Package ‘aplpack’

July 29, 2019

Title Another Plot Package: 'Bagplots', 'Iconplots', 'Summaryplots', Slider Functions and Others

Version 1.3.3

Date 2019-07-26

Author Hans Peter Wolf [aut, cre]

Maintainer Hans Peter Wolf <pwolf@wiwi.uni-bielefeld.de>

Depends R (>= 3.0.0)

Suggests tkrplot, jpeg, png, splines, utils, tcltk

Description Some functions for drawing some special plots:
The function 'bagplot' plots a bagplot, 'faces' plots chernoff faces, 'iconplot' plots a representation of a frequency table or a data matrix, 'plot hulls' plots hulls of a bivariate data set, 'plot summary' plots a graphical summary of a data set, 'put icon' adds icons to a plot, 'skyline.hist' combines several histograms of a one dimensional data set in one plot, 'slider' functions supports some interactive graphics, 'spin3R' helps an inspection of a 3-dim point cloud, 'stem.leaf' plots a stem and leaf plot, 'stem.leaf.backback' plots back-to-back versions of stem and leaf plot.

License GPL (>= 2)

R topics documented:

- bagplot
- bagplot.pairs
bagplot, a bivariate boxplot

Description

compute.bagplot() computes an object describing a bagplot of a bivariate data set. plot.bagplot() plots a bagplot object. bagplot() computes and plots a bagplot.

Usage

```r
bagplot(x, y, factor = 3, na.rm = FALSE, approx.limit = 300,
        show.outlier = TRUE, show.whiskers = TRUE,
        show.looppoints = TRUE, show.bagpoints = TRUE,
        show.loophull = TRUE, show.baghull = TRUE,
        create.plot = TRUE, add = FALSE, pch = 16, cex = 0.4,
        dkmethod = 2, precision = 1, verbose = FALSE,
        debug.plots = "no", col.loophull="#aaccff",
        col.looppoints="#3355ff", col.baghull="#7799ff",
        col.bagpoints="#000088", transparency=FALSE,
        show.center = TRUE, 
        ...
)
calculate.bagplot(x, y, factor = 3, na.rm = FALSE, approx.limit = 300,
                  dkmethod=2,precision=1,verbose=FALSE,debug.plots="no")
```
Arguments

- **x**: x values of a data set; in `bagplot`: an object of class `bagplot` computed by `compute.bagplot`.
- **y**: y values of the data set.
- **factor**: factor defining the loop.
- **na.rm**: if TRUE 'NA' values are removed otherwise exchanged by median.
- **approx.limit**: if the number of data points exceeds `approx.limit` a sample is used to compute some of the quantities; default: 300.
- **show.outlier**: if TRUE outlier are shown.
- **show.whiskers**: if TRUE whiskers are shown.
- **show.looppoints**: if TRUE loop points are plotted.
- **show.bagpoints**: if TRUE bag points are plotted.
- **show.loophull**: if TRUE the loop is plotted.
- **show.baghull**: if TRUE the bag is plotted.
- **create.plot**: if FALSE no plot is created.
- **add**: if TRUE the bagplot is added to an existing plot.
- **pch**: sets the plotting character.
- **cex**: sets characters size.
- **dkmethod**: 1 or 2, there are two method of approximating the bag, method 1 is very rough (only based on observations).
- **precision**: precision of approximation, default: 1.
- **verbose**: automatic commenting of calculations.
- **debug.plots**: if TRUE additional plots describing intermediate results are constructed.
- **col.loophull**: color of loop hull.
- **col.looppoints**: color of the points of the loop.
- **col.baghull**: color of bag hull.
- **col.bagpoints**: color of the points of the bag.
- **transparency**: see section details.
- **show.center**: if TRUE the center is shown.
- **...**: additional graphical parameters.
Details

A bagplot is a bivariate generalization of the well known boxplot. It has been proposed by Rousseeuw, Ruts, and Tukey. In the bivariate case the box of the boxplot changes to a convex polygon, the bag of bagplot. In the bag are 50 percent of all points. The fence separates points within the fence from points outside. It is computed by increasing the the bag. The loop is defined as the convex hull containing all points inside the fence. If all points are on a straight line you get a classical boxplot. bagplot() plots bagplots that are very similar to the one described in Rousseeuw et al. Remarks: The two dimensional median is approximated. For large data sets the error will be very small. On the other hand it is not very wise to make a (graphical) summary of e.g. 10 bivariate data points. In case you want to plot multiple (overlapping) bagplots, you may want plots that are semi-transparent. For this you can use the transparency flag. If transparency==TRUE the alpha layer is set to ’99’ (hex). This causes the bagplots to appear semi-transparent, but ONLY if the output device is PDF and opened using: pdf(file="filename.pdf",version="1.4"). For this reason, the default is transparency==FALSE. This feature as well as the arguments to specify different colors has been proposed by Wouter Meuleman.

Value

compute.bagplot returns an object of class bagplot that could be plotted by plot.bagplot(). An object of the bagplot class is a list with the following elements: center is a two dimensional vector with the coordinates of the center. hull.center is a two column matrix, the rows are the coordinates of the corners of the center region. hull.bag and hull.loop contain the coordinates of the hull of the bag and the hull of the loop. pxy.bag shows you the coordinates of the points of the bag. pxy.outer is the two column matrix of the points that are within the fence. pxy.outlier represent the outliers. The vector hdepths shows the depths of data points. is.one.dim is TRUE if the data set is (nearly) one dimensional. The dimensionality is decided by analysing the result of prcomp which is stored in the element prdata. xy shows you the data that are used for the bagplot. In the case of very large data sets subsets of the data are used for constructing the bagplot. A data set is very large if there are more data points than approx.limit. xydata are the input data structured in a two column matrix.

Description

bagplot.pairs calls pairs and use bagplot() as panel function. It can be used for the inspection of data matrices.

Usage

bagplot.pairs(dm, trim = 0.0, main, numeric.only = TRUE,
              factor = 3, approx.limit = 300, pch = 16,
              cex = 0.8, precision = 1, col.loophull = "#aaccff",
              col.looppoins = "#3355ff", col.baghull = "#7799ff",
              col.bagpoints = "#000088", ...)

---

bagplot.pairs      pairs plot with bagplots
Arguments

dm datamatrix, columns contain values of the variables
trim fraction or vector of fractions of data points that should be removed from the variables before computing
main title of the plot
numeric.only if TRUE only numerical variables will be used. Otherwise an transformation to numeric will be performed.
factor see help of bagplot
approx.limit see help of bagplot
pch see help of bagplot
cex see help of bagplot
precision see help of bagplot
col.loophull see help of bagplot
col.loopponts see help of bagplot
col.baghull see help of bagplot
col.bagpoints see help of bagplot
... further arguments to be passed to pairs

Details

bagplot.pairs is a cover function which calls pairs and uses bagplot to display the data.

Value

The data which has been used for the plot.

Note

Feel free to have a look inside of bagplot.pairs and to improve it according to your ideas.

boxplot2D

Boxplot of projection of two dimensional data

Description

boxplot2D computes summary statistics of a one dimensional projection of a two dimensional data set and plots a sloped boxplot of the statistics into the scatterplot of the two dimensional data set.

