alpaca-package

**Description**

Partials out factors with many levels during the optimization of the log-likelihood function of the corresponding generalized linear model (glm). The package is restricted to glm’s that are based on maximum likelihood estimation. This excludes all quasi-variants of glm. The package also offers an efficient algorithm to recover estimates of the fixed effects in a post-estimation routine and includes robust and multi-way clustered standard errors. Further the package provides analytical bias corrections for binary choice models (logit and probit) derived by Fernández-Val and Weidner (2016) and Hinz, Stammann, and Wanner (2020).

**Note:** Linear models are also beyond the scope of this package since there is already a comprehensive procedure available felm.
**biasCorr**

Asymptotic bias correction after fitting binary choice models with a two-/three-way error component

**Description**

*biasCorr* is a post-estimation routine that can be used to substantially reduce the incidental parameter bias problem (Neyman and Scott (1948)) present in non-linear fixed effects models (see Fernández-Val and Weidner (2018) for an overview). The command applies the analytical bias correction derived by Fernández-Val and Weidner (2016) and Hinz, Stammann, and Wanner (2020) to obtain bias-corrected estimates of the structural parameters and is currently restricted to logit and probit models with two- and three-way fixed effects.

**Usage**

```r
biasCorr(object = NULL, L = 0L, panel.structure = c("classic", "network"))
```

**Arguments**

- **object**
  an object of class "feglm": currently restricted to **binomial** with "logit" or "probit" link function.

- **L**
  unsigned integer indicating a bandwidth for the estimation of spectral densities proposed by Hahn and Kuersteiner (2011). Default is zero, which should be used if all regressors are assumed to be strictly exogenous with respect to the error term. In the presence of weakly exogenous or predetermined regressors, Fernández-Val and Weidner (2016, 2018) suggest to choose a bandwidth zero and four. Note that the order of factors to be partialed out is important for bandwidths larger than zero (see vignette for details).

- **panel.structure**
  a string equal to "classic" or "network" which determines the structure of the panel used. "classic" denotes panel structures where for example the same cross-sectional units are observed several times (this includes pseudo panels). "network" denotes panel structures where for example bilateral trade flows are observed for several time periods. Default is "classic".

**Value**

The function *biasCorr* returns a named list of classes "biasCorr" and "feglm".

**References**

Examples

# Generate an artificial data set for logit models
library(alpaca)
data <- simGLM(1000L, 20L, 1805L, model = "logit")

# Fit 'feglm()'
mod <- feglm(y ~ x1 + x2 + x3 | i + t, data)

# Apply analytical bias correction
mod.bc <- biasCorr(mod)
summary(mod.bc)

do invaluable

Description

coef.APEs is a generic function which extracts estimates of the average partial effects from objects returned by getAPes.

Usage

## S3 method for class 'APEs'
coef(object, ...)

Arguments

object an object of class "APEs".
...
other arguments.
The function `coef.APEs` returns a named vector of estimates of the average partial effects.

**See Also**

getAPEs

---

**Description**

`coef.feglm` is a generic function which extracts estimates of the structural parameters from objects returned by `feglm`.

**Usage**

```r
## S3 method for class 'feglm'
coef(object, ...)
```

**Arguments**

- `object`:
  - an object of class "feglm".
- `...`:
  - other arguments.

**Value**

The function `coef.feglm` returns a named vector of estimates of the structural parameters.

**See Also**

feglm

---

**Description**

`coef.summary.APEs` is a generic function which extracts a coefficient matrix of average partial effects from objects returned by `getAPEs`.

**Usage**

```r
## S3 method for class 'summary.APEs'
coef(object, ...)
```
coef.summary.feglm

Arguments

object an object of class "summary.APEs".
...
other arguments.

Value

The function coef.summary.APEs returns a named matrix of estimates related to the average partial effects.

See Also

getaPEs

c coef.summary.feglm

---

c coef.summary.feglm Extract coefficient matrix of structural parameters

d Description

c coef.summary.feglm is a generic function which extracts a coefficient matrix of structural parameters from objects returned by feglm.

Usage

## S3 method for class 'summary.feglm'
coef(object, ...)

Arguments

object an object of class "summary.feglm".
...
other arguments.

Value

The function coef.summary.feglm returns a named matrix of estimates related to the structural parameters.

