Package ‘adegraphics’

September 16, 2021

Type  Package
Title  An S4 Lattice-Based Package for the Representation of Multivariate Data
Version  1.0-16
Author  Stéphane Dray <stephane.dray@univ-lyon1.fr> and Aurélie Siberchicot <aurelie.siberchicot@univ-lyon1.fr>, with contributions from Jean Thioulouse. Based on earlier work by Alice Julien-Laferrière.
Maintainer  Aurélie Siberchicot <aurelie.siberchicot@univ-lyon1.fr>
Description  Graphical functionalities for the representation of multivariate data. It is a complete re-implementation of the functions available in the ‘ade4’ package.
Depends  R (>= 3.0.2)
License  GPL (>= 2)
Imports  ade4 (>= 1.7-13), graphics, grid, KernSmooth, lattice, latticeExtra, methods, RColorBrewer, sp (>= 1.1-1), stats
Suggests  Guerry, knitr, maptools, pixmap, markdown, markdown, spdep, splancs
BugReports  https://github.com/sdray/adegraphics/issues
 Encoding UTF-8
VignetteBuilder knitr
NeedsCompilation no

Description

This package was created to replace graphics functionalities of the ade4 package and to offer customizable representations of data and result analysis.

Graphics are objects of S4 class, which can be displayed but also stored for latter modifications. Those modifications can be graphical changes, but also superposition or juxtaposition of various graphical objects (creating another type of object). Each object will contain graphical parameters and instructions for the display (calls, positions, etc.) and the data set used. Sometimes data is heavy, due to its size for example. Two storing systems exist:

- full storage: data is assigned to an object's slot.
- names and position: data names (as a string, obtained using `deparse(substitute)`) and their frame position (using `sys.nframe()`) are stored. Then the full data can be retrieve with those two informations (and only if the data objects are still in the environment)

This new system is based on the lattice package and grid graphics.

Details

Package: adegraphics
Type: Package
Version: 1.0-12
Date: 2018-08-31
License: GPL (>=2)
Depends: ade4 (>= 1.7-13), graphics, grid, KernSmooth, lattice, latticeExtra, methods, RColorBrewer, sp (>= 1.1-1), stats

A lot of classes were implemented. Two superclass structures the architecture in class. Simple and complex graphics are distinguished in the former version:
add.ADEg

- ADEg class provides simple graphics using one kind of data (most of the time, only a data frame) and one representation method (points, labels, arrows...)
- ADEgS class provides complex graphics making juxtaposition, superposition and/or insertion of several simple graphics.

5 subclasses inherits from the superclass abstract ADEg:
- ADEg.S1: one-dimensional plot
- ADEg.S2: bi-dimensional plot
- ADEg.C1: one-dimensional data plotted in 2-D
- ADEg.T: table plot
- ADEg.Tr: triangle plot

```

---

**add.ADEg**

Superpose an new ADEg graph to the previous ones plotted

**Description**

Adds an ADEg to the current ADEg or ADEgS plot.

**Usage**

```
add.ADEg(object)
```

**Arguments**

- **object**
  - an ADEg object
Details

This function uses the last plotted ADEg or ADEgS object. It calls `superpose`.

Value

an ADEgS object

Author(s)

Alice Julien-Laferriere, Aurelie Siberchicot <aurelie.siberchicot@univ-lyon1.fr> and Stephane Dray

See Also

`superpose` ADEg ADEgS

Examples

```r
df1 <- cbind(rnorm(24), rnorm(24))
df2 <- cbind(rnorm(24), rnorm(24))
g1 <- s.label(df1, ppoints.col = "blue")
g2 <- s.label(df2, ppoints.col = "red", plot = FALSE)
add.ADEg(g2)

data(jv73, package = "ade4")
pcal1 <- ade4::dudi.pca(jv73$morpho, scannf = FALSE)
g5 <- s.label(pcal1$li, plabels.optim = TRUE)
g6 <- s.class(pcal1$li, jv73$fac.riv, starSize = 0, ellipseSize = 0, chullSize = 1,
  ppolygons.alpha = 0.4, col = rainbow(12), ppoints.cex = 0, plot = FALSE)
add.ADEg(g6)
```

---

`addhist`  
Adds histograms and density lines against a bi-dimensional graphics.

Description

Adds the two marginal histograms and density lines of each axis against an ADEg.S2 object.

Usage

`addhist(object, bandwidth, gridsize = 60, kernel = "normal", cbreaks = 2,
storeData = TRUE, plot = TRUE, pos = -1, ...)"
Arguments

- **object**: an ADEg.S2 object
- **bandwidth**: used for the calculations of the density lines (see the `bkde` function of the KernSmooth package).
- **gridsize**: used for the calculations of the density lines (see the `bkde` function of the KernSmooth package).
- **kernel**: used for the calculations of the density lines (see the `bkde` function of the KernSmooth package).
- **cbreaks**: number of cells for the histograms per interval of the grid of the bi-dimensional graphics.
- **plot**: a logical indicating if the graphics is displayed
- **storeData**: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored
- **pos**: an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if `storeData` is FALSE
- ... Additional graphical parameters (see `adegpar` and `trellis.par.get`)

Details

Density is calculated using the function `bkde` of the KernSmooth package.

Value

An `ADEgS` object, a list of four graphical objects, one `ADEg.S2` and three `trellis` (from lattice). Their names are:

- **object**: the `ADEg.S2` object
- **densX**: top histogram, a `trellis` object
- **densY**: right histogram, a `trellis` object
- **link**: corner graphics linking the two histograms, a `trellis` object

Note

Into the dots arguments, the usual parameters for the `s.label` can be given with the `object` key. Trellis parameters are used for the three remaining graphics. `plot.polygon` handles the histogram aspect, `add.line` the graduations lines and `plot.line` the density lines.

Finally, for the `link` graphic, labels aspect can be changed using a `plabels` list, as for an `S2.label` object.

ADEg.S2 ADEgS

Examples

data(rpjdl, package = "ade4")
coa1 <- ade4::dudi.coa(rpjdl$fau, scannf = FALSE, nf = 4)
labli <- s.label(coa1$li)
g1 <- addhist(labli)
g2 <- addhist(labli, plabels.cex = 0, cbreaks = 3)
labco <- s.label(coa1$co)
g3 <- addhist(labco, plabels.cex = 0, cbreaks = 3)
update(g3, pbackground.col = "grey85")

addline

---

addline \hspace{1cm} \textit{Adds lines on graphics.}

Description

Adds a \textit{trellis} object containing one or several lines on one or several graphical objects.

Usage

\begin{verbatim}
addline(object, a = NULL, b = 0, h = NULL, v = NULL, plot = TRUE, ...)
\end{verbatim}

Arguments

\begin{itemize}
\item \textbf{object} \hspace{1cm} an object of class ADEg or ADEgS
\item \textbf{a, b} \hspace{1cm} coefficients of the line to be added, passed to the \texttt{panel.abline} function of the \texttt{lattice} package
\item \textbf{h, v} \hspace{1cm} numeric vectors giving locations respectively of horizontal and vertical lines to be added to the plot, in native coordinates, passed to the \texttt{panel.abline} function of the \texttt{lattice} package
\item \textbf{plot} \hspace{1cm} a logical indicating if the graphics is displayed
\item \textbf{...} \hspace{1cm} Other arguments. Additional graphical parameters (see the \texttt{plines} list in \texttt{adegpar} and \texttt{trellis.par.get}). If object is an ADEgS, the argument which identify which ADEg is/are used for superposition.
\end{itemize}

Value

An object of class ADEgS.

ADEg ADEgS panel.abline

Examples

# example extracted from the pedagogic file, here: http://pbil.univ-lyon1.fr/R/pdf/tdr65.pdf
data(monde84, package = "ade4")
dfX <- cbind.data.frame(lpib = log(monde84$pib), croipop = monde84$croipop)
dfY <- cbind.data.frame(lmorta = log(monde84$morta), lanal = log(monde84$anal + 1),
  rscol = sqrt(100 - monde84$scol))
dfX0 <- ade4::scalewt(dfX)
dfY0 <- ade4::scalewt(dfY)
can1 <- cancor(dfX0, dfY0)
varcanoX <- dfX0
varcanoY <- dfY0
g1 <- s.label(cbind(varcanoY, varcanoX), labels = row.names(monde84), plabel.cex = 0.8, plot = FALSE)
addline(g1, 0, 1, plines.col = "red", plines.lwd = 0.5, plines.lty = 2)

Description

Adds a trellis object containing one or several points on one or several graphical objects.

Usage

addpoint(object, xcoord, ycoord, plot = TRUE, ...)

Arguments

object      an object of class ADEg or ADEgS
xcoord      an integer (or a vector) indicating where label is(are) plotted on the x-axis,
            passed to the panel.points function of the lattice package
ycoord      an integer (or a vector) indicating where label is(are) plotted on the y-axis,
            passed to the panel.points function of the lattice package
plot        a logical indicating if the graphics is displayed
...

Other arguments. Additional graphical parameters (see the ppoints list in adegpar
and trellis.par.get). If object is an ADEgS, the argument which identify
which ADEg is/are used for superposition.

Value

An object of class "ADEgS".

Author(s)

Aurelie Siberchicot <aurelie.siberchicot@univ-lyon1.fr> and Stephane Dray
addsegment

Adds segments on graphics.

Description

Adds a trellis object containing one or several segments on one or several graphical objects.

Usage

addsegment(object, x0 = NULL, y0 = NULL, x1, y1, plot = TRUE, ...)

Arguments

- **object**
  - an object of class ADEg or ADEgS

- **x0, y0**
  - coordinates of points FROM which to draw, passed to the panel.segments function of the lattice package. See Details.

- **x1, y1**
  - coordinates of points TO which to draw, passed to the panel.segments function of the lattice package. See Details.

- **plot**
  - a logical indicating if the graphics is displayed

- **...**
  - Other arguments. Additional graphical parameters (see the plines list in adegpar and trellis.par.get). If object is an ADEgS, the argument which identify which ADEg is/are used for superposition.

Details

x0, y0, x1 and y1 can be vectors. A line segment is drawn, for each i, between the point (x0[i], y0[i]) and the point (x1[i], y1[i]). The coordinate vectors will be recycled to the length of the longest.

Value

An object of class ADEgS.

Author(s)

Aurelie Siberchicot <aurelie.siberchicot@univ-lyon1.fr> and Stephane Dray

g11 <- sld.density(deug$tab[, 1], plot = FALSE)
g12 <- addsegment(g11, x0 = deug$cent[1], x1 = deug$cent[1], y0 = 0, y1 = 1,
                  plines = list(col = "grey30", lwd = 3))
g13 <- addsegment(g11,
                  x0 = deug$cent + seq(0, 1, length.out = length(deug$cent)),
                  x1 = deug$cent + seq(0, 1, length.out = length(deug$cent)),
                  y0 = 0, y1 = 1,
                  plines = list(col = 1:length(deug$cent), lty = 1:length(deug$cent)))

# example extracted from the pedagogic file, here: http://pbil.univ-lyon1.fr/R/pdf/tdr65.pdf
data(monde84, package = "ade4")
dfX <- cbind.data.frame(lpib = log(monde84$pib), croipop = monde84$croipop)
dfY <- cbind.data.frame(lmorta = log(monde84$morta), lanal = log(monde84$anal + 1),
                       rscol = sqrt(100 - monde84$scol))
dfX0 <- ade4::scalewt(dfX)
dfY0 <- ade4::scalewt(dfY)
can1 <- cancor(dfX0, dfY0)
varcanoX <- dfX0
varcanoY <- dfY0
g21 <- s.label(cbind(varcanoY, varcanoX), labels = row.names(monde84), plabel.cex = 0.8,
               plot = FALSE)
g22 <- addsegment(g21, -1.25, -1.25, 1.25, 1.25, plines.col = "purple", plines.lwd = 1.5,
                  plines.lty = 2)

addtext

Add labels on graphics.

Description

Add a trellis object containing one or several labels on one or several graphical objects.

Usage

addtext(object, xcoord, ycoord, label, plot = TRUE, ...)

Arguments

  object          an object of class ADEg, trellis or ADEgS
  xcoord          an integer (or a vector) indicating where label is(are) plotted on the x-axis,
                  passed to the adeg.panel.label
  ycoord          an integer (or a vector) indicating where label is(are) plotted on the y-axis,
                  passed to the adeg.panel.label
label 

a character string (or a vector) containing the label(s) displayed on object

plot 

a logical indicating if the graphics is displayed

... 

Other arguments. Additional graphical parameters (see the plabels list in adegpar and trellis.par.get). If object is an ADEgS, the argument which identify which ADEg is/are used for superposition.

Value

An object of class ADEgS.

g1 <- table.value(dunedata$veg, symbol = "circle", ppoints.cex = 0.5, plot = FALSE)
addtext(g1, 1, 20, "A", plabels.srt = 45, plabels.box.draw = FALSE, plabels.col = "red")

xy <- cbind.data.frame(x = runif(200, -1, 1), y = runif(200, -1, 1))
Posi <- factor(xy$x > 0) : factor(xy$y > 0)
g2 <- s.class(xy, fac = Posi, facets = Posi, pellipses.col = 1:4, plabels.cex = 0,
plegend.drawKey = FALSE, psub.cex = 0, plot = FALSE)
addtext(g2, c(0.5, 0.5, -0.5, -0.5), c(0.5, -0.5), levels(Posi), plabels.cex = 2, plabels.col = 1:4)

Description

An object of ADEg class is a simple graphic. This object can be blended in with another one (superposition, insertion and/or juxtaposition) to form a more complex graphics (an ADEgS object).

The ADEg class is a virtual class, i.e. a class which is not possible to create objects but which have heirs. This class has five son classes : ADEg.S1, ADEg.S2, ADEg.C1, ADEg.T and ADEg.Tr.

Objects from the Class

None object of this class can be instantiated.
ADEg-class

Slots

trellis.par a list of parameters for lattice call. It will be passed directly to par.settings arguments of the lattice function.

adeg.par a list of graphical parameters, corresponding to the ones given by adegpar() function.

lattice.call a list of two elements to create the trellis object:

- graphictype: the lattice function to use
- arguments: its parameters to obtain the trellis object

g.args a list containing some parameters linked with the created object of ADEg class:

- xlim, ylim
- main, sub
- xlab, ylab
- samelimits
- scales: a list of scales informations (ticks, marks and labels for the x-axis or the y-axis) in the form of the lattice argument scales in the xyplot function

stats a list of internal preliminary calculations

s.misc a list of some other internal parameters

Call an object of class call

Methods

panelbase signature(object = "ADEg"): draws grid and text and produces graphical output from the graphical object

getcall signature(object = "ADEg"): returns the Call slot

getlatticecall signature(object = "ADEg"): returns the lattice.call slot

getstats signature(object = "ADEg"): returns the stats slot

getparameters signature(object = "ADEg", number): if number is 1, returns the trellis.par slot, if it is 2, returns the adeg.par slot and if it is 0, returns the both slots

add.ADEg signature(object = "ADEg"): superposes an ADEg on the current one plotted

+ signature(e1 = "ADEg", e2 = "ADEg"): superposes e2 on e1

superpose signature(g1 = "ADEgOrtrellis", g2 = "ADEgOrtrellis", which = "ANY", plot = "ANY"): creates a new ADEgS object performing a superposition of g2 on g1.

printSuperpose signature(g1 = "ADEgOrtrellis", refg = "ADEgOrtrellis"): internal method, not for users.

cbindADEg signature(g1 = "ADEgORADEgS", g2 = "ADEgORADEgS"): creates a new "ADEgS" object combining g1 on g2.

rbindADEg signature(g1 = "ADEgORADEgS", g2 = "ADEgORADEgS"): creates a new "ADEgS" object combining g1 on g2 by rows.

insert signature(graphics = "ADEgOrtrellis", oldgraphics = "missing", posi, ratio, inset, plot, which): creates a new ADEgS object performing an insertion of graphics into the current device.

insert signature(graphics = "ADEgOrtrellis", oldgraphics = "ADEg", posi, ratio, inset, plot): creates a new ADEgS object performing an insertion of graphics into oldgraphics.
show signature(x = "ADEg"): prints the ADEg object
plot signature(x = "ADEg"): prints the ADEg object
print signature(x = "ADEg"): displays the ADEg object in the current device or in a new one
update signature(object = "ADEg"): modifies graphical parameters after the ADEg creation, updates the current display and returns the modified ADEg

Note
For any ADEg creation, various graphical parameters can be passed into the dots (...) arguments.
- the parameters listed in adegpar() can be changed, even if some of them do no modify the graphic representation chosen.
- the lattice parameters listed in trellis.par.get() can also be changed.
- limits, main and sub title, and axes labels can be changed using the keys xlim, ylim, main, sub, xlab and ylab.
- a neighbouring graph (object of class nb or listw) and a spatial one (object of class sp) can be display in the background using the keys nbobject, Sp and sp.layout.

ADEgS adegpar superpose insert

Examples
showClass("ADEg")

ADEg.C1-class

Description
An object of ADEg.C1 class represents unidimensional data into two dimensions.
The ADEg.C1 class is a virtual class, i.e. a class which is not possible to create objects but which have heirs. This class inherits from ADEg class and has three son classes: C1.barchart, C1.curve, C1.density, C1.dotplot, C1.gauss, C1.hist, C1.interval

Objects from the Class
None object of this class can be instantiated.
Slots

data  a list containing data or data’s name.
  • score: the displayed values in the form of a numeric vector, a name or a matching call.
  • frame: a positive or null integer. It is the number of the frame containing the data (used with `sys.frame(..., env = data$frame)`). Only if the data are not stored (i.e. `data$storeData = FALSE`).
  • storeData: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored.

trellis.par a list of parameters for `lattice` call. It will be passed directly to `par.settings` arguments of the `lattice` function.

adeg.par a list of graphical parameters, corresponding to the ones given by `adegpar()` function.

lattice.call a list of two elements to create the `trellis` object:
  • graphictype: `xyplot`
  • arguments: its parameters to obtain the `trellis` object

g.args a list containing some method parameters linked with the created object of `ADEg.C1` class

stats a list of internal preliminary calculations

s.misc a list of some others internal parameters:
  • hori.update: a logical indicating if the sense of direction of the graphics is updating
  • backgrid: a list of two elements for grid lines. `backgrid$x` defines the coordinates of the lines (horizontal or vertical depending on the graphics orientation) and `backgrid$d` the grid mesh

Call an object of class `call`

Extends

Class `ADEg`, directly.

Methods

prepare signature(object = "ADEg.C1"): performs the calculations before display the object (e.g. limits, grid and axis calculations)

setlatticecall signature(object = "ADEg.C1"): prepares the `lattice.call` slot

panelbase signature(object = "ADEg.C1"): defines the graphical background (e.g. grid, rugs and box)

gettrellis signature(object = "ADEg.C1"): converts the graphic into a `trellis` object of `lattice` class

Note

The `ADEg.S1` class and `ADEg.C1` class are both used to represent an unidimensional information (e.g. a score). The difference between these two classes is mainly ideological: an `ADEg.S1` object is a representation into one dimension (e.g. one line) while an `ADEg.C1` object is a representation into two dimensions (e.g. curves).
A panel function for adding histograms.

Description

Panel function for displaying histograms into a trellis graphic (lattice package) and level lines.

Usage

```r
adeg.panel.hist(histValues, horizontal = TRUE, densi, drawLines, params = list(), identifier = "histogramADEg")
```

Arguments

- `histValues`: an object of class histogram. See `hist`.
- `horizontal`: a logical indicating if the plot is horizontal.
- `densi`: a list returns by the `bkde` containing the coordinates of the binned kernel density estimate of the probability density of the data.
- `drawLines`: a vector containing the level values.
- `params`: graphical parameters: `plot.polygon`, `add.line` and `plot.line` (lattice).
- `identifier`: A character string that is prepended to the name of the grob that is created.

Value

Displays the histogram and level lines.

Note

For more information about the use of panel functions, please see the lattice package developed by Deepayan Sarkar.

`bkde` and `hist`

Examples

```r
if(require(KernSmooth, quietly = TRUE) & require(lattice, quietly = TRUE)) {
  z <- round(rnorm(100, 30, 5))
  h <- hist(z, plot = FALSE)
  d <- bkde(z, kernel = "normal", gridsize = 60)
  l <- c(10, 20, 30, 40)
  xyplot(1:50 ~ 1:50, histValues = h, densi = d, drawLines = l,
         panel = function(drawLines, histValues, densi){
           adeg.panel.hist(histValues = histValues, drawLines = drawLines, densi = densi))}
```

adeg.panel.join

Panel function for joining lines.

Description

Panel function for drawing lines as part of a circle centred in \((0, 0)\) into a `trellis` graphic (`lattice` package).

Usage

```r
adeg.panel.join(drawLines, params = list())
```

Arguments

- `drawLines`: a vector containing the level values used as radius of the circle
- `params`: graphical parameters: `plabels` and `add.line` (`lattice`)

Value

Displays level lines and their values.

Note

For more information about the use of panel functions, please see the `lattice` package developed by Deepayan Sarkar.

Author(s)

Alice Julien-Laferriere, Aurelie Siberchicot <aurelie.siberchicot@univ-lyon1.fr> and Stephane Dray
Examples

```r
if(require(lattice, quietly = TRUE)) {
  xyplot(0:20 ~ 0:20, drawLines = c(5, 10, 15), params = list(plabels.cex = 2),
         panel = function(drawLines, params){
           adeg.panel.join(drawLines = drawLines, params = params))
      }
```

---

**adeg.panel.label**  
Panel function for adding labels.

Description

Panel function for drawing labels into a trellis graphic (lattice package) with or without boxes around labels.

Usage

```r
adeg.panel.label(x, y, labels, plabels, pos = NULL)
```

Arguments

- **x**  
a numeric vector, x-coordinates for the labels
- **y**  
a numeric vector, y-coordinates for the labels
- **labels**  
a vector of character string, the labels
- **plabels**  
a list of parameters as an extract of `adegpar("plabels")`, used for labels’ drawing. Each value can be a vector and will be recycled if necessary:
  - `alpha`, `cex`, `col`: drawing parameters for the text
  - `srt`: orientation of the labels, `horizontal`, `vertical` or an angle indication (in degrees). Boxes are not rotated. If the orientation is not near to `horizontal/vertical` (0/90), it is best not to draw the boxes
  - `optim`: logical. If TRUE, uses an algorithm trying to avoid labels’ overlapping and outside limits
  - `boxes`: concerns the label’s boxes. a list:
    - `draw`: logical. If TRUE, labels are framed
    - `alpha`, `border`, `col`, `lwd`, `lty`: rule transparency, border lines and background color
- **pos**  
a position specifier for the text, used in `panel.text`. Values of 1, 2, 3 and 4 respectively indicate positions below, to the left of, above and to the right of the specified coordinates.

Value

Draws the labels.
Note

For more information about the use of panel functions, please see the lattice package developed by Deepayan Sarkar.

Author(s)

Alice Julien-Laferriere, Aurelie Siberchicot <aurelie.siberchicot@univ-lyon1.fr> and Stephane Dray

References

The algorithm used for labels positions optimization is inspired by the pointLabel function of the maptools package developed by Tom Short.

See Also

pointLabel

Examples

