Package ‘aqp’

February 11, 2022

Version 1.41
Date 2022-02-09
Title Algorithms for Quantitative Pedology
Author Dylan Beaudette [aut, cre],
  Pierre Roudier [aut, ctb],
  Andrew Brown [aut, ctb]
Maintainer Dylan Beaudette <dylan.beaudette@usda.gov>
Depends R (>= 3.5.0)
Imports grDevices, graphics, stats, utils, methods, plyr, grid,
  lattice, cluster, sp, stringr, data.table
Suggests colorspace, ape, soilDB, latticeExtra, tactile, compositions,
  sharpshootR, markovchain, xtable, testthat, Gmedian, farver,
  Hmisc, tibble, RColorBrewer, scales, digest, MASS, mpspline2,
  soiltexture, gower
Description The Algorithms for Quantitative Pedology (AQP) project was started in 2009 to organize a
  loosely-related set of concepts and source code on the topic of soil profile visualization,
  aggregation, and classification into this package (aqp). Over the past 8 years, the project has
  grown into a suite of related R packages that enhance and simplify the quantitative analysis
  of soil profile data. Central to the AQP project is a new vocabulary of specialized functions and
  data structures that can accommodate the inherent complexity of soil profile information; freeing the
  scientist to focus on ideas rather than boilerplate data processing tasks <doi:10.1016/j.cageo.2012.10.020>. These
  functions and data structures have been extensively tested and documented, applied to projects involving
  hundreds of thousands of soil profiles, and deeply integrated into widely used tools such as SoilWeb
  <https://casoilresource.lawr.ucdavis.edu/soilweb-apps/>. Components of the AQP project (aqp, soilDB, sharpshootR, soilReports packages) serve
  an important role in routine data analysis within the USDA-NRCS Soil Science Division. The AQP suite of R
  packages offer a convenient platform for bridging the gap between pedometric theory and practice.

The aqp (Algorithms for Quantitative Pedology) package for R was developed to address some of the difficulties associated with processing soils information, specifically related to visualization, aggregation, and classification of soil profile data. This package is based on a mix of S3/S4 functions and classes, and most functions use basic dataframes as input, where rows represent soil horizons and columns define properties of those horizons. Common to most functions are the requirements that horizon boundaries are defined as depth from 0, and that profiles are uniquely defined by an id column. The aqp package defines an S4 class, "SoilProfileCollection", for storage of profile-level metadata, as well as summary, print, and plotting methods that have been customized for common tasks related to soils data.

Usage

\texttt{aqp.env}

Format

An object of class \texttt{environment} of length 0.

Details

Demos: \texttt{demo(aqp)}

.as.data.frame.aqp  Wrapper method for data.frame subclass conversion

Description

Wrapper method for data.frame subclass conversion

Usage

.as.data.frame.aqp(x, as.class = "data.frame", ...)

Arguments

- **x**  ANY.
- **as.class**  "data.frame", "tibble", or "data.table" default: "data.frame"
- **...**  Additional arguments to coercion function as.data.frame, as_tibble or as.data.table

Value

A subclass of data.frame corresponding to as.class.

---

.data_dots  Make a data.frame from non-standard expressions evaluated in a data environment

Description

Make a data.frame from non-standard expressions evaluated in a data environment

Usage

.data_dots(.data, ...)

Arguments

- **.data**  A list, or object coercible to one, describing the data
- **...**  One or more expressions (preferably named e.g. foo = "bar") to evaluate in .data

Value

A list where names are expression "names" from ... and values are the result of evaluating expressions in context of .data
Examples

```r
# .data_dots(data.frame(a = 1:10, b = 2:11), cc = a + b, d = cc * 2)
# data("jacobs2000", package="aqp")
# .data_dots(compositeSPC(jacobs2000), clayprop = clay / 100)
```

accumulateDepths

Accumulate horizon depths, and reflect reversed depths, relative to new datum

Description

Fix old-style organic horizon depths or depths with a non-standard datum by the "depth accumulation" method.

Usage

```r
accumulateDepths(
  x,
  id = NULL,
  hzdepths = NULL,
  hzname = NULL,
  hzdatum = 0,
  seqnum = NULL,
  pattern = "O",
  fix = TRUE
)
```

Arguments

- `x` A `data.frame` or `SoilProfileCollection`
- `id` unique profile ID. Default: `NULL`, if `x` is a `SoilProfileCollection`
- `hzdepths` character vector containing horizon top and bottom depth column names. Default: `NULL`, if `x` is a `SoilProfileCollection`
- `hzname` character vector containing horizon designation or other label column names. Default: `NULL`, if `x` is a `SoilProfileCollection`
- `hzdatum` a numeric vector to add to accumulated depths. Default: `0`. Can be equal in length to number of profiles if `x` is a `SoilProfileCollection` or number of (unique) IDs if `x` is a `data.frame`.
- `seqnum` Optional: character vector containing record "sequence number" column name; used in-lieu of `hzname` (when NA) to identify "first" record in a profile
- `pattern` pattern to search for in `hzname` to identify matching horizons to append the profile to
- `fix` apply adjustments to missing (NA) depths and expand 0-thickness horizons? Default: `TRUE`
accumulateDepths

Details

The "depth accumulation" method calculates thicknesses of individual horizons and then cumulative sums them after putting them in id + top depth order. The routine tries to determine context based on hzname and pattern. The main transformation is if a top depth is deeper than the bottom depth, the depths are reflected on the Z-axis (made negative). The data are then id + top depth sorted again, the thickness calculated and accumulated to replace the old depths.

This function uses several heuristics to adjust data before transformation and thickness calculation:

**Regex matching of horizon designation patterns and similar:**
- matches of pattern where both top and bottom depth NA -> [0,1] [top,bottom] depth
- REMOVE horizons that do not match pattern where both top and bottom depths NA

**Over-ride hzname handling with the sequence column argument** seqnum:
- if seqnum column specified "first record with NA hzname" is considered a pattern match if seqnum == 1

**Trigger "fixing" with the fix argument:**
- Add 1 cm to bottom-most horizons with NA bottom depth
- Add 1 cm thickness to horizons with top and bottom depth equal
- Add 1 cm thickness to horizons with NA top depth and bottom depth 0

Value

A horizon-level data.frame, suitable for promoting to SPC with depths<-, or a SoilProfileCollection, depending on the class of x.

Examples

```r
# example using hzdatum argument
data(sp4)
depths(sp4) <- id ~ top + bottom
hz <- accumulateDepths(sp4,
  id = "id",
  hzdepths = c("top", "bottom"),
  hzname = "name",
  hzdatum = 5 * 1:length(sp4))
plot(hz)

# example using old-style O horizons
hz <- read.table(text = "peiid ref hzdept hzdepb hzname seqnum phiid
1 11 0 5 A 2 295
2 11 1 0 Oe 1 294
3 11 5 13 C1 3 296
4 11 13 58 C2 4 297
5 11 58 152 C3 5 298
6 13 0 5 A 2 303
7 13 1 0 Oe 1 302
8 13 5 25 Bw 3 304
```

```r
9 13 25  61  C  4  305
10 13  61   NA  R  5  306
11 136  0  13  A1  3  695
12 136  1   0   Oe  2  694
13 136  2   1   Oi  1  693
14 136  13  61  C1  4  696
15 136  61  76  C2  5  697)
```

```r
depths(hz) <- peiidref ~ hzdept + hzdepb

hz_fixed <- accumulateDepths(hz,
   id = "peiidref",
   hzdepths = c("hzdept", "hzdepb"),
   hzname = "hzname")

is_valid <- checkHzDepthLogic(hz_fixed)$valid

test0 <- subset(hz_fixed, !is_valid)
test1 <- subset(hz_fixed, is_valid)

origO <- subset(hz, grepl("O", hzname))
fixedO <- subset(hz_fixed, grepl("O", hzname))

par(mfrow=c(2,1), mar=c(0,0,3,2))
plotSPC(origO, max.depth = 25)
plotSPC(fixedO, max.depth = 25)
```

---

### addBracket

**Add Depth Brackets**

**Description**

Add depth brackets to soil profile sketches.

**Usage**

```r
addBracket(
  x,
  label.cex = 0.75,
  tick.length = 0.05,
  arrow.length = 0.05,
  offset = -0.3,
  missing.bottom.depth = NULL,
  ...
)
```

**Arguments**

- `x` data.frame object containing idname(x), top, bottom, and optionally label columns
addBracket

label.cex  scaling factor for label font
tick.length  length of bracket "tick" mark
arrow.length  length of arrowhead
offset  left-hand offset from each profile
missing.bottom.depth  distance (in depth units) to extend brackets that are missing a lower depth (defaults to max depth of collection)
...
  further arguments passed on to segments or arrows

Details

x may contain multiple records per profile. Additional examples can be found in this tutorial.

Note

This is a low-level plotting function: you must first plot a SoilProfileCollection object before using this function.

  bottom = max(h$bottom[idx], na.rm=TRUE)
)
names(res)[1] <- idn
return(res)

# return matching horizon top / bottom depths for A or C horizons
# result is a 0 or more row data.frame / profile
individualBrackets <- function(i) {
  h <- horizons(i)
  idn <- idname(i)
  this.id <- h[[idn]][1]
  idx <- grep("^A|^C", h$name)
  res <- data.frame(
    id = this.id,
    top = h$top[idx],
    bottom = h$bottom[idx]
  )
  names(res)[1] <- idn
  return(res)
}

# combined brackets
b1 <- profileApply(sp1, combinedBracket, frameify = TRUE)

# individual brackets
b2 <- profileApply(sp1, individualBrackets, frameify = TRUE)

# plot in reverse order
plotSPC(sp1, plot.order = rev(1:length(sp1)), width = 0.25)

# note that plotting order is derived from the call to `plotSPC(sp1)`
addBracket(b1, col='red', offset = -0.35)

# plot in reverse order
plotSPC(sp1, plot.order = rev(1:length(sp1)), width = 0.25)

# note that plotting order is derived from the call to `plotSPC(sp1)`
addBracket(b2, col='red', offset = -0.35)
Description

Annotate diagnostic features within a sketch of soil profiles.

Usage

addDiagnosticBracket(
  s,
  kind,
  feature = "featkind",
  top = "featdept",
  bottom = "featdepb",
  ...
)

Arguments

s SoilProfileCollection object
kind filter applied to feature column of diagnostic horizons registered within s
feature column name containing feature kind
top column name containing feature top depth
bottom column name containing feature top depth
...
additional arguments passed to addBracket

Details

Additional examples can be found in this tutorial.

Note

This is a low-level plotting function: you must first plot a SoilProfileCollection object before using this function.

addBracket, plotSPC
addVolumeFraction  
Symbolize Volume Fraction on a Soil Profile Collection Plot

Description
Symbolize volume fraction on an existing soil profile collection plot.

Usage
addVolumeFraction(
  x, 
colname, 
res = 10, 
cex.min = 0.1, 
cex.max = 0.5, 
pch = 1, 
col = "black"
)

Arguments
x  a SoilProfileCollection object
colname  character vector of length 1, naming the column containing volume fraction data (horizon-level attribute)
res  integer, resolution of the grid used to symbolize volume fraction
cex.min  minimum symbol size
cex.max  maximum symbol size
pch  integer, plotting character code
col  symbol color, either a single color or as many colors as there are horizons in x

Details
This function can only be called after plotting a SoilProfileCollection object. Details associated with a call to plotSPC are automatically accounted for within this function: e.g. plot.order, width, etc..

plotSPC
aggregateColor

Summarize Soil Colors

Description

Summarize soil color data, weighted by occurrence and horizon thickness.

Usage

aggregateColor(
  x,
  groups = "genhz",
  col = "soil_color",
  colorSpace = "CIE2000",
  k = NULL,
  profile_wt = NULL,
  mixingMethod = c("estimate", "exact")
)

Arguments

  x                          a SoilProfileCollection object
  groups                     the name of a horizon or site attribute used to group horizons, see examples
  col                        the name of a horizon-level attribute with soil color specified in hexadecimal (i.e. "#rrggbb")
  colorSpace                 the name of color space or color distance metric to use for conversion of aggregate colors to Munsell; either CIE2000 (color distance metric), LAB, or sRGB. Default = 'CIE2000'
  k                          single integer specifying the number of colors discretized via PAM (cluster package), see details
  profile_wt                 the name of a site-level attribute used to modify weighting, e.g. area
  mixingMethod               method used to estimate "aggregate" soil colors, see mixMunsell

Details

Weights are computed by: $w_i = \sqrt{\text{sum}(\text{thickness}_i)} \times n_i$ where $w_i$ is the weight associated with color $i$, $\text{thickness}_i$ is the total thickness of all horizons associated with the color $i$, and $n_i$ is the number of horizons associated with color $i$. Weights are computed within groups specified by groups.

