Package ‘alr3’

June 22, 2018

Version 2.0.8
Date 2018-06-22
Title Data to Accompany Applied Linear Regression 3rd Edition
Author Sanford Weisberg <sandy@umn.edu>
Maintainer Sanford Weisberg <sandy@umn.edu>
Depends R (>= 3.2.0), car
LazyData yes
Description Data files and a few functions used in the textbook S. Weisberg (2005), 'Applied Linear Regression,' 3rd edition, Wiley are presented. This package depends on the car package. Many functions formerly in alr3 have been renamed and now reside in car. Data files have been lightly modified to make some data columns row labels. Many of these files are also in the newer alr4 package.

**Description**

Data on 102 male and 100 female athletes collected at the Australian Institute of Sport.

**Format**

This data frame contains the following columns:

- **Sex** (0 = male or 1 = female)
- **Ht** height (cm)
- **Wt** weight (kg)
- **LBM** lean body mass
- **RCC** red cell count
- **WCC** white cell count
- **Hc** Hematocrit
- **Hg** Hemoglobin
- **Ferr** plasma ferritin concentration
- **BMI** body mass index, weight/(height)**2
- **SSF** sum of skin folds
- **Bfat** Percent body fat
- **Label** Case Labels
- **Sport** Sport
Source

Ross Cunningham and Richard Telford

head(allshoots)

<table>
<thead>
<tr>
<th>allshoots</th>
<th>Apple shoots data</th>
</tr>
</thead>
</table>

Description

Bland’s Apple Shoot data. allshoots includes all the data, shortshoots just the short shoot data, and longshoots includes long shoots only.

Format

This data frame contains the following columns:

- **Day** days from dormancy
- **n** number of shoots sampled
- **ybar** average number of stem units
- **SD** within-day standard deviation
- **Type** 1 if long shoots, 0 if shortshoots.

Degprecated Functions in the alr3 Package

Description

These functions are provided for compatibility with older versions of alr3 only, and may be removed eventually.

Usage

conf.intervals(...)
boot.case(...)
pure.error.anova(...)
delta.method(...)
powtran(...)
inv.tran.plot(...)
inv.tran_estimate(...)
inverse.response.plot(...)
inv.res.plot(...)
bctrans(...)
bctrans1(...)
lrt.bctrans(...)

resplot(...)
residual.plots(...)
marginal.model.plot(...)
marginal.model.plots(...)

alr3-deprecated
inf.index(...) 
outlier.t.test(...) 

Arguments
...
... pass arguments down.

Details
random.lin.comb pure.error.anova are now synonyms for sigmahat, randomLinComb and pureErrorAnova, all of which are still part of the alr3 package.
conf.intervals is a synonym for confint in the stats package.
All the remaining functions now shadow newer functions in the car package. In several cases, the arguments to the function have changed as well, and so there is no guarantee that any of these will work as expected. Please substitute the corresponding function from car.

alrWeb  Access to the Applied Linear Regression website

Description
This function will access the website for Applied Linear Regression

Usage
alrWeb(page = c("webpage", "errata", "primer"), script)

Arguments
page  A character string indicating what page to open. The default "webpage" will open the main webpage, "errata" displays the Errata sheet for the book, and "primer" fetches and displays the primer for R.
script  If set, this will open an R script for one of the chapters in the book in a browser window, or a script from one of the chapters in the R Primer. Possible values are "chapter1", "chapter2", ... "chapter12", "appendix" for chapters and appendix from the book, or "primer0", "primer1", ... "primer12", "primerappendix" for material corresponding to the R primer.

Value
Either a webpage or a pdf document is displayed. This function gives quick access to the website for the book and in particular to the R primer.

Author(s)
Sanford Weisberg, based on the function UsingR in the UsingR package by John Verzani

BigMac2003 World cities data

Description
Prices in many world cities from a 2003 Union Bank of Switzerland report.