```r
if(require(lattice, quietly = TRUE)) {
  param <- adegpar("plabels")[[1]]
  xyplot(1:10 ~ 1:10, panel = function(x, y, ...){
    adeg.panel.label(x, y, LETTERS[1:10], plabels = param))
}

if(require(lattice, quietly = TRUE)) {
  param$boxes$draw <- FALSE
  param$col <- "blue"
  xyplot(1:10 ~ 1:10, panel = function(x, y, ...){
    adeg.panel.label(x, y, LETTERS[1:10], plabels = param))
}
```

Description

Panel function for representing a graph into a trellis graphic (lattice package). Two types of graph objects can be used: nb or listw object (spdep package) or simple edges informations. Directions associated with the edges are not displayed.
Usage

```r
adeg.panel.nb(nbobject, coords, col.edge = "black", lwd = 1, lty = 1, pch = 20, cex = 1, col.node = "black", alpha = 1)

adeg.panel.edges(edges, coords, col.edge = "black", lwd = 1, lty = 1, pch = 20, cex = 1, col.node = "black", alpha = 1)
```

Arguments

- `nbobject` a object of class `nb` or `listw`
- `edges` a two columns matrix, representing the edges between the nodes. For a row i, x[i, 1] and x[i, 2] are linked, x[i, 1] and x[i, 2] being vertices number.
- `coords` a two columns matrix containing vertices’ coordinates
- `col.edge` edges’ color(s)
- `lwd` line width (edges). Can be a vector
- `lty` line type (edges). Can be a vector
- `pch` vertices’ representation type (symbols). Can be a vector
- `cex` symbols’ size(s) (vertices). Can be a vector
- `col.node` vertices’ color(s). Can be a vector
- `alpha` symbols’ transparency

Value

Displays the neighboring graph.

Note

For more information about the use of panel functions, please see the `lattice` package developed by Deepayan Sarkar.

          panel = function(...){adeg.panel.edges(edges, coords, lty = 1:4, cex = 5))}
}

adeg.panel.Spatial

Panel function for adding spatial objects.

Description

Panel function adapted from the Sp package for displaying all kind of spatial objects handled by Sp
(for classes inherited from the superclass Spatial) into a trellis graphic (lattice package).

Usage

adeg.panel.Spatial(SpObject, sp.layout = NULL, col = 1, border = 1, lwd = 1,
                   lty = 1, alpha = 0.8, cex = 1, pch = 20, n = length(col), spIndex = 1, ...)

Arguments

SpObject       an object of class "SpatialPoints", "SpatialPointsDataFrame",
               "SpatialPixels", "SpatialPixelsDataFrame", "SpatialGrid",
               "SpatialGridDataFrame", "SpatialLines", "SpatialLinesDataFrame",
               "SpatialPolygons" or "SpatialPolygonsDataFrame"
sp.layout      a list of layout items. See spplot for more information
col            background color (fill) of Spobject
border         border color
lwd             line width (border)
lty             line type (border)
alpha          background transparency of Spobject
cex             point size
pch             point type
if SpObject contains data, the _desired_ number of intervals splitting the data (using `pretty`).

spIndex

if the SpObject contains a data frame, its values are represented with a color code. Only the spIndex data frame is represented

... for coherence with panel functions

**Value**

Draws the Spatial object and layout.

**Note**

If SpObject contains several maps, only the first one is selected. Also for objects containing more data (for classes `data.frame` with a slot `data`), this information is also shown. To do so, various colors can be used (according to the `col` arguments).

For more information about the use of panel functions, please see the `lattice` package developed by Deepayan Sarkar.

```r
if(require(lattice, quietly = TRUE) & require(sp, quietly = TRUE)) {
  data(elec88, package = "ade4")

  xy <- elec88$xy
  arrow <- list("SpatialPolygonsRescale", offset = c(150000, 1700000),
                 layout.north.arrow(), scale = 100000)

  xyplot(xy[, 2] ~ xy[, 1], aspect = "iso", panel = function(...){
    adeg.panel.Spatial(SpObject = elec88$Spatial, sp.layout = list(arrow),
                      col = colorRampPalette(c("yellow", "blue"))(5), border =
                      "transparent")})
}
```
adeq.panel.values

Panel function drawing a third variable into a two-dimensional scatterplot

Description

Panel function for drawing coordinates with variable representation. The values can be represented through symbols with proportional size or various colors.

Usage

adeq.panel.values(x, y, z, method, symbol, ppoints, breaks, centerpar = NULL, center = 0)

Arguments

x a numeric vector, x-coordinates for the symbols
y a numeric vector, y-coordinates for the symbols
z a numeric vector, the third variable with one value per coordinates (x, y)
method a character string equal to color or size.
      If color, a palette of color is used for the symbols (one color per interval defined by breaks).
      If size, symbols’ area is proportional to the value. Area is 0 for values equals to center. Two colors are used, one for values smaller than center and the other for values larger than center.
symbol a character string equal to square or circle.
ppoints a list of parameters as an extract of adegpar("ppoints"), used for points’ drawing.
      • alpha: transparency of points
      • cex: size of points
      • col: border color of points
      • pch: symbol to use
      • fill: filling color
breaks a vector, the breaks used for splitting z if method is color
centerpar a list to represent center value using elements in the adegpar("ppoints") list or NULL value. If the method is size, z-values equals to center have a size of zero. If centerpar is not NULL, those z-values are shown as points with the centerpar drawing parameters.
center a center value for method size

Value

Draws the points.
ADEg.S1-class

Note

For more information about the use of panel functions, please see the lattice package developed by Deepayan Sarkar.

For the symbols size, the method is size uses perceptual scaling (Tanimura et al. 2006).

}
```

ADEg.S1-class

Class ADEg.S1

Description

An object of ADEg.S1 class represents unidimensional data into one dimension.

The ADEg.S1 class is a virtual class, i.e. a class which is not possible to create objects but which have heirs. This class inherits from ADEg class and has five son classes: S1.boxplot, S1.class, S1.distri, S1.label and S1.match.

Objects from the Class

None object of this class can be instantiated.
Slots

data a list containing data or data’s name.
  • score: the displayed values in the form of a numeric vector, a name or a matching call.
  • at: the index value.
  • frame: a positive or null integer. It is the number of the frame containing the data
    (used with `sys.frame(..., env = data$frame)`). Only if the data are not stored (i.e.
    `data$storeData = FALSE`).
  • storeData: a logical indicating if the data should be stored in the returned object. If
    FALSE, only the names of the data arguments are stored.

trellis.par a list of parameters for lattice call. It will be passed directly to `par.settings`
arguments of the lattice function.

adeg.par a list of graphical parameters, corresponding to the ones given by `adegpar()` function.
lattice.call a list of two elements to create the trellis object:
  • graphictype: `xyplot`
  • arguments: its parameters to obtain the trellis object

g.args a list containing some method parameters linked with the created object of ADEg.S1 class.
stats a list of internal preliminary calculations
s.misc a list of some others internal parameters:
  • hori.update: a logical indicating if the sense of direction of the graphics is updating
  • backgrid: a list of two elements for grid lines. `backgrid$x` defines the coordinates of
    the lines (horizontal or vertical depending on the graphics orientation) and `backgrid$d`
    the grid mesh
  • rug: an index value indicating where the rugs are drawn

Call an object of class call

Extends

Class ADEg, directly.

Methods

prepare signature(object = "ADEg.S1"): performs the calculations before display the object
  (e.g. limits, grid and axis calculations)

setlatticecall signature(object = "ADEg.S1"): prepares the lattice.call slot

panelbase signature(object = "ADEg.S1"): defines the graphical background (e.g. grid, rugs
  and box)

gettrellis signature(object = "ADEg.S1"): converts the graphic into a trellis object of lattice
  class

zoom signature(object = "ADEg.S1", zoom = "numeric", center = "missing"): performs a zoom
  in (if zoom < 1) or out (if zoom > 1) centered, only in one-dimension

zoom signature(object = "ADEg.S1", zoom = "numeric", center = "numeric"): performs a zoom
  in (if zoom < 1) or out (if zoom > 1) around the center passed in parameter, only in one-
  dimension
Note

Various graphical parameters are used for display an ADEg.S1 object. The list p1d in adegpar() is thought specific for ADEg.S1 objects.

The ADEg.S1 class and ADEg.C1 class are both used to represent an unidimensional information (e.g. a score). The difference between these two classes is mainly ideological: an ADEg.S1 object is a representation into one dimension (e.g. one line) while an ADEg.C1 object is a representation into two dimensions (e.g. curves).

ADEg.S2-class

Class ADEg.S2

Description

An object of ADEg.S2 class represents bi-dimensional data.

The ADEg.S2 class is a virtual class, i.e. a class which is not possible to create objects but which have heirs. This class inherits from ADEg class and has eleven son classes: S2.arrow, S2.class, S2.corcircle, S2.density, S2.distri, S2.image, S2.label, S2.logo, S2.match, S2.traject and S2.value.

Objects from the Class

None object of this class can be instantiated.

Slots

data  a list containing data or data’s name.

• dfxy: the displayed values in the form of a data frame, a name or a matching call.
• xax: an integer or a vector indicating the columns of dfxy kept for the x-axes.
• yax: an integer or a vector indicating the columns of dfxy kept for the y-axes.
• frame: a positive or null integer. It is the number of the frame containing the data (used with sys.frame(..., env = data$frame)). Only if the data are not stored (i.e. data$storedData = FALSE).
• storeData: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored.

trellis.par a list of parameters for lattice call. It will be passed directly to par.settings arguments of the lattice function.

deg.par a list of graphical parameters, corresponding to the ones given by adegpar() function.
lattice.call a list of two elements to create the trellis object:
  • graphictype: xyplot
  • arguments: its parameters to obtain the trellis object

g.args a list containing some method parameters linked with the created object of ADEg.S2 class:
  • fullcircle: only for S2.corcircle objects
  • method: only for S2.value objects
  • symbol: only for S2.value objects
  • center: only for S2.value objects
stats a list of internal preliminary calculations
s.misc a list of some others internal parameters:
  • xfullcircle.update and yfullcircle.update: a logical indicating if the circle size is updating (only for S2.corcircle objects)
  • plegend.update: a logical indicating if the legend parameters are updating
  • breaks.update: a logical indicating if the legend breaks are updating
  • backgrid: a list of elements for grid lines

Call an object of class call

Extends

Class ADEg, directly.

Methods

prepare signature(object = "ADEg.S2"): performs the calculations before display the object (e.g. limits, grid and axis calculations)

setlatticecall signature(object = "ADEg.S2"): prepares the lattice.call slot

panelbase signature(object = "ADEg.S2"): defines the graphical background (e.g. grid and box)

gtrellis signature(object = "ADEg.S2"): converts the graphic into a trellis object of lattice class

zoom signature(object = "ADEg.S2", zoom = "numeric", center = "missing"): performs a zoom in (if zoom < 1) or out (if zoom > 1) centered

zoom signature(object = "ADEg.S2", zoom = "numeric", center = "numeric"): performs a zoom in (if zoom < 1) or out (if zoom > 1) around the center passed in parameter (center should be a two-length vector)

addhist signature(object = "ADEg.S2"): adds histograms and density lines against a bi-dimensional graphics

ADEg.T-class

Class ADEg.T

Description
An object of ADEg.T class represents table data.

The ADEg.T class is a virtual class, i.e. a class which is not possible to create objects but which have heirs. This class inherits from ADEg class and has two son classes : T.image and T.value.

Objects from the Class
None object of this class can be instantiated.

Slots
data: a list containing data or data’s name.
  • dftab: the displayed values which can be table, dist or matrix in the form of a data frame, a name or a matching call
  • coordsx: an integer or a vector indicating the columns of dftab kept
  • coordsy: an integer or a vector indicating the rows of dftab kept
  • labelsx: the columns’ labels
  • labelsy: the rows’ labels
  • "frame: a positive or null integer. It is the number of the frame containing the data (used with sys.frame(...,env = data$frame)). Only if the data are not stored (i.e. data$storeData = FALSE).
  • storeData: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored.
trellis.par a list of parameters for lattice call. It will be passed directly to par.settings arguments of the lattice function.
adeg.par a list of graphical parameters, corresponding to the ones given by adegpar() function.
lattice.call a list of two elements to create the trellis object:
• graphictype: xyplot
• arguments: its parameters to obtain the trellis object

g.args a list containing some method parameters linked with the created object of ADEg.T class:
• method: only for T.value objects
• symbol: only for T.value objects
• center: only for T.value objects

stats a list of internal preliminary calculations

s.misc a list of some others internal parameters:
• breaks.update: a logical indicating if the legend breaks is updating
• axes$dx and axes$dy: intervals for the cell size

Description

An object of ADEg.Tr class represents triangular coordinates in 2D.

The ADEg.Tr class is a virtual class, i.e. a class which is not possible to create objects but which have heirs. This class inherits from ADEg class and has three son classes : Tr.class, Tr.label, T.match and T.traject.

Objects from the Class

None object of this class can be instantiated.

Slots

data: a list containing data or data’s name.
  • dfxyz: the displayed values in the form of a data frame with three columns, a name or a matching call.
  • frame: a positive or null integer. It is the number of the frame containing the data (used with sys.frame(...,env = data$frame)). Only if the data are not stored (i.e. data$storeData = FALSE).
  • storeData: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored.

trellis.par a list of parameters for lattice call. It will be passed directly to par.settings arguments of the lattice function.
adeg.par a list of graphical parameters, corresponding to the ones given by adegpar() function.
lattice.call a list of two elements to create the trellis object:
  • graphictype: xyplot
  • arguments: its parameters to obtain the trellis object
g.args a list containing some method parameters linked with the created object of ADEg.Tr class:
  • max3d and min3d: triangular limits
  • adjust: a logical to adjust the device with the limits
stats a list of internal preliminary calculations
s.misc a list of some others internal parameters:
  • adjust.update: a logical indicating if the adjust slot is updating
  • cornerp: coordinates of the triangle extremities.
  • lgrid: a list containing the three coordinates of the grid segments extremities(pts1, pts2, pts3) and the value of the division (posgrid)

Call an object of class call
Extends
Class `ADEg`, directly.

Methods

- **prepare** signature(object = "ADEg.Tr"): performs the calculations before display the object (e.g. limits, grid and axis calculations)
- **setlatticecall** signature(object = "ADEg.Tr"): prepares the `lattice.call` slot
- **panelbase** signature(object = "ADEg.Tr"): defines the graphical background (e.g. triangle and grid)
- **gettrellis** signature(object = "ADEg.Tr"): converts the graphic into a `trellis` object of `lattice` class

See Also

- `adegpar Tr.class Tr.label Tr.match Tr.traject ADEg`

Examples

```r
showClass("ADEg.Tr")
```

Description

`adegpar` can be used to set or query graphical parameters used in `ADEg` object display.
It is inspired by the `par` function of `graphics` package.

Usage

```r
adegpar(...)```

Arguments

- `...`
  - If it is empty, the return value is a named list containing all the current settings.
  - If it is a string of characters, the corresponding sub-list of parameters is returned as information.
  - If it is a list containing keys and values, the corresponding changes in current settings are made.
Details

The graphical parameters control appearance of the graphic. Calls can be made using either a list of list (e.g. `plabels = list(col = "red")`) or a list grouping both keys with ",." (e.g. `plabels.col = "red"`). Parameters are re-used if needed in all ADEg object. If set globally, meaning using adegpar, all created objects afterwards will be affected.

Value

Several parameters are used to create complete plot and accessible through adegpar.

`p1d`: parameters for one-dimension graphic, object of class inherited from "ADEg.S1" or "ADEg.C1"

- `horizontal`: a logical indicating if the plot is horizontal
- `reverse`: a logical indicating if the bottom of the plot is at the bottom (for horizontal as TRUE) or at the left of the device (for horizontal as FALSE). If FALSE, the graphical display bottom is at the top (for horizontal as TRUE) or at the right of the device (for horizontal as FALSE).
- `rug`: a list dedicated to tick marks
  - `draw`: a logical indicating if the rugs are drawn
  - `tck`: size of the rug (ticks) in proportion from the reference line and the origin of the device (0.5 by default)
  - `margin`: where to draw the reference line (0.07 by default)
  - `line`: a logical indicating if the reference line is drawn using `porigin` arguments

`parrows`: arrows' parameters. See `panel.arrows` for more information

- `angle`: angle from the shaft of the arrow to the edge of the arrow head
- `ends`: kind of arrows to be drawn. Can be `first`, `last` or `both`
- `length`: length of the edges of the arrow head

`paxes`: axis' parameters. Mostly inspired by `xyplot` function of lattice package

- `aspectratio`: a character string to control physical aspect ratio of the graphic (drawing panel more specifically). `iso` for isometric scales, `fill` for drawing as big as possible or `xy` for banking rule
- `draw`: a logical indicating if axis (tick marks and labels) are drawn around the graphic
- `x`: a list used for the creation of x-axis in the `trellis` object. See `xyplot` for more information
  - `draw`: a logical indicating if x-axis (tick marks and labels) are drawn around the graphic
- `y`: the same list as for `x` with `draw` parameters

`pbackground`: background's parameters

- `col`: background color
- `box`: a logical indicating if a box is drawn surrounding the plot

`pellipses`: ellipses' drawing parameters

- `alpha`: a value between 0 and 1 controlling ellipses' background transparency
- `axes`: a list dedicated to ellipses' axis
– draw: a logical indicating whether ellipses’ axis are drawn
– col: ellipses’ axis color
– lty: line type of ellipses’ axis
– lwd: line width of ellipses’ axis
• border: ellipses’ border color
• lty: line type of ellipses’ border
• lwd: line width of ellipses’ border
• col: ellipses’ background color

pgrid: grid’s drawing parameters
• draw: a logical indicating if grid is drawn in the background
• col: grid’s line color
• lty: line type of grid line
• lwd: line width of grid line
• nint: an integer indicating the number of grid intervals expected
• text: a list dedicated to grid legend text
  – cex: text size of grid legend
  – col: text color of grid legend
  – pos: a character string (topright, topleft, bottomleft, bottomright) or a vector
    of length 2 indicating text position of grid legend. If it is a vector, the default unit is
    npc (normalized parent coordinates).

plabels: labels’ drawing parameters
• alpha: a value between 0 and 1 controlling label transparency
• cex: labels’ text size
• col: labels’ text color
• srt: labels’ text orientation. It can be horizontal, vertical or an angle indication in
  degrees
• optim: a logical indicating if an algorithm is used to avoid labels’ overlapping or outside
  limits
• boxes: label’s boxes parameters
  – draw: a logical indicating if labels are framed
  – alpha: a value between 0 and 1 controlling labels’ boxes transparency
  – border: boxes’ border color
  – col: boxes’ background color
  – lty: line type of boxes’ border
  – lwd: line width of boxes’ border

plegend: legend’s drawing parameters (used for object of class inherited from T.value and S2.value)
• drawKey: a logical indicating if the legend should be drawn. Legend can be provided by
  the key argument or is automatically generated for *.class and *.value functions
• drawColorKey: a logical indicating if the color legend should be drawn (only for *.image
  functions)
• size: size of the legend

plines: lines’ drawing parameters
• col: lines color
• lty: lines type
• lwd: lines width

pnb: drawing parameters for neighbourhood graph
• edge: edge’s drawing parameters
  – col: edge color
  – lty: line type of edge
  – lwd: line width of edge
• node: node’s drawing parameters
  – pch: node’s symbol type
  – cex: node’s symbol size
  – col: node’s symbol color
  – alpha: a value between 0 and 1 controlling node’s symbol transparency

porigin: drawing parameters for origin’s lines. See panel.lines for more information
• draw: a logical indicating if vertical and horizontal lines are drawn to indicate origin
• include: a logical indicating if origin is included in the drawing limits
• origin: a two-length vector indicating origin coordinates
• alpha: a value between 0 and 1 controlling origin’s lines transparency
• col: color of origin’s lines
• lty: origin’s line type
• lwd: origin’s line width

ppalette: a function taking one integer in argument indicating the number of expecting colors (for example using colorRampPalette)
• quanti: adegpar()$ppalette$quanti(n) returns n colors shaded grey to white
• quali: adegpar()$ppalette$quali(n, name) returns n differentated colors. name argument is passed to the brewer.pal function of the RColorBrewer package and must be Accent, Dark2, Paired, Pastel1, Pastel2, Set1 (the default value), Set2 or Set3. When n is equal to 2, values for ‘white’ and ‘black’ colors are returned and can be not quite visible on the display.

ppoints: points’ drawing parameters
• alpha: a value between 0 and 1 controlling points transparency
• cex: points size
• col: points color
• pch: points type
• fill: points’ background color (only for filled points type)

ppolygons: polygons’ drawing parameters (used for example to draw convex hull for S2.class or Gaussian curves for C1.gauss objects). See lpolygon for more information.
• border: polygon’s border color
• col: polygon’s background color
• lty: line type of polygon border
• lwd: line width of polygon border
• **alpha**: a value between 0 and 1 controlling polygons’ background transparency

**pSp**: drawing parameters for spatial object

• **col**: spatial object’s background color
• **border**: spatial object’s border color
• **lty**: line type of spatial object border
• **lwd**: line width of spatial object border
• **alpha**: a value between 0 and 1 controlling spatial object transparency

**psub**: subtitle’s drawing parameters

• **cex**: text size of subtitle
• **col**: text color of subtitle
• **position**: a character string (topleft, topright, bottomleft, bottomright) or a vector of length 2 indicating text position of subtitle. If it is a vector, the default unit is npc (normalized parent coordinates).
• **text**: the character string to display

**ptable**: for table graphic, object of class inherited from ADEg.T

• **x**: x-axis parameters
  – **srt**: text rotation
  – **pos**: position of the axis. It can be top or bottom. Otherwise axis and labels’ axis are not drawn
  – **tck**: ticks size
  – **adj**: justification of labels

• **y**: same as x list, but for y-axis
  – **str, tck, adj**
  – **pos**: position of the axis. It can be left or right. Otherwise axis and labels’ axis are not drawn

• **margin**: margin surrounding the drawing panel. The numbers indicate the bottom, left, top and right margins. Results are obtained passing margin to padding argument in lattice. Please see layout.heights and layout.widths parameters in lattice package for more information

X <- data.frame(x = runif(50, -1, 2), y = runif(50, -1, 2))
s.label(X)
```
ADEgS

Creation of ADEgS objects

Description

Creates and displays an "ADEgS" object, a set of ADEg, trellis and/or ADEgS objects, managed by superposition, insertion and/or juxtaposition.