Value

A list with the following components:

  scaled.data                a list of colors and associated weights, one item for each generalized horizon label with at least one color specified in the source data
aggregateColor

aggregate.data a data.frame of weighted-mean colors, one row for each generalized horizon label with at least one color specified in the source data

Author(s)

D.E. Beaudette

aggregateSoilDepth

Probabilistic Estimation of Soil Depth within Groups

Description

Estimate the most-likely depth to contact within a collection of soil profiles. Consider getSoilDepthClass followed by group-wise percentile estimation as a faster alternative.

Usage

aggregateSoilDepth(
  x,
  groups,
  crit.prob = 0.9,
  name = hzdesgnname(x),
  p = "Cr|R|Cd",
  ...
)

Arguments

x a SoilProfileCollection object

groups the name of a site-level attribute that defines groups of profiles within a collection
alignTransect

Calculate Relative Positions from Transect Data

Description

This function is used to support relative positioning of soil profiles by plotSPC, based on transect or gradient values typically associated with a site level attribute (e.g. elevation). Gradient values specified in x are translated to the range used by plotSPC (usually 1, length(SPC)) specified in x.min and x.max.

crit.prob  probability cutoff used to determine where the most likely depth to contact will be, e.g. 0.9 translates to 90% of profiles are shallower than this depth
name  horizon-level attribute where horizon designation is stored, defaults to hzdesgnname(x)
p  a REGEX pattern that matches non-soil genetic horizons
...  additional arguments to slab

Details

This function computes a probability-based estimate of soil depth by group. If no grouping variable exists, a dummy value can be used to compute a single estimate. The crit.prob argument sets the critical probability (e.g. 0.9) at which soil depth within a group of profiles is determined. For example, a crit.prob of 0.95 might result in an estimated soil depth (e.g. 120cm) where 95% of the profiles (by group) had depths that were less than or equal to 120cm.

Value

A data.frame is returned, with as many rows as there are unique group labels, as specified in groups.

Author(s)

D.E. Beaudette

estimateSoilDepth() slab()

Examples

data(sp1)
depths(sp1) <- id ~ top + bottom
site(sp1) <- ~ group

# set horizon designation in SPC
hzdesgnname(sp1) <- 'name'

aggregateSoilDepth(sp1, 'group', crit.prob = 0.9)
alignTransect

Usage

alignTransect(x, x.min, x.max, fix = TRUE, ...)

Arguments

x numeric vector, describing values along a transect: distance, elevation, climatic variables, etc.. Typically sourced from the site level attributes of a SoilProfileCollection object. Order is not important.

x.min numeric, lower boundary to relative position scale

x.max numeric, upper boundary to relative position scale

fix logical, attempt fixing overlapping positions with fixOverlap

... additional arguments to fixOverlap

Details

See the Pair-Wise Distances by Generalized Horizon Labels tutorial for additional examples.

Value

list containing:

• grad: values of x in ascending order

• order: ordering vector of x

• relative.pos: elements of x translated to the new relative scale defined by x.min and x.max

Examples

data(“sierraTransect”)

# split transects
g <- subset(sierraTransect, transect == ’Granite’)
a <- subset(sierraTransect, transect == ’Andesite’)

g.p <- alignTransect(g$elev, x.min = 1, x.max = length(g), fix = FALSE)
a.p <- alignTransect(a$elev, x.min = 1, x.max = length(a), fix = FALSE)

op <- par(mar=c(2,0,0,2), mfrow=c(2,1))

plotSPC(g, width=0.25, name.style=’center-center’,
cex.names=0.75,
relative.pos = g.p$relative.pos, plot.order = g.p$order)

axis(1, at = g.p$relative.pos, labels = g.p$grad, line = -1.5)

plotSPC(a, width=0.25, name.style=’center-center’,
cex.names=0.75,
relative.pos = a.p$relative.pos, plot.order = a.p$order)
allocate

allocate(1, at = a.p$relative.pos, labels = a.p$grad, line = -1.5)

par(op)

allocate

Allocates soil properties within various classification systems.

Description

Generic function to allocate soil properties to different classification schemes.

Usage

allocate(..., to = c("FAO Salt Severity", "FAO Black Soil", "ST Diagnostic Features"),
          droplevels = TRUE)

Arguments

... arguments to specific allocation functions, see details and examples

 to character specifying the classification scheme: FAO Salt Severity, FAO Black Soil (see details for the required ...)

droplevels logical indicating whether to drop unused levels in factors. This is useful when the results have a large number of unused classes, which can waste space in tables and figures.

Details

This function is intended to allocate a set of soil properties to an established soil classification scheme, such as Salt Severity or Black Soil. Allocation is semantically different from classification. While classification is the ‘act’ of developing a grouping scheme, allocation is the assignment or identification of measurements to an established class (Powell, 2008).

Usage Details:

Each classification scheme (to argument) uses a different set of arguments.

- FAO Salt Severity
  - EC: electrical conductivity column name, dS/m
  - pH: pH column name, saturated paste extract
  - ESP: exchangeable sodium percentage column name, percent

- FAO Black Soils
  - object: a data.frame or SoilProfileCollection
  - pedonid: pedon ID column name, required when object is a data.frame
allocate

- **hztop**: horizon top depth column name, required when `object` is a `data.frame`
- **hzbot**: horizon bottom depth column name, required when `object` is a `data.frame`
- **OC**: organic carbon column name, percent
- **m_chroma**: moist Munsell chroma column name
- **m_value**: moist Munsell value column name
- **d_value**: dry Munsell value column name
- **CEC**: cation exchange capacity column name (NH4OAc at pH 7), units of cmol(+)/kg soil
- **BS**: base saturation column name (NH4OAc at pH 7), percent
- **tropical**: logical, data are associated with "tropical soils"

**ST Diagnostic Features**

- **object**: a `data.frame` or `SoilProfileCollection`
- **pedonid**: pedon ID column name, required when `object` is a `data.frame`
- **hzname**: horizon name column, required when `object` is a `data.frame`
- **hztop**: horizon top depth column name, required when `object` is a `data.frame`
- **hzbot**: horizon bottom depth column name, required when `object` is a `data.frame`
- **texture**: soil texture class (USDA) column name
- **rupresblkcem**: rupture resistance column name
- **m_value**: moist Munsell value column name
- **m_chroma**: moist Munsell chroma column name
- **d_value**: dry Munsell value column name
- **BS**: base saturation column name (method ??), percent
- **OC**: organic carbon column name, percent
- **n_value**: ??
- **featkind**: ??

**Value**

A vector or `data.frame` object.

**Note**

The results returned by `allocate(to = "ST Diagnostic Features")` currently return a limited set of diagnostic features that are easily defined. Also, the logic implemented for some features does not include all the criteria defined in the Keys to Soil Taxonomy.

  d_value = 'value',
  CEC = 'cec',
  BS = 'bs'
)

# Soil Taxonomy Diagnostic Features
data(sp1)
df <- allocate(object = sp1, pedonid = "id", hzname = "name",
               hzdept = "top", hzdepb = "bot", texture = "texture",
               to = "ST Diagnostic Features"
)  
aggregate(featdept ~ id, data = df, summary)
Description

This is an accessor and replacement method for the `aqp_df_class` entry in the metadata slot. This entry is used internally by methods that interact with `data.frame` objects and slots to ensure that the same class used to promote to the `SoilProfileCollection` initially is used throughout the process.

Usage

```r
## S4 method for signature 'SoilProfileCollection'
aqp_df_class(object)

## S4 replacement method for signature 'SoilProfileCollection'
aqp_df_class(object) <- value
```

Arguments

- `object`: a `SoilProfileCollection`
- `value`: "data.frame", "data.table" or "tbl_df"

---

argillic.clay.increase.depth

*Return upper boundary of argillic horizon*

Description

Returns the top depth of the argillic horizon as a numeric vector.

Usage

```r
argillic.clay.increase.depth(p, clay.attr = "clay")
```

Arguments

- `p`: A single-profile `SoilProfileCollection` object.
- `clay.attr`: OPTIONAL: horizon attribute name referring to clay content. default: clay

Details

Uses `crit.clay.argillic` to determine threshold clay increase, and `get.increase.matrix` to determine where increase is met within a vertical distance of 30 cm.

Value

A numeric vector containing top depth of argillic horizon, if present, or NA.

Author(s)

Andrew Gene Brown
See Also

getArgillicBounds, get.increase.matrix, crit.clay.argillic

Examples

data(sp1, package = 'aqp')
depths(sp1) <- id ~ top + bottom
site(sp1) <- ~ group

p <- sp1[1]
attr <- 'prop' # clay contents
foo <- argillic.clay.increase.depth(p, clay.attr = attr)
foo

Description

SoilProfileCollections can be coerced to other R object types using as(spc, 'type'). Possible endpoints include: list, data.frame, SpatialPointsDataFrame and SpatialPoints.

Value

list
data.frame
tbl_df
data.table
SpatialPointsDataFrame
SpatialPoints

Examples

# load example data stored as SoilProfileCollection
data(sp5)

# sp5
str(sp5)

# list output
str(as(sp5, 'list'))

# data.frame output
str(as(sp5, 'data.frame'))
# Spatial Objects
# make some random coordinate data for each profile
sp5$x <- sp5$y <- rnorm(length(sp5))
coordinates(sp5) <- ~ x + y

# SpatialPointsDataframe output
str(as(sp5, 'SpatialPointsDataFrame'))

# SpatialPoints output
str(as(sp5, 'SpatialPoints'))

barron.torrent.redness.LAB

Barron & Torrent (1986) Redness Index in LAB color space

Description

Usage

barron.torrent.redness.LAB(hue, value, chroma)

Arguments

hue A character vector containing Munsell hues (e.g. "7.5YR")
value A numeric vector containing Munsell values
chroma A numeric vector containing Munsell chromas

Value

A numeric vector of horizon redness index (higher values = redder).

Author(s)

Andrew G. Brown

References

**Description**

Simulate realistic sand/silt/clay values (a composition) using multivariate Normal distribution or Dirichlet distribution. Simulations from the multivariate Normal distribution are based on the compositional mean and variance-covariance matrix. Simulations from the Dirichlet distribution are based on maximum likelihood estimation of alpha parameters.

**Usage**

```r
bootstrapSoilTexture(ssc, method = c("dirichlet", "normal"), n = 100)
```

**Arguments**

- `ssc` a `data.frame` object with 3 columns: sand, silt, clay and at least three rows of data within the range of 0-100 (percent). NA are automatically removed, but care should be taken to ensure that the sand/silt/clay values add to 100 percent. Simulations are based on these examples.
- `method` type of simulation: `dirichlet` or `normal`. See details.
- `n` number of simulated compositions. See details.

**Details**

Simulations from the multivariate normal distribution will more closely track the marginal distributions of sand, silt, and clay—possibly a better fit for "squished" compositions (TODO elaborate). However, these simulations can result in extreme (unlikely) estimates.

Simulations from the Dirichlet distribution will usually be a better fit (fewer extreme estimates) but require a fairly large number of records in `ssc` (`n` >= 30?) for a reliable fit.

Additional examples will be added to this tutorial.

**Value**

A list containing:

- `samples` - `data.frame` of simulated sand, silt, clay values
- `mean` - compositional mean
- `var` - compositional variance-covariance matrix
- `D.alpha` - (fitted) alpha parameters of the Dirichlet distribution, NULL when `method = 'normal'`

**Note**

This is a work in progress.

Examples

```r
if(
  requireNamespace("compositions") &
  requireNamespace("soiltexture")
) {

  # sample data, data.frame
data('sp4')

  # filter just Bt horizon data
  ssc <- sp4[grep('^Bt', sp4$name), c('sand', 'silt', 'clay')]
  names(ssc) <- toupper(names(ssc))

  # simulate 100 samples
  s <- bootstrapSoilTexture(ssc, n = 100)
  s <- s$samples

  # empty soil texture triangle
  TT <- soiltexture::TT.plot(
    class.sys = "USDA-NCSS.TT",
    main = "",
    tri.sum.tst=FALSE,
    cex.lab=0.75,
    cex.axis=0.75,
    frame.bg.col = 'white',
    class.lab.col = 'black',
    lwd.axis=1.5,
    arrows.show=TRUE,
    new.mar = c(3, 0, 0, 0)
  )
}
```
brierScore

Multinominal Brier Score

Description

Compute a multinominal Brier score from predicted class probabilities and observed class label. Lower values are associated with a more accurate classifier.

Usage

brierScore(x, classLabels, actual = "actual")

Arguments

x data.frame of class probabilities (numeric) and observed class label (character), see examples
classLabels vector of predicted class labels (probabilities), corresponding to column names in x
actual name of column containing the observed class, should be character vector not factor
Value

A single Brier score, representative of data in x

Author(s)

D.E. Beaudette

References

Examples

# columns 'a', 'b', 'c' contain predicted probabilities
# column 'actual' contains observed class label

# a good classifier
d.good <- data.frame(

# message related to conversion of factor -> character
buntley.westin.index

brierScore(x = d.factors, classLabels = c('a', 'b', 'c'), actual = 'actual')

buntley.westin.index  Buntley-Westin (1965) Index

Description

Calculate "Color Development Equivalent" by the method of Buntley & Westin (1965) "A Comparative Study of Developmental Color in a Chestnut-Chernozem-Brunizem Soil Climosequence" DOI: 10.2136/sssaj1965.03615995002900050029x. Originally developed for Mollisols, the Buntley-Westin index has been used as a tool to separate soils based on depth to particular colors.