Format
This data frame uses the name of the city as row names, and contains the following columns:

BigMac Minutes of labor to purchase a Big Mac
Bread Minutes of labor to purchase 1 kg of bread
Rice Minutes of labor to purchase 1 kg of rice
FoodIndex Food price index (Zurich=100)
Bus Cost in US dollars for a one-way 10 km ticket
Apt Normal rent (US dollars) of a 3 room apartment
TeachGI Primary teacher’s gross income, 1000s of US dollars
TeachNI Primary teacher’s net income, 1000s of US dollars
TaxRate Tax rate paid by a primary teacher
TeachHours Primary teacher’s hours of work per week:

<tr>
<th>blowdown</th>
<th>Blowdown data</th>
</tr>
</thead>
</table>

Description
Data from the Boundary Waters Canoe Area Wilderness Blowdown. The data frame blowdown includes nine species of trees, blowAPB gives data for aspen and paper birch, while blowBF gives data for Balsam Fir only.

Format
This data frame contains the following columns:

- **D** Tree diameter, in cm
- **S** Proportion of basal area killed for the four species BF, C, PB, BS, a measure of local severity of the storm.
- **y** 1 if the tree died, 0 if it survived
- **SPP** BF= balsam fir, BS= black spruce, C= cedar, JP= jackpine, PB= paper birch, RP= red pine, RM= red maple, BA = black ash, A= aspen.

Source

Challenger data

Description
Contains data from the performance of O-rings in 23 U.S. space shuttle flights prior to the Challenger disaster of January 20, 1986.

Format
This data frame contains the following columns:
- Temp Air Temp at launch (degrees F)
- Pres Leak check pressure
- Fail Number of O-rings that failed
- n 6, number of O-rings in launch
- Erosion Number of erosion incidents
- BlowBy Number of blowby incidents
- Damage Total Damage Index
- Date date of flight

cloud

Description

The data summarize the results of the first Florida Area Cumulus Experiment, or FACE-I, designed to study the effectiveness of cloud seeding to increase rainfall in a target area (Woodley, Simpson, Biondini, and Berkley, 1977).

Format

This data frame contains the following columns:

- **A**: Action, 1=seed, 0=do not seed
- **D**: Day after June 16, 1975
- **S**: Suitability for seeding
- **C**: percent cloud cover in experimental area, measured using radar in Coral Gables, Florida
- **P**: $10^7 m^3$ prewetness
- **E**: echo motion category, either 1 or 2, a measure for type of cloud
- **Rain**: $10^7 m^3$ in target area

head(cloud)

domedata

Description

These files give the results of two experiments to see if manipulating the air conditioning fans in the Minneapolis metrodome can effect the distance travelled by a baseball. The data in domedata were collected in April 2003. The experiment was repeated in May 2003 and domedata1 gives the combined data from the two experiments.
Format

A data frame with 96 observations on the following 7 variables.

- **Date**  a factor with levels March- May
- **Cond**  a factor with levels Headwind, Tailwind
- **Angle**  the actual angle
- **Velocity**  in feet per second
- **BallWt**  weight of ball in grams
- **BallDia**  diameter of ball in inches
- **Dist**  distance in feet of the flight of the ball

---

**Description**

The Donner Party was the most famous tragedy in the history of the westward migration in the United States. In the winter of 1846-47, about ninety wagon train emigrants were unable to cross the Sierra Nevada Mountains of California before winter, and almost one-half starved to death. Perhaps because they were ordinary people – farmers, merchants, parents, children. These data include some information about each of the members of the party from Johnson (1996).

**Format**

This data frame uses the person’s name as row labels and contains the following columns:

- **Age**  Approximate age in 1846
- **Outcome**  1 if survived, 0 if died
- **Sex**  Male or Female
- **Family.name**  Either a family name, hired or single
- **Status**  Family, single or hired
Source

head(donner)

downer Downer data

Description

For unknown reasons, some dairy cows become recumbant—they lay down. This condition can be serious, and may lead to death of the cow. These data are from a study of blood samples of over 500 cows studied at the Ruakura (N.Z.) Animal Health Laboratory during 1983-84. A variety of blood tests were performed, and for many of the animals the outcome (survived, died, or animal was killed) was determined. The goal is to see if survival can be predicted from the blood measurements. Case numbers 12607 and 11630 were noted as having exceptional care—and they survived.