Usage

ADEgS(adeglist, positions, layout, add = NULL, plot = TRUE)

Arguments

adeglist a list of several trellis, ADEg and/or ADEgS objects.
positions a matrix with four columns and as many rows as the number of graphical objects in ADEglist slot. For each simple graphic, i.e. in each row, the coordinates of the top-right and the bottom-left hand corners are in npc unit (normalized parent coordinates).
layout a layout indication in two possible forms:
  • a list containing arguments of the layout function
  • a two-length vector containing rows' and columns' number of layout
add a square matrix with as many rows and columns as the number of graphical objects in ADEglist slot. The value at the i-th row and j-th column is equal to 1 whether the j-th graphical object in ADEglist slot is superpose to i-th graphical one. Otherwise, this value is equal to 0.
plot a logical. If the graphics should be displayed

Value

an ADEgS object. If plot = TRUE, the created object is displayed.

```r
xy <- matrix(rnorm(20), ncol = 2)
g1 <- s.label(xy)
g2 <- s.class(xy, fac = as.factor(rep(LETTERS[1:2], length.out = 10)), ppoints.cex = 0, col = c("blue", "red"))
g3 <- adegS(list(g1, g2), rbind(c(0, 0, 0.5, 1), c(0.5, 0, 1, 1))
g4 <- adegS(list(g1, g2), layout = c(2, 1))
g5 <- adegS(list(g1, g2))
g6 <- adegS(list(g1, g2), add = matrix(c(0, 1, 0, 0), byrow = TRUE, ncol = 2))

data(olympic, package = "ade4")
dudi1 <- ade4::dudi.pca(olympic$tab, scan = FALSE)
g7 <- s.arrow(dudi1$li)
g8 <- s.corcircle(dudi1$co, lab = names(olympic$tab))
g9 <- adegS(list(g7, g8), rbind(c(0, 0, 0.5, 1), c(0.5, 0, 1, 1)))
g9[[1]]
g9[1, drop = FALSE]
length(g9)
```

ADEgS-class

Class "ADEgS"

Description

An object of ADEgS class is a complex graphic. This class allows the superposition, the insertion and/or the juxtaposition of several ADEg, trellis and/or ADEgS objects.

The ADEgS class have neither father class nor son classes.

Objects from the Class

ADEgS objects can be created by calls of the form `new("ADEgS","...`.

The regular usage in this package is to use the ADEgS, add.ADEg, superpose, insert or + functions.

Slots

- **ADEglist**: a list of several trellis, ADEg and/or ADEgS objects.
- **positions**: a matrix with four columns and as many rows as the number of graphical objects in the ADEglist slot. For each simple graphic, i.e. in each row, the coordinates of the top-right and the bottom-left hand corners are in npc unit (normalized parent coordinates).
- **add**: a square matrix with as many rows and columns as the number of graphical objects in the ADEglist slot. The value at the i-th row and j-th column is equal to 1 whether the j-th graphical object in the ADEglist slot is superpose to i-th graphical one. Otherwise, this value is equal to 0.
- **Call**: an object of class call
ADEgS-class

Methods

[ signature(x = "ADEgS", i = "numeric", j = "missing", drop = "logical"): extracts the i-th sub-graphics in the x@ADEglist. i can be a vector. If i is a single number and if the extracted graphic in an ADEg object, the sub-selection is in the form of ADEg if drop is TRUE and in the form of ADEgS otherwise.

[ signature(x = "ADEgS", i = "numeric", j = "missing", drop = "missing"): the same than the previous method. drop is FALSE by default

[[ signature(x = "ADEgS", i = "numeric", j = "missing"): extracts one sub-graphic, the i-th one, in the x@ADEglist

[[ signature(x = "ADEgS", i = "character", j = "missing"): extracts one sub-graphic, named i in the x@ADEglist

[[ signature(x = "ADEgS", i = "numeric", j = "missing", value = "ADEg"): replaces one sub-graphic, the i-th one, by an ADEg object in the x@ADEglist

[[ signature(x = "ADEgS", i = "numeric", j = "missing", value = "ADEgS"): replaces one sub-graphic, the i-th one, by an ADEgS object in the x@ADEglist

$ signature(x = "ADEgS"): extracts one sub-graphic by its name in the x@ADEglist

getpositions signature(object = "ADEgS"): returns the positions matrix of the object, i.e. object@positions

getgraphics signature(object = "ADEgS"): returns the list of graphics of the object, i.e. object@ADEglist

getcalls signature(object = "ADEgS"): returns the call of the object, i.e. object@Call

names signature(object = "ADEgS"): returns the graphics’ names of the object, i.e. the names of object@ADEglist

names<- signature(object = "ADEgS"): replaces the graphics’ names of the object, i.e. the names of object@ADEglist

length signature(x = "ADEgS"): returns the number of graphics into x, i.e. the length of x@ADEglist

plot signature(x = "ADEgS"): same as print

print signature(x = "ADEgS"): displays the graphical elements into one device using positions and superposition management (x@add matrix)

show signature(object = "ADEgS"): same as print

superpose signature(g1 = "ADEgS", g2 = "ADEg", which = "numeric", plot = "logical"): creates a new "ADEgS" object performing a superposition of g2 on the which-th ADEg object of g1. This object is printed if plot is TRUE.

superpose signature(g1 = "ADEgS", g2 = "ADEg", which = "numeric", plot = "ANY"): creates a new "ADEgS" object performing a superposition of g2 on the which-th ADEg object of g1. This object is printed only if plot is TRUE.

superpose signature(g1 = "ADEgS", g2 = "ADEg", which = "missing", plot = "ANY"): creates a new "ADEgS" object performing a superposition of g2 on the last ADEg object of g1. This object is printed only if plot is TRUE.

superpose signature(g1 = "ADEgS", g2 = "ADEgS", which = "missing", plot = "ANY"): creates a new "ADEgS" object performing a superposition between two ADEgS having the same length and the same positions slot. It is used when g1 and g2 are both created with a partition of individual groups, variables or analysis’ axis.
signature(e1 = "ADEg", e2 = "ADEgS"): creates a new "ADEgS" object performing a superposition of e1 on e2.

+ signature(e1 = "ADEgS", e2 = "ADEg"): creates a new "ADEgS" object performing a superposition of e2 on e1.

cbindADEg signature(g1 = "ADEgORADEgS", g2 = "ADEgORADEgS"): creates a new "ADEgS" object combining g1 on g2 by columns.

rbindADEg signature(g1 = "ADEgORADEgS", g2 = "ADEgORADEgS"): creates a new "ADEgS" object combining g1 on g2 by rows.

update signature(object = "ADEgS"): modifies the graphical parameters of each sub-graphics listed in object@ADEglist and/or the object's names (with the key word names) and/or the object@positions slot (with the key word positions), after creation of the object. The current display is updated and a modified object is returned.

insert signature(graphics = "ADEgS", oldgraphics = "missing", posi, ratio, inset, plot, which, dispatch): creates a new "ADEgS" object performing an insertion of graphics into the current device.

insert signature(graphics = "ADEgS", oldgraphics = "ADEg", posi, ratio, inset, plot): creates a new "ADEgS" object performing an insertion of graphics into oldgraphics.

insert signature(graphics = "ADEgORtrellis", oldgraphics = "ADEgS", posi, ratio, inset, plot, which): creates a new "ADEgS" object performing an insertion of graphics into oldgraphics.

insert signature(graphics = "ADEgS", oldgraphics = "ADEgS", posi, ratio, inset, plot, which, dispatch): creates a new "ADEgS" object performing an insertion of graphics into oldgraphics.

Examples

showClass("ADEgS")
Slots

data a list containing data or data's name.
  • score: the displayed values in the form of a vector, a factor, a name or a matching call.
  • labels: the labels' names drawn on the top of bars.
  • at: the index value.
  • frame: a positive or null integer. It is the number of the frame containing the data
    (used with sys.frame(..., env = data$frame)). Only if the data are not stored (i.e.
    data$storeData = FALSE).
  • storeData: a logical indicating if the data should be stored in the returned object. If
    FALSE, only the names of the data arguments are stored.

trellis.par a list of parameters for lattice call. It will be passed directly to par.settings
arguments of the lattice function.

adeg.par a list of graphical parameters, corresponding to the ones given by adegpar() function.

lattice.call a list to create the trellis object.

g.args a list containing some method parameters linked with the created object of ADEg.C1 class.

The specific slot for C1.barchart objects is:

  • sort: a logical indicating if score is sorted in ascending order.

stats a list of internal preliminary calculations
s.misc a list of some others internal parameters

Call an object of class call

Extends

Class ADEg.C1, directly.
Class ADEg, by class ADEg.C1, distance 2.
Class ADEgORtrellis, by class ADEg.C1, distance 3.
Class ADEgORADEgORtrellis, by class ADEg.C1, distance 3.

Methods

The methods of the father classes "ADEg.C1" and "ADEg" can be used by inheritance. The specific
methods for C1.barchart are:

prepare signature(object = "C1.barchart"): calls the parent method (prepare for ADEg.C1)
  and modifies some graphical parameters used by default.

panel signature(object = "C1.barchart"): draws bar charts and labels.

**Description**

A class for the creation and display of a numeric score linked by curves. The `C1.curves` allows to deal with multiple scores.

**Objects from the Class**

`C1.curve` objects can be created by calls of the form `new("C1.curve",...)`. The regular usage in this package is to use the `s1d.curve` function.

`C1.curves` objects can be created by calls of the form `new("C1.curves",...)`. The regular usage in this package is to use the `s1d.curves` function. Class `C1.curves` extends `C1.curve` directly.

**Slots**

data a list containing data or data's name.

• score: the displayed values in the form of a vector, a factor, a name or a matching call.
• at: the index value.
• frame: a positive or null integer. It is the number of the frame containing the data (used with `sys.frame(...,env = data$frame)`). Only if the data are not stored (i.e. `data$storeData = FALSE`).
• storeData: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored.

trellis.par a list of parameters for lattice call. It will be passed directly to `par.settings` arguments of the lattice function.

adeg.par a list of graphical parameters, corresponding to the ones given by `adegpar()` function.

lattice.call a list to create the trellis object.

g.args a list containing some method parameters linked with the created object of `ADEg.C1` class.

stats a list of internal preliminary calculations

s.misc a list of some others internal parameters

**Call** an object of class call

**Extends**

Class `ADEg.C1`, directly.
Class `ADEg`, by class `ADEg.C1`, distance 2.
Class `ADEgORtrellis`, by class `ADEg.C1`, distance 3.
Class `ADEgORADEgSORtrellis`, by class `ADEg.C1`, distance 3.
Methods

The methods of the father classes "ADEg.C1" and "ADEg" can be used by inheritance. The specific methods for C1.curve and C1.curves are:

- \texttt{prepare} signature(object = "C1.curve"): calls the parent method (prepare for ADEg.C1) and modifies some graphical parameters used by default.
- \texttt{panel} signature(object = "C1.curve"): draws points and curves.
- \texttt{panel} signature(object = "C1.curves"): draws points and curves.

Description

A class for the creation and display of a numeric score using density curves.

Objects from the Class

C1.density objects can be created by calls of the form \texttt{new("C1.density", ...)}.

The regular usage in this package is to use the \texttt{s1d.density} function.

Slots

data \hspace{1em} a list containing data or data’s name.

- score: the displayed values in the form of a numeric vector, a name or a matching call.
- fac: a factor for \texttt{score} to split in the form of a vector, a factor, a name or a matching call.
- frame: a positive or null integer. It is the number of the frame containing the data (used with \texttt{sys.frame(..., env = data$frame)}). Only if the data are not stored (i.e. \texttt{data$storeData = FALSE}).
- storeData: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored.
trellis.par a list of parameters for lattice call. It will be passed directly to \texttt{par.settings} arguments of the lattice function.

\texttt{adeg.par} a list of graphical parameters, corresponding to the ones given by \texttt{adegpar()} function.

\texttt{lattice.call} a list to create the \texttt{trellis} object.

\texttt{g.args} a list containing some method parameters linked with the created object of \texttt{ADEg.C1} class.

The specific slots for \texttt{C1.density} objects are:

- \texttt{kernel}, \texttt{bandwidth} and \texttt{gridsize}: passed in parameters in \texttt{bkde} function of the \texttt{KernSmooth} package.
- \texttt{fill}: a logical to yield the polygons density curves filled.
- \texttt{col}: a logical, a color or a colors vector to color labels, rugs, lines and polygons.

\texttt{stats} a list of internal preliminary calculations. The specific slot for \texttt{C1.density} objects is:

- \texttt{densit}: the values of density curve calculated for each factor in \texttt{fac} computes with the \texttt{bkde} function of the \texttt{KernSmooth} package.

\texttt{s.misc} a list of some others internal parameters. The specific slot for \texttt{C1.density} objects is:

- \texttt{rug}: an index value indicating where the rugs are drawn

\texttt{Call} an object of class \texttt{call}

\texttt{Extends}

C1.gauss-class Class C1.gauss

Description
A class for the creation and display of a numeric score using gauss’ curves.

Objects from the Class
C1.gauss objects can be created by calls of the form new("C1.gauss",...).
The regular usage in this package is to use the s1d.gauss function.

Slots

- data a list containing data or data’s name.
  - score: the displayed values in the form of a numeric vector, a name or a matching call.
  - fac: a factor for score splitting in the form of a vector, a factor, a name or a matching call.
  - wt: a vector of weights for score
  - frame: a positive or null integer. It is the number of the frame containing the data (used with sys.frame(...,env = data$frame)). Only if the data are not stored (i.e. data$storeData = FALSE).
  - storeData: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored.

- trellis.par a list of parameters for lattice call. It will be passed directly to par.settings arguments of the lattice function.

- adeg.par a list of graphical parameters, corresponding to the ones given by adegpar () function.

- lattice.call a list to create the trellis object.

- g.args a list containing some method parameters linked with the created object of ADEg.C1 class. The specific slots for C1.gauss objects are:
  - fill: a logical to yield the gauss curves transparent.
  - col: a logical, a color or a colors vector to color labels, rugs, lines and polygons.
• steps: a value for the number of segments used to draw Gauss curves.

stats a list of internal preliminary calculations. The specific slots for C1.gauss objects are:
• means: the weighted mean calculated for each fac value.
• var: the weighted variance calculated for each fac value.
• gausscurves: the density gauss curve calculated for each fac value.

s.misc a list of some others internal parameters. The specific slot for C1.gauss objects is:
• rug: an index value indicating where the rugs are drawn

C1.hist-class

Class C1.hist

Description

A class for the creation and display of a numeric score using a histogram.

Objects from the Class

C1.hist objects can be created by calls of the form `new("C1.hist",...)`.

The regular usage in this package is to use the `s1d.hist` function.

Slots

data a list containing data or data's name.

- `score`: the displayed values in the form of a vector, a factor, a name or a matching call.
- `frame`: a positive or null integer. It is the number of the frame containing the data (used with `sys.frame(...,env = data$frame)`). Only if the data are not stored (i.e. `data$storeData = FALSE`).
- `storeData`: a logical indicating if the data should be stored in the returned object. If `FALSE`, only the names of the data arguments are stored.

trellis.par a list of parameters for `lattice` call. It will be passed directly to `par.settings` arguments of the `lattice` function.

adeg.par a list of graphical parameters, corresponding to the ones given by `adegpar()` function.

lattice.call a list to create the `trellis` object.

g.args a list containing some method parameters linked with the created object of `ADEg.C1` class.

The specific slots for `C1.hist` objects are:

- `breaks`: a vector of values to split `score`. If `NULL`, `pretty(score,nclass)` is used.
- `nclass`: an integer for the number of desired intervals, ignored if `breaks` is not missing.
- `type`: a value among `count`, `density`, `percent` to indicate the unit of the cell height.
- `right`: a logical indicating if the histogram cells are right-closed (left open) intervals.

stats a list of internal preliminary calculations. The specific slots for `C1.hist` objects are:

- `heights`: the cell height.
- `breaks`: the cell boundaries.

s.misc a list of some others internal parameters

Call an object of class `call`

Extends

Class `ADEg.C1`, directly.
Class `ADEg`, by class `ADEg.C1`, distance 2.
Class `ADEgORTrellis`, by class `ADEg.C1`, distance 3.
Class `ADEgORADEgSORtrellis`, by class `ADEg.C1`, distance 3.
Methods

The methods of the father classes "ADEg.C1" and "ADEg" can be used by inheritance. The specific methods for C1.hist are:

**prepare** signature(object = "C1.hist"): calls the parent method (prepare for ADEg.C1), modifies some graphical parameters used by default and calculates the boundaries and the height of cells.

**panel** signature(object = "C1.hist"): draws rectangles.

### C1.interval-class

#### Class C1.interval

Description

A class for the creation and display of an interval between two numeric scores.

Objects from the Class

C1.interval objects can be created by calls of the form `new("C1.interval",...)`.

The regular usage in this package is to use the `s1d.interval` function.

Slots

data a list containing data or data’s name.

- score: the displayed values in the form of a vector, a factor, a name or a matching call.
- at: the index value.
- frame: a positive or null integer. It is the number of the frame containing the data (used with `sys.frame(...,env = data$frame)`). Only if the data are not stored (i.e. `data$storeData = FALSE`).
- storeData: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored.

trellis.par a list of parameters for lattice call. It will be passed directly to `par.settings` arguments of the lattice function.
adeg.par  a list of graphical parameters, corresponding to the ones given by adegpar() function.

lattice.call  a list to create the trellis object.

g.args  a list containing some method parameters linked with the created object of ADEg.C1 class.

The specific slot for C1.density objects is:

• method: a value, bars or area, to represent either segments or areas between scores.

stats  a list of internal preliminary calculations

s.misc  a list of some others internal parameters

Call  an object of class call

Extends

Class ADEg.C1, directly.
Class ADEg, by class ADEg.C1, distance 2.
Class ADEgORtrellis, by class ADEg.C1, distance 3.
Class ADEgORADEgSORtrellis, by class ADEg.C1, distance 3.

Methods

The methods of the father classes "ADEg.C1" and "ADEg" can be used by inheritance. The specific methods for C1.interval are:

prepare signature(object = "C1.interval"): calls the parent method (prepare for ADEg.C1) and modifies some graphical parameters used by default.

panel signature(object = "C1.interval"): draws segments or polygons.

Examples

showClass("C1.interval")
cbindADEg  

Combine ADEg objects by columns or rows

Description

Take a sequence of ADEg, ADEgS or trellis arguments and combine by columns or rows, respectively.

Usage

cbindADEg(g1, g2, ..., plot = FALSE)
rbindADEg(g1, g2, ..., plot = FALSE)

Arguments

g1  
an object of class ADEg, ADEgS or trellis

g2  
an object of class ADEg, ADEgS or trellis

...  
other objects of class ADEg, ADEgS or trellis

plot  
a logical indicating if the graphics is displayed

Value

an ADEgS object

Examples

data(jv73, package = "ade4")
pca1 <- ade4::dudi.pca(jv73$morpho, scannf = FALSE)
g1 <- s.label(pca1$li, plabels.optim = TRUE, plot = FALSE)
g2 <- s.class(pca1$li, jv73$fac.riv, starSize = 0, ellipseSize = 0, chullSize = 1,
ppolygons.alpha = 0.4, col = rainbow(12), ppoints.cex = 0, plot = FALSE)
g3 <- s.corcircle(pca1$co, pbackground.box = FALSE, plot = FALSE)
g4 <- rbindADEg(cbindADEg(g1, g2), cbindADEg(superpose(g1, g2), g3), plot = TRUE)
changelatticetheme  

**Change the lattice theme used for adegraphics**

---

**Description**

This function allows to modify the default theme existing for adegraphics objects. The created theme also affects previously created objects.

**Usage**

changelatticetheme(...)

**Arguments**

...  lattice parameters, the same used in trellis.par.set and provided by trellis.par.get. If empty, reset the theme to the adegraphics one.

**Note**

The adegraphics theme removes all margins, sets a transparent background and grey regions. A further development will be the creation of various themes for adegraphics.

**Examples**

```r
if(require(lattice, quietly = TRUE)) {
  show.settings()
  changelatticetheme(list(superpose.symbol = list(pch = c(21, 22, 35), cex = 1)))
  show.settings()
  show.settings()[1]
}
```
### getcall-methods

*Method for ADEg and ADEgS objects*

**Description**

getcall returns the call used to create the object.

**Methods**

signature(object = "ADEg") returns the slot Call of the object ADEg

signature(object = "ADEgS") returns the slot Call of the object ADEgS

**Author(s)**

Alice Julien-Laferriere, Aurelie Siberchicot <aurelie.siberchicot@univ-lyon1.fr> and Stephane Dray

### insert

*Insert a graphic into an existing one*

**Description**

This function inserts a first graphic into a previously created and/or a displayed one.

**Usage**

```r
insert(graphics, oldgraphics, posi = c("bottomleft", "bottomright", "topleft", "topright"), ratio = 0.2, inset = 0.0, plot = TRUE, which, dispatch = FALSE)
```

**Arguments**

- **graphics**: an object of class ADEg, ADEgS or trellis
- **oldgraphics**: an object of class ADEg, ADEgS or missing. If oldgraphics is missing, graphics is added on the current device.
- **posi**: a character value or a two-length numeric vector (in normalized parent coordinates npc from 0 to 1) indicating the position of oldgraphics added into graphics
- **ratio**: a numeric value from 0 to 1 indicating the size of oldgraphics regarding the plot region
- **inset**: the inset from which the graph is drawn regarding the plot region. It can be a two-length vector giving the inset in x and y. If atomic, same inset is used in x and y.
- **plot**: a logical indicating if the graphics is displayed
which a numeric value or a vector of values only used if oldgraphics is an ADEgS object, indicating the which-th sub-graphic of oldgraphics where graphics is added.

dispatch a logical only used if both graphics and oldgraphics are ADEgS objects with same length, indicating if graphics is added one by one into oldgraphics. It is used when both graphics and oldgraphics are created with facets option.

Value

An object of class "ADEgS".

g6 <- s.corcircle(pca1$co, pbackground.box = FALSE, plot = FALSE)
g7 <- insert(g6, g5, posi = c(0.3, 0.4, 0.5, 0.6))
Transform a layout matrix into a position one

Description

This function transforms layout's informations into a position matrix useful for ADEgS and for lattice graphics.