See Also

feglm
Description

`feglm` can be used to fit generalized linear models with many high-dimensional fixed effects. The estimation procedure is based on unconditional maximum likelihood and can be interpreted as a "weighted demeaning" approach that combines the work of Gaure (2013) and Stammann et al. (2016). For technical details see Stammann (2018). The routine is well suited for large data sets that would be otherwise infeasible to use due to memory limitations.

Remark: The term fixed effect is used in econometrician’s sense of having intercepts for each level in each category.

Usage

```r
feglm(
  formula = NULL,
  data = NULL,
  family = binomial(),
  beta.start = NULL,
  eta.start = NULL,
  control = NULL
)
```

Arguments

- **formula**: an object of class "formula": a symbolic description of the model to be fitted. `formula` must be of type `y ~ x | k`, where the second part of the formula refers to factors to be concentrated out. It is also possible to pass additional variables to `feglm` (e.g. to cluster standard errors). This can be done by specifying the third part of the formula: `y ~ x | k | add`.
- **data**: an object of class "data.frame" containing the variables in the model.
- **family**: a description of the error distribution and link function to be used in the model. Similar to `glm.fit` this has to be the result of a call to a family function. Default is `binomial()`. See `family` for details of family functions.
- **beta.start**: an optional vector of starting values for the structural parameters in the linear predictor. Default is $\beta = 0$.
- **eta.start**: an optional vector of starting values for the linear predictor.
- **control**: a named list of parameters for controlling the fitting process. See `feglmControl` for details.

Details

If `feglm` does not converge this is usually a sign of linear dependence between one or more regressors and a fixed effects category. In this case, you should carefully inspect your model specification.
Value

The function `feglm` returns a named list of class "feglm".

References

Gaure, S. (2013). "OLS with Multiple High Dimensional Category Variables". Computational Statistics and Data Analysis, 66.

Examples

```r
# Generate an artificial data set for logit models
library(alpaca)
data <- simGLM(1000L, 20L, 1805L, model = "logit")

# Fit 'feglm()
mod <- feglm(y ~ x1 + x2 + x3 | i + t, data)
summary(mod)
```

Description

`feglm.nb` can be used to fit negative binomial generalized linear models with many high-dimensional fixed effects (see `feglm`).

Usage

```r
feglm.nb(
  formula = NULL,
  data = NULL,
  beta.start = NULL,
  eta.start = NULL,
  init.theta = NULL,
  link = c("log", "identity", "sqrt"),
  control = NULL
)
```
Arguments

- **formula, data, beta.start, eta.start, control**
  
  see [feglm](#).

- **init.theta**
  
  an optional initial value for the theta parameter (see [glm.nb](#)).

- **link**
  
  the link function. Must be one of "log", "sqrt", or "identity".

Details

If `feglm.nb` does not converge this is usually a sign of linear dependence between one or more regressors and a fixed effects category. In this case, you should carefully inspect your model specification.

Value

The function `feglm.nb` returns a named list of class "feglm".

### `feglmControl`

*Set feglm Control Parameters*

**Description**

Set and change parameters used for fitting `feglm`.

**Note:** `feglm.control` is deprecated and will be removed soon.

**Usage**

```r
feglmControl(
  dev.tol = 1e-08,
  center.tol = 1e-05,
  iter.max = 25L,
  limit = 10L,
  trace = FALSE,
  drop.pc = TRUE,
)```

---

---
conv.tol = NULL,
rho.tol = NULL,
pseudo.tol = NULL,
step.tol = NULL
}

feglm.control(...)

Arguments

dev.tol  
tolerance level for the first stopping condition of the maximization routine. The
stopping condition is based on the relative change of the deviance in iteration $r$
and can be expressed as follows: $|\text{dev}_r - \text{dev}_{r-1}|/(0.1 + |\text{dev}_r|) < \text{tol}$. Default is 1.0e-08.

center.tol  
tolerance level for the stopping condition of the centering algorithm. The stop-
ning condition is based on the relative change of the euclidean norm. Default is
1.0e-05.

iter.max  
unsigned integer indicating the maximum number of iterations in the maximiza-
tion routine. Default is 25L.

limit  
unsigned integer indicating the maximum number of iterations of theta.ml. Default is 10L.

trace  
logical indicating if output should be produced in each iteration. Default is FALSE.

drop.pc  
logical indicating to drop observations that are perfectly classified/separated and
hence do not contribute to the log-likelihood. This option is useful to reduce the
computational costs of the maximization problem and improves the numerical
stability of the algorithm. Note that dropping perfectly separated observations
does not affect the estimates. Default is TRUE.

conv.tol, rho.tol  
deprecated; step-halving is now similar to glm.fit2.

pseudo.tol  
deprecated; use center.tol instead.

step.tol  
deprecated; termination conditions is now similar to glm.

...  
arguments passed to the deprecated function feglm.control.

Value

The function feglmControl returns a named list of control parameters.

feglm
**fitted.feglm**

Extract feglm fitted values

---

**Description**

*fitted.feglm* is a generic function which extracts fitted values from an object returned by *feglm*.

**Usage**