Usage

boxplot2D(xy, add.to.plot = TRUE, box.size = 10, box.shift = 0, angle = 0, angle.type = "0", tukey.style = TRUE, coef.out = 1.5, coef.h.out = 3, design = "sl", na.rm=FALSE, ...)

Arguments

xy (nx2)-matrix, two dimensional data set
add.to.plot if TRUE the boxplot is added to the actual plot of the graphics device
box.size height of the box (of the boxplot)
box.shift shift of boxplot perpendicular to the projection direction
angle direction of projection in units defined by angle.type
angle.type "0": angle in (0,2*pi), "1": clock-like: angle.typ.0==2*pi*angle.typ.1/12, "2": degrees: angle.typ.0==2*pi*angle.typ.2/360, "3": by fraction: delta.y/delta.x
tukey.style if TRUE outliers are defined as described in Tukey (1977)
coef.out outliers are values that are more than coef.out*boxwidth away from the box, default: coef.out=1.5
coef.h.out heavy outliers are values that are more than coef.h.out*boxwidth away from the box, default: coef.h.out=3
design if sl then parallelogram else box
na.rm if TRUE 'NA' values are removed otherwise exchanged by mean
...
additional graphical parameters

plot(xy,xlim=c(-50,150),ylim=c(-50,150))
boxplot2D(xy,box.shift=-30,angle=3,angle.typ=1)
boxplot2D(xy,box.shift=20,angle=1,angle.typ=1)
boxplot2D(xy,box.shift=50,angle=5,angle.typ=1)
par(pty="m")

faces

Chernoff Faces

Description

faces represent the rows of a data matrix by faces. plot.faces plots faces into a scatterplot.

Usage

faces(xy, which.row, fill = FALSE, face.type = 1, nrow.plot, ncol.plot, scale = TRUE, byrow = FALSE, main, labels, print.info = TRUE, na.rm = FALSE, ncolors = 20, col.nose = rainbow(ncolors), col.eyes = rainbow(ncolors, start = 0.6, end = 0.85), col.hair = terrain.colors(ncolors), col.face = heat.colors(ncolors), col.lips = rainbow(ncolors, start = 0, end = 0.2), col.ears = rainbow(ncolors, start = 0, end = 0.2), plot.faces = TRUE, cex = 2)

## S3 method for class 'faces'
plot(x, x.pos, y.pos, face.type = 1, width = 1, height = 1, labels, ncolors = 20, col.nose = rainbow(ncolors), col.eyes = rainbow(ncolors, start = 0.6, end = 0.85), col.hair = terrain.colors(ncolors), col.face = heat.colors(ncolors), col.lips = rainbow(ncolors, start = 0, end = 0.2), col.ears = rainbow(ncolors, start = 0, end = 0.2), cex = 2, ...)

Arguments

xy xy data matrix, rows represent individuals and columns variables
which.row defines a permutation of the rows of the input matrix
fill if(fill==TRUE), only the first nc attributes of the faces are transformed, nc is the number of columns of xy
face.type an integer between 0 and 2 with the meanings: 0 = line drawing faces, 1 = the elements of the faces are painted, 2 = Santa Claus faces are drawn
nrow.plot number of columns of faces on graphics device
faces

ncol.plot  number of rows of faces
scale     if(scale==TRUE), variables will be normalized
byrow     if(byrow==TRUE), xy will be transposed
main      title
labels    character strings to use as names for the faces
print.info if TRUE information about usage of variables for face elements are printed
na.rm     if TRUE 'NA' values are removed otherwise exchanged by mean of data
plot.faces if FALSE no face is plotted
cex        size of labels of faces
x          an object of class faces computed by faces
x.pos      x coordinates of positions of faces
y.pos      y coordinates of positions of faces
width      width of the faces
height     height of the faces
ncolors    number of colors in the palettes for painting the elements of the faces
col.nose   palette of colors for painting the nose
col.eyes   palette of colors for painting the eyes
col.hair   palette of colors for painting the hair
col.face   palette of colors for painting the face
col.lips   palette of colors for painting the lips
col.ears   palette of colors for painting the ears
...        additional graphical arguments

Details

Explanation of parameters: 1-height of face, 2-width of face, 3-shape of face, 4-height of mouth,
5-width of mouth, 6-curve of smile, 7-height of eyes, 8-width of eyes, 9-height of hair, 10-width of
hair, 11-styling of hair, 12-height of nose, 13-width of nose, 14-width of ears, 15-height of ears.

For painting elements of a face the colors of are found by averaging of sets of variables: (7,8)-
eyes:iris, (1,2,3)-lips, (14,15)-ears, (12,13)-nose, (9,10,11)-hair, (1,2)-face.

Further details can be found in the literate program of faces.

Value

list of two elements: The first element out$faces is a list of standardized faces of class
faces, this object could be plotted by plot.faces; a plot of faces is created on the graphics de-
vice if plot.faces=TRUE. The second list is short description of the effects of the variables.

data(longley)
faces(longley[1:9,],face.type=0)
faces(longley[1:9,],face.type=1)

plot(longley[1:16,2:3],bty="n")
a<-faces(longley[1:16,],plot=FALSE)
plot.faces(a,longley[1:16,2],longley[1:16,3],width=35,height=30)

set.seed(17)
faces(matrix(sample(1:1000,128,),16,8),main="random faces")

a<-faces(rbind(1:3,5:3,3:5,5:7),plot.faces=FALSE)
plot(0:5,0:5,type="n")
plot(a,x.pos=1:4,y.pos=1:4,1.5,0.7)
# during Christmastime
faces(face.type=2)
```

hdepth

### hdepth of points

**Description**

hdepth() computes the h-depths of points.

**Usage**

hdepth(tp, data, number.of.directions=181)
Arguments

tp         two column matrix of the coordinates of points which h-depths are needed
data       two column matrix of the coordinates of the points of a data set
number.of.directions
            number of directions to be checked

Details

The function hdepth computes the h-depths of the points tp relative to data set data. If data
is missing tp will also be taken as data set.

Value

the h-depths of the test points

Note

Version of bagplot: 12/2012

bagplot

Examples

# computation of h-depths
data <- cbind(rnorm(40), rnorm(40))
xy <- cbind(runif(50,-2,2),runif(50,-2,2))
bagplot(data); text(xy, as.character(hdepth(xy,data)))

Description

An icon plot is a graphical representation of a contingency table. iconplot computes a icon
plot of a data matrix (matrix or data frame) or of an object of class table. Based on argument
grp.xy the data set is split into groups. Similarly the graphics region is divided into panels. Then
the elements of the groups are visualized within the associated panels.
Usage