Usage

`layout2position(mat, widths = rep(1, NCOL(mat)), heights = rep(1, NROW(mat)), ng, square = FALSE)`

Arguments

- `mat`: a matrix indicating the location of figures to display (each value must be 0 or a positive integer) or a two-length vector indicating the number of rows and columns in the corresponding layout.
- `widths`: a vector of relative values for the columns' widths on the device. Their sum must be equal to the number of columns.
- `heights`: a vector of relative values for the rows' heights on the device. Their sum must be equal to the number of rows.
- `ng`: a value for the number of positions needed (i.e. the number of graphics to plot).
- `square`: a logical indicating if the graphics is an isometric plot.

Value

A four-columns matrix indicating the coordinates (in normalized parent coordinates npc) of the top-right and bottom-left hand corners of each displayed figure on the device.

Note

This function is strongly inspired by the layout function in graphics package.

```
Methods panel for ADeG objects

Description

The method `panel` displays all specific graphical components.

Methods

- `signature(object = "C1.barchart")` draws bar charts and labels
- `signature(object = "C1.curve")` draws points and curves
- `signature(object = "C1.curves")` draws multiple points and curves
- `signature(object = "C1.density")` draws density curves
- `signature(object = "C1.dotplot")` draws segments and dots
- `signature(object = "C1.gauss")` draws Gauss curves and level names of each curve
- `signature(object = "C1.hist")` draws rectangles
- `signature(object = "C1.interval")` draws segments or polygons
- `signature(object = "S1.boxplot")` draws box-and-wiskers diagrams, mean points and labels
- `signature(object = "S1.class")` draws labels and lines matching with score values
- `signature(object = "S1.distri")` draws mean points and segments with matching labels
- `signature(object = "S1.label")` draws labels and its links with score points
- `signature(object = "S1.match")` draws score points and matching segments and labels
- `signature(object = "S2.arrow")` draws points, arrows and labels
- `signature(object = "S2.class")` draws ellipses, convex hulls, stars, labels and points
- `signature(object = "S2.corcircle")` draws arrows, labels and axes
- `signature(object = "S2.density")` draws densities and external points
- `signature(object = "S2.distri")` draws ellipses, stars, labels and points
- `signature(object = "S2.image")` draws raster image
- `signature(object = "S2.label")` draws points and labels
- `signature(object = "S2.logo")` displays the logos
- `signature(object = "S2.match")` draws arrows and labels
- `signature(object = "S2.traject")` draws points, arrows and labels
- `signature(object = "S2.value")` draws symbols
- `signature(object = "T.cont")` draws mean points and regression lines
- `signature(object = "T.image")` draws raster image
- `signature(object = "T.value")` draws symbols
- `signature(object = "Tr.class")` draws arrows, labels and points
- `signature(object = "Tr.label")` draws lines, labels and points
- `signature(object = "Tr.match")` draws arrows, labels and points
- `signature(object = "Tr.traject")` draws arrows, labels and points

## S3 method for class 'pca'
score(x, xax = 1, which.var = NULL, pos = -1, storeData = TRUE, plot = TRUE, ...)

## S3 method for class 'dudi'
screepplot(x, col.kept = "grey", col = "white", pos = -1, plot = TRUE, ...)

## S3 method for class 'dudi'
biplot(x, pos = -1, plot = TRUE, ...)

### Arguments

- **object, x**: objects used to select a method
- **xax**: an integer (or a vector) indicating which column(s) of object or x is(are) plotted on the x-axis
- **yax**: an integer (or a vector) indicating which column(s) of object or x is(are) plotted on the y-axis
which.tab  a numeric vector (used in kplot.*) containing the numbers of the tables used
for the analysis

option   a string of characters (only used in kplot.mfa) indicating the drawing option:
points plot of the projected scattergram onto the co-inertia axes, axis projections
of inertia axes onto the co-inertia axes, columns projections of variables
onto the synthetic variables planes.

which.graph an integer between 1 and 4 (only used in kplot.pta) indicating the drawing
option. For each table of which.tab, are drawn: 1 the projections of the principal
axes, 2 the projections of the rows, 3 the projections of the columns, 4 the
projections of the principal components onto the planes of the compromise.

permute   a logical value (used in kplot.sepan, kplotsepan.coa and scatter.dudi).
If FALSE, the rows are plotted by points or density surface and the columns by
arrows. If TRUE, it is the opposite.

traject   a logical value (used in kplot.sepan and kplot.statis) indicating whether
the trajectories between rows should be drawn in a natural order

posieig   a character value or a two-length numeric vector (in normalized parent coordi-
nates npc from 0 to 1) or none value indicating the position of the eigenvalues
bar plot (used in kplot.sepan, kplotsepan.coa and scatter.*).

arrow    a logical value (only used in kplot.statis) indicating whether the column
factorial diagrams should be plotted

class    if not NULL, a factor of length equal to the number of the total columns of the
K-tables (only used in kplot.statis)

prop     a logical value (only used in scatter.dudi) indicating if the size of the arrows’
labels is proportional to the analysis score.

density.plot a logical value (only used in scatter.dudi) indicating if the points are displayed
as density surface (using s.density).

method   an integer between 1 and 3 (only used in scatter.coa) indicating the drawing
option. Are drawn: 1 rows and columns with the coordinates of lambda variance,
2 rows variance 1 and columns by averaging, 3 columns variance 1 and rows by
averaging.

which.var the numbers of the kept columns for the analysis, otherwise all columns (used
in score.*)

type     a string of characters (only used in score.acm and score.mix) indicating if
points (points) or boxplot (boxplot) are used to represent levels of factors

col.kept one color value to color the kept axes in the barchart (used in screeplot.dudi)

col      one color value to color the axes in the barchart (used in screeplot.dudi)

plot     a logical indicating if the graphics is displayed

storeData a logical indicating if the data should be stored in the returned object. If FALSE,
only the names of the data arguments are stored

pos      an integer indicating the position of the environment where the data are stored,
relative to the environment where the function is called. Useful only if storeData is
FALSE

... additional graphical parameters (see adegpar and trellis.par.get)
plot.inertia

Value

Returns an ADEg or an ADEgS object. The result is displayed if plot is TRUE.

plot.inertia

Display the decomposition of inertia which measure the contributions of rows/columns in mutivariate methods

Description

S3 method to display the decomposition of inertia (inertia object) which measure the contributions of rows/columns in mutivariate methods (dudi objects from ade4)

Usage

## S3 method for class 'inertia'
plot(x, xax = 1, yax = 2, threshold = 0.1, contrib = c("abs", "rel"), type = c("label", "cross", "ellipse", "both"), ellipseSize = 1.5, posieig = "none", plot = TRUE, storeData = TRUE, pos = -1, ...)
## S3 method for class 'inertia'
score(x, xax = 1, threshold = 0.1, contrib = c("abs", "rel"), posieig = "none", pos = -1, storeData = TRUE, plot = TRUE, ...)

Arguments

x an object of the dudi class; it must be the output of a correspandence analysis (coa object).
xax an integer indicating which column of x is plotted on the x-axis
yax an integer indicating which column of x is plotted on the y-axis. If yax is equal to xax, a one-dimensional graph is display.
threshold

threshold is a numeric value containing the contribution threshold (between 0 and 1) at which points should be drawn on the graphic. Low contribution points will be represented by a grey point and without label. When the contributions are displayed on a single axis, a dotted line describes the contribution threshold.

contrib

contrib is a character value indicating which contributions are plotted: abs for absolute contributions (rows/columns involved in the factor axis/map construction) and rel for relative contribution (quality of rows/columns representation on the factor axis/map).

type

type is a character value indicating which type represents contribution. Labels size (label), crosses size(cross) or ellipses size (ellipse) can be proportional to the contributions. If type is both, crosses and ellipses both have sizes proportional to the contributions.

ellipseSize

ellipseSize is a positive number for ellipse size when type is ellipse

posieig

posieig is a character value or a two-length numeric vector (in normalized parent coordinates npc from 0 to 1) or none value indicating the position of the eigenvalues bar plot.

plot

plot is a logical indicating if the graphics is displayed

storeData

storeData is a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored

pos

pos is an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if storeData is FALSE

...

additional graphical parameters (see adegpar and trellis.par.get)

Value

Returns an ADEgS object. The result is displayed if plot is TRUE.

  pellipse.col = "purple", pellipses.border = "black")
```

---

**plotEig**

*Plot a barchart of eigen values*

**Description**

This function represents a simplified barchart adapted to display eigen values. The bar color depends on whether the axis is displayed, kept or not.

**Usage**

```r
plotEig(eigvalue, nf, xax = 1, yax = 2, col.plot = "black", col.kept = "grey",
  col = "white", facets = NULL, plot = TRUE, storeData = FALSE, pos = -1, ...)
```
plotEig

Arguments

- **eigvalue**: a numeric vector of eigenvalues
- **nf**: the number of retained factors, NULL if not provided
- **xax**: an integer indicating which factor is plotted on the x-axis
- **yax**: an integer indicating which factor is plotted on the y-axis
- **col.plot**: a color value to fill the bar corresponding to the displayed factors
- **col.kept**: a color value to fill the bar corresponding to the kept by not displayed factors
- **col**: a color value to fill the bar corresponding to the other factors
- **facets**: a factor splitting the rows of dfxy so that subsets of the data are represented on different sub-graphics
- **plot**: a logical indicating if the graphics is displayed
- **storeData**: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored
- **pos**: an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if storeData is FALSE
- **...**: additional graphical parameters (see adegpar and trellis.par.get)

Details

Graphical parameters for bars are available in ppolylgons of adegpar. Some appropriated graphical parameters in p1d are also available.

Value

An object of class ADEg (subclass C1.barchart).

The result is displayed if plot is TRUE.

C1.barchart ADEg.C1

Examples

```r
data(microsatt, package = "ade4")
w <- ade4::dudi.coa(data.frame(t(microsatt$tab)), scann = FALSE, nf = 3)
g1 <- s.label(w$co, plot = FALSE)
g2 <- plotEig(w$eig, w$nf, psub = list(text = "Eigenvalues"), pbackground = list(box = TRUE),
plot = FALSE)
G <- insert(g2, g1, posi = "bottomright", ratio = 0.25)
```
Description

The method prepare performs the first calculus needed for the display.

Methods

signature(object = "ADEg.C1") performs the calculations before display the object (e.g. limits, grid and axis calculations)

signature(object = "C1.barchart") calls the parent method (prepare for ADEg.C1) and modifies some graphical parameters used by default

signature(object = "C1.curve") calls the parent method (prepare for ADEg.C1) and modifies some graphical parameters used by default

signature(object = "C1.density") calls the parent method (prepare for ADEg.C1), modifies some graphical parameters used by default and calculates the density curves according to the numeric score and the values' categories

signature(object = "C1.dotplot") calls the parent method (prepare for ADEg.C1) and modifies some graphical parameters used by default

signature(object = "C1.gauss") calls the parent method (prepare for ADEg.C1), modifies some graphical parameters used by default and calculates the Gauss curves according to the numeric score and the values' categories (using weighted mean and standard deviation)

signature(object = "C1.hist") calls the parent method (prepare for ADEg.C1), modifies some graphical parameters used by default and calculates the boundaries and the height of cells

signature(object = "C1.interval") calls the parent method (prepare for ADEg.C1) and modifies some graphical parameters used by default

signature(object = "ADEg.S1") performs the calculations before display the object (e.g. limits, grid and axis calculations)

signature(object = "S1.boxplot") calls the parent method (prepare for ADEg.S1) and modifies some graphical parameters used by default

signature(object = "S1.class") calls the parent method (prepare for ADEg.S1) and modifies some graphical parameters used by default

signature(object = "S1.distri") calls the parent method (prepare for ADEg.S1), modifies some graphical parameters used by default and calculates weighted mean and standard deviation

signature(object = "S1.label") calls the parent method (prepare for ADEg.S1) and modifies some graphical parameters used by default

signature(object = "S1.match") calls the parent method (prepare for ADEg.S1) and modifies some graphical parameters used by default

signature(object = "ADEg.S2") performs the calculations before display the object (e.g. limits, grid and axis calculations)
signature(object = "S2.arrow") calls the parent method (prepare for ADEg.S2), modifies some graphical parameters used by default and calculates limits.

signature(object = "S2.class") calls the parent method (prepare for ADEg.S2), modifies some graphical parameters used by default and calculates limits, convex hulls and centroids.

signature(object = "S2.corcircle") calls the parent method (prepare for ADEg.S2), modifies some graphical parameters used by default and prepares the drawn grid.

signature(object = "S2.density") calls the parent method (prepare for ADEg.S2), modifies some graphical parameters used by default and calculates densities.

signature(object = "S2.distri") calls the parent method (prepare for ADEg.S2), modifies some graphical parameters used by default and calculates ellipses and centroids.

signature(object = "S2.image") calls the parent method (prepare for ADEg.S2), modifies some graphical parameters used by default and calculates grid expansion and limits.

signature(object = "S2.label") calls the parent method (prepare for ADEg.S2) and modifies some graphical parameters used by default.

signature(object = "S2.logo") calls the parent method (prepare for ADEg.S2) and modifies some graphical parameters used by default.

signature(object = "S2.match") calls the parent method (prepare for ADEg.S2) and modifies some graphical parameters used by default.

signature(object = "S2.traject") calls the parent method (prepare for ADEg.S2) and modifies some graphical parameters used by default.

signature(object = "S2.value") calls the parent method (prepare for ADEg.S2), modifies some graphical parameters used by default and calculates limits.

signature(object = "ADEg.T") performs the calculations before display the object (e.g. limits, grid and axis calculations).

signature(object = "T.image") calls the parent method (prepare for ADEg.T) and modifies some graphical parameters used by default and calculates limits and grid.

signature(object = "T.value") calls the parent method (prepare for ADEg.T) and modifies some graphical parameters used by default and calculates limits and grid.

signature(object = "ADEg.Tr") performs the calculations before display the object (e.g. limits, grid and axis calculations).

signature(object = "Tr.class") calls the parent method (prepare for ADEg.Tr), modifies some graphical parameters used by default and calculated ellipses, convex hulls and centroids.

signature(object = "Tr.label") calls the parent method (prepare for ADEg.Tr) and modifies some graphical parameters used by default.

signature(object = "Tr.match") calls the parent method (prepare for ADEg.Tr), modifies some graphical parameters used by default and defines the mean point and the axis.

signature(object = "Tr.traject") calls the parent method (prepare for ADEg.Tr) and modifies some graphical parameters used by default.

s.arrow 2-D scatter plot with arrows

Description
This function represents a two dimensional scatter plot with arrows linking points to the origin.

Usage
s.arrow(dfxy, xax = 1, yax = 2, labels = row.names(as.data.frame(dfxy)),
facets = NULL, plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, ...)

Arguments
dfxy a data frame used to produce the plot
xax an integer (or a vector) indicating which column(s) of dfxy is(are) plotted on
      the x-axis
yax an integer (or a vector) indicating which column(s) of dfxy is(are) plotted on
      the y-axis
labels a character vector containing labels for arrows
facets a factor splitting the rows of dfxy so that subsets of the data are represented on
        different sub-graphics
plot a logical indicating if the graphics is displayed
storeData a logical indicating if the data are stored in the returned object. If FALSE, only
          the names of the data arguments are stored
add a logical. If TRUE, the graphic is superposed to the graphics already plotted in
      the current device
pos an integer indicating the position of the environment where the data are stored,
      relative to the environment where the function is called. Useful only if storeData
      is FALSE
... additional graphical parameters (see adegpar and trellis.par.get)

Details
An other origin for arrows can be specified using an adegpar parameters: porigin. Graphical
parameters for points and arrows are available in parrows and ppoints of adegpar.

Value
An object of class ADEg (subclass S2.arrow) or ADEgS (if add is TRUE and/or if facets or vectors for
xax/yax are used).
The result is displayed if plot is TRUE.
s.class

2-D scatter plot with a partition in classes (levels of a factor)

Description

This function represents a two dimensional scatter plot grouping points to the same class. Classes are represented by ellipses, stars and/or convex hulls.

Usage

```r
s.class(dfxy, fac, xax = 1, yax = 2, wt = rep(1, NROW(fac)), labels = levels(fac),
        ellipseSize = 1.5, starSize = 1, chullSize = NULL, col = NULL, facets = NULL,
        plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, ...)
```

Arguments

- `dfxy`: a data frame used to produce the plot
- `fac`: a factor (or a matrix of factors) splitting the rows of `dfxy`
- `xax`: an integer (or a vector) indicating which column(s) of `dfxy` is(are) plotted on the x-axis
- `yax`: an integer (or a vector) indicating which column(s) of `dfxy` is(are) plotted on the y-axis
- `wt`: a vector of weights for `fac`
- `labels`: a character vector containing the class' labels
ellipseSize  a positive number for ellipse size
starSize    a number between 0 and 1 for the size of the stars segments joining the stars’ center (centroids) and the matching points
chullSize   NULL or a vector of numbers between 0 and 1 for the fraction of points included in the convex hull
col         a color or a colors vector to color points, ellipses, labels, lines and polygons
facets      a factor splitting the rows of dfxy so that subsets of the data are represented on different sub-graphics
plot        a logical indicating if the graphics is displayed
storeData   a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored
add         a logical. If TRUE, the graphic is superposed to the graphics already plotted in the current device
pos         an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if storeData is FALSE

Details

Graphical parameters for ellipses, stars and convex hulls are available in pellipses, plines and ppolygons of adegpar.

Value

An object of class ADEg (subclass S2.class) or ADEgS (if add is TRUE and/or if facets or multidimensional fac or vectors for xax/yax are used). The result is displayed if plot is TRUE.

s.corcircle  Correlation circle

Description

This function produces a correlation circle.

Usage

s.corcircle(dfxy, xax = 1, yax = 2, labels = row.names(as.data.frame(dfxy)),
fullcircle = TRUE, facets = NULL, plot = TRUE, storeData = TRUE,
add = FALSE, pos = -1, ...)

Arguments

dfxy a data frame used to produce the plot
labels a vector containing the points’ labels
xax an integer (or a vector) indicating which column(s) of dfxy is(are) plotted on
the x-axis
yax an integer (or a vector) indicating which column(s) of dfxy is(are) plotted on
the y-axis
fullcircle  a logical to include the complete circle (limits are then c(-1, 1))
facets   a factor splitting the rows of dfxy so that subsets of the data are represented on
different sub-graphics
plot    a logical indicating if the graphics is displayed
storeData a logical indicating if the data should be stored in the returned object. If FALSE,
only the names of the data arguments are stored
add     a logical. If TRUE, the graphic is superposed to the graphics already plotted in
the current device
pos     an integer indicating the position of the environment where the data are stored,
relative to the environment where the function is called. Useful only if storeData
is FALSE
... additional graphical parameters (see adepar and trellis.par.get)

Value

An object of class ADEg (subclass S2.corcircle) or ADEgS (if add is TRUE and/or if facets or vectors
for xax/yax are used).
The result is displayed if plot is TRUE.

Author(s)

Alice Julien-Laferriere, Aurelie Siberchicot <aurelie.siberchicot@univ-lyon1.fr> and Stephane Dray

S2.corcircle ADEg.S2

Examples

data (olympic, package = "ade4")
dudi1 <- ade4::dudi.pca(olympic$tab, scannf = FALSE)
g1 <- s.corcircle(dudi1$co)
g2 <- s.corcircle(dudi1$co, fullcircle = FALSE, pback.col = "grey")

s.density  2-D scatter plot with kernel density estimation

Description

This function represents a two dimensional scatter plot of points distribution. Densities’ representa-
tion is based on the levelplot graphic in lattice (density’s surface, filled with colors and/or
contour lines).
Usage

s.density(dfxy, xax = 1, yax = 2, bandwidth = NULL, gridsize = c(450L, 450L),
          nrpoints = 300, threshold = 0.1, col = NULL, contour = FALSE, region = !contour,
          nclass = 8, facets = NULL, plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, ...)

Arguments

dfxy           a data frame used to produce the plot
xax            an integer (or a vector) indicating which column(s) of dfxy is(are) plotted on
               the x-axis
yax            an integer (or a vector) indicating which column(s) of dfxy is(are) plotted on
               the y-axis
bandwidth      bandwidth for density calculations which is passed in parameters in the bkde2d
               function of the KernSmooth package
gridsize       grid dimension
nrpoints       number of points on the density image
threshold      a value between 0 and 1 to draw densities greater than this threshold. No density
               is visible whether it is equal to 1
col            a color or a colors vector to color densities
contour        a logical to draw contour lines
region         a logical to fill grid regions with col
nclass         number of class for density
facets         a factor splitting the rows of dfxy so that subsets of the data are represented on
               different sub-graphics
plot           a logical indicating if the graphics is displayed
storeData      a logical indicating if the data should be stored in the returned object. If FALSE,
               only the names of the data arguments are stored
add            a logical. If TRUE, the graphic is superposed to the graphics already plotted in
               the current device
pos            an integer indicating the position of the environment where the data are stored,
               relative to the environment where the function is called. Useful only if storeData
               is FALSE
...            additional graphical parameters (see adegpar and trellis.par.get)

Details

Density calculation is made using the kde2d function of the KernSmooth package.

Value

An object of class ADEg (subclass S2.density) or ADEgS (if add is TRUE and/or if facets or vectors
for xax/yax are used).

The result is displayed if plot is TRUE.
s.distri

An algorithm is a two-dimensional scatter plot with means/standard deviations computed using an external table of weights.

Usage

s.distri(dfxy, dfdistri, xax = 1, yax = 2, starSize = 1, ellipseSize = 1.5, col = NULL, facets = NULL, plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, ...)

Arguments

dfxy a data frame used to produce the plot
dfdistri a data frame containing the mass distribution in columns
xax an integer (or a vector) indicating which column(s) of dfxy is(are) plotted on the x-axis
yax an integer (or a vector) indicating which column(s) of dfxy is(are) plotted on the y-axis
starSize NULL or number between 0 and 1 for the size of the stars segments joining the stars' center (centroids) and the matching points
ellipseSize NULL or number between 0 and 1 for ellipse size
col a color or a colors vector to color points, ellipses, labels, lines and polygons
facets a factor splitting the rows of dfxy so that subsets of the data are represented on different sub-graphics

Examples

xx2 <- c(rnorm(50000, 1, 1), rnorm(50000, -1, 1))
yy2 <- c(rnorm(50000, -1, 0.5), rnorm(50000, 1, 0.5))
s.density(cbind(xx2, yy2), paxes.draw = TRUE, gridsize = c(200, 200), region = TRUE, contour = TRUE, plabels.cex = 0, threshold = 0.05, nclass = 3, col = colorRampPalette(c("lightgrey", "black"))(100))

Description

This function represents a two dimensional scatter plot of a frequency distribution. Class are defined by ellipses and/or stars.
plot a logical indicating if the graphics is displayed
storeData a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored
add a logical. If TRUE, the graphic is superposed to the graphics already plotted in the current device
pos an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if storeData is FALSE
... additional graphical parameters (see adegpar and trellis.par.get)

Value

An object of class ADEg (subclass S2.distri) or ADEgS (if add is TRUE and/or if facets or vectors for xax/yax are used).
The result is displayed if plot is TRUE.