```r
## S3 method for class 'feglm'
fitted(object, ...)
```

**Arguments**

- `object`: an object of class "feglm".
- `...`: other arguments.

**Value**

The function *fitted.feglm* returns a vector of fitted values.

**See Also**

*feglm*

---

**getAPEs**

Compute average partial effects after fitting binary choice models with a two-/three-way error component

---

**Description**

*getAPEs* is a post-estimation routine that can be used to estimate average partial effects with respect to all covariates in the model and the corresponding covariance matrix. The estimation of the covariance is based on a linear approximation (delta method). Note that the command automatically determines which of the regressors are continuous or binary.

**Remark:** The routine currently does not allow to compute average partial effects based on functional forms like interactions and polynomials.

**Usage**

```r
getAPEs(
  object = NULL,
  n.pop = NULL,
  panel.structure = c("classic", "network"),
  sampling.fe = c("independence", "unrestricted"),
  weak.exo = FALSE
)
```
getAPEs

Arguments

object an object of class "biasCorr" or "feglm"; currently restricted to \texttt{binomial} with "logit" or "probit" link function.
n.pop unsigned integer indicating a finite population correction for the estimation of the covariance matrix of the average partial effects proposed by Cruz-Gonzalez, Fernández-Val, and Weidner (2017). The correction factor is computed as follows: \( (n^* - n)/(n^* - 1) \), where \( n^* \) and \( n \) are the size of the entire population and the full sample size. Default is \texttt{NULL}, which refers to a factor of one and is equal to an infinitely large population.

panel.structure a string equal to "classic" or "network" which determines the structure of the panel used. "classic" denotes panel structures where for example the same cross-sectional units are observed several times (this includes pseudo panels). "network" denotes panel structures where for example bilateral trade flows are observed for several time periods. Default is "classic".

sampling.fe a string equal to "independence" or "unrestricted" which imposes sampling assumptions about the unobserved effects. "independence" imposes that all unobserved effects are mutually independent sequences. "unrestricted" does not impose any sampling assumptions. Note that this option only affects the estimation of the covariance. Default is "independence".

weak.exo logical indicating if some of the regressors are assumed to be weakly exogenous (e.g. predetermined). If object is of class "biasCorr", the option will be automatically set to \texttt{TRUE} if the chosen bandwidth parameter is larger than zero. Note that this option only affects the estimation of the covariance matrix. Default is \texttt{FALSE}, which assumes that all regressors are strictly exogenous.

Value

The function \texttt{getAPEs} returns a named list of class "APEs".

getFEs  

**Efficiently recover estimates of the fixed effects after fitting feglm**

Description

Recover estimates of the fixed effects by alternating between the normal equations of the fixed effects as shown by Stammann (2018).

Remark: The system might not have a unique solution since we do not take collinearity into account. If the solution is not unique, an estimable function has to be applied to our solution to get meaningful estimates of the fixed effects. See Gaure (n. d.) for an extensive treatment of this issue.

Usage

getFEs(object = NULL, alpha.tol = 1e-08)

Arguments

- **object**: an object of class "feglm".
- **alpha.tol**: tolerance level for the stopping condition. The algorithm is stopped in iteration \(i\) if \(\|\alpha_i - \alpha_{i-1}\|_2 < tol \|\alpha_{i-1}\|_2\). Default is 1.0e-08.
Value

The function `getFEs` returns a named list containing named vectors of estimated fixed effects.

`feglm`

predict.feglm

Predict method for `feglm` fits

Description

`predict.feglm` is a generic function which obtains predictions from an object returned by `feglm`.

Usage

```r
## S3 method for class 'feglm'
predict(object, type = c("link", "response"), ...)
```

Arguments

- **object**: an object of class "feglm".
- **type**: the type of prediction required. "link" is on the scale of the linear predictor whereas "response" is on the scale of the response variable. Default is "link".
- **...**: other arguments.

Value

The function `predict.feglm` returns a vector of predictions.

## S3 method for class 'summary.feglm'
print(x, digits = max(3L, getOption("digits") - 3L), ...)
```

Arguments

- `x` an object of class "summary.feglm".
- `digits` unsigned integer indicating the number of decimal places. Default is `max(3L,getOption("digits") - 3L)`.
- `...` other arguments.