```r
iconplot(data
  , grp.xy = 2 ~ 1
  , grp.color = NULL
  , grp.icon = NULL
  , colors
  , icons
  , vars.to.factors
  , panel.reverse.y = FALSE
  , panel.space.factor = 0.05
  , panel.prop.to.size = c(FALSE, FALSE)
  , panel.margin = 0.03
  , panel.frame = TRUE
  , panel.adjust = c(0.5, 0.5)
  , icon.horizontal = TRUE
  , icon.stack.type = c("lt", "lb", "rt", "rb")[1]
  , icon.cex = NA
  , icon.aspect = 1
  , icon.stack.len = NA
  , icon.space.factor = 0.3
  , icon.grey.levels = 2
  , icon.frame = TRUE
  , icon.draft = TRUE
  , lab.side = c("bl", "br", "tl", "tr")[1]
  , lab.parallel = c(TRUE, TRUE)
  , lab.cex = 1
  , lab.boxes = 2
  , lab.color = c("#CCCCCC", "white")
  , lab.type = c("expanded", "compact")[2]
  , lab.n.max = c(20, 30)
  , lab.legend = c("cols","rows","skewed","horizontal","vertical")[2]
  , packer = c("icons", "numbers", "panel.legend", "stars")[1]
  , panel.text = NULL
  , mar = rep(1, 4)
  , main
  , verbose = !TRUE
  , ...)
```

Arguments

data a data matrix, a data frame or an object of class `table`. Note: If the column or dimension names are elements of the following set of reserved names: `.sign,.fraction,.color,.icon,.job.no,.x0,.x1,.y0,.y1` strange results may occur; therefore, avoid these variable names.

grp.xy a formula specifying how the data set is divided into groups and defines in which panel an element of the data is represented. The formula `y1 ~ x1` means that the data set is split according to the levels of the variables `y1` and `x1` into groups. If `n.level.y1` and `n.level.x1` are the numbers of levels of the two variables
the plotting region is divided like a chessboard into \( n_{level.y1} \) rows and \( n_{level.x1} \) columns. In this way we get \( n_{level.y1} \times n_{level.x1} \) fields that are called panels. In each of the panels the elements of the associated group are represented by pictogram elements or icons.

If the argument \( grp.xy \) hasn’t been set by default the first variable of the data set defines the grouping of the data along the x-axis and the second one the grouping along the y-axis.

Instead of variable names the indices of the variables can be used.

The definition of recursive groupings is allowed and is expressed by operator "+": \( y \sim 3 + 4 \) means that the horizontal range of the graphical region is split twice: At first the segmentation of the region is computed according to variable 3, in the second step the subranges of step 1 will be divided as a function of the levels of variable 4.

A "0" on one side of the ~ character indicates that no splitting of the correspondent region is desired.

\( grp.color \) defines how the data are grouped with respect to coloring. The name of the variable used for coloring the icons (or pictogram elements) has to be assigned to \( grp.color \). colors[i] defines the color of the icon belonging to the level \( i \) of the variable fixed by \( grp.color \).

\( grp.icon \) defines how the data are grouped with respect the associated icon. The name of the variable used for selecting symbols or icons has to be fixed by argument icons. The symbol (icon) representing an observation depends on its level of the variable specified by \( grp.icon \).

If additional variables – separated by a + character – are found the values of these variables will be used in the call of a icon generating function. For details see paragraph 'Details'.

\( colors \) set of colors used for pictogram elements.

\( icons \) defines the icons or the set of icons used by iconplot. If \( icons \) is a vector \( icons[i] \) is used to represent the observations whose level of the variable fixed by \( grp.icon \) is \( i \). There are some alternatives to define the icons or pictogram elements:

* default: the default symbol is a rectangle.
* vector of numbers: numbers specify plotting characters of the graphics system similar to \( points(..., pch = 13) \).
* list of raster images: the images are used as icons.
* character vector: \( icons[i] \) with an extension indicating a pnm, ppm, jpg or png image file: iconplot tries to use the image of the file as icon. Otherwise \( icons[i] \) is interpreted as the name of an internal icon generating function.
* list of functions: \( icons[i] \) is interpreted as an icon generating function and is called to compute the icon for level \( i \).
* list of icon descriptions. For details see paragraph "Details".

Note: If an image file is defined by an internet link it is temporarily downloaded using \( tempfile() \) and \( download.file() \).

Note: Mixtures of these alternative definition don’t work usually. Therefore, it is recommended to use one type of definition only.
vars.to.factors
controls the transformation of variables to factors. If missing it is set to TRUE for each of the relevant variables. If vars.to.factors is a vector and if its elements don’t have names the variables 1:length(vars.to.factors)
are transformed.
If vars.to.factors consists of named elements the names indicate the variables to be transformed.
If vars.to.factors[i] == FALSE variable i will not be transformed.
If vars.to.factors[i] == 1 variable i is transformed to a factor.
If vars.to.factors[i] < 1 the range of variable i is cut into groups in a way that we approximately get round(1/vars.to.factors[i]) groups and each of the groups approximately contain 100 * vars.to.factors[i] percent of the data. If vars.to.factors[i] > 1 the range of variable i will be cut into floor(vars.to.factors[i]) subranges of equal size and you get a factor variable with floor(vars.to.factors[i]) levels.

panel.reverse.y
logical, if TRUE the vertical axis is reversed.

panel.space.factor
relative space inserted between the panels.

panel.prop.to.size
a vector containing two elements which controls the sizes of the panels. The first entry determines the widths of the panels and the second one their heights.
panel.prop.to.size[1] == 0 means all panels are of the same width.
If panel.prop.to.size[2] == 0 the panels are of the same height. A value of 1 indicates that sizes should be computed proportional to the frequencies of the levels. Otherwise the sizes of the panels are fixed proportional to: frequencies^panel.prop.to.size.

panel.margin
controls the margins around the regions of the panels. If this argument is a vector of length four the elements refer to the four sides of the plot: bottom, left, top, and right. If this argument is set to c(0, 0.1, 0.5, 0) we get no additional margin below the panels and on the right-hand side. However, there will be an upper margin of size 100 * 0.5 percent of the height of the area containing the panels and a margin of size code 100 * 0.1 percent of the width on the left-hand side is provided.

panel.frame
logical, if TRUE a border line is drawn around each of the panels.

panel.adjust
controls the adjustment of the panels within their regions. This argument modifies the internal coordinates and do usually not change the appearance of the plot.

panel.text
vector of strings. The text panel.text[i] is written into panel[i]. The texts can be used for short descriptions of the contents of the panels. To get an idea of the numbering of the panels you can set panel.text = 1:20.

icon.horizontal
logical, if TRUE the stacks of icons or pictogram elements are plotted horizontally. This argument effects the way how icons are put into the panels.

icon.stack.type
defines the method of plotting the stacks of icons: "r" or "l" are shortcuts for "right" or "left". "t", "b" correspond to "top" and "bottom", respectively. Note:
Fractional parts of frequencies are represented by smaller icons. Adding the letter "s" (as a abbreviation for "shrinkage") to the argument icon.stack.type both dimensions of the icons are reduced. If icon.stack.type is a vector its elements define the different types of stacking for the panels.

icon.cex  size of icons; this argument is similar to cex of points().
icon.aspect aspect ratio of icons: width / height.
icon.stack.len maximal number of icons gathered to build a stack. If this length is decreased the number of stacks (rows or columns of icons) will increase.
icon.space.factor relative space between two icons.
icon.grey.levels  controls the coloring of icons of class raster or images. If icon.grey.levels is of length 1 and if it is an integer the argument defines the number of color- or grey-levels of the icons. If icon.grey.levels consists of two or more values between 0 and 1 they are interpreted as grey limits. Level 0 represents "black", and 1 indicates the maximal brightness. The default setting generates one color only (besides black and white).
icon.frame  logical, if TRUE a border is drawn around each of the pictograms.
icon.draft  logical, if TRUE raster images are generated by calling rasterImage() with the setting interpolate = TRUE.
mar this argument is delivered to the graphics device via par() and manipulates the margins of the plot.
main defines the title of the plot.
lab.side defines one or two sides that are used for margin information: "l" indicates the "left" side, "b" identifies the "bottom" as well as "r" the "right" and "t" the "top" side.
lab.parallel logical, if FALSE margin labels are perpendicularly constructed to the axes. If lab.parallel is a vector the first element is used for controlling the labels of the bottom or top side and the second one specifies the orientation of the y-labels. If one elements is set to 0.5 the labels of the last xy grouping variable are printed perpendicularly only.
lab.legend a character string indicating the kind of legend out of the vector c("cols", "rows", "skewed", "horizontal", "vertical"). Assigning a number of the set 1:5 to the argument is interpreted as an index of the set of the five types of legends.
"cols": vertical legends, side by side at the bottom side of the plot.
"rows": horizontal legends, line by line at the bottom side of the plot.
"skewed": horizontal legends, line by line and the level names are rotated.
"horizontal": horizontal legends, side by side at the bottom side of the plot.
"vertical": vertical legends, line by line at the right side of the plot.
lab.cex sets the size of the characters of the labels and the legends.
lab.boxed defines the types of boxes around the margin labels: lab.boxed == 0: no boxes are drawn.
lab.boxes >= 1: small boxes around the labels are drawn.
lab.boxes >= 2: big boxes around the labels are drawn.
lab.boxes %% 1: defines the size of the separation line between the names of the variables and the names of the levels.

lab.color The first element defines the color of the box containing the names of variables or levels in the margins. The second element sets the color of the separation line between the variable names and the level names within the margins.

lab.type defines the design style of margin labeling: "c" or "e" are shortcuts for "compact" or "expanded".

lab.n.max is an integer vector consisting of three elements. The first element sets the number of characters during printing the labels of the levels. The second element defines the maximal number of level names to be plotted in the margins. lab.n.max[3] limits the number of labels of the color- or icon-legend.

packer defines the packer(s) which are used to fill the panels. If "icons" is an element of packer the observations will be represented by icons, pictogram elements or symbols.
If the character string "numbers" is found in packer in each of the panels the numbers of its observations will be printed into the areas of the panels.
The packer "panel.legend" plots the level combinations into the panels. This may be a useful feature as long as the number of the panels is small. Otherwise the texts of level combinations will overlap each other. The argument cex controls the size of the text strings.

verbose logical, if TRUE internal information is printed during the computation.

... arguments that will be passed to the graphics functions and suitable ones to the icon generating functions.

Details

iconplot() constructs an icon plot of a data matrix and a contingency table. In an icon plot each observation of the data set is represented by a small symbol or an image called pictogram or icon. A cell of a contingency table is visualized by a set of icons. The icons of a cell are plotted within a rectangular region which we call panel and an icon plot consists of a lot of panels containing the icons of the cells.

Similar to the layout of contingency tables the set of panels are arranged in a grid-like manner. Considering a high dimensional contingency table you can concentrate on some of the variables and can construct suitable margin tables. Equivalently you can build a lot of icon plots to emphasize your viewpoint. By varying the actual arguments of iconplot() a huge set of appearances of plots results and the nicest one for your purpose can be choosen.

table, matrix or data frames can be used as data input of iconplot(). Tables are allowed to have fractional or negative entries; these cases may occur by computing the difference of two tables or by changing the units of counting. Internally a table will be expanded to a data matrix. Fractional numbers are coded in a data matrix by the additional column or variable .fraction, to handle negative numbers the new variable .sign is added.

The argument grp.xy of iconplot defines the variables used for grouping and splitting the data dependent on the levels of the specified variables. Each group is represented within a panel as stated above. Let’s have a look at an example: Consider you have a 2x3 contingency table and
would like to represent it by an icon plot. So a plot to be constructed should have 2x3 panels and
the number of icons of the panels should be given by the cell entries. To get an icon plot with
desired panel structure you define the xy-grouping by grp.xy = 1 ~ 2. This means: The data
set has to be split according to the two levels of the first variable and the y-range of the plot has
to be divided in two rows of panels. On the other side the second variable defines the grouping
concerning the the x-range and three columns of panels appear. As a result a icon plot is generated
that consists of six panels arranged in two rows and three columns. The panels of a fixed level of
the first variable are placed side by side, whereas the panels of a fixed level of the second variable
are stacked one upon the other and a layout known from a chessboard results. As an example
try: x <- as.table(matrix(1:6,2,3)); iconplot(x, grp.xy = 1 ~ 2) grp.xy = 0
~1 + 2 leads a double grouping on the x-axis and no vertical grouping. grp.xy = 1 + 2 ~ 3 + 4
presums four or more variables and splits the graphics region twice along the x- and twice along the
y-direction.

Within a panel the entry of one cell is represented. Several arguments control the way how the icons
are placed in a panel. The absolute size of the icons can be defined by icon.cex. icon.aspect
fixes the aspect ratio of the pictograms (width / height). The elements in a panel are assembled into
stacks; the maximal length of these stacks can be set by icon.stack.len; horizontal stacks are
plotted if icon.horizontal is TRUE. Framing icons and spacing between them is controlled
by the arguments icon.frame and icon.space.factor.

The icons or pictogram elements may be colored dependent on the levels of a variable. The variable
has to be established by argument grp.color. A set of colors can be defined by argument
colors. Accordingly, the symbols or images are determined by grp.icon and icons.

An icon or pictogram element can be generated by an icon generating function. The result of an
icon generating function describes a standardized icon by a set of segments, polygons, splines and
texts which are combined in a list. segments: segments are defined by a matrix or a data frame
of 5 or 6 columns: Columns 1 to 4 keep the coordinates of the starting and ending points of the
segments: x.0, y.0, x.1, y.1.

The 5th column contains the widths of the segments. The coordinates and the widths have to be
chosen in a way that the icon fits pretty well into a plotting field of size 100mm x 100mm assuming
the coordinates of the world window defined by: usr = c(0,100,0,100).

If the 6th column is available it defines the coloring of the segments. A value of "0" codes the
color "white" and the other values are interpreted as usually: "1" means "black" and any other
color is processed as col in points, for example. An NA value instead of a color instructs
iconplot() to color the segment dependent on the associated level of the variable fixed by
grp.color. Segment objects must have the class attribute "segments".

polygon: Polygons are defined by a matrix or data frame of 2 or 3 columns. Columns 1 and 2 store
the coordinates of the vertices of the polygon. A third column fixes the coloring of the polygon.
The class attribute of this kind of element has to be set to "polygon".

spline: Splines are defined by a matrix or data frame of 3 or 4 columns. Columns 1 and 2 store the
coordinates of the points which form the basis of the spline. The third column keeps the line width
of the curve. The optional fourth column shows how to color the spline. Splines are identified by
class attribute "spline".

text: Text elements of a generated icon are defined by a data frame of 3, 4 or 5 columns. The first
two columns of the object store the coordinates of the positions of the text(s). The third element
stores the text information and the fourth is used to set the size of the characters. The fifth fixes the
coloring of the text. The class attribute of a text element is "text". There are some internal icon
generating functions. Here is a list of them:
Value

`iconplot()` returns a list consisting of three elements. The first element is the matrix `jobs` whose lines show some attributes of the panels. In a row of this matrix you find the number of the panel `.job.no` and the location of the panel (in user coordinates: `xmin`, `xmax`, `ymin`, `ymax`). The second element is a copy of the modified data matrix which is used for the construction of the icon plot: Besides the data delivered by the user there are columns showing the colors, icons and coordinates of the pictogram elements. The third element contains the output of `par()` and describes the graphics device during the computation; this list differs from the parameter settings after leaving `iconplot()` because the state of graphics parameter before calling `iconplot()` is restored. These three lists may be helpful if you want to add further graphical elements to the plot.

Note

Remark: the version of `iconplot` of this package is an experimental version. Therefore, in the future some of the features may be changed and it is not sure that the function works as described on all types of graphics devices. In case of errors feel free to write a mail. Additional information and examples are found on the web page [http://www.wiwi.uni-bielefeld.de/lehrbereiche/statoekoinf/comet/wolf/wolf_aplpack](http://www.wiwi.uni-bielefeld.de/lehrbereiche/statoekoinf/comet/wolf/wolf_aplpack).

**plothulls**

**plothulls for data peeling**

**Description**

plothulls plots convex hulls of a bivariate data set.

**Usage**