---

s.image 2-D scatter plot with loess estimation of an additional numeric score (levelplot)

Description

This function represents a two dimensional scatter plot with a continuous convex colored surface and/or contour lines representing a third variable.
Usage

s.image(dfxy, z, xax = 1, yax = 2, span = 0.5, gridsize = c(80L, 80L),
contour = TRUE, region = TRUE, outsideLimits = NULL, breaks = NULL,
nclass = 8, col = NULL, facets = NULL,
plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, ...)

Arguments

dfxy a data frame used to produce the plot
z a vector (or a matrix) of values on the dfxy rows
xax an integer (or a vector) indicating which column(s) of dfxy is(are) plotted on
the x-axis
yax an integer (or a vector) indicating which column(s) of dfxy is(are) plotted on
the y-axis
span a value to control the degree of smoothing
gridsize a 1 or 2-length vector indicating the cell numbers (horizontally and vertically)
of the grid for the colored surface
contour a logical to draw contour lines
region a logical to fill inter-contour regions
breaks a vector of values to split z. If NULL, pretty(z, nclass) is used.
nclass an integer for the number of desired intervals, ignored if breaks is not missing.
outsideLimits specific limits for the surface as a set of polygons. It must be an SpatialPolygons
object. Hole are authorized.
col a color or a colors vector used for the colored cells
facets a factor splitting the rows of dfxy so that subsets of the data are represented on
different sub-graphics
plot a logical indicating if the graphics is displayed
storeData a logical indicating if the data should be stored in the returned object. If FALSE,
only the names of the data arguments are stored
add a logical. If TRUE, the graphic is superposed to the graphics already plotted in
the current device
pos an integer indicating the position of the environment where the data are stored,
relative to the environment where the function is called. Useful only if storeData
is FALSE
... additional graphical parameters (see adegpar and trellis.par.get)

Value

An object of class ADEg (subclass S2.image) or ADEgS (if add is TRUE and/or if facets or multi-
dimensional z or vectors for xax/yax are used).
The result is displayed if plot is TRUE.
s.label

2-D scatter plot with labels

Description

This function represents a two dimensional scatter plot associating labels with points.

Examples

```r
df1 <- data.frame(expand.grid(-3:3, -3:3))
names(df1) <- c("x", "y")
z1 <- (1 / sqrt(2)) * exp(-(df1$x^2 + df1$y^2) / 2)
g1 <- s.image(df1, z1)

# add a continuous color bar as legend
# update(g1, plegend.drawColorKey = TRUE)

g2 <- s.image(df1, z1, gridsize = 50)

g3 <- s.image(df1, z1, gridsize = 100)
## g4 <- s.image(df1, z1, gridsize = 1000, plot = FALSE)
## Not run:
if(require(splancs, quietly = TRUE) & require(sp, quietly = TRUE)) {
  Sr1 <- Polygon(cbind(c(0, 1, 2, 1, 2, 0, -2, -1, -2, -1, 0),
                      c(2.5, 1.5, 2, 0, -2, -1, -2, 0, 2, 1.5, 2.5)))
  Sr2 <- Polygon(cbind(c(-0.5, 0.5, 0.5, -0.5, -0.5, c(0, 0, 1 ,1, 0)), hole = TRUE)
  Srs2 <- Polygons(list(Sr1, Sr2), ID = "star and hole")
  SPP <- SpatialPolygons(list(Srs2))
  df2 <- cbind(c(rnorm(2000, 1, 0.25), rnorm(3000, -1, 1.5)),
                c(rnorm(2000, 1, 0.5), rnorm(3000, -1, 3)))
  zz2 <- c(rnorm(2000, 12, 1), rnorm(3000, 1, 2))
  g5 <- s.image(df2, zz2, outsideLimits = SPP, grid = 200, xlim = c(-2.5, 2.5),
                ylim = c(-2, 3), ppalette.quanti = colorRampPalette(c(grey(0.1), grey(0.9))))
  data(t3012, package = "ade4")
  g6 <- s.image(t3012$xy, ade4::scalewt(t3012$temp), porigin.include = FALSE)
  g7 <- s.image(t3012$xy, ade4::scalewt(t3012$temp), outsideLimits = t3012$Spatial,
                Sp = t3012$Spatial)
}
## End(Not run)
```
Usage
s.label(dfxy, labels = rownames(dfxy), xax = 1, yax = 2,
facets = NULL, plot = TRUE, storeData = TRUE, add = FALSE,
pos = -1, ...)

Arguments
dfxy          a data frame used to produce the plot
labels        a vector of character strings for the points’ labels
xax           an integer (or a vector) indicating which column(s) of dfxy is(are) plotted on
              the x-axis
yax           an integer (or a vector) indicating which column(s) of dfxy is(are) plotted on
              the y-axis
facets        a factor splitting the rows of dfxy so that subsets of the data are represented on
different sub-graphics
plot          a logical indicating if the graphics is displayed
storeData     a logical indicating if the data should be stored in the returned object. If FALSE,
              only the names of the data arguments are stored
add           a logical. If TRUE, the graphic is superposed to the graphics already plotted in
              the current device
pos           an integer indicating the position of the environment where the data are stored,
              relative to the environment where the function is called. Useful only if storeData
              is FALSE
...           additional graphical parameters (see adegpar and trellis.par.get)

Value
An object of class ADEg (subclass S2.label) or ADEgS (if add is TRUE and/or if facets or vectors for
xax/yax are used).
The result is displayed if plot is TRUE.

s.logo

2-D scatter plot with logos (bitmap objects)

Description
This function represents a two dimensional scatter plot associating logos with points.

Usage
s.logo(dfxy, logos, xax = 1, yax = 2, facets = NULL,
       plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, ...)

Arguments
dfxy   a data frame used to produce the plot
logos  a list containing the picture to use for each point
xax    an integer (or a vector) indicating which column(s) of dfxy is(are) plotted on
        the x-axis
yax    an integer (or a vector) indicating which column(s) of dfxy is(are) plotted on
        the y-axis
facets a factor splitting the rows of dfxy so that subsets of the data are represented on
different sub-graphics
plot   a logical indicating if the graphics is displayed
storeData a logical indicating if the data should be stored in the returned object. If FALSE,
only the names of the data arguments are stored
add    a logical. If TRUE, the graphic is superposed to the graphics already plotted in
        the current device
pos    an integer indicating the position of the environment where the data are stored,
        relative to the environment where the function is called. Useful only if storeData
        is FALSE
...   additional graphical parameters (see adegpar and trellis.par.get)
Value

An object of class ADEg (subclass S2.logo) or ADEgS (if add is TRUE and/or if facets or vectors for xax/yax are used).
The result is displayed if plot is TRUE.

  pgrid.draw = FALSE)

s.match

2-D scatter plot of the matching between two sets of coordinates

Description

This function represents a two dimensional scatter plot linking paired coordinates.

Usage

s.match(dfxy1, dfxy2, xax = 1, yax = 2, labels = row.names(as.data.frame(dfxy1)), arrows = TRUE,
  facets = NULL, plot = TRUE, storeData = TRUE,
  add = FALSE, pos = -1, ...)
Arguments

- **dfxy1**: a data frame, the first system of coordinates, used to produce the plot.
- **dfxy2**: a data frame, the second system of coordinates, with as many rows as **dfxy1**, used to produce the plot.
- **labels**: a vector of character strings containing the matches’ labels.
- **xax**: an integer (or a vector) indicating which column(s) of **dfxy** is(are) plotted on the x-axis.
- **yax**: an integer (or a vector) indicating which column(s) of **dfxy** is(are) plotted on the y-axis.
- **arrows**: a logical to draw arrows.
- **facets**: a factor splitting the rows of **dfxy** so that subsets of the data are represented on different sub-graphics.
- **plot**: a logical indicating if the graphics is displayed.
- **storeData**: a logical indicating if the data should be stored in the returned object. If **FALSE**, only the names of the data arguments are stored.
- **add**: a logical. If **TRUE**, the graphic is superposed to the graphics already plotted in the current device.
- **pos**: an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if **storeData** is **FALSE**.
- **...**: additional graphical parameters (see adegpar and trellis.par.get).

Value

An object of class ADEg (subclass S2.match) or ADEgS (if **add** is **TRUE** and/or if facets or vectors for xax/yax are used).

The result is displayed if **plot** is **TRUE**.

coin1 <- ade4::coinertia(dudi1, dudi2, scannf = FALSE, nf = 2)
g2 <- s.match(dfxy1 = coin1$mX, dfxy2 = coin1$mY)

---

### s.Spatial

 Mapping of a Spatial* object

---

**Description**

This function represents a background map linked with data or not.

**Usage**

```r
s.Spatial(spObj, col = TRUE, nclass = 5, scale = TRUE, plot = TRUE,
          storeData = TRUE, pos = -1, ...)
```

**Arguments**

- `spObj`: an object deriving from class Spatial (package sp)
- `col`: a logical or a color to fill the background color of `spObj`
- `nclass`: if `spObj` contains data, the desired number of intervals splitting the data (using `pretty`)
- `scale`: a logical indicating if numeric variables should be scaled
- `plot`: a logical indicating if the graphics is displayed
- `storeData`: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored
- `pos`: an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if `storeData` is FALSE
- `...`: additional graphical parameters (see `adegpar` and `trellis.par.get`)

**Value**

An object of class ADEg (subclass S2.label) or ADEgS (if `spObj` contains more than one column). The result is displayed if `plot` is TRUE.

**Author(s)**

Alice Julien-Laferriere, Aurelie Siberchicot <aurelie.siberchicot@univ-lyon1.fr> and Stephane Dray

s.traject

Examples

```r
data(elec88, package = "ade4")
## mapping without data
g1 <- s.Spatial(elec88$Spatial)

## Not run:
if(require(sp, quietly = TRUE)) {
## mapping with data
obj <- SpatialPolygonsDataFrame(Sr = elec88$Spatial, data = elec88$tab)
g2 <- s.Spatial(obj)
g3 <- s.Spatial(obj, nclass = 2, col = c("red", "blue"))
}
## End(Not run)
```

s.traject 2-D scatter plot with trajectories

Description

This function represents a two dimensional scatter plot with trajectories.

Usage

```r
s.traject(dfxy, fac = gl(1, nrow(dfxy)), order, labels = levels(fac),
xax = 1, yax = 2, col = NULL, facets = NULL, plot = TRUE,
storeData = TRUE, add = FALSE, pos = -1, ...)
```

Arguments

- `dfxy` a data frame used to produce the plot
- `fac` a factor (or a matrix of factors) splitting the rows of `dfxy`
- `order` a vector containing the drawing order of the trajectories. A vector of length equal to factor.
- `labels` a vector of character strings containing the trajectories’ labels
- `xax` an integer (or a vector) indicating which column(s) of `dfxy` is(are) plotted on the x-axis
- `yax` an integer (or a vector) indicating which column(s) of `dfxy` is(are) plotted on the y-axis
- `col` a color or a colors vector to color points, labels and lines
- `facets` a factor splitting the rows of `dfxy` so that subsets of the data are represented on different sub-graphics
- `plot` a logical indicating if the graphics is displayed
- `storeData` a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored
add  a logical. If TRUE, the graphic is superposed to the graphics already plotted in the current device

pos  an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if storeData is FALSE

... additional graphical parameters (see adegpar and trellis.par.get)

Details

The fac factor is used to display several trajectories: each level of fac is a specific trajectory.

Value

An object of class ADEg (subclass S2.traject) or ADEgS (if add is TRUE and/or if facets or multidimensional fac or vectors for xax/yax are used).

The result is displayed if plot is TRUE.

Examples

```r
rw <- function(a) {
  x <- 0
  for(i in 1:49) x <- c(x, x[length(x)] + runif(1, -1, 1))
  x
}
x1 <- unlist(lapply(1:5, rw), use.names = FALSE)
y1 <- unlist(lapply(1:5, rw), use.names = FALSE)
z1 <- gl(5, 50)
g1 <- s.traject(data.frame(x1, y1), z1, ppoints.pch = 19:23, plines.col = rainbow(5))
x2 <- unlist(lapply(1:2, rw), use.names = FALSE)
y2 <- unlist(lapply(1:2, rw), use.names = FALSE)
z2 <- gl(2, 50)
g2 <- s.traject(data.frame(x2, y2), z2, ppoints.pch = 21:20, plines.col = 1:2)
```
s.value 2-D scatter plot with proportional symbols (bubble plot)

Description
This function represents a two dimensional scatter plot with a third value represented by symbols.

Usage
s.value(dfxy, z, breaks = NULL, xax = 1, yax = 2, method = c("size", "color"), symbol = c("square", "circle", "diamond", "uptriangle", "downtriangle"), col = NULL, nclass = 4, center = 0, centerpar = NULL, facets = NULL, plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, ...)

Arguments
dfxy a data frame used to produce the plot
z a vector (or a matrix) with as many values as rows in dfxy
breaks a vector containing the breaks used for splitting z value. If NULL, pretty(z,n) is used.
xax an integer (or a vector) indicating which column(s) of dfxy is(are) plotted on the x-axis
yax an integer (or a vector) indicating which column(s) of dfxy is(are) plotted on the y-axis
method color or size value for represent z. If color, a palette of color is used for the symbols (one color per interval). If size, symbols of proportional area are used. Area is 0 for values equals to center (default 0). Two colors are used, for values less than center and larger than center.
symbol value for symbol type
col a color or a colors vector to color symbols. If method is size, a 2-length vector of color is expected. If method is color, it must have as many colors as the number of class.
nclass an integer for the number of desired intervals, ignored if breaks is not missing.
center a center value for method size
centerpar a logical or a list to represent center value using elements in the adegpar("ppoints") list
facets a factor splitting the rows of dfxy so that subsets of the data are represented on different sub-graphics
plot a logical indicating if the graphics is displayed
storeData a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored
add a logical. If TRUE, the graphic is superposed to the graphics already plotted in the current device
pos  
an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if storeData is FALSE

...  
additional graphical parameters (see adegpar and trellis.par.get)

Value

An object of class ADEg (subclass S2.value) or ADEgS (if add is TRUE and/or if facets or multidimensional z or vectors for xax/yax are used). The result is displayed if plot is TRUE.

Note

For the symbol size, if the method is size, we use perceptual scaling (Tanimura et al. 2006).

Description

A class for the representation of the link between a variable and a qualitative variable using box-and-whisker plots.

Objects from the Class

S1.boxplot objects can be created by calls of the form new("S1.boxplot","...").

The regular usage in this package is to use the s1d.boxplot function.

Slots

data  a list containing data or data’s name.
  • score: the displayed values in the form of a numeric vector, a name or a matching call.
  • fac: a factor for score splitting in the form of a vector, a factor, a name or a matching call.
  • at: the index value.
  • frame: a positive or null integer. It is the number of the frame containing the data (used with sys.frame(...,env = data$frame)). Only if the data are not stored (i.e. data$storeData = FALSE).
  • storeData: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored.

trellis.par  a list of parameters for lattice call. It will be passed directly to par.settings arguments of the lattice function.

adeg.par  a list of graphical parameters, corresponding to the ones given by adegpar() function.
lattice.call  a list to create the trellis object.
g.args  a list containing some method parameters linked with the created object of ADEg.S1 class.

The specific slot for S1.boxplot objects is:
  • col: a NULL value, a color or a colors vector to color points, labels, lines and polygons.

stats  a list of internal preliminary calculations

s.misc  a list of some others internal parameters

Call  an object of class call

Extends

Class ADEg.S1, directly.
Class ADEg, by class ADEg.S1, distance 2.
Class ADEgORtrellis, by class ADEg.S1, distance 3.
Class ADEgORADEgSORtrellis, by class ADEg.S1, distance 3.
Methods

The methods of the father classes "ADEg.S1" and "ADEg" can be used by inheritance. The specific methods for S1.boxplot are:

- **prepare** signature(object = "S1.boxplot"): calls the parent method (prepare for ADEg.S1) and modifies some graphical parameters used by default.

- **panel** signature(object = "S1.boxplot"): draws box-and-whiskers diagrams, mean points and labels.

- **setlatticecall** signature(object = "S1.boxplot"): prepares the lattice.call slot

ADEg ADEg.S1 s1d.boxplot

Examples

```r
showClass("S1.boxplot")
```

Description

A class for the creation and display of a numeric score aggregated in class by an associated factor.

Objects from the Class

S1.class objects can be created by calls of the form `new("S1.class", ...)`. The regular usage in this package is to use the `s1d.class` function.

Slots

data  a list containing data or data’s name.

- score: the displayed values in the form of a numeric vector, a name or a matching call.
- fac: a factor for score splitting in the form of a vector, a factor, a name or a matching call.
- wt: a vector of weights for score
- labels: the labels’ names drawn for each class.
- at: the index value.

- **frame**: a positive or null integer. It is the number of the frame containing the data (used with `sys.frame(...)`, `env = data$frame`). Only if the data are not stored (i.e. `data$storeData = FALSE`).

- **storeData**: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored.

`trellis.par` a list of parameters for `lattice` call. It will be passed directly to `par.settings` arguments of the `lattice` function.

`adeg.par` a list of graphical parameters, corresponding to the ones given by `adegpar()` function.

`lattice.call` a list to create the `trellis` object.

`g.args` a list containing some method parameters linked with the created object of `ADEg`, `S1` class.

The specific slots for `S1.class` objects are:

- **col**: a NULL value, a color or a colors vector to color points, labels and lines.
- **poslabel**: the label position of each class, it can be regular or value.

`stats` a list of internal preliminary calculations. The specific slot for `S1.class` objects is:

- **means**: the weighted mean calculated for each fac value.

`s.misc` a list of some others internal parameters. The specific slot for `S1.class` objects is:

- **rug**: an index value indicating where the rugs are drawn.

Call an object of class `call`.

**Extends**

Class `ADEg.S1`, directly.

Class `ADEg`, by class `ADEg.S1`, distance 2.

Class `ADEgORtrellis`, by class `ADEg.S1`, distance 3.

Class `ADEgORADEgSORtrellis`, by class `ADEg.S1`, distance 3.

**Methods**

The methods of the father classes "ADEg.S1" and "ADEg" can be used by inheritance. The specific methods for `S1.class` are:

- **prepare** signature(object = "S1.class"): calls the parent method (prepare for `ADEg.S1`) and modifies some graphical parameters used by default.

- **panel** signature(object = "S1.class"): draws labels and lines matching with score values.

S1.distri-class

Class S1.distri

Description

A class for the representation of a set of distributions on a numeric score.

Objects from the Class

S1.distri objects can be created by calls of the form new("S1.distri",...).
The regular usage in this package is to use the s1d.distri function.

Slots

data a list containing data or data's name.
  • score: the displayed values in the form of a numeric vector, a name or a matching call.
  • dfdistri: the mass distribution in which each column is a class.
  • labels: the labels' names drawn for each distribution.
  • at: the index value.
  • frame: a positive or null integer. It is the number of the frame containing the data
    (used with sys.frame(...,env = data$frame)). Only if the data are not stored (i.e.
    data$storeData = FALSE).
  • storeData: a logical indicating if the data should be stored in the returned object. If
    FALSE, only the names of the data arguments are stored.
trellis.par a list of parameters for lattice call. It will be passed directly to par.settings
  arguments of the lattice function.
adeg.par a list of graphical parameters, corresponding to the ones given by adegpar() function.
lattice.call a list to create the trellis object.
g.args a list containing some method parameters linked with the created object of ADEg.S1 class.
  The specific slots for S1.distri objects are:
    • sdSize: the size of the standard deviation segments.
    • yrank: a logical to draw the distributions sorted by means ascending order.
stats a list of internal preliminary calculations. The specific slots for S1.distri objects are:
  • means: the weighted mean calculated for each distribution.
  • sds: the weighted variance calculated for each distribution.
s.misc a list of some others internal parameters

\textbf{Methods}

The methods of the father classes "\texttt{ADEg.S1}" and "\texttt{ADEg}" can be used by inheritance. The specific methods for \texttt{S1.label} are:

- \texttt{prepare} signature(object = "S1.label"): calls the parent method (prepare for \texttt{ADEg.S1}) and modifies some graphical parameters used by default.

- \texttt{panel} signature(object = "S1.label"): draws labels and its links with score points.

\textbf{See Also}

\texttt{ADEg ADEg.S1 s1d.label}

\textbf{Examples}

\texttt{showClass("S1.label")}
Description

A class for the creation and display of paired scores.

Objects from the Class

S1.match objects can be created by calls of the form new("S1.match",...).

The regular usage in this package is to use the s1d.match function.

Slots

data  a list containing data or data’s name.

  • score: the displayed values in the form of a numeric vector, a name or a matching call.
  • labels: the labels’ names drawn for each score.
  • at: the index value.
  • frame: a positive or null integer. It is the number of the frame containing the data
    (used with sys.frame(...,env = data$frame)). Only if the data are not stored (i.e.
    data$storeData = FALSE).
  • storeData: a logical indicating if the data should be stored in the returned object. If
    FALSE, only the names of the data arguments are stored.

trellis.par  a list of parameters for lattice call. It will be passed directly to par.settings
arguments of the lattice function.

adeg.par  a list of graphical parameters, corresponding to the ones given by adegpar() function.

lattice.call  a list to create the trellis object.

g.args  a list containing some method parameters linked with the created object of ADEg.S1 class.

stats  a list of internal preliminary calculations

s.misc  a list of some others internal parameters. The specific slot for S1.match objects is:

  • rug: an index value indicating where the rugs are drawn.

Call  an object of class call

Extends

Class ADEg.S1, directly.
Class ADEg, by class ADEg.S1, distance 2.
Class ADEgORtrellis, by class ADEg.S1, distance 3.
Class ADEgORADEgSORtrellis, by class ADEg.S1, distance 3.
Methods

The methods of the father classes "ADEg.S1" and "ADEg" can be used by inheritance. The specific methods for S1.match are:

- **prepare** signature(object = "S1.match"): calls the parent method (prepare for ADEg.S1) and modifies some graphical parameters used by default.
- **panel** signature(object = "S1.match"): draws score points and matching segments and labels.