Usage

buntley.westin.index(hue, chroma)

Arguments

hue         A character vector containing Munsell hues (e.g. "7.5YR")
chroma      A numeric vector containing Munsell chromas

Value

A numeric vector reflecting horizon color development.

Combine SoilProfileCollection objects

Description

Combine SoilProfileCollection objects or lists of SoilProfileCollection objects. This method provides ... expansion for the pbindlist method.

Usage

## S4 method for signature 'SoilProfileCollection'
c(x, ...)

## S4 method for signature 'SoilProfileCollection'
combine(...)

## S4 method for signature 'list'
combine(...)

Arguments

x
A SoilProfileCollection

... SoilProfileCollection objects

Value

A SoilProfileCollection

Examples

# example data
spc1 <- random_profile(1, SPC = TRUE)
spc2 <- random_profile(2, SPC = TRUE)
spc3 <- random_profile('A', SPC = TRUE)

# combine into a single SPC, ... interface
spc <- combine(spc1, spc2, spc3)

# combine into a single SPC, list interface
spc <- combine(list(spc1, spc2, spc3))

# input are combined into a single SPC
spc <- c(spc1, spc2, spc3)

# result is a list when a mixture of objects are provided
spc <- c(spc1, bar=spc2, baz="foo")
Soil Data from the Central Sierra Nevada Region of California

Description

Site and laboratory data from soils sampled in the central Sierra Nevada Region of California.

Usage

data(ca630)

Format

List containing:

$site : A data frame containing site information.

user_site_id  national user site id
mlra  the MLRA
county  the county
ssa  soil survey area
lon  longitude, WGS84
lat  latitude, WGS84
pedon_key  national soil profile id
user_pedon_id  local soil profile id
cntrl_depth_to_top  control section top depth (cm)
cntrl_depth_to_bot  control section bottom depth (cm)
sampled_taxon_name  soil series name

$lab : A data frame containing horizon information.

pedon_key  national soil profile id
layer_key  national horizon id
layer_sequence  horizon sequence number
hzn_top  horizon top (cm)
hzn_bot  horizon bottom (cm)
hzn_desgn  horizon name
texture_description  USDA soil texture
nh4_sum_bases  sum of bases extracted by ammonium acetate (pH 7)
ex_acid  exchangeable acidity [method ?]
CEC8.2  cation exchange capacity by sum of cations method (pH 8.2)
CEC7  cation exchange capacity by ammonium acetate (pH 7)
bs_8.2  base saturation by sum of cations method (pH 8.2)
bs_7  base saturation by ammonium acetate (pH 7)
Details

These data were extracted from the NSSL database. ca630 is a list composed of site and lab data, each stored as data.frame objects. These data are modeled by a 1:many (site:lab) relation, with the pedon_id acting as the primary key in the site table and as the foreign key in the lab table.

Note

These data are out of date. Pending some new data + documentation. Use with caution

## End(Not run)

---

**checkHzDepthLogic**

Check a SoilProfileCollection object for errors in horizon depths.

**Description**

This function inspects a SoilProfileCollection object, looking for four common errors in horizon depths:

1. bottom depth shallower than top depth
2. equal top and bottom depth
3. missing top or bottom depth (e.g. NA)
4. gap or overlap between adjacent horizons

**Usage**

```r
checkHzDepthLogic(
  x, 
  hzdepths = NULL, 
  idname = NULL, 
  fast = FALSE, 
  byhz = FALSE
)
```

**Arguments**

- **x**: SoilProfileCollection or data.frame object to check
- **hzdepths**: SoilProfileCollection uses horizonDepths(x) Default: NULL; if x is a data.frame, character vector of column names of top and bottom depths
### checkHzDepthLogic

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>idname</td>
<td>SoilProfileCollection uses <code>idname(x)</code> Default: NULL; if <code>x</code> is a data.frame, character vector with column name of unique profile ID;</td>
</tr>
<tr>
<td>fast</td>
<td>If details about specific test results are not needed, the operation can allocate less memory and run approximately 5x faster. Default: FALSE</td>
</tr>
<tr>
<td>byhz</td>
<td>Apply logic tests to profiles or individual horizons?</td>
</tr>
</tbody>
</table>

#### Value

A data.frame containing profile IDs, validity boolean (`valid`) and test results if `fast = FALSE`. The data.frame will have as many rows as profiles in `x` (`length(x)`).

- **id**: Profile IDs, named according to `idname(x)`
- **valid**: boolean, profile passes all of the following tests
  - depthLogic: boolean, errors related to depth logic
  - sameDepth: boolean, errors related to same top/bottom depths
  - missingDepth: boolean, NA in top / bottom depths
  - overlapOrGap: boolean, gaps or overlap in adjacent horizons

#### Author(s)

D.E. Beaudette, A.G. Brown, S.M. Roecker

#### Examples

```r
## sample data

data(sp3)
depths(sp3) <- id ~ top + bottom

# these data should be clean
res <- checkHzDepthLogic(sp3)
head(res)

# less memory if only concerned about net validity
res2 <- checkHzDepthLogic(sp3, fast = TRUE)
head(res2)
```
checkSPC  Test for a valid SoilProfileCollection

Description
Test for a valid SoilProfileCollection

Usage
checkSPC(x)

Arguments
x  a SoilProfileCollection object

Details
Test for valid SoilProfileCollection by checking for slots defined in the class prototype. Likely only used between major versions of aqp where internal structure of SoilProfileCollection has changed. Use checkHzDepthLogic to check for common errors in horizon depths.

Value
TRUE or FALSE. Consider using rebuildSPC() if FALSE.

Author(s)
D.E. Beaudette

See Also
rebuildSPC, checkHzDepthLogic

colorChart  Visualize soil colors in Munsell notation according to within-group frequency.

Description
Visualize soil colors in Munsell notation according to within-group frequency.
Usage

colorChart(
  m,
  g = factor("All"),
  size = TRUE,
  annotate = FALSE,
  chip.cex = 3,
  chip.cex.min = 0.1,
  chip.cex.max = 1.5,
  chip.border.col = "black",
  annotate.cex = chip.cex * 0.25,
  annotate.type = c("count", "percentage")
)

Arguments

- **m**: character vector of color in Munsell notation ('10YR 4/6')
- **g**: factor describing group membership, typically a generalization of horizon designation, default value will generate a fake grouping that covers all of the colors in m
- **size**: logical, encode group-wise frequency with chip size
- **annotate**: logical, annotate color chip frequency
- **chip.cex**: scaling factor applied to each color chip
- **chip.cex.min**: lower limit for color chip frequency depiction
- **chip.cex.max**: lower limit for color chip frequency depiction
- **chip.border.col**: color for chip borders (outline)
- **annotate.cex**: scaling factor for chip frequency annotation
- **annotate.type**: character, within-group count or percentage

Value

A trellis object

Examples

```r
# required for latticeExtra:useOuterStrip
if(!requireNamespace('latticeExtra')) {
  # two hue pages
  ric <- expand.grid(
    hue = c('5YR', '7.5YR'),
    value = 2:8,
    chroma = 2:8
  )
}
```
# combine hue, value, chroma into standard Munsell notation
ric <- sprintf("%s %s/%s", ric$hue, ric$value, ric$chroma)

# note that chip frequency-based size is disabled
# because all chips have equal frequency
colorChart(ric, chip.cex = 4, size = TRUE)

# annotation of frequency
colorChart(ric, chip.cex = 4, annotate = TRUE)

# bootstrap to larger size
ric.big <- sample(ric, size = 100, replace = TRUE)

# frequency can be encoded in size
colorChart(ric.big, chip.cex = 3)
colorChart(ric.big, chip.cex = 5, annotate = TRUE)

# constant size
colorChart(ric.big, chip.cex = 3, size = FALSE)
colorChart(ric.big, chip.cex = 3, size = FALSE, chip.border.col = 'NA')

# simulate colors based dE00 thresholding
p <- list(
  list(m = '10YR 4/4', thresh = 10, hues = c('10YR', '7.5YR'))
)

# perform 500 simulations
s <- simulateColor(method = 'dE00', n = 500, parameters = p)

# result is a list, use the first element
colorChart(s[[1]], chip.cex = 4)

# increase the possible range of color chip sizes
colorChart(s[[1]], chip.cex = 4, chip.cex.min = 0.01, chip.cex.max = 2)

# slightly funky support for neutral hues
N <- sprintf("N %s", 2:8)
cols <- c(rep(N, times = 5), ric.big)

# note special panel used to show neutral hues
colorChart(cols, size = FALSE, annotate = TRUE)

}

Metrics of Contrast Suitable for Comparing Soil Colors
Description
Pair-wise comparisons of Munsell color specifications, based on the NCSS color contrast classes (Soil Survey Technical Note 2) and CIE delta-E 2000 metric.

Usage
```
colorContrast(m1, m2)
```

Arguments
- `m1` vector of Munsell colors ('10YR 3/3')
- `m2` vector of Munsell colors ('10YR 3/6')

Details
This function is fully vectorized but expects input to be of the same length. Use `expand.grid()` to generate suitable input from 1:many or many:1 type comparisons. See this tutorial for an expanded discussion and more examples. Neutral colors are not mentioned in SSTN2: in this function any comparison to a neutral color (e.g. 'N 3/') are assigned a delta-hue of 1. Since SSTN2 expects hues to be counted clockwise from 5R, it possible to get very large delta-hue values for otherwise adjacent colors: '5R' vs. '2.5R'. This will be addressed in an update to the standards.

The most meaningful representation of color contrast is the CIE2000 (dE00) metric.

Value
A data.frame with the following columns:

- `m1`: Munsell color 1
- `m2`: Munsell color 2
- `dH`: delta-hue, as computed by `huePosition`
- `dV`: delta-value, absolute value of difference in Munsell value (m1 vs. m2)
- `dc`: delta-chroma, absolute value of difference in Munsell chroma (m1 vs. m2)
- `dE00`: delta-E00, e.g. the CIE delta-E as refined in 2000
- `cc`: soil color contrast class, as specified in Soil Survey Technical Note 2

Note
delta-E00 is computed by the `farver` package.

Examples

# two sets of colors to compare
m1 <- c('10YR 6/3', '7.5YR 3/3', '10YR 2/2', '7.5YR 3/4')
m2 <- c('5YR 3/4', '7.5YR 4/4', '2.5YR 2/2', '7.5YR 6/3')

# contrast metrics
colorContrast(m1, m2)

# adjacent chips
colorContrast('10YR 3/3', '10YR 3/4')
colorContrast('10YR 3/3', '7.5YR 3/3')

# highly contrasting colors
# http://colour.granjow.net/fabercastell-polychromos.html
colorContrastPlot('10B 4/13', '10YR 10/15',
labels = c('helioblue-reddish', 'light cadmium yellow'))

## Note: neutral hues aren't defined in TN2
# approximation / extension of the concept
colorContrast(m1 = 'N 3/', m2 = 'N 6/')

#
colorContrast(m1 = '10YR 3/3', m2 = 'N 3/')

m1 <- c('10YR 6/3', '7.5YR 3/3', '10YR 2/2', 'N 3/')
m2 <- c('5YR 3/4', '7.5YR 4/4', '2.5YR 2/2', '7.5YR 6/3')
colorContrast(m1, m2)

colorContrastPlot

Description

A simple display of two sets of colors, NCSS color contrast class and CIE delta-E00.

Usage

colorContrastPlot(
  m1,
  m2,
  col.cex = 1,
Arguments

- **m1**: first set of Munsell colors for comparison (e.g. '5YR 3/2')
- **m2**: second set of Munsell colors for comparison
- **col.cex**: scaling factor for color labels
- **col.font**: font for color labels
- **d.cex**: contrast for contrast metric labels
- **cc.font**: font for contrast class
- **dE00.font**: font for delta-E00
- **labels**: labels for compared colors, vector length 2
- **label.cex**: scaling factor for labels
- **label.font**: font for labels
- **printMetrics**: logical, print metrics between color swatches
- ... further arguments to `colorspace::swatchplot`

Details

This function requires the `farver` package for calculation of CIE delta-E00

```r
# two sets of colors to compare
m1 <- c("10YR 6/3", "7.5YR 3/3", "10YR 2/2", "7.5YR 3/4")
m2 <- c("5YR 3/4", "7.5YR 4/4", "2.5YR 2/2", "7.5YR 6/3")

# contrast metrics
colorContrast(m1, m2)
```
colorQuantiles

Soil Color Range via Quantiles

Description

Estimate central tendency and spread of soil color using marginal quantiles and L1 median of CIELAB coordinates.