```r
plothulls(x, y, fraction, n.hull = 1, main, add = FALSE, col.hull, lty.hull, lwd.hull, density = 0, ...)
```

**Arguments**

- `x`  
  two column matrix of the coordinates of points of x-values of a data set
- `y`  
  if x is one dimensional then y contains the y-values of the data set
- `fraction`  
  ... of points that lies inside the hull to be plotted
- `n.hull`  
  number of directions sequential hulls to be plotted
`plothulls`

- `main` title for the graphics
- `add` if TRUE no new plot is initialized
- `col.hull` color(s) of the hull(s)
- `lty.hull` line type(s) of the hull(s)
- `lwd.hull` line width(s) of the hull(s)
- `density` density argument of `polygon()` that draws the hulls
- `...` further arguments used in the call of `plot()` or `points()`

**Details**

The function `plothulls` computes hulls of a bivariate data set using the function `chull`. After finding a hull the hull maybe plotted. Then the data points of the hull will be removed and the hull of the remaining points is computed. The style of plotting a hull depends on the setting of `col.hull`, `lty.hull`, `lwd.hull` and `density`. `density=NA` has the effect that the regions of the hulls are filled by a color. Using `fraction` you can plot a single hull. `n.hull` defines the number of hull that should be drawn one after the other.

**Value**

The hull(s) are stored as a list of matrices with two columns, the innermost first and so on.

**Note**

Version of `plothulls`: 10/2013

**Author(s)**

Peter Wolf

**References**

**See Also**

`bagplot`

**Examples**