Format

This data frame contains the following columns:

- **Calving** 0 if measured before calving, 1 if after
- **Daysrec** Days recumbent
- **CK** Serum creatine phosphokinase (U/l at 30C)
- **AST** serum asparate amino transferase (U/l at 30C)
- **Urea** serum urea (mmol/l)
- **PCV** Packed Cell Volume (Haemactocrit),
- **Inflamat** inflammation 0=no, 1=yes
- **Myopathy** Muscle disorder, 1 if present, 0 if absent
- **Outcome** outcome: 1 if survived, 0 if died or killed

Source

## References

## Examples

```r
head(drugcost)
```

<table>
<thead>
<tr>
<th>drugcost</th>
<th>Drug cost.</th>
</tr>
</thead>
</table>

## Description

These data are to try to understand the effect of health plan characteristics on drug costs. Health plans vary in size, given as member months. Some plans use generic drugs more than others. All differ on copayments. Some have strong restrictions on which drugs can be dispensed: value of RI=0 means that all drugs are dispensed, RI=100 means that only one per category is available. The goal is to determine the terms that are related to cost, and in particular to understand the role of GS and RI in determining cost.

## Format

This data frame uses a short code name for the drug plan as row labels and contains the following columns:

- **COST**: Ave. cost to plan for 1 prescription for 1 day
- **RXPM**: Number of prescriptions per member per year
- **GS**: Percent generic substitution, number between 0 (no substitution) to 100 (always use generic substitute)
- **RI**: Restrictiveness index (0=none, 100=total)
- **COPAY**: Average Rx copayment
- **AGE**: Average age of member
- **F**: Percent female members
- **MM**: Member months, a measure of the size of the plan

An experiment was conducted to study the \textit{O2UP}, oxygen uptake in milligrams of oxygen per minute, given five chemical measurements: biological oxygen demand (BOD), total Kjeldahl nitrogen (TKN), total solids (TS), total vital solids (TVS), which is a component of TS, and chemical oxygen demand (COD), each measured in milligrams per liter (Moore, 1975). 

This data frame contains the following columns:

- \textbf{Day} Day number
- \textbf{BOD} Biological oxygen demand
- \textbf{TKN} Total Kjeldahl nitrogen
- \textbf{TS} Total Solids
- \textbf{TVS} Total volatile solids
- \textbf{COD} Chemical oxygen demand
- \textbf{O2UP} Oxygen uptake

<table>
<thead>
<tr>
<th>highway</th>
<th>Highway accidents</th>
</tr>
</thead>
</table>

**Description**

The data comes from an unpublished master’s paper by Carl Hoffstedt. They relate the automobile accident rate, in accidents per million vehicle miles to several potential terms. The data include 39 sections of large highways in the state of Minnesota in 1973. The goal of this analysis was to understand the impact of design variables, Acpts, Slim, Sig, and Shld that are under the control of the highway department, on accidents.

**Format**

This data frame contains the following columns:

- **ADT**  average daily traffic count in thousands
- **Trks**  truck volume as a percent of the total volume
- **Lane**  total number of lanes of traffic
- **Acpt**  number of access points per mile
- **Sigs**  number of signalized interchanges per mile
- **Itg**  number of freeway-type interchanges per mile
- **Slim**  speed limit in 1973
- **Len**  length of the highway segment in miles
- **Lwid**  lane width, in feet
- **Shld**  width in feet of outer shoulder on the roadway
- **Hwy**  An indicator of the type of roadway or the source of funding for the road; 0 if MC, 1 if FAI, 2 if PA, 3 if MA
- **Rate**  1973 accident rate per million vehicle miles

jevons

Jevon's gold coin data

Description

In a study of coinage, W. Stanley Jevons weighed 274 gold sovereigns that he had collected from circulation in Manchester, England. For each coin, he recorded the weight, after cleaning, to the nearest .001 gram, and the date of issue. The age classes are coded 1 to 5, roughly corresponding to the age of the coin in decades. The standard weight of a gold sovereign was suppose to be 7.9876 grams; minimum legal weight was 7.9379 grams.
Format

This data frame contains the following columns:

- **Age**: Age of coins, decades
- **n**: Number of coins
- **Weight**: Average weight, grams
- **SD**: Standard deviation.
- **Min**: Minimum weight
- **Max**: Maximum weight

*Lake zooplankton diversity*

### Description

These data give the number of known crustacean zooplankton species for 69 world lakes. Also included are a number of characteristics of each lake. There are missing values.