Usage

colorQuantiles(soilColors, p = c(0.05, 0.5, 0.95))

Arguments

soilColors vector of R colors (sRGB colorspace)
p marginal quantiles of interest

Details

Colors are converted from sRGB to CIELAB (D65 illuminant), marginal quantiles of L,A,B coordinates are estimated, and L1 median L,A,B is estimates. The closest Munsell chips (via Munsell/CIELAB lookup table provided by munsell) and R colors are determined by locating chips closest to the marginal quantiles and L1 median.

The results can be conveniently inspected using plotColorQuantiles.

Value

A List containing the following elements:

- marginal: data.frame containing marginal quantiles in CIELAB (D65), closest Munsell chips, and dE00
- L1: L1 median CIELAB (D65) values, closest Munsell chip, and dE00

Author(s)

D.E. Beaudette
Examples

```r
## Not run:
# example data, see manual page for details
data(sp5)

# slice top 25 cm
s <- slice(sp5, 1:25 ~ .)

# check some of the data
par(mar=c(0,0,0,0))
plot(sample(s, 25), divide.hz=FALSE, name='', print.id=FALSE, width=0.5)

# colors
previewColors(unique(s$soil_color))

# compute marginal quantiles and L1 median
cq <- colorQuantiles(s$soil_color)

# simple graphical display of results
plotColorQuantiles(cq)

## End(Not run)
```

---

**compositeSPC**  
*Return a list representation of site and horizon level data*

**Description**  

`compositeSPC()` is a convenience function that returns a named list representation of the columns from the `@site` and `@horizons` slots.

**Usage**  

```r
compositeSPC(object)
```

**Arguments**  

- `object`  
  A `SoilProfileCollection`

**Value**  

A list.

**Author(s)**  

Andrew G. Brown.
Description

Calculate the confusion index of Burrough et al., 1997.

Usage

confusionIndex(x)

Arguments

x vector of probabilities (0,1), should not contain NA

Value

A single numeric value.

Author(s)

D.E. Beaudette

References

Examples

# a very simple example
p <- c(0.25, 0.25, 0.4, 0.05, 0.05)
confusionIndex(p)

# for comparison
shannonEntropy(p)
**Description**

Compare one or more pages from a simulated Munsell book of soil colors to a reference color.

**Usage**

```r
contrastChart(
  m,
  hues,
  ccAbbreviate = 1,
  style = "hue",
  gridLines = FALSE,
  thresh = NULL,
  returnData = FALSE
)
```

**Arguments**

- `m`  
  Munsell representation of a single color for comparison e.g. '10YR 4/3'
- `hues`  
  vector of one or more Munsell hue pages to display
- `ccAbbreviate`  
  length of abbreviated contrast classes, use 0 to suppress labels
- `style`  
  'hue' or 'CC', see details
- `gridLines`  
  logical, add grid lines to the color contrast chart
- `thresh`  
  threshold (<) applied to pair-wise comparisons and resulting color chips
- `returnData`  
  logical, return lattice figure + data used to generate the figure

**Details**

A simulated Munsell color book page or pages are used to demonstrate color contrast between all chips and the reference color `m` (highlighted in red). NCSS color contrast class and CIE delta-E00 values are printed below all other color chips. Munsell color chips for chroma 5 and 7 are omitted, but axis labels are retained as a reminder of this fact.

Setting `style='hue'` emphasizes the contrast classes and CIE delta-E00 of chips adjacent to `m`. Setting `style='CC'` emphasizes adjacent chips according to respective contrast class via lattice panels.

Two-way panels are used when multiple hues are provided and `style='CC'`. The default output can be greatly enhanced via:

```r
latticeExtra::useOuterStrips(...,strip = strip.custom(bg=grey(0.85)),strip.left = strip.custom(bg=grey(0.85)))
```

**Author(s)**

D.E. Beaudette
Examples

# single hue page
contrastChart(m = '10YR 3/3', hues = '10YR')

# multiple hue pages
contrastChart(m = '10YR 3/3', hues = c('10YR', '2.5Y'))

# contrast class, single hue
contrastChart(m = '10YR 3/3', hues = '10YR', style='CC')

# contrast class, multiple hues
# consider latticeExtra::useOuterStrips()
contrastChart(m = '10YR 5/6', hues = c('10YR', '2.5Y'), style='CC')

---

contrastClass  Soil Color Contrast

Description

Determine soil color contrast class according to methods outlined in the Soil Survey Manual. This function is typically called from colorContrast() which is simpler to use and provides more information.

Usage

contrastClass(v1, c1, v2, c2, dH, dV, dC, verbose = FALSE)

Arguments

v1  Munsell value of first color
c1  Munsell chroma of first color
v2  Munsell value of second color
c2  Munsell chroma of second color
dH  delta Hue
dV  delta Value
dC  delta Chroma
verbose  return a list for testing rules/cases

Details

This function is fully vectorized but expects all inputs have the same length.

Value

A vector of color contrast classes (ordered factor). A list when verbose is TRUE.
## coordinates,SoilProfileCollection-method

*Get coordinates from spatial slot*

### Description

Get coordinates from spatial slot, if present.

### Usage

```r
## S4 method for signature 'SoilProfileCollection'
coordinates(obj)

## S4 replacement method for signature 'SoilProfileCollection'
coordinates(object) <- value
```

### Arguments

- `obj`: A SoilProfileCollection
- `object`: A SoilProfileCollection
- `value`: A formula specifying columns containing x and y coordinates

### Examples

```r
## standard use, result is an ordered factor
# 10YR 6/3 vs 5YR 3/4
contrastClass(v1=6, c1=3, v2=3, c2=4, dH=2, dV=3, dC=1)

## verbose output, useful for testing rules/cases
# 10YR 6/3 vs 5YR 3/4
contrastClass(v1=6, c1=3, v2=3, c2=4, dH=2, dV=3, dC=1, verbose = TRUE)
```

### References

- Soil Survey Technical Note 2

### See Also

- `colorContrast`
Examples

```r
data(sp5)

# coordinates are stored in x and y column of site
sp5$x <- rnorm(length(sp5))
sp5$y <- rnorm(length(sp5))

# coordinates takes a formula object as input
coordinates(sp5) <- ~ x + y
```

correctAWC

Apply rock fragment or salt correction to available water content

Usage

```r
correctAWC(awc, total_rf, gravel = NULL, ec = NULL)
```

Arguments

- `awc`: Numeric vector of available water capacities (e.g. from `estimateAWC`)
- `total_rf`: Numeric vector of rock fragment volume percentage, 0 - 100
- `gravel`: Numeric vector of gravel volume percentage, 0 - 100
- `ec`: Numeric vector of electrical conductivity, mmhos/cm

Value

A numeric vector (double) containing estimated available water capacities corrected for rock fragments and salts

Examples

```r
# medium organic matter, loam texture
base.awc <- 0.18 # estimateAWC(texcl = "l", omcl = 2, na.rm = TRUE)

# medium organic matter, loam texture w/ 23% rock fragments by volume
corrected.awc <- correctAWC(base.awc, total_rf = 23)
corrected.awc

# medium organic matter, loam texture w/ 0% frags by volume and 8 mmhos/cm salts
salty.awc <- correctAWC(base.awc, total_rf = 0, ec = 8)
salty.awc
```
crit.clay.argillic

Determines threshold (minimum) clay content for argillic upper bound

Description

Given a vector or matrix of "eluvial" horizon clay contents \( \text{crit.clay.argillic()} \) returns a vector or matrix of minimum clay contents (thresholds) that must be met for an argillic horizon clay increase.

Usage

\[ \text{crit.clay.argillic(eluvial\_clay\_content)} \]

Arguments

- eluvial\_clay\_content
  - A numeric vector or matrix containing clay contents of potential "eluvial" horizons. May contain \texttt{NA}.

Details

Uses the standard equations for clay contents less than 15 \% and 40 \% the definition of the argillic horizon from 12th Edition Keys to Soil Taxonomy (Soil Survey Staff, 2014).

Value

A vector or matrix (input-dependent) containing minimum "illuvial" horizon clay contents (thresholds) to be met for argillic horizon clay increase.

Note

This function is intended for identifying clay content threshold required for an argillic horizon. These thresholds may not apply depending on the specifics of your soil. E.g. if the upper part of argillic has been plowed (has Ap immediately over upper boundary) the clay increase requirement can be waived (Soil Survey Staff, 2014).

Author(s)

Andrew Gene Brown

References

See Also

\[ \text{getArgillicBounds, get.increase.matrix} \]
Examples

```r
# crit.clay.argillic uses different equations for clay content
# less than 15 %, between 15 and 40 %, and >40 %

crit.clay.argillic(eluvial_clay_content=c(5, 20, 45))
```

---

**denormalize**  
Create a (redundant) horizon-level attribute from a site-level attribute

**Description**

Create a (redundant) horizon-level attribute from a site-level attribute. Specify a SoilProfileCollection and a site-level attribute from that SPC (by name) to receive a vector of length equal to the number of horizons containing the site-level values. This vector is directly usable with the SoilProfileCollection horizon setter.

denormalize is the inverse operation for the formula interface that "normalizes" a horizon level variable to site level:

```r
site(object) <-~ horizonvar
```

**Usage**

```r
denormalize(object, attr)
```

**Arguments**

- `object`: A SoilProfileCollection
- `attr`: Site-level attribute name (character string) to denormalize to horizon.

**Details**

"Denormalization" is the process of trying to improve the read performance of a database, at the expense of losing some write performance, by adding redundant copies of data or by grouping data. Sometimes it is beneficial to have site-level attributes denormalized for grouping of horizon-level data in analyses. denormalize achieves this result for SoilProfileCollections.

**Value**

A vector of values of equal length to the number of rows in the horizon table of the input SPC.

**Author(s)**

Andrew G. Brown, Dylan Beaudette
Examples

```r
data(sp1)

# create a SoilProfileCollection from horizon data
depths(sp1) <- id ~ top + bottom

# create random site-level attribute 'sitevar' with a binary (0/1) outcome
sp1$sitevar <- round(runif(length(sp1)))

# use denormalize() to create a mirror of sitevar in the horizon table
# name the attribute something different (e.g. 'hz.sitevar') to
# prevent collision with the site attribute
# the attributes can have the same name but you will then need
# site() or horizons() to access explicitly
sp1$hz.sitevar <- denormalize(sp1, 'sitevar')

# compare number of profiles to number of sitevar assignments
length(sp1)
table(sp1$sitevar)

# compare number of horizons to number of horizon-level copies of sitevar 'hz.'sitevar'
nrow(sp1)
table(sp1$hz.sitevar)
```

---

**depthOf**

*Get top or bottom depths of horizons matching a regular expression pattern*

**Description**

The `depthOf` family of functions calculate depth of occurrence of a horizon designation pattern, or any other value that can be coerced to character and matched with a regular expression.

If you need all depths of occurrence for a particular pattern, `depthOf` is what you are looking for. `minDepthOf` and `maxDepthOf` are wrappers around `depthOf` that return the minimum and maximum depth. They are all set up to handle missing values and missing “contacts” with the target pattern.

**Usage**

```r
depthOf(
  p,
  pattern,
  FUN = NULL,
  top = TRUE,
  hzdesgn = guessHzDesgnName(p),
  no.contact.depth = NULL,
  no.contact.assigned = NA_real_,
  na.rm = TRUE,
)```
depthOf

simplify = TRUE

Arguments

p a SoilProfileCollection
pattern a regular expression to match in the horizon designation column. See:hzdesgn
FUN a function that returns a single value, and takes argument na.rm
top should the top (TRUE) or bottom (FALSE) depth be returned for matching horizons? Default: TRUE.
hzdesgn column name containing horizon designations. Default: guessHzDesignName(p)
no.contact.depth depth to assume that contact did not occur.
no.contact.assigned depth to assign when a contact did not occur.
na.rm logical. Remove NA? (default: TRUE)
simplify logical. Return single profile results as vector (default: TRUE) or data.frame (FALSE)

Value

a numeric vector containing specified depth(s) of horizons matching a pattern. If length(p) > 1 then a data.frame containing profile ID, horizon ID, top or bottom depths, horizon designation and pattern.

Author(s)

Andrew G. Brown

Examples

# construct a fake profile
spc <- data.frame(id=1, taxsubgrp = "Lithic Haploxerepts",
                   hzname = c("A", "AB", "Bw", "BC", "R"),
                   hzdept = c(0, 20, 32, 42, 49),
                   hzdepb = c(20, 32, 42, 49, 200),
                   clay = c(19, 22, 22, 21, NA),
                   texcl = c("l", "l", "l", "l", "br"),
                   d_value = c(5, 5, 5, 6, NA),
                   m_value = c(2.5, 3, 3, 4, NA),
                   m_chroma = c(2, 3, 4, 4, NA))

# promote to SoilProfileCollection
depths(spc) <- id ~ hzdept + hzdepb
hzdesgnname(spc) <- 'hzname'
hztextclname(spc) <- 'textcl'

# multiple horizons contain B
depthOf(spc, "B")
# deepest top depth of horizon containing B
maxDepthOf(spc, "B")

# shallowest top depth
minDepthOf(spc, "B")

# deepest bottom depth
maxDepthOf(spc, "B", top = FALSE)

# deepest bottom depth above 35cm
maxDepthOf(spc, "B", top = FALSE, no.contact.depth = 35)

# assign infinity (Inf) if B horizon does not start within 10cm
minDepthOf(spc, "B", no.contact.depth = 10, no.contact.assigned = Inf)

depths<-,SoilProfileCollection-method

Initialize a SoilProfileCollection from a data.frame object

Description

Initialize a SoilProfileCollection from a data.frame object

Usage

## S4 replacement method for signature 'SoilProfileCollection'
depths(object) <- value

## S4 replacement method for signature 'data.frame'
depths(object) <- value

Arguments

object An object to promote to SoilProfileCollection (inherits from data.frame)
value A formula specifying the unique profile ID, top and bottom depth column names

Details

The input horizon data, and the resulting profile order, is sorted based on unique profile ID and top depth. ID columns are converted to character, depth columns are converted to integer. If NA values exist in all of the top depths, a prototype with 1 horizon per profile ID is returned, with NA in all non-essential columns. If the input object has 0 rows, a prototype with 0 horizons and 0 rows, but same column names as object, is returned.
Examples