```r
# 10 hulls computed from the faithful data and plotted
plothulls(faithful, n.hull=10, lty.hull=1)
# plotting additionally a hull with 90 percent of points within the hull
plot(faithful)
plothulls(faithful, fraction=.90, add=TRUE, col.hull="red", lwd.hull=3)
# hull with 10 percent of points within the hull
plothulls(faithful, fraction=.10, col.hull="red", lwd.hull=3)
# first 3 hulls of the cars data set
```
plotsummary <- graphical summaries of variables of a data set

Description

plotsummary shows some important characteristics of the variables of a data set. For each variable a plot is computed consisting of a barplot, an ecdf, a density trace and a boxplot.

Usage

plotsummary(data, trim = 0, types = c("stripes", "ecdf", "density", "boxplot"), y.sizes = 4:1, design = "chessboard", main, mycols = "RB")

Arguments

data Data set for computing a graphical summary.
trim trim defines the fraction of observation for trimming on both ends of the data.
types vector of types of representation of the data set. The elements of the vector will induce small plots which are stacked in vertical order. The first letter of the types is sufficient for defining a type.
y.sizes defines the relative sizes of the small plots. The values are divided by their sum to get percentages.
design if design is "chessboard" the graphics device is fragmented into rows and cols. Otherwise the images of a variable build vertical stripes.
main defines a title for the graphics.
mycols allows to define some colors for the showing the regions separated by the quartiles.
plotsummary

Details

plotsummary can be used for a quick and dirty inspection of a data matrix or a list of variables. Without further specification some representation of each of the variables is built and stacked into a plot. The sizes of the types of representation can be set as well as the layout design of the graphics device. It is helpful to trim the data before processing because outliers will often hide the interesting characteristics.

  # Sys.sleep(1)
}
puticon

Add Icon(s) to a Plot

Description

`puticon()` draws icons at the coordinates given by `x` and `y`.

Usage

```r
puticon(x = 0, y = 0, icon = "", grey.levels = 0.5, icon.cex = 10,
        color = "red", ..., adj = c(0.5, 0.5), xpd = NA)
```

Arguments

- `x, y` numeric vectors of coordinates where to plot icon(s). If `x` is missing some information about internal icon generators are printed or plotted.
- `icon` icon to use. There are several ways to define an icon: If `icon` is a file name with one of the extensions `c(".jpg", "JPG", ".pnm", ".PNM", ".png", ".PNG")` `puticon()` tries to use the graphics file to plot the icon(s). To read `jpeg` and `png` files the functions `jpeg` and `png` of the packages `jpeg` and `png` are called. Note: If an image file is defined by an internet link it is temporarily downloaded using `tempfile()` and `download.file()`.
- `grey.levels` An image from a file is transformed to a black-and-white picture. `grey.levels` defines the grey levels of the black-and-white picture that are replaced by `color`. If `grey.levels` is a single decimal number and is in (0,1) the pixels with a level greater than `grey.levels` are recolored by `color`. If `grey.levels` consists of two decimal numbers lower 1 pixels with grey levels lying in the interval are recolored by `color`. If `grey.levels` is an integer a vector of levels is created. If `grey.levels` is a vector and all(`grey.levels < 1`) `puticon` tries to different intensities of colors of `color` for recoloring pixels.
- `icon.cex` size(s) of icon(s) in mm. If `icon.cex < 1` it is interpreted as ratio (width of icon) / (width of plotting area (par()$pin[1])) and is transformed to mm.
- `color` color(s) to be used for the pictogram(s). `color` can be a color code or name, for details see section Color Specification of the help of `par`.
Further parameters to be passed to the icon generating function.

adj  
adj one or two values usually lying in [0, 1] and which specify the x (and y) adjustment of the icon(s).

xpd  
controls clipping. See help of par for further explanations.

Details

For details concerning icon generating function see the help of iconplot(). If puticon() is called without argument x and icon is an empty string a list of internal generators will be returned. If x is missing and icon is the name of an internal generator a standardized version of the icon is plotted and the arguments of the generator (function) are printed.

Value

Usually Null is returned. However, if no coordinates are set and the name of an internal generator is assigned to icon puticon returns the definition of the generator function.

Note

Remark: the version of puticon of this package is an experimental version. Therefore, in the future some of the features may be changed and it is not sure that the function works as described on all types of graphics devices. In case of errors feel free to write a mail. Additional information and examples are found on the web page

  res <- data.frame(x, y, color = col2)
  # add class "polygon" to the object and store it in "result"
  class(res) <- c(class(res), "polygon"); result <- c(result, list(res))
  # compose another object of type "polygon"
  res <- data.frame(x[c(1, 3, 4, 2)], y[c(1, 3, 4, 2)], color = col3)
  # add class "polygon" to the object and store it in "result"
  class(res) <- c(class(res), "polygon"); result <- c(result, list(res))
  n <- length(x)
  # compose object of type "segments" consisting of x1-, y1-, x2-, y2-values, line widths and colors
  res <- data.frame(x[-n], y[-n], x[-1], y[-1], lwd.mm = 5, color = col1)
  # add class "segments" to the object and store it in "result"
  class(res) <- c(class(res), "segments"); result <- c(result, list(res))
  # output result object
  result
}
skyline.hist