---

**s1d.barchart**

*1-D plot of a numeric score by bars*

Description

This function represents a score using a chart with rectangular bars for which length is proportional to this score.

Usage

s1d.barchart(score, labels = NULL, at = 1:NROW(score), sort = FALSE,
facets = NULL, plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, ...)

Arguments

- **score**: a numeric vector (or a data frame) used to produce the plot
- **labels**: the labels’ names drawn on the top of bars
- **at**: a numeric vector used as an index
- **sort**: a logical indicating if score is sorted in ascending order
- **facets**: a factor splitting score so that subsets of the data are represented on different sub-graphics
- **plot**: a logical indicating if the graphics is displayed
- **storeData**: a logical indicating if the data are stored in the returned object. If FALSE, only the names of the data arguments are stored
add a logical. If TRUE, the graphic is superposed to the graphics already plotted in
the current device
pos an integer indicating the position of the environment where the data are stored,
relative to the environment where the function is called. Useful only if storeData
is FALSE
...
additional graphical parameters (see adepar and trellis.par.get)

Details

Graphical parameters for bars are available in ppolygons of adepar. Some appropriated graphical
parameters in p1d are also available.

Value

An object of class ADEg (subclass C1.barchart) or ADEgS (if add is TRUE and/or if facets or data
frame for score are used).
The result is displayed if plot is TRUE.

rpjdl.coa <- ade4::dudi.coa(rpjdl$fau, scannf = FALSE, nf = 4)
s1d.barchart(rpjdl.coa$eig, p1d.horizontal = FALSE, ppolygons.col = "grey")

s1d.boxplot
1-D box plot of a numeric score partitioned in classes (levels of a
factor)

Description

This function represents the link between a variable and a set of qualitative variables using box-
and-whisker plots.

Usage

s1d.boxplot(score, fac = gl(1, NROW(score)), at = 1:nlevels(fac), col = NULL,
facets = NULL, plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, ...)

1-D box plot of a numeric score partitioned in classes (levels of a
factor)
Arguments

- **score**: a numeric vector (or a data frame) used to produce the plot
- **fac**: a factor (or a matrix of factors) to split score
- **at**: a numeric vector used as an index
- **col**: a color or a colors vector for points, labels, lines and polygons according to their factor level. Colors are recycled whether there are not one color by factor level.
- **facets**: a factor splitting score so that subsets of the data are represented on different sub-graphics
- **plot**: a logical indicating if the graphics is displayed
- **storeData**: a logical indicating if the data are stored in the returned object. If FALSE, only the names of the data arguments are stored
- **add**: a logical. If TRUE, the graphic is superposed to the graphics already plotted in the current device
- **pos**: an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if storeData is FALSE
- **...**: additional graphical parameters (see adegpar and trellis.par.get)

Details

Graphical parameters for rugs are available in plines of adegpar and the ones for boxes in ppolygons. Some appropriated graphical parameters in p1d are also available.

Value

An object of class ADEg (subclass S1.boxplot) or ADEgS (if add is TRUE and/or if facets or data frame for score or data frame for fac are used).

The result is displayed if plot is TRUE.

Examples

data(banque, package = "ade4")
bisque.acm <- ade4::dudi.acm(banque, scan = FALSE, nf = 4)
s1d.boxplot(banque.acm$l1[, 1], banque[, 2], psub.text = names(banque)[2],
            psub.position = "topleft", col = c("red", "blue", "green", "purple", "orange"))
s1d.boxplot(banque.acm$l1[, 1], banque[, 1:6], psub.position = "topleft")
s1d.class  

1-D plot of a numeric score partitioned in classes (levels of a factor)

Description

This function represents the link between scores values and their matching labeled classes.

Usage

s1d.class(score, fac, wt = rep(1, NROW(fac)), labels = levels(fac), at = 0.5, poslabel = c("regular", "value"), col = NULL, facets = NULL, plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, ...)

Arguments

- **score**: a numeric vector (or a data frame) used to produce the plot
- **fac**: a factor (or a matrix of factors) to split
- **wt**: a vector of weights for score
- **labels**: the labels’ names drawn for each class
- **at**: a numeric vector used as an index
- **poslabel**: the label position of each class (each level of fac), it can be regular or value. If regular, labels are evenly spaced. If value, labels are placed on the weighted mean of their class.
- **col**: a color or a colors vector for points, labels and lines according to their factor level. Colors are recycled whether there are not one color by factor level.
- **facets**: a factor splitting score so that subsets of the data are represented on different sub-graphics
- **plot**: a logical indicating if the graphics is displayed
- **storeData**: a logical indicating if the data are stored in the returned object. If FALSE, only the names of the data arguments are stored
- **add**: a logical. If TRUE, the graphic is superposed to the graphics already plotted in the current device
- **pos**: an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Usefull only if storeData is FALSE
- **...**: additional graphical parameters (see adegpar and trellis.par.get)

Details

The weighted means of class are available in the object slot stats using object@stats$means. Graphical parameters for rugs are available in plines of adegpar. Some appropriated graphical parameters in p1d are also available.
Value

An object of class ADEg (subclass S1.class) or ADEgS (if add is TRUE and/or if facets or data frame for score or data frame for fac are used).
The result is displayed if plot is TRUE.

s1d.curve

1-D plot of a numeric score linked by curves

Description

This function represents a score using points linked by curves.

Usage

s1d.curve(score, at = 1:NROW(score), facets = NULL, plot = TRUE,
  storeData = TRUE, add = FALSE, pos = -1, ...)

Arguments

score a numeric vector (or a data frame) used to produce the plot
at a numeric vector used as an index
facets a factor splitting score so that subsets of the data are represented on different
  sub-graphics
plot a logical indicating if the graphics is displayed
storeData a logical indicating if the data are stored in the returned object. If FALSE, only the names of the data arguments are stored.

add a logical. If TRUE, the graphic is superposed to the graphics already plotted in the current device.

pos an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if storeData is FALSE.

... additional graphical parameters (see adegpar and trellis.par.get).

Details

Graphical parameters for lines and points are available in plines and in ppoints of adegpar. Some appropriated graphical parameters in p1d are also available.

Value

An object of class ADEg (subclass C1.curve) or ADEg$ (if add is TRUE and/or if facets or data frame for score are used). The result is displayed if plot is TRUE.

sld.curves 1-D plot of multiple scores linked by curves

Description

This function represents multiple scores using points linked by curves.
Usage

`s1d.curves(score, at = 1:NROW(score), facets = NULL, plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, ...)`

Arguments

- **score**: a numeric matrix (or a data frame) used to produce the plot
- **at**: a numeric vector used as an index
- **facets**: a factor splitting `score` so that subsets of the data are represented on different sub-graphics
- **plot**: a logical indicating if the graphics is displayed
- **storeData**: a logical indicating if the data are stored in the returned object. If `FALSE`, only the names of the data arguments are stored
- **add**: a logical. If `TRUE`, the graphic is superposed to the graphics already plotted in the current device
- **pos**: an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if `storeData` is `FALSE`
- **...**: additional graphical parameters (see `adegpar` and `trellis.par.get`)

Details

Graphical parameters for lines and points are available in `plines` and in `ppoints` of `adegpar`. Some appropriated graphical parameters in `p1d` are also available.

Value

An object of class `ADEg` (subclass `C1.curves`) or `ADEgS` (if `add` is `TRUE` and/or if facets are used). The result is displayed if `plot` is `TRUE`.

Examples

```r
scores <- matrix(1:50, nrow = 10)
s1d.curves(scores)
```
s1d.density

1-D plot of a numeric score by density curves

Description

This function represents a score with a density curve for each level of a factor.

Usage

s1d.density(score, fac = gl(1, NROW(score)), kernel = c("normal", "box", "epanech", "biweight", "triweight"), bandwidth = NULL, gridsize = 450, col = NULL, fill = TRUE, facets = NULL, plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, ...)

Arguments

- **score**: a numeric vector (or a data frame) used to produce the plot
- **fac**: a factor (or a matrix of factors) to split score
- **kernel**: the smoothing kernel used, see bkde
- **bandwidth**: the kernel bandwidth smoothing parameter
- **gridsize**: the number of equally spaced points at which to estimate the density
- **col**: a logical, a color or a colors vector for labels, rugs, lines and polygons according to their factor level. Colors are recycled whether there are not one color by factor level.
- **fill**: a logical to yield the polygons density curves filled
- **facets**: a factor splitting score so that subsets of the data are represented on different sub-graphics
- **plot**: a logical indicating if the graphics is displayed
- **storeData**: a logical indicating if the data are stored in the returned object. If FALSE, only the names of the data arguments are stored
- **add**: a logical. If TRUE, the graphic is superposed to the graphics already plotted in the current device
- **pos**: an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if storeData is FALSE
- **...**: additional graphical parameters (see adegpar and trellis.par.get)

Details

kernel, bandwidth and gridsize are passed as parameters to bkde function of the KernSmooth package.

Graphical parameters for rugs are available in plines of adegpar and the ones for density curves filled in ppolygons. Some appropriated graphical parameters in p1d are also available.
Value
An object of class ADEg (subclass C1.density) or ADEgS (if add is TRUE and/or if facets or data frame for score or data frame for fac are used).
The result is displayed if plot is TRUE.

s1d.density(score, fac, col = c(2, 4), p1d.reverse = TRUE)
```

---

s1d.distri 1-D plot of a numeric score by means/standard deviations computed using an external table of weights

Description
This function represents a set of distributions on a numeric score using a mean-standard deviation display.

Usage
```r
s1d.distri(score, dfdistri, labels = colnames(dfdistri), at = 1:NCOL(dfdistri),
            yrank = TRUE, sdSize = 1, facets = NULL, plot = TRUE,
            storeData = TRUE, add = FALSE, pos = -1, ...)
```

Arguments
- `score`: a numeric vector (or a data frame) used to produce the plot.
- `dfdistri`: a data frame containing the mass distribution in which each column is a class.
- `yrank`: a logical to draw the distributions sorted by means ascending order.
- `labels`: the labels’ names drawn for each distribution.
- `at`: a numeric vector used as an index.
- `sdSize`: a numeric for the size of the standard deviation segments.
- `facets`: a factor splitting score so that subsets of the data are represented on different sub-graphics.
**s1d.distri**

- **plot**
  - a logical indicating if the graphics is displayed
- **storeData**
  - a logical indicating if the data are stored in the returned object. If FALSE, only the names of the data arguments are stored
- **add**
  - a logical. If TRUE, the graphic is superposed to the graphics already plotted in the current device
- **pos**
  - an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if storeData is FALSE
- ... additional graphical parameters (see adegpar and trellis.par.get)

**Details**

Graphical parameters for rugs are available in plines of adegpar. Some appropriated graphical parameters in p1d are also available. The weighted means and standard deviations of class are available in the object slot stats using object@stats$means and object@stats$sds.

**Value**

An object of class ADEg (subclass S1.distri) or ADEgS (if add is TRUE and/or if facets or data frame for score are used).

The result is displayed if plot is TRUE.

```
s1d.dotplot

1-D plot of a numeric score by dots

Description

This function represents a score using dots.

Usage

s1d.dotplot(score, at = 1:NROW(score), facets = NULL, plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, ...)

Arguments

score a numeric vector (or a data frame) used to produce the plot
at a numeric vector used as an index
facets a factor splitting score so that subsets of the data are represented on different sub-graphics
plot a logical indicating if the graphics is displayed
storeData a logical indicating if the data are stored in the returned object. If FALSE, only the names of the data arguments are stored
add a logical. If TRUE, the graphic is superposed to the graphics already plotted in the current device
pos an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if storeData is FALSE
...
additional graphical parameters (see adepar and trellis.par.get)

Details

Graphical parameters for segments and dots are available in plines and in ppoints of adepar. Some appropriated graphical parameters in p1d are also available.

Value

An object of class ADEg (subclass C1.dotplot) or ADEg$ (if add is TRUE and/or if facets or data frame for score are used).

The result is displayed if plot is TRUE.

s1d.dotplot(rpjdl.coa$eig)

set.seed(40)
score1 <- rnorm(10)
s1d.dotplot(score1)
```

s1d.gauss

1-D plot of a numeric score by Gaussian curves

Description
This function represents a score with a Gauss curve for each level of a factor.

Usage

```r
s1d.gauss(score, fac = gl(1, NROW(score)), wt = rep(1, NROW(score)), steps = 200, col = NULL, fill = TRUE, facets = NULL, plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, ...)
```

Arguments

- `score`: a numeric vector (or a data frame) used to produce the plot
- `fac`: a factor (or a matrix of factors) to split `score`
- `wt`: a vector of weights for `score`
- `steps`: a value for the number of segments used to draw the Gauss curves
- `col`: a logical, a color or a colors vector for labels, rugs, lines and polygons according to their factor level. Colors are recycled whether there are not one color by factor level.
- `fill`: a logical to yield the polygons Gauss curves filled
- `facets`: a factor splitting `score` so that subsets of the data are represented on different sub-graphics
- `plot`: a logical indicating if the graphics is displayed
storeData a logical indicating if the data are stored in the returned object. If FALSE, only the names of the data arguments are stored.

add a logical. If TRUE, the graphic is superposed to the graphics already plotted in the current device.

pos an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if storeData is FALSE.

... additional graphical parameters (see adepar and trellis.par.get)

Details

Graphical parameters for rugs are available in plines of adepar and the ones for Gauss curves filled in ppolygons. Some appropriated graphical parameters in p1d are also available.

Value

An object of class ADEg (subclass C1.gauss) or ADEgS (if add is TRUE and/or if facets or data frame for score or data frame for fac are used).

The result is displayed if plot is TRUE.

g1 <- s1d.gauss(enpvca$li[, 1], fac = dffac, fill = TRUE, col = 1:6)
update(g1, steps = 10)
g2 <- s1d.gauss(enpvca$li[, 1], dffac[, 2], ppoly.col = 1:4, paxes.draw = TRUE, ylim = c(0, 2), fill = TRUE, p1d.hori = FALSE)

Description

This function represents a score using a chart with rectangular bars.
**Usage**

```r
sld.hist(score, breaks = NULL, nclass = round(log2(length(score)) + 1),
    type = c("count", "density", "percent"), right = TRUE, facets = NULL,
    plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, ...)
```

**Arguments**

- `score`: a numeric vector (or a data frame) used to produce the plot
- `breaks`: a vector of values to split `score`. If NULL, pretty(score, nclass) is used.
- `nclass`: an integer for the number of desired intervals, ignored if `breaks` is not missing.
- `type`: a value among `count`, `density`, `percent` to indicate the unit of the cell height.
- `right`: a logical indicating if the histogram cells are right-closed (left open) intervals.
- `facets`: a factor splitting `score` so that subsets of the data are represented on different sub-graphics
- `plot`: a logical indicating if the graphics is displayed
- `storeData`: a logical indicating if the data are stored in the returned object. If FALSE, only the names of the data arguments are stored
- `add`: a logical. If TRUE, the graphic is superposed to the graphics already plotted in the current device
- `pos`: an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if `storeData` is FALSE
- `...`: additional graphical parameters (see `adegpar` and `trellis.par.get`)

**Details**

Graphical parameters for polygons are available in `ppolygons` of `adegpar`. Some appropriated graphical parameters in `p1d` are also available.

**Value**

An object of class `ADEg` (subclass `C1.hist`) or `ADEgS` (if `add` is `TRUE` and/or if `facets` or data frame for `score` are used).

The result is displayed if `plot` is `TRUE`.

```

\texttt{s1d.interval} \hspace{1cm} \textit{1-D plot of the interval between two numeric scores}

Description

This function represents the interval between two scores using either segments or filled areas.

Usage

\[\text{s1d.interval(score1, score2, at = 1: \text{NROW(score1)}, method = c(\\"bars\\", \"area\\"), facets = NULL, plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, \ldots)}\]

Arguments

- \texttt{score1} \hspace{1cm} a numeric vector (or a data frame) used to produce the plot
- \texttt{score2} \hspace{1cm} a numeric vector with as many values as values (or rows) in \texttt{score1}
- \texttt{at} \hspace{1cm} a numeric vector used as an index
- \texttt{method} \hspace{1cm} a value, \texttt{bars} or \texttt{area}, to represent either segments or areas between scores.
- \texttt{facets} \hspace{1cm} a factor splitting \texttt{score} so that subsets of the data are represented on different sub-graphics
- \texttt{plot} \hspace{1cm} a logical indicating if the graphics is displayed
- \texttt{storeData} \hspace{1cm} a logical indicating if the data are stored in the returned object. If \texttt{FALSE}, only the names of the data arguments are stored
- \texttt{add} \hspace{1cm} a logical. If \texttt{TRUE}, the graphic is superposed to the graphics already plotted in the current device
- \texttt{pos} \hspace{1cm} an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if \texttt{storeData} is \texttt{FALSE}
- \texttt{...} \hspace{1cm} additional graphical parameters (see \texttt{adeqpar} and \texttt{trellis.par.get})

Details

Graphical parameters for polygons, lines and segment boundaries are available in respectively \texttt{ppolygons}, \texttt{plines} and \texttt{parrows} of \texttt{adeqpar}. Some appropriated graphical parameters in \texttt{p1d} are also available.

Value

An object of class \texttt{ADEg (subclass C1.interval)} or \texttt{ADEgS} (if \texttt{add} is \texttt{TRUE} and/or if \texttt{facets} or data frame for \texttt{score} are used).

The result is displayed if \texttt{plot} is \texttt{TRUE}.

C1.interval ADEg.C1

Examples

```r
set.seed(40)
sc1 <- rnorm(10)
sc2 <- rnorm(10)
s1d.interval(sc1, sc2, method = "bars")
s1d.interval(sc1, sc2, method = "area")
```

---

**Description**

This function represents a numeric labeled score

**Usage**

```r
s1d.label(score, labels = 1:NROW(score), at = 0.5, poslabel = c("regular", "value"), facets = NULL, plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, ...)
```

**Arguments**

- `score`: a numeric vector (or a data frame) used to produce the plot
- `labels`: the labels' names drawn for each score value
- `at`: a numeric vector used as an index
- `poslabel`: the label position, it can be `regular` or `value`. If `regular`, labels are evenly spaced. If `value`, labels are placed on the weighted mean of their class.
- `facets`: a factor splitting `score` so that subsets of the data are represented on different sub-graphics
- `plot`: a logical indicating if the graphics is displayed
- `storeData`: a logical indicating if the data are stored in the returned object. If `FALSE`, only the names of the data arguments are stored
- `add`: a logical. If `TRUE`, the graphic is superposed to the graphics already plotted in the current device
- `pos`: an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if `storeData` is `FALSE`
- `...`: additional graphical parameters (see adegpar and trellis.par.get)
Details

Graphical parameters for rugs are available in p1dlines of adegpar. Some appropriated graphical
parameters in p1d are also available.

Value

An object of class ADEg (subclass S1.label) or ADEgS (if add is TRUE and/or if facets or data frame
for score are used).
The result is displayed if plot is TRUE.

S1.label ADEg.S1

Examples

data(meau, package = "ade4")
envpca <- ade4::dudi.pca(meau$env, scannf = FALSE)
g1 <- s1d.label(envpca$l1[, 1], row.names(envpca$l1), plot = FALSE)
g2 <- s1d.label(envpca$co[, 1], row.names(envpca$co), p1d.reverse = TRUE, plot = FALSE)
G <- ADEgS(c(g1, g2), layout = c(2, 1))

s1d.match

1-D plot of the matching between two numeric scores

Description

This function represents paired scores with evenly spaced labels.

Usage

s1d.match(score1, score2, labels = 1:NROW(score1), at = 0.5,
facets = NULL, plot = TRUE, storeData = TRUE, add = FALSE,
pos = -1, ...)
S2.arrow-class

facets
plot
storeData
add
pos
... additional graphical parameters (see adegpar and trellis.par.get)

Details

Graphical parameters for rugs are available in plines of adegpar. Some appropriated graphical parameters in p1d are also available.

Value

An object of class ADEg (subclass S1.match) or ADEgS (if add is TRUE and/or if facets or data frame for score or data frame for fac are used).
The result is displayed if plot is TRUE.

S2.arrow-class

Class S2.arrow

Description

A class for creating and drawing bi-dimensional plot with arrows from the origin to the coordinates and labeled.

Objects from the Class

S2.arrow objects can be created by calls of the form new("S2.arrow", ...).
The regular usage in this package is to use the s.arrow function.
S2.arrow-class

Slots

data a list containing data or data's name.
  • dfxy: the displayed values in the form of a data frame, a name or a matching call.
  • xax: an integer or a vector indicating the columns of dfxy kept for the x-axes.
  • yax: an integer or a vector indicating the columns of dfxy kept for the y-axes.
  • labels: a vector containing the arrows' labels.
  • frame: a positive or null integer. It is the number of the frame containing the data
    (used with sys.frame(..., env = data$frame)). Only if the data are not stored (i.e.
    data$storeData = FALSE).
  • storeData: a logical indicating if the data should be stored in the returned object. If
    FALSE, only the names of the data arguments are stored.

trellis.par a list of parameters for lattice call. It will be passed directly to par.settings
  arguments of the lattice function.

adeg.par a list of graphical parameters, corresponding to the ones given by adegpar() function.

lattice.call a list to create the trellis object.

g.args a list containing some method parameters linked with the created object of ADEg.S2 class.

The specific slot for S2.arrow objects is:
  • Sp: a spatial object stem from Sp package.

stats a list of internal preliminary calculations

s.misc a list of some others internal parameters:
  • lim.update: a logical indicating if the limits are updating

Call an object of class call

Extends

Class ADEg.S2, directly.
Class ADEg, by class ADEg.S2, distance 2.
Class ADEgORtrellis, by class ADEg.S2, distance 3.
Class ADEgORAdegsortrellis, by class ADEg.S2, distance 3.

Methods

The methods of the father classes "ADEg.S2" and "ADEg" can be used by inheritance. The specific
methods for S2.arrow are:

prepare signature(object = "S2.arrow"): calls the parent method (prepare for ADEg.S2),
  modifies some graphical parameters used by default and calculates limits.

panel signature(object = "S2.arrow"): draws points, arrows and labels.

S2.class-class

Class S2.class

Description

A class for group representation in bi-dimensional plot.

Objects from the Class

S2.class objects can be created by calls of the form new("S2.class", ...).

The regular usage in this package is to use the s.class function.

Slots

data a list containing data or data's name.