```r
## init SoilProfileCollection objects from data.frame of horizon data

# load demo data
data(sp1)

# promote to SPC
depths(sp1) <- id ~ top + bottom

# plot
plot(sp1)

# number of profiles
length(sp1)

# number of horizons
nrow(sp1)
```

---

**depthWeights**  
*Return a vector of contributing fractions over a depth interval*

**Description**

`depthWeights()` calculates the contributing fraction for each pair of horizon top and bottom depths, given an upper and lower boundary.

**Usage**

```r
depthWeights(top, bottom, upper, lower)
```

**Arguments**

- `top`  
  A numeric vector of horizon top depths.

- `bottom`  
  A numeric vector of horizon bottom depths.

- `upper`  
  A unit length numeric vector with upper boundary.

- `lower`  
  A unit length numeric vector with lower boundary.

**Value**

A named list.

**Author(s)**

Andrew G. Brown.
depth_units, SoilProfileCollection-method

*Get depth units from metadata*

**Description**

Get units of depth measurement from metadata. Default value is centimeters.

**Usage**

```r
## S4 method for signature 'SoilProfileCollection'
depth_units(object)

## S4 replacement method for signature 'SoilProfileCollection'
depth_units(object) <- value
```

**Arguments**

- `object`: A `SoilProfileCollection`
- `value`: character, a value representing units. Default 'cm'.

**Examples**

```r
data(sp5)

## get depth units
du <- depth_units(sp5)

# set alternate units; e.g. inches
depth_units(sp5) <- 'in'

# replace original value (cm)
depth_units(sp5) <- du
```

---

diagnostic_hz, SoilProfileCollection-method

*Retrieve diagnostic data from SoilProfileCollection*

**Description**

Get diagnostic feature data from `SoilProfileCollection`. Result is returned in the same `data.frame` class used to initially construct the `SoilProfileCollection`. 
Usage

```r
## S4 method for signature 'SoilProfileCollection'
-diagnostic_hz(object)
```

Arguments

- `object` a SoilProfileCollection

Description

Diagnostic data in an object inheriting from data.frame can easily be added via merge (LEFT JOIN). There must be one or more same-named columns containing profile ID on the left and right hand side to facilitate the join: `diagnostic_hz(spc) <- newdata`

Usage

```r
diagnostic_hz(object) <- value
```

Arguments

- `object` A SoilProfileCollection
- `value` An object inheriting data.frame

Examples

```r
# load test data
data(sp2)

# promote to SPC
depths(sp2) <- id ~ top + bottom

# assign two profiles a zone related to the mollic epipedon
newdata <- data.frame(id = c("hon-1","hon-17"),
                      featkind = "fixed-depth surface sample",
                      featdept = 0,
                      featdepb = 18)

# do left join
diagnostic_hz(sp2) <- newdata

# inspect site table: newvalue TRUE only for horizons
# with top depth equal to zero
diagnostic_hz(sp2)
```
**Description**

Cut ("dice") soil horizons into 1-unit thick slices. This function will eventually replace `aqp::slice()`.

**Usage**

```r
dice(
  x,
  fm = NULL,
  SPC = TRUE,
  pctMissing = FALSE,
  fill = FALSE,
  strict = TRUE,
  byhz = FALSE
)
```

**Arguments**

- **x**: a `SoilProfileCollection` object
- **fm**: optional formula describing top depths and horizon level attributes to include: `integer.vector ~ var1 + var2 + var3` or `integer.vector ~ .` to include all horizon level attributes. When NULL profiles are "diced" to depth and results will include all horizon level attributes.
- **SPC**: return the diced `SoilProfileCollection`, if FALSE a data.frame of horizon-level attributes
- **pctMissing**: compute "percent missing data" by slice (when TRUE expect 6-8x longer runtime)
- **fill**: logical, fill with empty placeholder horizons in gaps within profiles, and/or, above/below interval specified in fm. Automatically set to TRUE when fm is specified. Backwards compatibility with slice is maintained by setting fill = TRUE with or without fm.
- **strict**: perform horizon depth logic checking / flagging / removal
- **byhz**: Evaluate horizon depth logic at the horizon level (TRUE) or profile level (FALSE). Invalid depth logic invokes HzDepthLogicSubset which removes offending profiles or horizon records.

**Details**

For large and potentially messy collections that include missing horizon bottom depths, or 0-thickness horions, consider using `repairMissingHzDepths()` before `dice()`.
duplicate

**Value**

A simple function to duplicate the contents of a `SoilProfileCollection` object. Old profile IDs are saved as a site-level attribute (oldID) and new IDs are generated using a numeric serial number.

**Usage**

```r
duplicate(x, times = 3, oldID = ".oldID")
```

**Arguments**

- `x` a `SoilProfileCollection` object with 1 or more profiles
- `times` requested number of copies
- `oldID` site-level attribute used to store the original profile IDs

**Examples**

```r
# sample data
data('sp4')

# promote to SPC

equivalentMunsellChips

Identify "equivalent" (whole number value/chroma) Munsell chips

Description

Uses a pre-calculated lookup list (equivalent_munsell) based on pair-wise CIE2000 contrast (dE00) of LAB color with D65 illuminant for all whole value/chroma "chips" in the aqp::munsell data set.

The intention is to identify Munsell chips that may be "functionally equivalent" to some other given whole value/chroma chip elsewhere in the Munsell color space – as discretized in the aqp::munsell data table. This basic assumption needs to be validated against your end goal: probably by visual inspection of some or all of the resulting sets. See colorContrast and colorContrastPlot.

"Equivalent" chips table are based (fairly arbitrarily) on the 0.001 probability level of dE00 (default Type 7 quantile) within the upper triangle of the 8467x8467 contrast matrix. This corresponds to a dE00 contrast threshold of approximately 2.15.

Usage

equivalentMunsellChips(hue = NULL, value = NULL, chroma = NULL)

Arguments

hue A character vector containing Munsell hues
value A numeric vector containing Munsell values (integer only)
chroma A numeric vector containing Munsell chromas (integer only)

Value

A named list; Each list element contains a data.frame with one or more rows of "equivalent" Munsell, RGB and LAB color coordinates from munsell data set.

```
equivalent_munsell

Indices of "equivalent" Munsell chips in the munsell data set

Description

A pre-calculated lookup list (made with \texttt{farver::compare\_colour}) based on pair-wise color contrast (CIE2000 or \texttt{dE00}) evaluated over all "chips" in the \texttt{aqp::munsell} data set.

The intention is to identify Munsell chips that may be "functionally equivalent" to some other given whole chip elsewhere in the Munsell color space – as discretized in the \texttt{aqp::munsell} lookup table. "Equivalent" chips are based (fairly arbitrarily) on the 0.001 probability level of \texttt{dE00} (default Type 7 quantile) within the upper triangle of the 8467x8467 contrast matrix. This corresponds to a \texttt{dE00} threshold of approximately 2.15.

This is a naive (to the subtleties of human color perception, and overall magnitude of contrast between some of the "chips") but computationally consistent approach. Using the lookup list, as opposed to manual contrast via e.g. \texttt{farver::compare\_colour} may have some benefits for efficiency in certain applications where the exact contrast value is not as important as the concept of having some threshold that is non-zero, but very small.

Usage

\texttt{data(equivalent_munsell)}

Format

A named list with 8467 elements, each containing a numeric vector of indices corresponding to the \texttt{munsell} data set, which has 8467 rows (unique, whole-number chips). Names have the format HUE VALUE/CHROMA, e.g. "7.5YR 4/4"

estimateAWC

Estimate available water capacity for fine-earth fraction

Description

Estimate available water capacity for fine-earth fraction

Usage

estimateAWC(texcl, omcl, precision = 2, FUN = mean, ...)

Arguments

texcl character, USDA textural class fine earth fraction

omcl integer, Organic matter class. 1: less than 1.5 percent, 2: less than 5, 3: greater than 5

precision integer, Number of decimal places in result default: 2

FUN Function for interpolating between table values default: mean

... Additional arguments to FUN

Value

A numeric vector double containing estimated available water capacities for fine-earth fraction.

Examples

# organic matter, loam texture, low medium and high OM
base.awc <- estimateAWC(c("l","l","l"), c(1, 2, 3), na.rm = TRUE)
base.awc
estimatePSCS

Estimate boundaries of the particle size control section (U.S Soil Taxonomy: 12th edition)

Description

Estimates the upper and lower boundary of the particle size control section by applying a programmatic version of the particle size control section key from the Keys to Soil Taxonomy (12th edition).

Usage

estimatePSCS(
  p,
  hzdesgn = "hzname",
  clay.attr = "clay",
  texcl.attr = "texcl",
  tax_order_field = "tax_order",
  bottom.pattern = "Cr|R|Cd",
  ...
)

Arguments

p A single-profile SoilProfileCollection object
hzdesgn Name of the horizon attribute containing the horizon designation. Default 'hzname'
clay.attr Name of the horizon attribute containing clay contents. Default 'clay'
texcl.attr Name of the horizon attribute containing textural class (used for finding sandy textures). Default 'texcl'
tax_order_field Name of the site attribute containing taxonomic order; for handling PSCS rules for Andisols in lieu of lab data. May be NA or column missing altogether, in which case Andisol PSC possibility is ignored.
bottom.pattern Regular expression pattern to match a root-restrictive contact. Default matches Cr, R or Cd. This argument is passed to both estimateSoilDepth and getArgillicBounds.
... additional arguments are passed to getArgillicBounds()

Details

Requires information to identify argillic horizons (clay contents, horizon designations) with getArgillicBounds() as well as the presence of plow layers and surface organic soil material. Any getArgillicBounds() arguments may be passed to estimatePSCS.

Requires information on taxonomic order (to handle andisols).

WARNING: Soils in arenic or grossarenic subgroups, with fragipans, or with strongly contrasting PSCs may not be classified correctly. The author would welcome a dataset to develop this functionality for.
Value

A numeric vector containing the top and bottom depth of the particle size control section. First value is top, second value is bottom.

Author(s)

Andrew Gene Brown

getArgillicBounds, getSurfaceHorizonDepth

Examples

data(sp1, package = 'aqp')
depths(sp1) <- id ~ top + bottom
site(sp1) <- ~ group

p <- sp1[1]
attr <- 'prop' # clay contents
foo <- estimatePSCS(p, hzdesgn='name', clay.attr = attr, texcl.attr="texture")
foo

estimateSoilDepth

Estimate Soil Depth

Description

Estimate the soil depth of a single profile within a SoilProfileCollection object. This function would typically be called by profileApply.

Usage

estimateSoilDepth(
  f,
  name = hzdesgnname(f),
  p = "Cr|R|Cd",
  selection = min,
  no.contact.depth = NULL,
  no.contact.assigned = NULL
)
estimateSoilDepth

Arguments

- **f**: SoilProfileCollection object of length 1, e.g. a single profile
- **name**: name of the column that contains horizon designations
- **p**: REGEX pattern for determining "contact", or depth to some morphologic feature (e.g. Bt)
- **selection**: an R function applied in the presence of multiple matching horizons: min (default), max, mean, etc.
- **no.contact.depth**: in the absence of contact matching p, a depth at which we can assume a standard depth-to-contact
- **no.contact.assigned**: value assigned when no contact is encountered at or below no.contact.depth

Details

The choice of a selection function usually follows:

- **min**: the top of the first matching horizon,
- **max**: the top bot the last matching horizon, or possibly
- **mean**: somewhere in-between.

Value

single value representing the depth to contact or no.contact.assigned

Author(s)

D.E. Beaudette and J.M. Skovlin

```r
## consider a situation where there were multiple candidate
## "contacts": 2 Cd horizons over an R