```r
plot(1:100, type = "n")
for(i in 1:10){
  puticon( runif(1, 0, 100), runif(1, 0, 100), icon = my.star, icon.cex = 20,
           xx = list(runif(14, 2, 10)), max.xx = 10, star.txt = letters[i])
}
```

---

**skyline.hist** computes a skyline plot which is special histogram.

---

**Description**

The function `skyline.hist` draws several histograms in one plot. The resulting image may look like a skyline.

**Usage**

```r
skyline.hist(x, n.class, n.hist = 1, main, ylab="density",
             night = FALSE, col.bars = NA, col.border = 4, lwd.border = 2.5,
             n.shading = 6, lwd.shading = 2, col.shading = NA, lty.shading = 3,
             pcol.data = "green", cex.data = 0.3, pch.data = 16, col.data = 1,
             lwd.data = .2, permutation = FALSE,
             xlab, xlim, ylim, new.plot=TRUE, bty="n", ...)```

**Arguments**

- **x**: one dimensional data set.
- **n.class**: number of classes that should be used to find the width of the bars of the histogram(s).
- **n.hist**: number of histograms that should be plotted.
- **main**: used for call of `title`.
- **ylab**: text for y axis.
- **night**: If `TRUE` the background will be colored blue. If `FALSE` there will be no colored background. Otherwise `night` is used as background color.
- **col.bars**: defines the color of the bars. If `is.na(col.bars)` and `night==TRUE` the bars will be colored gray.
- **col.border**: color of the borders of the bars.
- **lwd.border**: line width of the borders of the bars.
- **n.shading**: number of vertical lines for filling the bars of the histograms.
- **lwd.shading**: line width of the vertical lines for shading the bars.
- **col.shading**: color for the vertical lines for shading. If NA heat colors are used.
- **lty.shading**: line type for the vertical lines for shading.
- **pcol.data**: color of data points.
### Details

`skyline.hist` computes several histograms and plots them one upon the other. The histograms differ in the positions of the first cells, but all cells have the same width. The parameters `n.class` and `n.hist` have the greatest effect on the design of the result. `col.border` allows to color the border of the rectangular boxes of the histogram bars. `col.bars` defines the fill color of the bars. `n.shading` defines the number of vertical lines of type `lty.shading` and width `lwd.shading` that are drawn within the boxes. Another feature of `skyline.hist` is to represent the data points. The data points of a cell are plotted according their x-values and their ranks (within the points of the cell). The resulting points are connected by line segments and you will see a time series running from bottom to top in each cell. The points and lines can be specified by `pcol.data`, `cex.data`, `pch.data`, `lwd.data`, `col.data`. To get rid of the original order of the data you can permuted them (`permutation=1`). The "skyline" of the plot may be similar to the skyline of a town and the vertical lines may look like small windows of buildings. In Young et. al. you find "shaded histograms". These histograms have triggered the idea of `skyline.hist` and the representation of a one dimensional data set by laying histograms on top of otheroverlied histograms.

### Value

The result of a call of `hist` is returned.

```

slider

slider / button control widgets

Description

slider and gslider construct a Tcl/Tk-widget with sliders and buttons to demonstrate the effects of variation of parameters on calculations and plots.
Usage

slider(sl.functions, sl.names, sl.mins, sl.maxs, sl.deltas, sl.defaults, but.functions,
but.names, no, set.no.value, obj.name, obj.value, reset.function, title, prompt=FALSE,
sliders.frame.vertical=TRUE)

gslider(sl.functions, sl.names, sl.mins, sl.maxs, sl.deltas, sl.defaults, but.functions,
but.names, no, set.no.value, obj.name, obj.value, reset.function, title, prompt=FALSE,
sliders.frame.vertical=TRUE, hscale=1, vscale=1,
pos.of.panel = c("bottom","top","left","right")[1])

Arguments

sl.functions  set of functions or function connected to the slider(s)
sl.names labels of the sliders
sl.mins minimum values of the sliders’ ranges
sl.maxs maximum values of the sliders’ ranges
sl.deltas change of step per click
sl.defaults default values for the sliders
but.functions function or list of functions that are assigned to the button(s)
but.names labels of the buttons
no slider(no=i) requests slider i
set.no.value slider(set.no.value=c(i,val)) sets slider i to value val
obj.name slider(obj.name=name) requests the value of variable name from environment slider.env
obj.value slider(obj.name=name, obj.value=value) assigns value to variable name in environment slider.env
reset.function function that induce a reset.button and contains the commands of it.
title title of the control window
prompt if TRUE slider functions are called by moving a slider, if FALSE slider functions are called after releasing the mouse button
sliders.frame.vertical if TRUE the sliders are stacked one above the other; otherwise they are positioned side by side
hscale horizontal scale factor for image size; compare tkrplot in package tkrplot
vscale vertical scale factor for image size; compare tkrplot in package tkrplot
pos.of.panel position of the panel field for sliders and buttons. Value of pos.of.panel: bottom, top, left or right.
slider constructs a separated panel for controlling the parameters whereas gslider integrates a graphical device and buttons and sliders within one window.

The following actions can be done: a) definition of (multiple) sliders and buttons, b) request or specification of slider values, and c) request or specification of variables in the environment slider.env. The management takes place in the environment slider.env. If slider.env is not found it is generated.

**Definition** ... of sliders: First of all you have to define sliders, buttons and the attributes of them. Sliders are established by six arguments: sl.functions, sl.names, sl.minima, sl.maxima, sl.deltas, and sl.defaults. The first argument, sl.functions, is either a list of functions or a single function that contains the commands for the sliders. If there are three sliders and slider 2 is moved with the mouse the function stored in sl.functions[[2]] (or in case of one function for all sliders the function sl.functions) is called.

**DEFINITION** ... of buttons: Buttons are defined by a vector of labels but.names and a list of functions: but.functions. If button i is pressed the function stored in but.functions[[i]] is called.

**REQUESTING** ... a slider: slider(no=1) returns the actual value of slider 1. slider(no=2) returns the value of slider 2, etc. You are allowed to include expressions of the type slider(no=i) in functions describing the effect of sliders or buttons.

**SETTING** ... a slider: slider(set.no.value=c(2,333)) sets slider 2 to value 333. slider(set.no.value=c(i,value)) can be included in the functions defining the effects of moving sliders or pushing buttons.

**VARIABLES** ... of the environment slider.env: Sometimes information has to be transferred back and forth between functions defining the effects of sliders and buttons. Imagine for example two sliders: one to control p and another one to control q, but they should satisfy: p+q=1. Consequently, you have to correct the value of the first slider after the second one was moved. To prevent the creation of global variables store them in the environment slider.env. Use slider(obj.name="p.save",obj.value=1-slider(no=2)) to assign value 1-slider(no=2) to the variable p.save. slider(obj.name=p.save) returns the value of variable p.save.

**Dependencies** The function gslider depends on package tkrplot.

**Value**

Using slider in definition mode slider returns the value of new created the top level widget. slider(no=i) returns the actual value of slider i. slider(obj.name=name) returns the value of variable name in environment slider.env. gslider return in definition mode the result of tkrplot which was called to construct the widget.

**Examples**