• dfxy: the displayed values in the form of a data frame, a name or a matching call.
• fac: a factor (or a matrix of factors) splitting the rows of dfxy.
• xax: an integer or a vector indicating the columns of dfxy kept for the x-axes.
• yax: an integer or a vector indicating the columns of dfxy kept for the y-axes.
• wt: a vector of weights for fac.
• labels: a vector containing the class' labels.
• frame: a positive or null integer. It is the number of the frame containing the data (used with sys.frame(..., env = data$frame)). Only if the data are not stored (i.e. data$storeData = FALSE).
• storeData: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored.

trellis.par a list of parameters for lattice call. It will be passed directly to par.settings arguments of the lattice function.

adeq.par a list of graphical parameters, corresponding to the ones given by adeqpar() function.
lattice.call a list to create the trellis object.
g.args a list containing some method parameters linked with the created object of ADEg.S2 class.

The specific slots for S2.class objects are:

• ellipseSize: a positive number for ellipse size.
• starSize: a number between 0 and 1 for star size.
• chullSize: NULL or a vector of numbers between 0 and 1 for the convex hulls.
• col: a logical or a vector of colors that apply to points, ellipses, labels, lines and polygons.
stats  a list of internal preliminary calculations. The specific slots for S2.class objects are:
  • means: a matrix containing the weighted mean calculated for each fac value.
  • covvar: a list containing the weighted variance-covariance matrices calculated for each fac value.

s.misc  a list of some others internal parameters:
  • ellipses: ellipses’ coordinates.
  • chullcoord: convex hulls’ coordinates.

Call  an object of class call

Extends

ADEg ADEg.S2 s.class

Examples

showClass("S2.class")
Description

A class for creating and drawing a correlation circle.

Objects from the Class

S2.corcircle objects can be created by calls of the form new("S2.corcircle",...).

The regular usage in this package is to use the s.corcircle function.

Slots

data a list containing data or data’s name.

• dfxy: the displayed values in the form of a data frame, a name or a matching call.
• xax: an integer or a vector indicating the columns of dfxy kept for the x-axes.
• yax: an integer or a vector indicating the columns of dfxy kept for the y-axes.
• labels: a vector containing the points’ labels.
• frame: a positive or null integer. It is the number of the frame containing the data (used with sys.frame(...,env = data$frame)). Only if the data are not stored (i.e. data$storeData = FALSE).
• storeData: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored.

trellis.par a list of parameters for lattice call. It will be passed directly to par.settings arguments of the lattice function.

adeg.par a list of graphical parameters, corresponding to the ones given by adegpar() function.

lattice.call a list to create the trellis object.

g.args a list containing some method parameters linked with the created object of ADEg.S2 class.

The specific slot for S2.corcircle objects is:

• fullcircle: a logical to include the complete circle (limits are then c(-1, 1)).

stats a list of internal preliminary calculations

s.misc a list of some others internal parameters:

• backgrid: a list of elements for grid lines

Call an object of class call

Extends

Class ADEg.S2, directly.
Class ADEg, by class ADEg.S2, distance 2.
Class ADEgORtrellis, by class ADEg.S2, distance 3.
Class ADEgORADEgSORtrellis, by class ADEg.S2, distance 3.
Methods

The methods of the father classes "ADEg.S2" and "ADEg" can be used by inheritance. The specific methods for S2.corcircle are:

- **prepare** signature(object = "S2.corcircle"): calls the parent method (prepare for ADEg.S2), modifies some graphical parameters used by default and prepares the drawn grid.
- **panel** signature(object = "S2.corcircle"): draws arrows, labels and axes.

**S2.density-class**

**Class** S2.density

Description

A class for the creation and display of bi-dimensional plot with density estimation.

Objects from the Class

S2.density objects can be created by calls of the form new("S2.density", ...).

The regular usage in this package is to use the s.density function.

Slots

data a list containing data or data’s name.
  - dfxy: the displayed values in the form of a data frame, a name or a matching call.
  - xax: an integer or a vector indicating the columns of dfxy kept for the x-axes.
  - yax: an integer or a vector indicating the columns of dfxy kept for the y-axes.
  - frame: a positive or null integer. It is the number of the frame containing the data (used with sys.frame(..., env = data$frame)). Only if the data are not stored (i.e. data$storeData = FALSE).
  - storeData: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored.

trellis.par a list of parameters for lattice call. It will be passed directly to par.settings arguments of the lattice function.
adeg.par a list of graphical parameters, corresponding to the ones given by adegpar() function.
lattice.call a list to create the trellis object.
g.args a list containing some method parameters linked with the created object of ADEg.S2 class.

The specific slots for S2.density objects are:

- bandwidth: bandwidth for density calculations which is passed in parameters in the bkde2D function of the KernSmooth package.
- gridsize: grid dimension.
- threshold: a value between 0 and 1 to draw densities greater than this threshold. No density is visible whether it is equal to 1.
- col: a NULL value, a color or a colors vector to color densities.
- nrpoints: number of points on the density image.
- contour: a logical to draw contour lines.
- region: a logical to fill grid regions with col.
- nclass: number of class for density.

stats a list of internal preliminary calculations. The specific slot for S2.density objects is:

- densit: a list containing the results of the bkde2D function.

s.misc a list of some others internal parameters

Call an object of class call

Extends

S2.distri-class

Description

A class for distributions on a numeric score using a mean-standard deviation display.

Objects from the Class

S2.distri objects can be created by calls of the form new("S2.distri",...).

The regular usage in this package is to use the s.distri function.

Slots

data a list containing data or data's name.

  - dfxy: the displayed values in the form of a data frame, a name or a matching call.
  - dfdistri: the mass distribution in which each column is a class.
  - xax: an integer or a vector indicating the columns of dfxy kept for the x-axes.
  - yax: an integer or a vector indicating the columns of dfxy kept for the y-axes.
  - frame: a positive or null integer. It is the number of the frame containing the data
    (used with sys.frame(...,env = data$frame)). Only if the data are not stored (i.e.
    data$storeData = FALSE).
  - storeData: a logical indicating if the data should be stored in the returned object. If
    FALSE, only the names of the data arguments are stored.

trilis.par a list of parameters for lattice call. It will be passed directly to par.settings
arguments of the lattice function.

adeg.par a list of graphical parameters, corresponding to the ones given by adegpar() function.

lattice.call a list to create the trellis object.

g.args a list containing some method parameters linked with the created object of ADEg.S2 class.

The specific slots for S2.distri objects are:

  - ellipseSize: NULL or number between 0 and 1 for ellipse size.
  - starSize: NULL or number between 0 and 1 for star size.
  - col: a NULL value, a color or a colors vector to color ellipses, labels, lines and polygons.

stats a list of internal preliminary calculations. The specific slots for S2.distri objects are:

  - means: a matrix containing the weighted mean calculated for each class indfdistri.
  - covvar: a list containing the weighted variance-covariance matrices calculated for each
    class indfdistri.

s.misc a list of some others internal parameters:

  - ellipses: ellipses’ coordinates.

S2.image-class  Class S2.image

----------------------

Description

A class for the creation of a bi-dimensional plot with a third value represented as a continuous colored surface.

Objects from the Class

S2.image objects can be created by calls of the form new("S2.image", ...).
The regular usage in this package is to use the s.image function.
Slots

data  a list containing data or data’s name.
  • dfxy: the displayed values in the form of a data frame, a name or a matching call.
  • z: a vector (or a matrix) of values on the dfxy rows.
  • xax: an integer or a vector indicating the columns of dfxy kept for the x-axes.
  • yax: an integer or a vector indicating the columns of dfxy kept for the y-axes.
  • frame: a positive or null integer. It is the number of the frame containing the data
    (used with sys.frame(...,env = data$frame)). Only if the data are not stored (i.e.
    data$storeData = FALSE).
  • storeData: a logical indicating if the data should be stored in the returned object. If
    FALSE, only the names of the data arguments are stored.

trellis.par  a list of parameters for lattice call. It will be passed directly to par.settings
  arguments of the lattice function.

adeg.par  a list of graphical parameters, corresponding to the ones given by adegpar() function.

lattice.call  a list to create the trellis object.

g.args  a list containing some method parameters linked with the created object of ADEg.S2 class.

The specific slots for S2.image objects are:
  • gridsize: a 1 or 2-length vector indicating the cell numbers (horizontally and vertically)
    of the grid for the colored surface.
  • outsideLimits: specific limits for the surface as a set of polygons. It must be an
    SpatialPolygons object. Hole are authorized.
  • span: a value to control the degree of smoothing.
  • contour: a logical to draw contour lines.
  • region: a logical to fill inter-contour regions.
  • col: a NULL value, a color or a colors vector used for the colored cells.

stats  a list of internal preliminary calculations. The specific slot for S2.image objects is:
  • value: a prediction value yielded by a local polynomial regression fitting.

s.misc  a list of some others internal parameters:
  • newgrid: the grid expansion calculated within the prepare method.

**S2.match-class**

---

**Description**

A class for the creation and display of paired coordinates in a bi-dimensional plot.

**Objects from the Class**

S2.match objects can be created by calls of the form `new("S2.match",...)`.

The regular usage in this package is to use the `s.match` function.

**Slots**

- **data**: a list containing data or data’s name.
  - `dfxy`: the displayed values in the form of a data frame, a name or a matching call.
  - `xax`: an integer or a vector indicating the columns of `dfxy` kept for the x-axes.
  - `yax`: an integer or a vector indicating the columns of `dfxy` kept for the y-axes.
  - `labels`: a vector of character strings containing the matches’ labels.
  - `frame`: a positive or null integer. It is the number of the frame containing the data (used with `sys.frame(...,env = data$frame)`). Only if the data are not stored (i.e. `data$storeData = FALSE`).
  - `storeData`: a logical indicating if the data should be stored in the returned object. If `FALSE`, only the names of the data arguments are stored.

- **trellis.par**: a list of parameters for `lattice` call. It will be passed directly to `par.settings` arguments of the `lattice` function.

- **adeg.par**: a list of graphical parameters, corresponding to the ones given by `adegpar()` function.

- **lattice.call**: a list to create the `trellis` object.

- **g.args**: a list containing some method parameters linked with the created object of ADEg.S2 class.

  The specific slot for S2.match objects is:
  - `arrows`: a logical to draw arrows.

- **stats**: a list of internal preliminary calculations

- **s.misc**: a list of some others internal parameters

**Call**

an object of class `call`

**Extends**

Class ADEg.S2, directly.
Class ADEg, by class ADEg.S2, distance 2.
Class ADEgORTrellis, by class ADEg.S2, distance 3.

S2.traject-class  Class S2.traject

Description

A class for the creation of a bi-dimensional plot with trajectories linking the points.

Objects from the Class

S2.traject objects can be created by calls of the form new("S2.traject", ...).

The regular usage in this package is to use the s.traject function.

Slots

data  a list containing data or data’s name.

- dfxy: the displayed values in the form of a data frame, a name or a matching call.
- fac: a factor (or a matrix of factors) splitting the rows of dfxy.
- labels: a vector of character strings containing the trajectories’ labels.
- xax: an integer or a vector indicating the columns of dfxy kept for the x-axes.
- yax: an integer or a vector indicating the columns of dfxy kept for the y-axes.
- frame: a positive or null integer. It is the number of the frame containing the data (used with Sys.frame(..., env = data$frame)). Only if the data are not stored (i.e. data$storeData = FALSE).
- storeData: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored.
trellis.par a list of parameters for lattice call. It will be passed directly to \texttt{par.settings} arguments of the lattice function.

adeq.par a list of graphical parameters, corresponding to the ones given by \texttt{adeqpar()} function.

\texttt{lattice.call} a list to create the trellis object.

g.args a list containing some method parameters linked with the created object of \texttt{ADEg.S2} class.

The specific slots for \texttt{S2.traject} objects are:

- \texttt{order}: a vector containing the drawing order of the trajectories. A vector of length equal to factor.
- \texttt{col}: a \texttt{NULL} value, a color or a colors vector to color points, labels and lines.

\texttt{stats} a list of internal preliminary calculations

\texttt{s.misc} a list of some others internal parameters

\texttt{Call} an object of class \texttt{call}

\textbf{Extends}

Class \texttt{ADEg.S2}, directly.
Class \texttt{ADEg}, by class \texttt{ADEg.S2}, distance 2.
Class \texttt{ADEgORtrellis}, by class \texttt{ADEg.S2}, distance 3.
Class \texttt{ADEgORADEgSORtrellis}, by class \texttt{ADEg.S2}, distance 3.

\textbf{Methods}

The methods of the father classes "ADEg.S2" and "ADEg" can be used by inheritance. The specific methods for \texttt{S2.traject} are:

\texttt{prepare} \texttt{signature(object = "S2.traject")}: calls the parent method (\texttt{prepare} for \texttt{ADEg.S2}) and modifies some graphical parameters used by default.

\texttt{panel} \texttt{signature(object = "S2.traject")}: draws points, arrows and labels.

\textbf{Author(s)}

\textbf{See Also}

\texttt{ADEg} \texttt{ADEg.S2} \texttt{s.traject}

\textbf{Examples}

\texttt{showClass("S2.traject")}
Description

A class for the creation and display of bi-dimensional plot with a third value represented (as a variable) by symbols.

Objects from the Class

S2.value objects can be created by calls of the form new("S2.value", ...).

The regular usage in this package is to use the s.value function.

Slots

data: a list containing data or data’s name.

- dfxy: the displayed values in the form of a data frame, a name or a matching call.
- z: a vector (or a matrix) with as many values as rows in dfxy.
- xax: an integer or a vector indicating the columns of dfxy kept for the x-axes.
- yax: an integer or a vector indicating the columns of dfxy kept for the y-axes.
- frame: a positive or null integer. It is the number of the frame containing the data (used with sys.frame(..., env = data$frame)). Only if the data are not stored (i.e. data$storeData = FALSE).
- storeData: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored.

- trellis.par: a list of parameters for lattice call. It will be passed directly to par.settings arguments of the lattice function.
- adeg.par: a list of graphical parameters, corresponding to the ones given by adegpar() function.
- lattice.call: a list to create the trellis object.
- g.args: a list containing some method parameters linked with the created object of ADEg.S2 class.

The specific slots for S2.value objects are:

- method: the method of representation for z (color shading or proportional size).
- symbol: the type of symbol (square or circle).
- center: a center value for method size.
- centerpar: a logical or a list to represent center value using elements in the adegpar("ppoints") list.
- breaks: a vector containing the breaks used for splitting z value. If NULL, pretty(z,n) is used.
- nclass: an integer for the number of desired intervals, ignored if breaks is not missing.
- col: a NULL value, a color or a colors vector to color symbols.

stats: a list of internal preliminary calculations

s.misc: a list of some others internal parameters:
• `plegend.update`: a logical indicating if the legend parameters are updating
• `breaks.update`: a logical indicating if the legend breaks are updating
• `lim.update`: a logical indicating if the limits are updating

Call

an object of class call

Extends

Class `ADEg.S2`, directly.
Class `ADEg`, by class `ADEg.S2`, distance 2.
Class `ADEgORtrellis`, by class `ADEg.S2`, distance 3.
Class `ADEgORADEgSORtrellis`, by class `ADEg.S2`, distance 3.

Methods

The methods of the father classes "ADEg.S2" and "ADEg" can be used by inheritance. The specific methods for `S2.value` are:

- `prepare` signature(object = "S2.value"): calls the parent method (prepare for `ADEg.S2`), modifies some graphical parameters used by default and calculates limits.
- `panel` signature(object = "S2.value"): draws symbols.

Note

For the symbol size, if the method is size, we use perceptual scaling (Tanimura et al. 2006).

`ADEg` `ADEg.S2` `s.value`

Examples

```r
showClass("S2.value")
```
setlimits1D

Description

Computes limits for 1D and 2D displays adding 10% of margins around the extreme values.

Usage

setlimits1D(mini, maxi, origin, includeOr)
setlimits2D(minX, maxX, minY, maxY, origin = c(0, 0), aspect.ratio = "iso", includeOr)

Arguments

mini the smallest value of a unidimensional dataset
maxi the largest value of a unidimensional dataset
minX the smallest value of the first dimension of a bidimensional dataset
maxX the largest value of the first dimension of a bidimensional dataset
minY the smallest value of the second dimension of a bidimensional dataset
maxY the largest value of the second dimension of a bidimensional dataset
origin a value (in setlimits1D) or a two-length vector (in setlimits2D) indicating origin coordinate(s)
aspect.ratio a character string to control physical aspect ratio of the graphic. iso for isometric scales, fill for drawing as big as possible or xy for banking rule
includeOr a boolean value indicating whether the origin is included in the graphics window

Value

setlimits1D returns a two-length vector containing the limits of the graphics window on one axis.
setlimits2D returns a two-length list where the first element, named xlim, contains a two-length vector containing the limits of the graphics window on the first axis and the second, named ylim, contains the limits on the second axis.

Author(s)

Alice Julien-Laferriere, Aurelie Siberchicot <aurelie.siberchicot@univ-lyon1.fr> and Stephane Dray

Examples

setlimits1D(mini = -2, maxi = 2, origin = 0, includeOr = TRUE)
setlimits2D(minX = -2, maxX = 2, minY = -3, maxY = 4, origin = c(0, 0), includeOr = TRUE)
sortparamADEg

Sort a sequence of graphical parameters

Description

Sort a sequence of graphical parameters in several lists.

Usage

sortparamADEg(...)

sortparamADEgS(..., graphsnames, nbsubgraphs = rep(1, length(graphsnames)))

Arguments

... a sequence of graphical parameters
graphsnames a sequence containing the name of each simple graph of the ADEgS
nbsubgraphs a sequence containing the number of sub-graphs in each graph named in graphsnames

Value

sortparamADEg return a list of four lists named adepar, trellis, g.args and rest. sortparamADEgS return a list of as many lists as the length of graphsnames, i.e., as the number of sub-graphs of the ADEgS. The names of the lists are graphsnames and each sub-list is the result of the sortparamADEg function aplly on each sub-graph.

Author(s)

Alice Julien-Laferriere, Aurelie Siberchicot <aurelie.siberchicot@univ-lyon1.fr> and Stephane Dray

Examples

l1 <- sortparamADEg(xlab = "x-axis label", ylab = "y-axis label", plabels.cex = 1.5,
                   porigin.include = FALSE)
length(l1)
names(l1)

l2 <- sortparamADEgS(xlab = "x-axis label", eig.main = "Eigenvalues", row.ppoints.col = "red",
                    porigin.include = FALSE, graphsnames = c("row", "col", "eig"))
names(l2)
names(l2$rownames)

l3 <- sortparamADEgS(xlab = "x-axis label", eig.main = "Eigenvalues", row.ppoints.col = "pink",
                    porigin.include = FALSE, graphsnames = c("row", "col", "eig"), nbsubgraphs = c(1, 2, 1))
names(l3)
length(l3$rownames)
length(l3$colnames)
superpose

Superpose two graphics

Description

This function superposes two graphics and extends the graphical constraints of a first graphic to a second one.

Usage

`superpose(g1, g2, which, plot = FALSE)`

## S4 method for signature 'ADEg'
e1 + e2

Arguments

g1 an object of class ADEg, ADEgS or trellis
g2 an object of class ADEg, ADEgS or trellis superposed on g1
e1 an object of class ADEg or ADEgS
e2 an object of class ADEg or ADEgS superposed on e1
which if g1 is an ADEgS, which ADEg is used as the base of superposition (g2 is superposed on g1[[which]])
plot a logical indicating if the graphics is displayed

Details

The created ADEgS object is a layout of two graphical objects. Each of the two objects superposed still have its graphical parameters in the created layout. However, the ADEgS displayed favour the graphical parameters of the object below : displayed limits, grid, legend and axes are those of g1 (respectively e1) and g2 (respectively e2) has transparent background and labels’ boxes.

The superpose method is defined for:

- `signature(g1 = "ADEgS",g2 = "ADEg",which = "numeric",plot = "logical")`
- `signature(g1 = "ADEgS",g2 = "ADEg",which = "numeric",plot = "ANY")`
- `signature(g1 = "ADEgS",g2 = "ADEg",which = "missing",plot = "ANY"): If which is missing, the last ADEg of g1@ADEglist is used as the base of superposition. In that case, which = length(g1)`
- `signature(g1 = "ADEgORtrellis",g2 = "ADEgORtrellis",which = "ANY",plot = "ANY")`: If g1 is an ADEg object, no which is needed.
- `signature(g1 = "ADEgS",g2 = "ADEgS",which = "missing",plot = "ANY")`

The + method is defined for:

- `signature(e1 = "ADEg",e2 = "ADEg"): superpose e2 on e1`
- `signature(e1 = "ADEg",e2 = "ADEgS"): superpose e2 to e1`
- `signature(e1 = "ADEgS",e2 = "ADEg"): calls the + method with signature (e1 = "ADEg",e2 = "ADEgS").`
Value

An object of class "ADEgS".

## End(Not run)

T.cont-class

Class T.cont

Description

A class for the representation of a contingency table object with statistical information (mean and regression lines).

Objects from the Class

T.cont objects can be created by calls of the form new("T.cont",...).

The regular usage in this package is to use the table.value function with a table object.
Slots

data: a list containing data or data’s name.
  • dftab: a contingency table object in the form of a data frame, a name or a matching call
  • coordsx: an integer or a vector indicating the columns of dftab kept
  • coordsy: an integer or a vector indicating the rows of dftab kept
  • labelsx: the columns’ labels
  • labelsy: the rows’ labels
  • "frame": a positive or null integer. It is the number of the frame containing the data
    (used with sys.frame(..., env = data$frame)). Only if the data are not stored (i.e.
    data$storeData = FALSE).
  • storeData: a logical indicating if the data should be stored in the returned object. If
    FALSE, only the names of the data arguments are stored.

trellis.par a list of parameters for lattice call. It will be passed directly to par.settings
  arguments of the lattice function.

adeg.par a list of graphical parameters, corresponding to the ones given by adegpar() function.

lattice.call a list to create the trellis object.

g.args a list containing some method parameters linked with the created object of T.value class.

  The specific slots for T.cont objects are:
  • meanX: a logical to represent columns’ means by points.
  • meanY: a logical to represent rows’ means by points.
  • ablineX: a logical to represent columns’ regression lines.
  • ablineY: a logical to represent columns’ regression lines.

stats a list of internal preliminary calculations

s.misc a list of some others internal parameters

Call an object of class call

T.image-class

### Description

A class for the representation of a matrix or table object in which values have different colors.

### Objects from the Class

T.image objects can be created by calls of the form `new("T.image", ...)`. The regular usage in this package is to use the `table.image` function.