# init hypothetical profile
d <- data.frame(
id = '1',
top = c(0, 10, 20, 30, 40, 50, 60),
bottom = c(10, 20, 30, 40, 50, 60, 80),
name = c('A', 'Bt1', 'Bt2', 'BC', 'Cd1', 'Cd2', 'R'),
stringsAsFactors = FALSE)

# upgrade to SPC
depths(d) <- id ~ top + bottom
```
estimateSoilDepth

# init horizon designation
hzdesgnname(d) <- 'name'

# visual check
par(mar = c(0, 0, 0, 1))
plotSPC(d, hz.depths = TRUE, name.style = 'center-center', cex.names = 1, width = 0.1)

# top of the first Cd
estimateSoilDepth(d, name = 'name')

# top of the first Cd
estimateSoilDepth(d, name = 'name', selection = min)

# top of the R
estimateSoilDepth(d, name = 'name', selection = max)

# top of the second Cd
estimateSoilDepth(d, name = 'name', selection = max, p = 'Cd')

## another example

data(sp1)
depths(sp1) <- id ~ top + bottom

# init horizon designation
hzdesgnname(d) <- 'name'

# apply to each profile in a collection, and save as site-level attribute
sp1$depth <- profileApply(sp1, estimateSoilDepth, name='name')

# this function can be used to "find" depth to any feature
# that can be defined via REGEX pattern matching on the horizon name
# for example, locate the depth to the top "Bt" horizon
# returning NA when there is no match
sp1$top_Bt <- profileApply(
  sp1, estimateSoilDepth,
  name='name',
  p='Bt',
  no.contact.depth=0,
  no.contact.assigned=NA
)

# reduced margins
par(mar=c(1,1,1,2))
# adjust default y-offset and depth scaling for following examples
plotSPC(sp1, y.offset=10, scaling.factor=0.5)

# get plotting parameters for profile widths and depth scaling factors
lsp <- get("last_spc_plot", envir = aqp.env)

# positions on x-axis, same for both depth and top "Bt" horizon
x.positions <- (1:length(sp1)) - lsp$width

# annotate contact with unicode right-arrow
# y-position is adjusted based on plot y-offset and scaling factor
y.positions <- lsp$y.offset + (sp1$depth * lsp$scaling.factor)
text(x.positions, y.positions, \u2192, col='red', adj=1, cex=1.25, lwd=2)

# annotate top "Bt" depth with unicode right-arrow
# y-position is adjusted based on plot y-offset and scaling factor
y.positions <- lsp$y.offset + (sp1$top_Bt * lsp$scaling.factor)
text(x.positions, y.positions, \u2192, col='blue', adj=1, cex=1.25, lwd=2)

## Not run:
# sample data
data(gopheridge, package='soilDB')

# run on a single profile
estimateSoilDepth(gopheridge[1, ], name = 'hzname')

# apply to an entire collection
profileApply(gopheridge, estimateSoilDepth, name = 'hzname')

## End(Not run)

evalGenHZ

Evaluate Generalized Horizon Labels

Description
Data-driven evaluation of generalized horizon labels using nMDS and silhouette width.

Usage
evalGenHZ(
  obj,
  genhz,
  vars,
  non.matching.code = "not-used",
  stand = TRUE,
  trace = FALSE,
  metric = "euclidean"
)

Arguments

obj a SoilProfileCollection object
genhz name of horizon-level attribute containing generalized horizon labels
vars character vector of horizon-level attributes to include in the evaluation
non.matching.code
  code used to represent horizons not assigned a generalized horizon label
stand
  standardize variables before computing distance matrix (default = TRUE), passed to daisy
trace
  verbose output from passed to isoMDS, (default = FALSE)
metric
  distance metric, passed to daisy

Details

Non-metric multidimensional scaling is performed via isoMDS. The input distance matrix is generated by daisy using (complete cases of) horizon-level attributes from obj as named in vars.

Silhouette widths are computed via silhouette. The input distance matrix is generated by daisy using (complete cases of) horizon-level attributes from obj as named in vars. Note that observations with genhz labels specified in non.matching.code are removed filtered before calculation of the distance matrix.

Value

a list is returned containing:

  horizons c('mds.1', 'mds.2', 'sil.width', 'neighbor')
  stats mean and standard deviation of vars, computed by generalized horizon label
  dist the distance matrix as passed to isoMDS

-------------------------------

evalMissingData Evaluate Missing Data

Description

  Evaluate missing data in a SoilProfileCollection object

Usage

evalMissingData(x, vars, name = "hzname", p = "Cr|R|Cd", method = "relative")
evalMissingData

**Arguments**

- `x`: a SoilProfileCollection object
- `vars`: a character vector naming horizon-level attributes in `x`
- `name`: the name of a horizon-level attribute where horizon designations are stored
- `p`: REGEX pattern used to match non-soil horizons
- `method`: 'relative' (proportion of total) or 'absolute' depths

**Details**

Data completeness is evaluated by profile, based on the thickness of horizons with complete horizon-level attribute values (specified in `vars`) divided by the total thickness. The default REGEX pattern, `p`, should catch most non-soil horizons which are excluded from the evaluation.

**Value**

A vector values ranging from 0 to 1 (`method='relative'`) or 0 to maximum depth in specified depth units (`method='absolute'`), representing the quantity of non-NA data (as specified in `vars`) for each profile.

**Author(s)**

D.E. Beaudette

**Examples**

```r
# example data
data(sp2)
# init SPC object
depths(sp2) <- id ~ top + bottom

# compute data completeness
sp2$data.complete <- evalMissingData(sp2, vars = c('r', 'g', 'b'), name = 'name')
sp2$data.complete.abs <- evalMissingData(sp2, vars = c('r', 'g', 'b'),
                                          name = 'name', method = 'absolute')

# rank
new.order <- order(sp2$data.complete)

# plot along data completeness ranking
plot(sp2, plot.order=new.order, name='name')

# add relative completeness axis
# note re-ordering of axis labels
axis(side=1, at=1:length(sp2), labels = round(sp2$data.complete[new.order], 2),
     line=-1.5, cex.axis=0.75)

# add absolute completeness (cm)
axis(side=1, at=1:length(sp2), labels = sp2$data.complete.abs[new.order],
      line=-1.5, cex.axis=0.75)
```
explainPlotSPC

Visual Explanation for plotSPC

Description

Create a visual explanation for the many arguments to plotSPC. Call this function instead of plotSPC, all objects after x are passed on to plotSPC. Nearly all of the figures in the Introduction to SoilProfileCollection Objects tutorial are created with this function.

Usage

explainPlotSPC(x, ...)

Arguments

x a SoilProfileCollection object
...

arguments passed to plotSPC

Value

a list of internally-used ordering vectors and graphical offsets / scaling factors

Author(s)

D.E. Beaudette

plotSPC

Examples

# sample data
data(sp4)
depths(sp4) <- id ~ top + bottom

# proposed vector of relative positions, overlap likely
pos <- c(1, 1.1, 3, 4, 5, 5.2, 7, 8, 9, 10)

# try it
explainPlotSPC(sp4, name='name', relative.pos=pos)

# attempt to fix using an integer sequence, short-circuit will prevent adjustments
explainPlotSPC(sp4, name='name', relative.pos=fixOverlap(1:10))
fillHzGaps

# attempt to adjust using defaults
explainPlotSPC(sp4, name='name', relative.pos=fixOverlap(pos))

# attempt to adjust and tinker with defaults
explainPlotSPC(sp4, name='name', relative.pos=fixOverlap(pos, adj = 0.2))

# repeatable adjustments
set.seed(10101)
explainPlotSPC(sp4, name='name', relative.pos=fixOverlap(pos, thresh = 0.7))

# more complex adjustments required
pos <- c(1, 2, 3, 3.3, 5, 5.1, 5.5, 8, 9, 9.1)

# tinker
explainPlotSPC(sp4, name='name', relative.pos=pos)
explainPlotSPC(sp4, name='name', relative.pos=fixOverlap(pos))
explainPlotSPC(sp4, name='name', relative.pos=fixOverlap(pos, thresh = 0.7))
explainPlotSPC(sp4, name='name', relative.pos=fixOverlap(pos, thresh=0.7, adj = 0.2))

# no solution possible given these constraints
explainPlotSPC(sp4, name='name', relative.pos=fixOverlap(pos, thresh=1, adj = 0.2))

---

**fillHzGaps**

*Find and Fill Horizon Gaps*

**Description**

This function attempts to find "gaps" in the horizon records of a SoilProfileCollection object and fill with placeholder horizons (profile ID, horizon ID, to/bottom depths, all else NA). Missing horizon records between the top of each profile and to_top, or the bottom of each profile and to_bottom are treated as gaps when those arguments are not NULL. You can use this function to prepare a potentially messy SoilProfileCollection for subsequent analyses that are sensitive to horizon sequence inconsistencies or require a conformal "rectangle" of data spanning known depths. Gaps are defined as:

- within each profile, for horizons i to n_hz:
  - bottom_i != top_i+1 (but only to i = 1:(n_hz - 1))

**Usage**

`fillHzGaps(x, flag = TRUE, to_top = 0, to_bottom = max(x))`

**Arguments**

- `x` SoilProfileCollection object
- `flag` logical, flag empty horizons that have been added. default: TRUE
to_top numeric, fill from shallowest top depth in each profile to specified depth? default: 0

to_bottom numeric, fill from deepest bottom depth in each profile to specified depth? default: \texttt{aqp::max(x)}

\textbf{Value}

\texttt{SoilProfileCollection} object

\textbf{Author(s)}

A.G. Brown and D.E. Beaudette

\textbf{Examples}

data(sp4)
depths(sp4) <- id ~ top + bottom

# introduce depth logic errors
idx <- c(2, 6:7, 8, 12)
sp4$top[idx] <- NA

# check
horizons(sp4)[idx, ]

# create gaps by removing logic errors
x <- HzDepthLogicSubset(sp4, byhz = TRUE)

# inspect
par(mar = c(0, 0, 0, 1))
plotSPC(x, width = 0.3, default.color = 'royalblue', name = 'hzID')

z <- fillHzGaps(x, flag = TRUE)

plotSPC(z, width = 0.3, color = '.filledGap', name = 'hzID', show.legend = FALSE)

# fill top to 0 cm
z2 <- fillHzGaps(x, flag = TRUE, to_top = 0)

plotSPC(z2, width = 0.3, color = '.filledGap', name = 'hzID', show.legend = FALSE)

# fill bottom to max(SPC)
z3 <- fillHzGaps(x, flag = TRUE, to_top = 0, to_bottom = max(x))

plotSPC(z3, width = 0.3, color = '.filledGap', name = 'hzID', show.legend = FALSE)

## another example

data(sp4)
depths(sp4) <- id ~ top + bottom

# remove 1st horizons from profiles 1:4
idx <- sp4[, , .FIRST, .HZID]

replaceHorizons(sp4) <- horizons(sp4)[-idx[1:4], ]
findOverlap

Find Overlap within a Sequence

Description

Establish which elements within a vector of horizontal positions overlap beyond a given threshold.

Usage

findOverlap(x, thresh)

Arguments

x vector of relative horizontal positions, one for each profile
thresh threshold defining "overlap", typically < 1

Value

unique index to affected (overlapping) elements in x

Examples

x <- c(1, 2, 3, 3.4, 3.5, 5, 6, 10)
findOverlap(x, thresh = 0.5)
Description

This function makes small adjustments to elements of x until overlap defined by \( \text{thresh} \) is removed, or until \( \text{maxIter} \) is reached. Rank order and boundary conditions (defined by \( \text{min.x} \) and \( \text{max.x} \)) are preserved. The underlying algorithm is based on simulated annealing. The "cooling schedule" parameters \( T_0 \) and \( k \) can be used to tune the algorithm for specific applications.

Usage

```r
fixOverlap(
  x, 
  thresh = 0.6, 
  adj = thresh * 2/3, 
  min.x = min(x) - 0.2, 
  max.x = max(x) + 0.2, 
  maxIter = 1000, 
  trace = FALSE, 
  tiny = 1e-04, 
  T0 = 500, 
  k = 10
)
```

Arguments

- \( x \): vector of horizontal positions
- \( \text{thresh} \): horizontal threshold defining "overlap" or distance between elements of \( x \). For adjusting soil profile sketches values are typically < 1 and likely in (0.3, 0.8).
- \( \text{adj} \): specifies the size of perturbations within \( \text{runif}(\text{min} = \text{adj} * -1, \text{max} = \text{adj}) \). Larger values will sometimes reduce the number of iterations required to solve particularly difficult overlap conditions. See coolingRate argument when \( \text{adj} \) is large.
- \( \text{min.x} \): left-side boundary condition, consider expanding if a solution cannot be found within \( \text{maxIter} \).
- \( \text{max.x} \): right-side boundary condition, consider expanding if a solution cannot be found within \( \text{maxIter} \).
- \( \text{maxIter} \): maximum number of iterations to attempt before giving up and returning a regularly-spaced sequence
- \( \text{trace} \): print diagnostics, result is a list vs vector
- \( \text{tiny} \): the smallest allowable overlap
- \( T_0 \): starting temperature
- \( k \): cooling constant

**Details**

Ideas for solving difficult overlap scenarios:

- **widen** the boundary conditions by adjusting \( \min.x \) and \( \max.x \) beyond the original scale of \( x \)
- **reduce** the allowable overlap threshold \( \text{thresh} \)
- **reduce** the magnitude of perturbations (adj) and increase \( \text{maxIter} \)
- **increase** \( k \)

**Value**

When \( \text{trace} = \text{FALSE} \), a vector of the same length as \( x \), preserving rank-ordering and boundary conditions. When \( \text{trace} = \text{TRUE} \) a list containing the new sequence along with information about objective functions and decisions made during iteration.

**Author(s)**

D.E. Beaudette

**Examples**

```r
x <- c(1, 2, 3, 3.4, 3.5, 5, 6, 10)
# easy
z <- fixOverlap(x, thresh = 0.2, trace = TRUE)
# harder
z <- fixOverlap(x, thresh = 0.6, trace = TRUE)
# much harder
z <- fixOverlap(x, thresh = 0.9, trace = TRUE)

# interpret `trace` output

# relatively challenging
x <- c(1, 2, 3.4, 3.4, 3.4, 3.4, 6, 8, 10, 12, 13, 13, 15, 15.5)
# fix overlap, return debugging information
set.seed(10101)
z <- fixOverlap(x, thresh = 0.8, trace = TRUE)
# setup plot device
par(mar = c(4, 4, 1, 1))
layout(matrix(c(1,2,3)), widths = 1, heights = c(1,1,2))
# objective function = overlap + SSD
plot(
    seq_along(z$stats), z$stats,
    type = 'h', las = 1,
    xlab = 'Iteration', ylab = 'Overlap',
)```

generalize.hz

Description

Generalize a vector of horizon names, based on new classes, and REGEX patterns.