See Also

- `feglm`
**Description**

Constructs an artificial data set with \( n \) cross-sectional units observed for \( t \) time periods for logit, poisson, or gamma models. The “true” linear predictor (\( \eta \)) is generated as follows:

\[
\eta_{it} = x'_{it}\beta + \alpha_i + \gamma_t,
\]

where \( X \) consists of three independent standard normally distributed regressors. Both parameter referring to the unobserved heterogeneity (\( \alpha_i \) and \( \gamma_t \)) are generated as iid. standard normal and the structural parameters are set to \( \beta = [1, -1, 1]' \).

**Note:** The poisson and gamma model are based on the logarithmic link function.

**Usage**

```r
simGLM(n = NULL, t = NULL, seed = NULL, model = c("logit", "poisson", "gamma"))
```

**Arguments**

- \( n \) a strictly positive integer equal to the number of cross-sectional units.
- \( t \) a strictly positive integer equal to the number of time periods.
- \( seed \) a seed to ensure reproducibility.
- \( model \) a string equal to "logit", "poisson", or "gamma". Default is "logit".

**Value**

The function `simGLM` returns a data.frame with 6 variables.

**See Also**

- `feglm`

---

**summary.APEs**

**Summarizing models of class APEs**

**Description**

Summary statistics for objects of class "APEs".

**Usage**

```r
## S3 method for class 'APEs'
summary(object, ...)
```
Arguments

object an object of class "APEs".
... other arguments.

Value

Returns an object of class "summary.APEs" which is a list of summary statistics of object.

See Also

gtAPEs

Description

Summary statistics for objects of class "feglm".

Usage

## S3 method for class 'feglm'
summary(
  object,
  type = c("hessian", "outer.product", "sandwich", "clustered"),
  cluster = NULL,
  cluster.vars = NULL,
  ...
)

Arguments

object an object of class "feglm".

type the type of covariance estimate required. "hessian" refers to the inverse of the negative expected Hessian after convergence and is the default option. "outer.product" is the outer-product-of-the-gradient estimator, "sandwich" is the sandwich estimator (sometimes also referred as robust estimator), and "clustered" computes a clustered covariance matrix given some cluster variables.

cluster a symbolic description indicating the clustering of observations.

cluster.vars deprecated; use cluster instead.

... other arguments.

Details

Multi-way clustering is done using the algorithm of Cameron, Gelbach, and Miller (2011). An example is provided in the vignette "Replicating an Empirical Example of International Trade".
Value

Returns an object of class "summary.feglm" which is a list of summary statistics of object.

References

See Also

feglm

Description

vcov.feglm computes an estimate of the covariance matrix of the estimator of the structural parameters from objects returned by feglm. The estimate is obtained using the Hessian, the scores, or a combination of boths after convergence.

Usage

## S3 method for class 'feglm'
vcov(
  object,
  type = c("hessian", "outer.product", "sandwich", "clustered"),
  cluster = NULL,
  cluster.vars = NULL,
  ...
)

Arguments

object an object of class "feglm".

type the type of covariance estimate required. "hessian" refers to the inverse of the negative expected Hessian after convergence and is the default option. "outer.product" is the outer-product-of-the-gradient estimator, "sandwich" is the sandwich estimator (sometimes also refered as robust estimator), and "clustered" computes a clustered covariance matrix given some cluster variables.

cluster a symbolic description indicating the clustering of observations.

cluster.vars deprecated; use cluster instead.

... other arguments.
Details

Multi-way clustering is done using the algorithm of Cameron, Gelbach, and Miller (2011). An example is provided in the vignette "Replicating an Empirical Example of International Trade".

Value

The function \texttt{vcov.feglm} returns a named matrix of covariance estimates.