```R
# example 1, sliders only
if(interactive()){

```
This example cannot be run by examples() but should work in an interactive R session

```r
plot.sample.norm<-function(){
  refresh.code<-function(...){
    mu<-slider(no=1); sd<-slider(no=2); n<-slider(no=3)
    x<-rnorm(n,mu,sd)
    plot(x)
  }
  slider(refresh.code,sl.names=c("value of mu","value of sd","n number of observations"),
    sl.mins=c(-10,.01,5),sl.maxs=c(+10,50,100),sl.deltas=c(.01,.01,1),sl.defaults=c(0,1,20),
    sl.iters=10)
  plot.sample.norm()
}
}
```

# example 2, sliders and buttons

```r
if(interactive()){
  ## This example cannot be run by examples() but should work in an interactive R session
  plot.sample.norm.2<-function(){
    refresh.code<-function(...){
      mu<-slider(no=1); sd<-slider(no=2); n<-slider(no=3)
      type= slider(obj.name="type")
      x<-rnorm(n,mu,sd)
      plot(seq(x),x,ylim=c(-20,20),type=type)
    }
    slider(obj.name="type",obj.value="l")
    slider(refresh.code,sl.names=c("value of mu","value of sd","n number of observations"),
      sl.mins=c(-10,.01,5),sl.maxs=c(10,10,100),sl.deltas=c(.01,.01,1),sl.defaults=c(0,1,20),
      but.functions=list(
        function(...){slider(obj.name="type",obj.value="l");refresh.code()},
        function(...){slider(obj.name="type",obj.value="p");refresh.code()},
        function(...){slider(obj.name="type",obj.value="b");refresh.code()}),
      but.names=c("lines","points","both")
    )
  }
  plot.sample.norm.2()
}
```

# example 2a, sliders and buttons and graphics in one window

```r
if(interactive()){
  ## This example cannot be run by examples() but should work in an interactive R session
  plot.sample.norm.2<-function(){
    refresh.code<-function(...){
      mu<-slider(no=1); sd<-slider(no=2); n<-slider(no=3)
      type= slider(obj.name="type")
      x<-rnorm(n,mu,sd)
      plot(seq(x),x,ylim=c(-20,20),type=type)
    }
    slider(obj.name="type",obj.value="l")
    gslider(refresh.code,sl.names=c("value of mu","value of sd","n number of observations"),
      sl.mins=c(-10,.01,5),sl.maxs=c(10,10,100),sl.deltas=c(.01,.01,1),sl.defaults=c(0,1,20),
      but.functions=list(
        function(...){slider(obj.name="type",obj.value="l");refresh.code()},
        function(...){slider(obj.name="type",obj.value="p");refresh.code()},
        function(...){slider(obj.name="type",obj.value="b");refresh.code()}
    ),
    but.names=c("lines","points","both")
  )
  plot.sample.norm.2()
}

    }
    R.veil.in.the.wind()
  }
}
**slider.bootstrap.lm.plot**

*interactive bootstapping for lm*

---

**Description**

*slider.bootstrap.lm.plot* computes a scatterplot and adds regression curves of samples of the data points. The number of samples and the degree of the model are controlled by sliders.

**Usage**

```
slider.bootstrap.lm.plot(x, y, ...)  
```

**Arguments**

- `x`  
  - two column matrix or vector of x values if y is used
- `y`  
  - y values if x is not a matrix
- `...`  
  - additional graphics parameters

**Details**

*slider.bootstrap.lm.plot* draws a scatterplot of the data points and fits a linear model to the data set. Regression curves of samples of the data are then added to the plot. Within a Tcl/Tk control widget the degree of the model, the repetitions and the start of the random seed are set. After modification of a parameter the plot is updated.

slider.bootstrap.lm.plot(daten)

## End(Not run)
```
slider.brush

**interactive brushing functions**

**Description**

These functions compute a pairs plot or a simple xy-plot and open a slider control widget for brushing.

- `slider.brush.pairs` computes a pairs plot; the user defines an interval for one of the variables and in effect all data points in this interval will be recolored.
- `slider.brush.plot.xy` computes an xy-plot; the user defines a interval for a third variable $z$ and all points $(x, y)$ will be recolored red if the $z$ value is in the interval.

**Usage**

```
slider.brush.pairs(x, ...)  
slider.brush.plot.xy(x, y, z, ...)  
```

**Arguments**

- `...` new settings for global graphics parameters
- `x` matrix or data frame or vector
- `y` vector of y values if `x` is not a matrix
- `z` vector of z values if `x` is not a matrix

**Details**

- `slider.brush.pairs` draws a pairs plot of the data set $x$. The first slider defines the lower limit of the interval and the second its width. By the third slider a variable is selected. All data points for which the selected variable is in the interval are recolored red.
- `slider.brush.plot.xy` draws an xy-plot of the data set $x$. The first slider defines the lower limit of the interval of $z$ values and the second one its width. All data points for which the variable $z$ is in the interval are recolored red.

**slider.hist**

*interactive histogram and density traces*

**Description**

The functions `slider.hist` and `slider.density` compute histograms and density traces whereas some parameter are controlled by sliders.

`slider.hist` computes a histogram; the number of classes is defined by a slider.

`slider.density` computes a density trace; width and type of the kernel are defined by sliders.

**Usage**

```r
slider.hist(x, panel, ...)
slider.density(x, panel, ...)
```

**Arguments**

- `x` data set to be used for plotting
- `panel` function constructing additional graphical elements to the plot
- `...` additional (graphics) parameters which are passed to the invoked high level plotting function

**Details**

`slider.hist` draws a histogram of the data set `x` by calling `hist` and opens a Tcl/Tk widget with one slider. The slider defines the number of classes of the histogram. Changing the slider results in redrawing of the plot. For further details see the help page of `hist`. `rug` is used as the default panel function.

`slider.density` draws a density trace of the data set `x` by `plot(density(...))` and opens a Tcl/Tk-widget with two sliders. The first slider defines the width of the density trace and the
second one the kernel function: "1-gaussian", "2-epanechnikov", "3-rectangular", "4-triangular", "5-biweight", "6-cosine", "7-optcosine".

Changing one of the sliders results in a redrawing of the plot. For further details see the help page of `density`. `rug` is used as the default panel function.

  })
)

## End(Not run)
```
slider.lowess.plot  interactive lowess smoothing

Description
slider.lowess.plot computes an xy-plot of the data and adds LOWESS lines. The smoother span and the number of iterations are selected by sliders.