Usage

generalize.hz(x, new, pat, non.matching.code = "not-used", hzdepm = NA, ...)

Arguments

x a character vector of horizon names
new a character vector of new horizon classes
pat a character vector of REGEX, same length as x
non.matching.code text used to describe any horizon not matching any item in pat
hzdepm a numeric vector of horizon mid-points, must not contain NA, same length as x
... additional arguments passed to grep() such as perl=TRUE for advanced REGEX

Value

factor of the same length as x
get.increase.depths

Author(s)
D.E. Beaudette

Examples

## Not run:

data(sp1)

# check original distribution of hz designations
table(sp1$name)

# generalize
sp1$genhz <- generalize.hz(sp1$name,
    new=c('O','A','B','C','R'),
    pat=c('O','^A','^B','C','R'))

# see how we did / what we missed
table(sp1$genhz, sp1$name)

## a more advanced example, requires perl=TRUE
# example data
x <- c('A', 'AC', 'Bt1', '^AC', 'C', 'BC', 'CB')

# new labels
n <- c('A', '^AC', 'C')
# patterns:
# "A anywhere in the name"
# "literal '^A' anywhere in the name"
# "C anywhere in name, but without preceding A"
p <- c('A', '^A', '(?<!A)C')

# note additional argument
res <- generalize.hz(x, new = n, pat=p, perl=TRUE)

# double-check: OK
table(res, x)

## End(Not run)

get.increase.depths

Return the horizon top depths from a call to get.increase.matrix()

Description

get.increase.depths performs the conversion of the square matrix output of get.increase.matrix back to horizon top depth for where criteria were met.
get.increase.depths

Usage

get.increase.depths(p, attr, threshold.fun, vertical.distance)

Arguments

- `p`: a SoilProfileCollection, containing a single profile
- `attr`: horizon attribute name to get the "increase" of
- `threshold.fun`: a function that returns the threshold (as a function of `attr`); may return a constant single value
- `vertical.distance`: the vertical distance (determined from difference SPC top depth variable) within which increase must be met

Details

Note that the `threshold.fun` result is allowed to contain NA, but that will result in no output for affected cells.

Value

Returns a numeric vector of depths where the increase requirement is met. For the argillic, the first is the one of interest.

get.increase.depths converts to horizon dop depth by using above matrix output to determine depths where increase is met.

getArgillicBounds, crit.clay.argillic

Examples

data(sp1, package = 'aqp')
depths(sp1) <- id ~ top + bottom
site(sp1) <- ~ group

p <- sp1[1]
attr <- 'prop' # clay contents
foo <- get.increase.depths(p, threshold.fun = crit.clay.argillic, attr = attr, vertical.distance = 30)

foo
get.increase.matrix  

**compute pair-wise distances to determine where an attribute increases within a vertical distance specified**

---

**Description**

Uses matrix outer product to determine all pair-wise differences in `attr` for the horizons of `p`. Supplies `attr` to `threshold.fun` to determine the minimum value criterion to return `TRUE` in output matrix for an "increase". Also, computes all pair-wise distances in depth dimension to determine whether the vertical distance criteria have been met simultaneously with `attr` increase.

**Usage**

```r
get.increase.matrix(p, attr, threshold.fun, vertical.distance)
```

**Arguments**

- `p`  
  a `SoilProfileCollection`, containing a single profile
- `attr`  
  horizon attribute name to get the "increase" of
- `threshold.fun`  
  a function that returns the threshold (as a function of `attr`); may return a constant single value
- `vertical.distance`  
  the vertical distance (determined from difference SPC top depth variable) within which increase must be met

**Details**

This function assumes that the `threshold.fun` supplied by the user returns either a constant or a vector of equal length to its input.

Note that the `threshold.fun` result is allowed to contain NA, but that will result in no output for affected cells.

`get.increase.depths` performs the conversion of the square matrix output of `get.increase.matrix` back to horizon top depth for where criteria were met.

**Value**

Returns a square logical matrix reflecting where the increase criteria were met.

`get.increase.depths` converts to horizon dop depth by using above matrix output to determine depths where increase is met.

definition

Determine ML Horizon Boundaries

Description

This function accepts input from `slab()` along with a vector of horizon names, and returns a `data.frame` of the most likely horizon boundaries.

Usage

```
get.ml.hz(x, o.names = attr(x, which = "original.levels"))
```

Arguments

- **x**: output from `slab`
- **o.names**: an optional character vector of horizon designations that will be used in the final table

Details

This function expects that `x` is a `data.frame` generated by `slab`. If `x` was not generated by `slab`, then `o.names` is required.

Value

A dataframe with the following columns:

- **hz**: horizon names
- **top**: top boundary
- **bottom**: bottom boundary
- **confidence**: integrated probability over thickness of each ML horizon, rounded to the nearest integer
getArgillicBounds

pseudo.brier

A "pseudo" Brier Score for a multi-class prediction, where the most-likely horizon label is treated as the "correct" outcome. Details on the calculation for traditional Brier Scores here: https://en.wikipedia.org/wiki/Brier_score. Lower values suggest better agreement between ML horizon label and class-wise probabilities.

mean.H

mean Shannon entropy (bits), derived from probabilities within each most-likely horizon. Larger values suggest more confusion within each ML.

# compute slice-wise probability so that it sums to contributing fraction, from 0-150
a <- slab(sp1, fm= ~ name, cpm=1, slab.structure=0:150)

# generate table of ML horizonation
get.ml.hz(a)

getArgillicBounds  Estimate upper and lower boundary of argillic diagnostic subsurface horizon

Description

getArgillicBounds estimates the upper and lower boundary of argillic diagnostic subsurface horizon for a profile in a single-profile SoilProfileCollection object (p).

The upper boundary is where the clay increase threshold is met. The function uses crit.clay.argillic as the threshold function for determining whether a clay increase occurs and get.increase.matrix to determine whether the increase is met, whether vertical distance of increase is sufficiently small, and in which horizon.
Usage

getArgillicBounds(
  p,
  hzdesgn = "hzname",
  clay.attr = "clay",
  texcl.attr = "texcl",
  require_t = TRUE,
  bottom.pattern = "Cr|R|Cd",
  lower.grad.pattern = "^[2-9]*B*CB*[^rtd]*[1-9]*$",
  sandy.texture.pattern = "-S|$|^S$|COS$|L[^V]FS$|^L[V]FS$|LS$|LFS$",
  verbose = FALSE
)

Arguments

p A single-profile SoilProfileCollection
hzdesgn the name of the column/attribute containing the horizon designation; default="hzname"
clay.attr the name of the column/attribute containing the clay content; default="clay"
texcl.attr the name of the column/attribute containing the textural class (used for finding sandy horizons); default="texcl"
require_t require a "t" subscript for positive identification of upper and lower bound of argillic? default: TRUE
bottom.pattern regular expression passed to estimateSoilDepth to match the lower boundary of the soil. default is "Cr|R|Cd" which approximately matches paralithic, lithic and densic contacts.
lower.grad.pattern this is a pattern for adjusting the bottom depth of the argillic horizon upwards from the bottom depth of the soil. The absence of illuviation is used as a final control on horizon pattern matching.
sandy.texture.pattern this is a pattern for matching sandy textural classes: -S|$|^S$|COS$|L[^V]FS$|^L[V]FS$|LS$|LFS$
verbose Print out information about 't' subscripts, sandy textures, plow layers and lower gradational horizons?

Details

The lower boundary is first approximated as the depth to a lithic/paralithic/densic contact, or some other horizon matchable by a custom regular expression pattern. Subsequently, that boundary is extended upwards to the end of "evidence of illuviation."

The depth to contact is estimated using 'bottom.pattern' "Cr|R|Cd" by default. It matches anything containing Cr, R or Cd.

The lower gradational horizon regular expression 'lower.grad.pattern' default is "^[2-9]*B*CB*[^rtd]*[1-9]*$". It matches anything that starts with a lithologic discontinuity (or none) and a C master horizon designation. May contain B as second horizon designation in transitional horizon. May not contain 'r' or 't' subscript.
The minimum thickness of the argillic horizon is dependent on whether all subhorizons are "sandy" or not. The sandy.texture.pattern default -S\[^L\]VS|L\[^V\]FS|S\[^L\]VFS captures USDA textural class fine earth fractions that meet "sandy" particle size class criteria.

There also is an option 'require_t' to omit the requirement for evidence of eluviation in form of 't' subscript in 'hzdesgn'. Even if "t" subscript is not required for positive identification, the presence of lower gradational C horizons lacking 't' will still be used to modify the lower boundary upward from a detected contact, if needed. If this behavior is not desired, just set 'lower.grad.pattern' to something that will not match any horizons in your data.

**Value**

Returns a numeric vector; first value is top depth, second value is bottom depth. If as.list is TRUE, returns a list with top depth named "ubound" and bottom depth named "lbound"

**Author(s)**

Andrew G. Brown

**Examples**

```r
data(sp1, package = 'aqp')
depths(sp1) <- id ~ top + bottom
site(sp1) <- ~ group

p <- sp1[1]
attr <- 'prop' # clay contents
foo <- getArgillicBounds(p, hzdesgn='name', clay.attr = attr, texcl.attr="texture")
foo
```

---

**getCambicBounds**

*Find all intervals that are potentially part of a Cambic horizon*

**Description**

Find all intervals that are potentially part of a Cambic horizon excluding those that are part of an argillic horizon (defined either by depth interval or getArgillicBounds()).

There may be multiple cambic horizons (indexes) in a profile. Each cambic index has a top and bottom depth associated: cambic_top and cambic_bottom. This result is designed to be used for single profiles, or with profileApply(...,frameify = TRUE)

**Usage**

```r
getCambicBounds(
p,  
  hzdesgn = guessHzDesgnName(p, required = TRUE),  
  texcl.attr = guessHzTexClName(p, required = TRUE),  
  clay.attr = guessHzAttrName(p, attr = "clay", c("total", ",_r")),
```

```r
```
getCambicBounds

argi_bounds = NULL,
d_value = "d_value",
m_value = "m_value",
m_chroma = "m_chroma",
...
)

Arguments

p A single-profile SoilProfileCollection
hzdesgn Column name containing horizon designations.
texcl.attr Arguments to getArgillicBounds()
clay.attr Arguments to getArgillicBounds()
argi_bounds Optional: numeric vector of length 2 with top and bottom of argillic; (Default: NULL)
d_value Column name containing dry value. Default: d_value
m_value Column name containing moist value. Default: m_value
m_chroma Column name containing moist chroma. Default: m_chroma
sandy.texture.pattern this is a pattern for matching sandy textural classes: -S$|^S$|COS$|L[^V]FS$|[^L]VFS$|LS$|LFS$
...
Arguments to getArgillicBounds()

Value

A data.frame containing profile, cambic indexes, along with top and bottom depths.

