satorra and Saris (1985). The other is based on RMSEA proposed by MacCallum et al. (1996). This function is for SEM power analysis based on RMSEA.

Usage

wp.sem.rmsea(n = NULL, df = NULL, rmsea0 = NULL, rmsea1 = NULL, power = NULL, alpha = 0.05, type = c("close", "notclose"))

Arguments

- **n** Sample size.
- **df** Degrees of freedom. The degrees of freedom of the chi-squared test.
- **rmsea0** RMSEA for H0. It usually equals zero.
- **rmsea1** RMSEA for H1.
- **power** Statistical power.
- **alpha** Significance level chosen for the test. It equals 0.05 by default.
- **type** Close fit or non-close fit ('close' or 'notclose'). It is 'close' by default.
Value

An object of the power analysis.

References

Examples

#To calculate the statistical power given sample size and effect size:

### wp.t

**Statistical Power Analysis for t-Tests**

**Description**

A t-test is a statistical hypothesis test in which the test statistic follows a Student's t distribution if the null hypothesis is true and follows a non-central t distribution if the alternative hypothesis is true. The t test can assess the statistical significance of (1) the difference between population mean and a specific value, (2) the difference between two independent population means, and (3) difference between means of matched pairs.

**Usage**

```r
wp.t(n1 = NULL, n2 = NULL, d = NULL, alpha = 0.05, power = NULL,
    type = c("two.sample", "one.sample", "paired", "two.sample.2n"),
    alternative = c("two.sided", "less", "greater"),
    tol = .Machine$double.eps^0.25)
```

**Arguments**

- **n1**: Sample size of the first group.
- **n2**: Sample size of the second group if applicable.
- **d**: Effect size. See the book by Cohen (1988) for details.
- **alpha**: Significance level chosen for the test. It equals 0.05 by default.
- **power**: Statistical power.
- **type**: Type of comparison ("one.sample" or "two.sample" or "two.sample.2n" or "two.sample.2n" or "paired"). "two.sample" is two-sample t-test with equal sample sizes, two.sample.2n is two-sample t-test with unequal sample sizes, "paired" is paired t-test
- **alternative**: Direction of the alternative hypothesis ("two.sided" or "less" or "greater"). The default is "two.sided".
- **tol**: Tolerance in root solver.

**Value**

An object of the power analysis.