### Slots

- **data**: a list containing data or data's name.
  - `dftab`: the displayed values which can be table, dist or matrix in the form of a data frame, a name or a matching call
  - `coordsx`: an integer or a vector indicating the columns of `dftab` kept
  - `coordsy`: an integer or a vector indicating the rows of `dftab` kept
  - `labelsx`: columns labels
  - `labelsy`: rows labels
  - `frame`: a positive or null integer. It is the number of the frame containing the data (used with `sys.frame(..., env = data$frame)`). Only if the data are not stored (i.e. `data$storeData = FALSE`).
  - `storeData`: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored.
- **trellis.par**: a list of parameters for `lattice` call. It will be passed directly to `par.settings` arguments of the `lattice` function.
- **adeg.par**: a list of graphical parameters, corresponding to the ones given by `adegpar()` function.
- **lattice.call**: a list to create the `trellis` object.
- **g.args**: a list containing some method parameters linked with the created object of ADEg.T class.
  - The specific slots for T.image objects are:
    - `breaks`: a vector of values to split `dftab`. If `NULL`, `pretty(dftab, nclass)` is used.
    - `nclass`: an integer for the number of desired intervals, ignored if `breaks` is not missing.
    - `col`: a `NULL` value, a color or a colors vector used for the cells.
- **stats**: a list of internal preliminary calculations
- **s.misc**: a list of some others internal parameters:
  - `breaks.update`: a logical indicating if the legend `breaks` is updating.

</table>

**Description**

A class for the representation of a matrix, a data frame, or a distance matrix using symbols, varying in size or color.

**Objects from the Class**

`T.value` objects can be created by calls of the form `new("T.value",...)`.

The regular usage in this package is to use the `table.value` function.
Slots

data: a list containing data or data’s name.

• dftab: the displayed values which can be table, dist or matrix in the form of a data frame, a name or a matching call
• coordsx: an integer or a vector indicating the columns of dftab kept
• coordsy: an integer or a vector indicating the rows of dftab kept
• labelsx: the columns’ labels
• labelsy: the rows’ labels
• frame: a positive or null integer. It is the number of the frame containing the data (used with sys.frame(..., env = data$frame)). Only if the data are not stored (i.e. data$storeData = FALSE).
• storeData: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored.

trellis.par a list of parameters for lattice call. It will be passed directly to par.settings arguments of the lattice function.

adeg.par a list of graphical parameters, corresponding to the ones given by adegpar() function.
lattice.call a list to create the trellis object.
g.args a list containing some method parameters linked with the created object of adeg.T class.

The specific slots for T.value objects are:

• breaks: a vector of values to split dftab. If NULL, pretty(dftab, nclass) is used.
• nclass: an integer for the number of desired intervals, ignored if breaks is not missing.
• col: a NULL value, a color or a colors vector to color symbols.
• method: the method of representation for dftab (color shading or proportional size).
• symbol: the type of symbol (square or circle).
• center: a center value for method size.
• centerpar: a logical or a list to represent center value using elements in the adegpar("ppoints") list.

stats a list of internal preliminary calculations
s.misc a list of some others internal parameters:

• breaks.update: a logical indicating if the legend breaks is updating.

Examples

showClass("T.value")

---

**table.image**

*Heat map-like representation with colored cells*

Description

This function represents a two dimensional table plot in which cells are colored according with their value.

Usage

table.image(dftab, coordsx = 1:ncol(as.matrix(dftab)), coordsy = nrow(as.matrix(dftab)):1, labelsx, labelsy, nclass = 3, breaks = NULL, col = NULL, plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, ...)
Arguments

dftab  a data frame, matrix, contingency table or distance matrix used to produce the plot
coordsx an integer or a vector indicating the columns of dftab kept
coordsy an integer or a vector indicating the rows of dftab kept
labelsx columns labels
labelsy rows labels
breaks  a vector of values to split dftab. If NULL, pretty(dftab, nclass) is used.
nclass an integer for the number of desired intervals, ignored if breaks is not missing.
col  a color or a colors vector used for the cells
plot a logical indicating if the graphics is displayed
storeData a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored
add  a logical. If TRUE, the graphic is superposed to the graphics already plotted in the current device
pos an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if storeData is FALSE
... additional graphical parameters (see adegpar and trellis.par.get)

Value

An object of class ADEg (subclass T.image) or ADEgS (if add is TRUE). The result is displayed if plot is TRUE.

Author(s)

Alice Julien-Laferriere, Aurelie Siberchicot <aurelie.siberchicot@univ-lyon1.fr> and Stephane Dray

T.image ADEg.T

Examples

tax <- as.table(matrix(rnorm(900), ncol = 30))
g1 <- table.image(tab)

# add a continuous color bar as legend
# update(g1, plegend.drawColorKey = TRUE)
g2 <- table.image(tab, n = 100, coordsx = c(30, 1:29), plegend.drawKey = FALSE)
data(rpjdl, package = "ade4")
X <- data.frame(t(rpjdl$fau))
Y <- data.frame(t(rpjdl$mil))
coa1 <- ade4::dudi.coa(X, scannf = FALSE)
g3 <- table.image(Y, coordsx = rank(coa1$co[, 1]), coordsy = 1:8, nclas = 5,
  labelsx = "", plegend.drawKey = FALSE)

table.value

Heat map-like representation with proportional symbols

Description

This function represents a two dimensional table plot with proportional or colored squares or circles for each value.

Usage

```r
table.value(dftab, coordsx = 1:ncol(as.matrix(dftab)), coordsy =
nrow(as.matrix(dftab)):1, labelsx, labelsy, breaks = NULL, method =
c("size", "color"), symbol = c("square", "circle", "diamond",
"uptriangle", "downtriangle"), col = NULL, nclass = 3, center = 0,
centerpar = NULL, plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, ...)
```

Arguments

dftab a data frame, matrix, contingency table or distance matrix used to produce the plot
coordsx an integer or a vector indicating the columns of dftab kept
coordsy an integer or a vector indicating the rows of dftab kept
labelsx columns labels
labelsy rows labels
breaks a vector of values to split dftab. If NULL, pretty(dftab, nclass) is used.
method color or size value for represent z. If color, a palette of color is used for the symbols (one color per interval). If size, symbols of proportional area are used. Area is 0 for values equals to center (default 0). Two colors are used, for values less than center and larger than center.
symbol value for symbol type
col a color or a colors vector to color symbols. If method is size, a 2-length vector of color is expected. If method is color, it must have as many colors as the number of class
nclass an integer for the number of desired intervals, ignored if breaks is not missing.
center a center value for method size
centerpar a logical or a list to represent center value using elements in the adegpar("ppoints") list
plot a logical indicating if the graphics is displayed
storeData  a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored
add  a logical. If TRUE, the graphic is superposed to the graphics already plotted in the current device
pos  an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if storeData is FALSE
... additional graphical parameters (see adepar and trellis.par.get)

Value
An object of class ADEg (subclass T.cont if dftab is an table object, otherwise subclass T.value) or ADEgS (if add is TRUE).
The result is displayed if plot is TRUE.

Note
For the symbol size, if the method is size, we use perceptual scaling (Tanimura et al. 2006).

### Tr.class-class

**Class Tr.class**

#### Description

A class for group representation in triangular plot.

#### Objects from the Class

Tr.class objects can be created by calls of the form `new("Tr.class", ...)`

The regular usage in this package is to use the triangle.class function.

#### Slots

- **data** a list containing data or data’s name.
  - dfxyz: the displayed values in the form of a data frame with three columns, a name or a matching call.
  - fac: a factor partitionning the rows of dfxyz.
  - wt: a vector of weights for fac.
  - labels: a vector containing the class’ labels.
  - frame: a positive or null integer. It is the number of the frame containing the data (used with `sys.frame(..., env = data$frame)`). Only if the data are not stored (i.e. `data$storeData = FALSE`).
  - storeData: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored.

- **trellis.par** a list of parameters for lattice call. It will be passed directly to `par.settings` arguments of the lattice function.

- **adeg.par** a list of graphical parameters, corresponding to the ones given by `adegpar()` function.

- **lattice.call** a list to create the trellis object.
g.args a list containing some method parameters linked with the created object of ADEg.Tr class.
The specific slots for Tr.class objects are:

- **ellipseSize**: a positive number for ellipse size.
- **starSize**: a number between 0 and 1 for star size.
- **chullSize**: NULL or a vector of numbers between 0 and 1 for the convex hulls.
- **col**: a NULL value, a color or a colors vector to color points, ellipses, labels, lines and polygons.
- **max3d** and **min3d**: vectors of three values for triangular maximal and minimal limits.
- **adjust**: a logical to adjust the device with the limits of the smaller equilateral triangle containing the values.

Stats a list of internal preliminary calculations. The specific slots for S2.class objects are:

- **means**: a matrix containing the weighted mean calculated for each fac value.
- **mean2d**: a matrix containing the weighted mean calculated for each fac value on two-dimension.
- **covvar**: a list containing the weighted variance-covariance matrices calculated for each fac value.
- **covvar2d**: a list containing the weighted variance-covariance matrices calculated for each fac value on two-dimension.

s.misc a list of some others internal parameters:

- **ellipses**: ellipses' coordinates.
- **chullcoord**: convex hulls' coordinates.

Call an object of class call

Extends

Class ADEg.Tr, directly.
Class ADEg, by class ADEg.Tr, distance 2.
Class ADEgORtrellis, by class ADEg.Tr, distance 3.
Class ADEgORADEgSORtrellis, by class ADEg.Tr, distance 3.

Methods

The methods of the father classes "ADEg.Tr" and "ADEg" can be used by inheritance. The specific methods for Tr.class are:

- **prepare** signature(object = "Tr.class"): calls the parent method (prepare for ADEg.Tr), modifies some graphical parameters used by default and calculates ellipses, convex hulls and centroids.

- **panel** signature(object = "Tr.class"): draws arrows, labels and points.

**Class** Tr.label

**Description**

A class for creating and drawing triangular plot with point label.

**Objects from the Class**

Tr.label objects can be created by calls of the form new("Tr.label", ...).

The regular usage in this package is to use the triangle.label function.

**Slots**

data  a list containing data or data's name.

- dfxyz: the displayed values in the form of a three columns data frame, a name or a matching call.
- labels: a character vector containing labels for points.
- frame: a positive or null integer. It is the number of the frame containing the data (used with sys.frame(...,env = data$frame)). Only if the data are not stored (i.e. data$storeData = FALSE).
- storeData: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored.

trellis.par  a list of parameters for lattice call. It will be passed directly to par.settings arguments of the lattice function.

adeg.par  a list of graphical parameters, corresponding to the ones given by adegpar() function.

lattice.call  a list to create the trellis object.

g.args  a list containing some method parameters linked with the created object of ADEg.Tr class.

The specific slots for Tr.class objects are:

- addmean: a logical to plot the mean.
- addaxes: a logical to draw the principal axes.
- meanpar: a list to represent mean points using pch, cex and col.
- axespar: a list to represent axes lines using col, lwd and lty.
- max3d and min3d: vectors of three values for triangular maximal and minimal limits.
- adjust: a logical to adjust the device with the limits of the smaller equilateral triangle containing the values.
stats a list of internal preliminary calculations
s.misc a list of some others internal parameters:
  • cornerp: coordinates of the triangle extremities.

Tr.match-class Class Tr.match

Description
A class for the creation and display of paired coordinates in a triangular plot.

Objects from the Class
Tr.match objects can be created by calls of the form new("Tr.match", ...).
The regular usage in this package is to use the triangle.match function.
Slots

- **data**: a list containing data or data's name.
  - **dfxyz**: the displayed values in the form of a three columns data frame, a name or a matching call.
  - **labels**: a vector of character strings containing the matches' labels.
  - **frame**: a positive or null integer. It is the number of the frame containing the data (used with `sys.frame(..., env = data$frame)`). Only if the data are not stored (i.e. `data$storeData = FALSE`).
  - **storeData**: a logical indicating if the data should be stored in the returned object. If FALSE, only the names of the data arguments are stored.

- **trellis.par**: a list of parameters for `lattice` call. It will be passed directly to `par.settings` arguments of the `lattice` function.

- **adeg.par**: a list of graphical parameters, corresponding to the ones given by `adegpar()` function.

- **lattice.call**: a list to create the `trellis` object.

- **g.args**: a list containing some method parameters linked with the created object of ADEg.Tr class.

The specific slots for `Adegas.Tr` objects are:

- **max3d** and **min3d**: vectors of three values for triangular maximal and minimal limits.
- **adjust**: a logical to adjust the device with the limits of the smaller equilateral triangle containing the values.

- **stats**: a list of internal preliminary calculations

- **s.misc**: a list of some others internal parameters

Tr.traject-class

Description

A class for the creation and display of triangular plot with trajectories linking the points.

Objects from the Class

Tr.traject objects can be created by calls of the form new("Tr.traject", ...).

The regular usage in this package is to use the triangle.traject function.

Slots

data a list containing data or data’s name.
  • dfxyz: the displayed values in the form of a three columns data frame, a name or a
    matching call.
  • fac: a factor (or a matrix of factors) splitting the rows of dfxyz.
  • labels: a vector of character strings containing the trajectories’ labels.
  • frame: a positive or null integer. It is the number of the frame containing the data
    (used with sys.frame(..., env = data$frame)). Only if the data are not stored (i.e.
    data$storeData = FALSE).
  • storeData: a logical indicating if the data should be stored in the returned object. If
    FALSE, only the names of the data arguments are stored.

trellis.par a list of parameters for lattice call. It will be passed directly to par.settings
arguments of the lattice function.

adeg.par a list of graphical parameters, corresponding to the ones given by adegpar() function.

lattice.call a list to create the trellis object.

g.args a list containing some method parameters linked with the created object of ADEg.Tr class.

The specific slots for Tr.traject objects are:
  • max3d and min3d: vectors of three values for triangular maximal and minimal limits.
  • adjust: a logical to adjust the device with the limits of the smaller equilateral triangle
    containing the values
  • order: a vector containing the drawing order of the trajectories. A vector of length equal
    to factor.
  • col: a NULL value, a color or a colors vector to color points, labels and lines.

stats a list of internal preliminary calculations

triangle.class Ternary plot with a partition in classes (levels of a factor)

Description

This function represents a three dimensional scatter plot with a partition in classes (levels of a factor).

Usage

triangle.class(dfxyz, fac, wt = rep(1, NROW(fac)), labels = levels(fac),
col = NULL, ellipseSize = 1, starSize = 1, chullSize = NULL, adjust = TRUE,
min3d = NULL, max3d = NULL, showposition = TRUE, facets = NULL, plot = TRUE,
storeData = TRUE, add = FALSE, pos = -1, ...
Arguments

dfxyz a three columns data frame used to produce the plot
fac a factor (or a matrix of factors) splitting the rows of dfxyz
wt a vector of weights for fac
labels a character vector containing the class' labels
col a logical, a color or a colors vector to color points, ellipses, labels, lines and polygons
ellipseSize a positive number for ellipse size
starSize a number between 0 and 1 for the size of the stars segments joining the stars’ center (centroids) and the matching points
chullSize NULL or a vector of numbers between 0 and 1 for the fraction of points included in the convex hull
adjust a logical to adjust the device with the limits of the smaller equilateral triangle containing the values
min3d a vector of three values for triangular minimal limits
max3d a vector of three values for triangular maximal limits
showposition a logical indicating whether the used triangle should be shown in the complete one
facets a factor splitting the rows of dfxyz so that subsets of the data are represented on different sub-graphics
plot a logical indicating if the graphics is displayed
storeData a logical indicating if the data are stored in the returned object. If FALSE, only the names of the data arguments are stored
add a logical. If TRUE, the graphic is superposed to the graphics already plotted in the current device
pos an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if storeData is FALSE
... additional graphical parameters (see adegpar and trellis.par.get)

Value

An object of class ADEg (subclass Tr.class) or ADEgS (if showposition is TRUE, if add is TRUE and/or if facets are used).
The result is displayed if plot is TRUE.

Author(s)

Alice Julien-Laferriere, Aurelie Siberchicot <aurelie.siberchicot@univ-lyon1.fr> and Stephane Dray

Examples

```r
data(euro123, package = "ade4")
fac1 <- euro123$plan$an
df1 <- rbind.data.frame(euro123$in78, euro123$in86, euro123$in97)
triangle.class(df1, fac = fac1, showposition = TRUE, col = c(1, 2, 3))
triangle.class(df1, fac = fac1, showposition = FALSE, plabels.cex = 0, col = c(1, 2, 3),
key = list(space = "left"))
```

---

**Description**

This function represents a three-dimensional scatter plot with labels.

**Usage**

```r
triangle.label(dfxyz, labels = rownames(dfxyz), adjust = TRUE, min3d = NULL,
max3d = NULL, addaxes = FALSE, addmean = FALSE, meanpar = NULL, axespar = NULL,
showposition = TRUE, facets = NULL, plot = TRUE, storeData = TRUE, add = FALSE,
pos = -1, ...)
```

**Arguments**

- `dfxyz`: a three columns data frame used to produce the plot
- `labels`: a character vector containing labels for points
- `adjust`: a logical to adjust the device with the limits of the smaller equilateral triangle containing the values
- `min3d`: a vector of three values for triangular minimal limits
- `max3d`: a vector of three values for triangular maximal limits
- `addaxes`: a logical to draw the principal axes
- `addmean`: a logical to plot the mean
- `meanpar`: a list to represent mean points using `pch`, `cex` and `col`
- `axespar`: a list to represent axes lines using `col`, `lwd` and `lty`
- `showposition`: a logical indicating whether the used triangle should be shown in the complete one
- `facets`: a factor splitting the rows of `dfxyz` so that subsets of the data are represented on different sub-graphics
- `plot`: a logical indicating if the graphics is displayed
- `storeData`: a logical indicating if the data are stored in the returned object. If `FALSE`, only the names of the data arguments are stored
- `add`: a logical. If `TRUE`, the graphic is superposed to the graphics already plotted in the current device
pos

an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if \textit{storeData} is \texttt{FALSE}.

... additional graphical parameters (see \texttt{adegpar} and \texttt{trellis.par.get})

\textbf{Value}

An object of class \texttt{ADEg} (subclass \texttt{Tr.label}) or \texttt{ADEgS} (if \textit{showposition} is \texttt{TRUE}, if \texttt{add} is \texttt{TRUE} and/or if facets are used).
The result is displayed if \texttt{plot} is \texttt{TRUE}.

G <- ADEgS(c(g1, g2, g3, g4), layout = c(2, 2))

\begin{verbatim}
triangle.match  Ternary plot of the matching between two sets of coordinates
\end{verbatim}

\textbf{Description}

This function represents a three dimensional scatter plot of paired coordinates.

\textbf{Usage}

\begin{verbatim}
triangle.match(dfxyz1, dfxyz2, labels = row.names(as.data.frame(dfxyz1)),
min3d = NULL, max3d = NULL, adjust = TRUE, showposition = TRUE, facets = NULL,
plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, ...)
\end{verbatim}
triangle.match

Arguments

\textbf{dfxyz1} a three columns data frame, the first system of coordinates, used to produce the plot

\textbf{dfxyz2} a three columns data frame, the second system of coordinates, with as many rows as \textbf{dfxyz1}, used to produce the plot.

\textbf{labels} a vector of character strings containing the matches’ labels

\textbf{adjust} a logical to adjust the device with the limits of the smaller equilateral triangle containing the values

\textbf{min3d} a vector of three values for triangular minimal limits

\textbf{max3d} a vector of three values for triangular maximal limits

\textbf{showposition} a logical indicating whether the used triangle should be shown in the complete one

\textbf{facets} a factor splitting the rows of \textbf{dfxyz} so that subsets of the data are represented on different sub-graphics

\textbf{plot} a logical indicating if the graphics is displayed

\textbf{storeData} a logical indicating if the data are stored in the returned object. If FALSE, only the names of the data arguments are stored

\textbf{add} a logical. If TRUE, the graphic is superposed to the graphics already plotted in the current device

\textbf{pos} an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if \textbf{storeData} is FALSE

\ldots additional graphical parameters (see \texttt{adegpar} and \texttt{trellis.par.get})

Value

An object of class \texttt{ADEg} (subclass \texttt{Tr.match}) or \texttt{ADEgS} (if \texttt{showposition} is TRUE, if \texttt{add} is TRUE and/or if facets are used). The result is displayed if \texttt{plot} is TRUE.

\texttt{Tr.match} \texttt{ADEg.Tr}

Examples

data(euro123, package = "ade4")
triangle.match(euro123$in78, euro123$in86, plabels.cex = 0.8)
Description

This function represents a three dimensional scatter plot with trajectories.

Usage

triangle.traject(dfxyz, fac = gl(1, nrow(dfxyz)), order, labels = levels(fac),
col = NULL, adjust = TRUE, min3d = NULL, max3d = NULL, showposition = TRUE,
facets = NULL, plot = TRUE, storeData = TRUE, add = FALSE, pos = -1, ...)

Arguments

- **dfxyz**: a three columns data frame, the first system of coordinates, used to produce the plot
- **fac**: a factor (or a matrix of factors) splitting the rows of dfxyz
- **order**: a vector containing the drawing order of the trajectories. A vector of length equal to factor.
- **labels**: a vector of character strings containing the trajectories’ labels
- **col**: a color or a colors vector to color points, labels and lines
- **adjust**: a logical to adjust the device with the limits of the smaller equilateral triangle containing the values
- **min3d**: a vector of three values for triangular minimal limits
- **max3d**: a vector of three values for triangular maximal limits
- **showposition**: a logical indicating whether the used triangle should be shown in the complete one
- **facets**: a factor splitting the rows of dfxyz so that subsets of the data are represented on different sub-graphics
- **plot**: a logical indicating if the graphics is displayed
- **storeData**: a logical indicating if the data are stored in the returned object. If FALSE, only the names of the data arguments are stored
- **add**: a logical. If TRUE, the graphic is superposed to the graphics already plotted in the current device
- **pos**: an integer indicating the position of the environment where the data are stored, relative to the environment where the function is called. Useful only if storeData is FALSE
- **...**: additional graphical parameters (see adegpar and trellis.par.get)

Details

The fac factor is used to display several trajectories: each level of fac is a specific trajectory.
**Value**

An object of class `ADEg` (subclass `Tr.traject`) or `ADEgS` (if `showposition` is TRUE, if `add` is TRUE and/or if facets are used).
The result is displayed if `plot` is TRUE.

```

---

**Description**

This function performs a zoom on a `ADEg.S1` or `ADEg.S2` displayed object.

**Usage**

`zoom(object, zoom, center)`

**Arguments**

- `object` a `ADEg.S1` or `ADEg.S2` object
- `zoom` a numeric value to zoom in (if `zoom > 1`) or out (if `zoom < 1`)
- `center` a numeric value (if `object` is a `ADEg.S1` object) or a two-length vector (if `object` is a `ADEg.S2` object) as a reference point to zoom (in or out). If it is missing, the displayed center point is used.
Value

Updated display after zoom.