### Format

This data frame uses lake name as row label and contains the following columns:

- **Species**: Number of zooplankton species
- **MaxDepth**: Maximum lake depth, m
- **MeanDepth**: Mean lake depth, m
- **Cond**: Specific conductance, micro Siemans
- **Elev**: Elevation, m
- **Lat**: N latitude, degrees
- **Long**: W longitude, degrees
- **Dist**: Distance to nearest lake, km
- **NLakes**: Number of lakes within 20 km
- **Photo**: Rate of photosynthesis, mostly by the 14C method
- **Area**: Lake area, in hectares

*Lathe data*

**Description**

These data are the results of an experiment to study the performance of cutting-tool material in cutting steel on a lathe. The two factors are revolution speed and feed rate. The response is tool life in minutes.

**Format**

This data frame contains the following columns:

- **Feed** Coded feed rate, coded as (actual feed rate -13)/6. Feed is in thousandths of an inch per revolution.
- **Speed** Coded speed, coded as (actual speed -900)/300. Speed is in feet per minute.
- **Life** Life of tool until failure, minutes

The Alaska pipeline data consists of in-field ultrasonic measurements of the depths of defects in the Alaska pipeline. The depth of the defects were then re-measured in the laboratory. These measurements were performed in six different batches. The data were analyzed to calibrate the bias of the field measurements relative to the laboratory measurements. In this analysis, the field measurement is the response variable and the laboratory measurement is the predictor variable.

These data were originally provided by Harry Berger, who was at the time a scientist for the Office of the Director of the Institute of Materials Research (now the Materials Science and Engineering Laboratory) of NIST. These data were used for a study conducted for the Materials Transportation Bureau of the U.S. Department of Transportation.

This data frame contains the following columns:

- **Field**: Number of defects measured in the field.
- **Lab**: Number of defects measured in the laboratory.
- **Batch**: Batch number

A partial one-dimensional model, or a POD model, provides a concise description of a regression model with many predictors and one grouping variable. It requires a nonlinear regression fit.
Usage

## This is a generic function with different arguments depending on the class of the
## first argument. The generic form is

pod(x, ...)

## If the first argument to pod is a formula suitable for defining a linear model,

## S3 method for class 'formula'
pod(formula, data = sys.parent(), group, subset, weights,
    na.action, mean.function = c("pod", "common", "parallel",
    "general"), singular.ok = FALSE, contrasts = NULL, offset,
    control = nls.control(), ...)

## If the first argument to pod is the result of a linear model fit, the following
## function call is used. All the arguments for pod.formula can also be passed to
## pod.lm.

## S3 method for class 'lm'
pod(x, group, mean.function, control, ...)

## The following related function require a pod fit as the first argument:

## S3 method for class 'pod'
anova(object, scale=0, test="F", ...)

## S3 method for class 'pod'
plot(x, colors=1:nlevels(x$group),
   pch=1:nlevels(x$group), key="topleft", identify=FALSE,
    xlab="Linear Predictor", ylab=as.character(c(formula(x)[[2]])),
    ...)

## S3 method for class 'pod.lm'
plot(x, colors=1:nlevels(x$group),
    pch=1:nlevels(x$group), key="topleft", identify=FALSE,
    xlab="Linear Predictor", ylab=as.character(c(formula(x)[[2]])),
    ...)

Arguments

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>formula</strong></td>
<td>A linear regression formula, as used in <code>lm</code>, or the results of a call to pod or a <code>lm</code> fit. See details below.</td>
<td></td>
</tr>
<tr>
<td><strong>x</strong></td>
<td>The result of a <code>lm</code> fit from which the formula and the arguments <code>data</code>, <code>subset</code>, <code>weights</code>, <code>na.action</code>, <code>singular.ok</code>, <code>contrasts</code> and <code>offset</code> will be taken.</td>
<td></td>
</tr>
<tr>
<td><strong>data</strong></td>
<td>An optional data frame for the data to be used</td>
<td></td>
</tr>
<tr>
<td><strong>group</strong></td>
<td>The name of a grouping variable (not quoted) that defines the groups; see details below.</td>
<td></td>
</tr>
</tbody>
</table>
Which mean function should be fit? The default is “pod”, that fits the partial one-dimensional mean function. The other options are “common”, which fits a linear model with no grouping effects; “parallel” fits a parallel within-group regression, and “general”, available in pod but not plot.pod, fits a separate coefficient for each term in the model for each level of the grouping variable.

As in lm, the subset of cases to be used in the analysis

Weights will be used in fitting non-pod models. Since this argument is not supported for nls models, weights are ignored for fitting pod models. If nls is ever updated, then pod models will correctly use the weights.