Usage
slider.lowess.plot(x, y, ...)

Arguments
x  data set to be used for plotting or vector of x values
y  vector of y values in case x is not a matrix
...  additional (graphics) parameter settings

Details
slider.lowess.plot computes a scatterplot of the data. Then a LOWESS smoother line is added to the plot. For more details about the lowess parameters f and iter take a look at the help page of lowess. The parameters are set by moving sliders of the control widget. The first slider defines the smoother span f and the second one the number of iterations.

slider.smooth.plot.ts

interactive Tukey smoothing

Description

slider.smooth.plot.ts computes smooth curves of a time series plot by Tukey’s smoothers. The kind of smoothing is controlled by a Tcl/Tk widget.

Usage

slider.smooth.plot.ts(x, ...)

Arguments

x
time series

... additional graphical parameters

Details

slider.smooth.plot.ts draws the time series x. The user selects a filter of the set c("3RS3R", "3RSS", "3RSR", "3R", "3", "S") step by step and the resulting curve is added to the plot. The selection is performed by pressing a button of the control widget of slider.smooth.plot.ts. The button reset restarts the smoothing process.

*interactive splitting of time series*

**Description**

`slider.split.plot.ts` plots linear fitted lines or summary statistics in sections of a time series. The sections are controlled by sliders.

**Usage**

```r
slider.split.plot.ts(x, type="l", ...)
```

**Arguments**

- `x` time series or vector
- `type` plotting type: type will be forwarded to function `plot`
- `...` additional graphics parameters

**Details**

`slider.split.plot.ts` draws a time series plot and let you define sections of the series by fixing a limit on the time scale as well as a window width. The whole range of the series is partitioned in pieces of the same length in a way that the fixed limit will be one of the section limits. Then linear models are fitted and plotted in the sections. Alternatively – by pressing the button `fivenum summary` – summary statistics are drawn instead of the model lines.

The first slider fixes the width of the sections and the second one the limit between two of them.

By clicking on button `linear model` or `fivenum summary` the user switches between drawing model curves and five number summary.

**slider.stem.leaf**  
*(construction of stem and leaf display interactively)*

Description

'slider.stem.leaf' computes a stem and leaf display within a graphics device. The parameters are controlled by a control widget.

Usage

```r
slider.stem.leaf(x, main = main)
```

Arguments

- `x` data set for plotting
- `main` main title of the plot

Details

The function 'slider.stem.leaf' allows the user to construct a stem and leaf display within a graphics device. The main parameters will be set by a Tcl/Tk control widget. The line rule is selected by pressing one of the buttons 'Dixon', 'Sturges', 'Velleman'. A slider controls the separation of the stem. Additionally the character size device could be set.

Value

A short message is returned

Note

The function is a function of the package aplpack

**slider.zoom.plot.ts**

*interactive zooming of time series*

### Description

This function shows one or two sections of a time series. The window(s) is (are) controlled by sliders.

### Usage

`slider.zoom.plot.ts(x, n.windows, ...)`

### Arguments

- `x` time series
- `n.windows` if `n.windows > 1` two sections are defined
- `...` additional graphical parameters

### Details

`slider.zoom.plot.ts` plots the original time series and it lets you select one or two sections of the series by fixing the width(s) and the starting point(s) of the region(s). Then the section(s) of the series is (are) plotted separately one below the other.

The first slider defines the width of the section(s). The second (third) one sets the start of the first (second) section.

### Value

a message about the usage

### Author(s)

Hans Peter Wolf

spin3R

Description

Simple spin function to rotate and to inspect a 3-dimensional cloud of points

Usage

spin3R(x, alpha = 1, delay = 0.015, na.rm=FALSE)

Arguments

x  (nx3)-matrix of points
alpha  angle between successive projections
delay  delay in seconds between two plots
na.rm  if TRUE 'NA' values are removed otherwise exchanged by mean

Details

spin3R computes two-dimensional projections of (nx3)-matrix x and plots them on the graphics device. The cloud of points is rotated step by step. The rotation is defined by a tcl/tk control widget. spin3R requires tcl/tk package of R.

Examples

```r
xyz <- matrix(rnorm(300), 100, 3)
# now start:    spin3R(xyz)
```

Description

Creates a classical ("Tukey-style") stem and leaf display / back-to-back stem and leaf display.

Usage

```r
stem.leaf(data, unit, m, Min, Max, rule.line = c("Dixon", "Velleman", "Sturges"),
          style = c("Tukey", "bare"), trim.outliers = TRUE, depths = TRUE,
          reverse.negative.leaves = TRUE, na.rm = FALSE, printresult = TRUE)
stem.leaf.backback(x, y, unit, m, Min, Max, rule.line = c("Dixon", "Velleman", "Sturges"),
                   style = c("Tukey", "bare"), trim.outliers = TRUE,
                   depths = TRUE, reverse.negative.leaves = TRUE, na.rm = FALSE,
                   printresult = TRUE, show.no.depths = FALSE, add.more.blanks = 0,
                   back.to.back = TRUE)
```

Arguments

- `data`: a numeric vector of data
- `x`: first dataset for `stem.leaf.backback`
- `y`: first dataset for `stem.leaf.backback`
- `unit`: leaf unit, as a power of 10 (e.g., 100, .01); if `unit` is missing `unit` is chosen by `stem.leaf`.
- `m`: number of parts (1, 2, or 5) into which each stem will be separated; if `m` is missing the number of parts/stem (`m`) is chosen by `stem.leaf`.
- `Min`: smallest non-outlying value; omit for automatic choice.
- `Max`: largest non-outlying value; omit for automatic choice.
- `rule.line`: the rule to use for choosing the desired number of lines in the display; "Dixon" = 10*log10(n); "Velleman" = 2*sqrt(n); "Sturges" = 1 + log2(n); the default is "Dixon".
- `style`: "Tukey" (the default) for "Tukey-style" divided stems; "bare" for divided stems that simply repeat the stem digits.
- `trim.outliers`: if `TRUE` (the default), outliers are placed on LO and HI stems.
- `depths`: if `TRUE` (the default), print a column of "depths" to the left of the stems; the depth of the stem containing the median is the stem-count enclosed in parentheses.
reverse.negative.leaves
  if TRUE (the default), reverse direction the leaves on negative stems (so, e.g.,
  the leaf 9 comes before the leaf 8, etc.).
na.rm
  if TRUE "NA" values are removed otherwise the number of NAs are counted.
printresult
  if TRUE output of the stem and leaf display by cat.
show.no.depths
  if TRUE no depths are printed.
add.more.blanks
  number of blanks that are added besides the leaves.
back.to.back
  if FALSE two parallel stem and leaf displays are constructed.

Details

Unlike the stem function in the base package, stem.leaf produces classic stem-and-leaf
displays, as described in Tukey’s Exploratory Data Analysis. The function stem.leaf.backback
creates back-to-back stem and leaf displays.

Value

The computed stem and leaf display is printed out. Invisibly stem.leaf returns the stem and
leaf display as a list containing the elements info (legend), display (stem and leaf display
as character vector), lower (very small values), upper (very large values), depths (vector of
depths), stem (stem information as a vector), and leaves (vector of leaves).