At present, only na.omit is likely to work.

The default equal to FALSE is recommended.

Same as in lm

Same as in lm

A pod model is fit using the nonlinear least squares routine nls. This routine is very sensitive to starting values and other parameters set in the algorithm. This routine selects starting values for you that will often work very well, but in some problems the user may want to change the defaults to nls program using the nls.control function.

In pod, other arguments passed to nls, such as control parameters. In pod.anova, there are two additional arguments

The result of a call to pod.

Used for test in anova

Default is to compute F tests.

Colors for groups in the pod plot

Ploting symbol for the groups in the pod plot

If TRUE, clicking the mouse on a graph will print the case name of the nearest point. This continues until turned off (by pushing the escape key, among other ways of doing this).

The default is "topleft", in which case a legend is added to the top left corner of the plot; other choices include "bottomright". If key is a vector of two coordinates, the legend is drawn at the coordinates specified. If key is FALSE, no key is drawn; if TRUE, you can place the key interactively by clicking on the plot.

Horizontal label, optional

Vertical label, optional

Suppose we start with a linear mean function specified by $y \sim x_1 + x_2 + x_3$, where the right-side variables can be any valid R variables, such as transformations, but NOT factors or interactions (if you want to include these, you need to create the dummy variables yourself). The right-hand side variables must also be linearly independent. We also specify a grouping variable $z$ with, say, g
levels. Let $G_i$ be a dummy variable with values equal to 1 when $z = i$, and zero otherwise. The pod mean function is then has the nonlinear mean function

$$E(y|x, z) = \beta_0 + \beta' x + \sum_{j=2}^{g} G_j (\theta_0 + \theta_j \beta' x)$$

This is a nonlinear mean function that specifies that the response depends on the predictors only through one linear combination, that the dependence is linear, but the slope and intercept may be different for each group.

The pod mean function is easily fit using nls. For example, if $z$ has two levels, a nonlinear mean function that would work is $y \sim b0 + b1*x1 + b2*x2 + b3*x3 + G2*(th02 + th12*(b1*x1 + b2*x2 + b3*x3))$. Starting values can be determined by fitting the parallel mean function, for this is a linear mean function and easily fit.

The function pod automates this process; you need only input the linear part of the mean function, and pod does the rest.

The function anova.pod is a little different from the generic anova function. It fits and compares all four mean functions that can be fit with the pod function: (1) no group effect; (2) parallel within group method; (3) pod mean function; (4) mean function with all main effects and two-factor interactions with the grouping variable.

The function plot will plot the response versus the fitted linear combination for either the common, parallel or pod models. There is no 2D plot for the general model.

Objects of class pod have methods defined for the generic functions print, summary, coef, anova, deviance, vcov, resid, formula, fitted, df.residual and predict. podresponse returns the values of the response.

**Value**

If `mean.function="pod"`, a list of class pod, with the following components

- `nls.fit` The usual output from a nls fit.
- `linear.part` The estimated linear predictor $\beta' x$.
- `call` The original call to pod
- `group` The grouping variable

If `mean.function` has any other value, an object of class c("pod.lm", "lm") is returned. Since the only method for pod.lm objects is a plotting method, except for plotting these objects behave like lm objects.

Soil productivity scores for farms in townships in four counties in the Minneapolis St. Paul metropoli-
tan area, 1981-82. The goal is to see if the productivity score is a good predictor of the assessed
value of the farmland. If so, then productivity score could be used to set assessed value for farms
enrolled in the “green acres” program that requires that urban farmland be taxed at its agricultural
value only without regard to development potential.

This data frame contains the following columns:

**County** Name of the county
**Value** Assessed value in dollars per acre.
**P** Productivity score, a number between 1 and 100.
**Year** Tax year, either 1981 or 1982.

head(prodscore)
pureErrorAnova

pureErrorAnova Pure Error analysis of variance

Description
For a linear model object, finds the sum of squares for lack of fit and the sum of squares for pure error. These are added to the standard anova table to give a test for lack of fit. If there is no pure error, then the regular anova table is returned.

Usage

### This is a generic function.

pureErrorAnova(mod)

## S3 method for class 'lm'
pureErrorAnova(mod)

### Methods for other than models for type lm have not been defined.

Arguments

mod an object of type lm

Details
For regression models with one predictor, say y ~ x, this method fits y ~ x + factor(x) and prints the anova table. With more than one predictor, it computes a random linear combination L of the terms in the mean function and then gives the anova table for update(mod, ~.+factor(L)).

Value
Returns an analysis of variance table.

randomLinComb

Compute a random linear combination of the columns of a matrix or data frame

Description

Computes \( Xa \) where \( X \) is an \( n \times p \) matrix, and \( a \) is a random vector of length \( p \).

Usage

randomLinComb(X, seed = NULL)

## S3 method for class 'lm'
randomLinComb(X, seed=NULL)

Arguments

- **X**: An \( n \times p \) matrix or data frame. For the \( \text{lm} \) method, \( X \) is a linear regression model, and \( \text{randomLinComb} \) is applied to \( \text{model.matrix}(X) \)
- **seed**: If not NULL, use this to initialize the random number generator

Details

The matrix \( X \) is first scaled and centered. \( a \) is computed to have random uniform components on \((-1, 1)\).

Value

A vector of length \( n \).

### Simple windmill data

**Description**

Windspeed data collected at a test site for a windmill, and also at a nearby long-term weather site, in Northern South Dakota. Data collected every six hours for all of 2002, except that all of the month of May and a few other observations are missing.

**Format**

A data frame with 1116 observations on the following 3 variables.

- **Date** A text variable with values like "2002/1/2/6" meaning the reading at 6AM on January 2, 2002
- **CSpd** Windspeed in m/s at the candidate site
- **RSpd** Windspeed for the reference site

**Source**

Mark Ahlstrom and Rolf Miller, WindLogics, Inc.

**Examples**

```r
head(wm1)
```

### Windmill data with direction information

**Description**

Windspeed data collected at a test site for a windmill, and also at a nearby long-term weather site, in Northern South Dakota. Data collected every six hours for all of 2002, except that all of the month of May and a few other observations missing.

**Format**

A data frame with 1116 observations on the following 5 variables.

- **Date** A text variable with values like "2002/1/2/6" meaning the reading at 6AM on January 2, 2002
- **CSpd** Windspeed in m/s at the candidate site
- **RSpd** Windspeed for the reference site
- **RDir** Wind direction, in degrees, at the reference site
- **Bin** Wind direction binned into 16 equal width bins

**wm3**

*Binned wind speed data*

---

Description

For the windspeed data in the file *wm2*, this is the number of observations in each of the bins, and the average windspeed in that bin.

Format

A data frame with 16 observations on the following 2 variables.

- **bin.count** Number of observations in the bin
- **RSpd** Average windspeed in the bin

Windmill data with direction information and four reference sites

Description

Windspeed data collected at a test site for a windmill, and also at four nearby long-term weather site, in Northern South Dakota. Data collected every six hours for all of 2002, except that all of the month of May and a few other observations are missing.

Format

A data frame with 1114 observations on the following 14 variables.

- **Date** A text variable with values like "2002/1/2/6" meaning the reading at 6AM on January 2, 2002
- **CSpd** Wind speed (m/s) at candidate site
- **Spd1** Wind speed (m/s) at reference site 1
- **Spd2** Wind speed (m/s) at reference site 2
- **Spd3** Wind speed (m/s) at reference site 3
- **Spd4** Wind speed (m/s) at reference site 4
- **Spd1Lag1** Lag 1 Wind speed (m/s) at reference site 1
- **Spd2Lag1** Lag 1 Wind speed (m/s) at reference site 2
- **Spd3Lag1** Lag 1 Wind speed (m/s) at reference site 3
- **Spd4Lag1** Lag 1 Wind speed (m/s) at reference site 4
- **Spd1sin1** Spd times sin(direction) at site 1
- **Spd1cos1** Spd times cos(direction) at site 1
- **bin1** Wind direction bin for site 1
- **Dir1** Wind direction for site 1, in degrees

### Description

This is a three-factor experiment with each factor at three levels, for a total of 27 runs. Samples of worsted yarn were with different levels of the three factors were given a cyclic load until the sample failed. The goal is to understand how cycles to failure depends on the factors.

### Format

This data frame contains the following columns:

- **Len** length of specimen (250, 300, 350 mm)
- **Amp** amplitude of loading cycle (8, 9, 10 min)
- **Load** load (40, 45, 50g)
- **Cycles** number of cycles until failure