Author(s)

Andrew G. Brown

Examples

# construct a fake profile
spc <- data.frame(id=1, taxsubgrp = "Lithic Haploxerepts",
  hzname = c("A","AB","Bw","BC","R"),
  hzdept = c(0, 20, 32, 42, 49),
  hzdepb = c(20, 32, 42, 49, 200),
  clay = c(19, 22, 22, 21, NA),
  texcl = c("l","l","l","l","br"),
  d_value = c(5, 5, 5, 6, NA),
  m_value = c(2.5, 3, 3, 4, NA),
  m_chroma = c(2, 3, 4, 4, NA))

# promote to SoilProfileCollection
depths(spc) <- id ~ hzdept + hzdepb
hzdesgnname(spc) <- 'hzname'
hztextclname(spc) <- 'texcl'
getClosestMunsellChip

# print results in table
getCambicBounds(spc)

getClosestMunsellChip  Get Approximate Munsell Chip

Description

Non-standard Munsell notation (e.g. '7.9YR 2.7/2.0') can be matched (nearest-neighbor, no interpolation) to the closest color within the munsell sRGB/CIELAB look-up table via getClosestMunsellChip(). A more accurate estimate of sRGB values from non-standard notation can be achieved with the munsellinterpol package.

Usage

getClosestMunsellChip(munsellColor, convertColors = TRUE, ...)

Arguments

munsellColor character vector of strings containing Munsell notation of color, e.g. '10YR 4/3'
convertColors logical, should parsed Munsell colors be converted into sRGB values
...
  further arguments to munsell2rgb

Value

a data.frame when convertColors=TRUE, otherwise character vector

Examples

# convert a non-standard color to closest "chip" in `munsell` look-up table
getClosestMunsellChip("7.9YR 2.7/2.0", convertColors = FALSE)
# convert directly to R color
getClosestMunsellChip("7.9YR 2.7/2.0")
getSoilDepthClass

Description
Generate a boolean matrix of soil depth classes, actual soil depth class, and estimate of soil depth from a SoilProfileCollection object. Soil depths are estimated using pattern matching applied to horizon designations, by estimateSoilDepth(). The default REGEX pattern (p = 'Cr|R|Cd') will match most "contacts" described using the USDA / Soil Taxonomy horizon designation conventions.

Usage
getSoilDepthClass(
  f,
  depth.classes = c(very.shallow = 25, shallow = 50, mod.deep = 100, deep = 150, very.deep = 10000),
  ...
)

Arguments
  f a SoilProfileCollection object
  depth.classes a named vector of classes and depth breaks
  ... arguments passed to estimateSoilDepth

Value
  a data.frame containing soil depth and depth class for each profile, see examples
getSurfaceHorizonDepth

Determine thickness of horizons (continuous from surface) matching a pattern.

Description

Find the thickness of horizon designations, or any other character patterns, that are continuous from the soil surface (depth = 0 or shallowest depth in profile).

Usage

getSurfaceHorizonDepth(
  p,
  pattern,
  hzdesgn = guessHzDesgnName(p),
  simplify = TRUE
)
getSurfaceHorizonDepth

Arguments

- **p** a SoilProfileCollection
- **pattern** a regular expression pattern to match for all horizons to be considered part of the "surface".
- **hzdesgn** column name containing horizon designation. Default: guessHzDesignName(p, required = TRUE).
- **simplify** logical. Return single profile results as vector (default: TRUE) or data.frame (FALSE)

Details

The horizon designation to match is specified with the regular expression pattern 'pattern'. All horizons matching that pattern, that are continuous from the soil surface, count towards the depth / thickness value that is ultimately returned. For instance: horizon designations: A1-A2-A3-C-Ab, would return A3 bottom depth given pattern = "^[A-9]*$". getSurfaceHorizonDepth is used by getPlowLayerDepth for matching Ap horizons; and, it is used by getMineralSoilSurfaceDepth to find the thickness of O horizons in lieu of lab data.

Value

a numeric value corresponding to the bottom depth of the last horizon matching 'pattern' that is contiguous with other matching horizons up to the soil surface. If length(p) > 1 then a data.frame containing profile ID, horizon ID, top or bottom depths, horizon designation and pattern.

Author(s)

Andrew G. Brown

Examples

library(aqp)
data(sp1, package = 'aqp')
depths(sp1) <- id ~ top + bottom
site(sp1) <- ~ group

p <- sp1[1]
qu <- sp1[2]

# look at horizon designations in p and q
p$name
q$name

# thickness of all surface horizons containing A
getSurfaceHorizonDepth(p, pattern = 'A', hzdesgn = 'name')

# thickness of all surface horizons that start with A
getSurfaceHorizonDepth(p, pattern = '^A', hzdesgn = 'name')

# thickness of all surface horizons that start with A, and the A is not followed by B
glom,SoilProfileCollection-method

Subset soil horizon data using a depth or depth interval

Description

Make a "clod" of horizons from a SoilProfileCollection given a point or a depth interval to intersect. The interval \([z1, z2]\) may be profile-specific (equal in length to \(p\)), or may be recycled over all profiles (if boundaries are length 1). For "point" intersection, \(z2\) may be left as the default value \(\text{NULL}\).

Usage

```r
## S4 method for signature 'SoilProfileCollection'

glom(p, z1, z2 = NULL, ids = FALSE, df = FALSE, truncate = FALSE, invert = FALSE, modality = "all")
```

Arguments

- \(p\) a SoilProfileCollection
- \(z1\) numeric vector of top depth to intersect horizon (required). Can be an expression involving `siteNames(p)` or quoted column name. Should evaluate to numeric length 1 or length equal to length\((p)\)
z2 numeric vector bottom depth of intersection interval (optional). Can also be an expression involving siteNames(p) or quoted column name. Should evaluate to numeric length 1, length equal to length(p) or NULL. Default: NULL is "point" intersection

ids return only horizon IDs? default: FALSE
df return a data.frame, by intersection with horizons(p)? default: FALSE
truncate truncate horizon top and bottom depths to z1 and z2? default: FALSE
invert get horizons outside the interval [z1,z2]? default: FALSE
modality default: "all" return all horizons; or modality = "thickest") to return the thickest horizon in interval. If multiple horizons have equal thickness, the first (shallowest) is returned.

Details

"To glom" is "to steal" or to "become stuck or attached to". The word is related to the compound "glomalin", which is a glycoprotein produced by mycorrhizal fungi in soil.

The full depth range of horizons included within the interval are returned (a "ragged" SoilProfileCollection) unless the truncate argument is set as TRUE. Horizon intersection is based on unique ID hzidname(spc) and depth range of interest. Profiles that lack data in the range of interest will be dropped from the resulting SoilProfileCollection.

If inverting results with invert, it is possible that thick horizons (whose boundaries span wider than the specified interval) will be split into two horizons, where previously they were one. This may make the results from ids = TRUE different from what you expect, as they will be based on a profile with an "extra" horizon and re-calculated unique horizon ID (hzidname(spc)) "hzID".

Value

a SoilProfileCollection, data.frame, or a vector of horizon IDs. NULL if no result.

glomApply trunc

Examples

data(spl, package = 'aqp')
depths(spl) <- id ~ top + bottom
site(spl) <- ~ group

p <- glom(spl, 25, 150)

# 28 horizons
nrow(p)
glomApply

Subset an SPC by applying glom to each profile

Description

`glomApply()` is a function used for subsetting `SoilProfileCollection` objects by depth. It is a wrapper around `glom` which is intended to subset single-profile SPCs based on depth intervals/intersection.
glomApply works by accepting a function \( .\text{fun} \) as argument. This function is used on each profile to process a multi-profile SPC for input to \texttt{glom} (via \texttt{profileApply}). For each profile, \( .\text{fun} \) returns a 2-length numeric vector of top and bottom boundaries \texttt{glom} arguments: \( z_1, z_2 \).

\texttt{glomApply} provides the option to generate profile-specific \texttt{glom} depths for a large SPC and handles iteration and rebuilding of a subset SPC object. Optional arguments include: \texttt{truncate} to cut the boundaries to specified [\( z_1, z_2 \)]; \texttt{invert} to the portion outside [\( z_1, z_2 \)], \texttt{modality} to either "all" horizons or "thickest" horizon in the \texttt{glom} interval. ... are various expressions you can run on the individual profiles using NSE, similar to \texttt{mutate}.

**Usage**

\[
\texttt{glomApply(}
\begin{align*}
\texttt{object,} & \quad \text{A SoilProfileCollection} \\
\texttt{.fun = NULL,} & \quad \text{A function that returns vector with top and bottom depth (} z_1 \text{ and } z_2 \text{ arguments to } \texttt{glom} \text{ for a single profile } p \text{ (as passed by } \texttt{profileApply}) \\
\texttt{truncate = FALSE,} & \quad \text{Truncate horizon top and bottom depths to } [z_1,z_2] \\
\texttt{invert = FALSE,} & \quad \text{Truncate horizon top and bottom depths to } [z_1,z_2] \text{ and then invert result?} \\
\texttt{modality = "all",} & \quad \text{Aggregation method for } \texttt{glom} \text{ result. Default "all": return all horizons; "thickest": return (shallowest) thickest horizon} \\
\texttt{...} & \quad \text{A set of comma-delimited R expressions that resolve to a transformation to be applied to a single profile e.g } \texttt{glomApply(hzdept = max(hzdept) -hzdept)} \text{ like } \texttt{aqp::mutate} \\
\texttt{chunk.size = 100} & \quad \text{Chunk size parameter for } \texttt{profileApply}
\end{align*}
\)

**Arguments**

- \texttt{object} : A SoilProfileCollection
- \texttt{.fun} : A function that returns vector with top and bottom depth (\( z_1 \) and \( z_2 \) arguments to \texttt{glom}) for a single profile \( p \) (as passed by \texttt{profileApply})
- \texttt{truncate} : Truncate horizon top and bottom depths to [\( z_1, z_2 \)]
- \texttt{invert} : Truncate horizon top and bottom depths to [\( z_1, z_2 \)] and then invert result?
- \texttt{modality} : Aggregation method for \texttt{glom} result. Default "all": return all horizons; "thickest": return (shallowest) thickest horizon
- \texttt{...} : A set of comma-delimited R expressions that resolve to a transformation to be applied to a single profile e.g \texttt{glomApply(hzdept = max(hzdept) -hzdept)} like \texttt{aqp::mutate}
- \texttt{chunk.size} : Chunk size parameter for \texttt{profileApply}

**Value**

A SoilProfileCollection.

**Author(s)**

Andrew G. Brown.

Examples

data(sp3)
depths(sp3) <- id ~ top + bottom

# init horizon designation column in metadata, used by estimateSoilDepth
hzdesgnname(sp3) <- 'name'

# constant depths, whole horizon returns by default
plot(glomApply(sp3, function(p) c(25,100)))

# constant depths, truncated
#(see aqp::trunc for helper function)
plot(glomApply(sp3, function(p) c(25,30), truncate = TRUE))

# constant depths, inverted
plot(glomApply(sp3, function(p) c(25,100), invert = TRUE))

# constant depths, inverted + truncated (same as above)
plot(glomApply(sp3, function(p) c(25,30), invert = TRUE, truncate=TRUE))

# random boundaries in each profile
plot(glomApply(sp3, function(p) round(sort(runif(2, 0, max(sp3)))))

# random boundaries in each profile (truncated)
plot(glomApply(sp3, function(p) round(sort(runif(2, 0, max(sp3))))), truncate = TRUE))

# calculate some boundaries as site level attributes
sp3$glom_top <- profileApply(sp3, getMineralSoilSurfaceDepth)
sp3$glom_bottom <- profileApply(sp3, estimateSoilDepth)

# use site level attributes for glom intervals for each profile
plot(glomApply(sp3, function(p) return(c(p$glom_top, p$glom_bottom))))

grepSPC

Subset SPC with pattern-matching for text-based attributes

Description

grepSPC() is a shorthand function for subsetting SoilProfileCollections. For example, by filter(grepl(spc,...)) or filter(stringr::str_detect(spc,...)). It provides pattern matching for a single text-based site or horizon level attribute.

Usage

grepSPC(object, attr, pattern, ...)
groupedProfilePlot

Arguments

object  A SoilProfileCollection
attr    A character vector (column in object) for matching patterns against.
pattern REGEX pattern to match in attr
...    Additional arguments are passed to grep()

Value

A SoilProfileCollection.

Author(s)

Andrew G. Brown.

groupedProfilePlot   Grouped Soil Profile Plot

Description

Plot a collection of soil profiles, sorted and labeled by group.

Usage

groupedProfilePlot(
  x,
  groups,
  group.name.offset = -5,
  group.name.cex = 0.75,
  group.line.col = "RoyalBlue",
  group.line.lwd = 2,
  group.line.lty = 2,
  break.style = "line",
  arrow.offset = group.name.offset + 5,
  arrow.length = 0.1,
  ...
)

Arguments

x               a SoilProfileCollection object
groups          the name of a site-level attribute that defines groups, factor levels will influence plotting order
group.name.offset  vertical offset for group names, single numeric value or vector of offsets
group.name.cex   font size for group names
groupedProfilePlot

- `group.line.col` color for line that splits groups
- `group.line.lwd` width of line that splits groups
- `group.line.lty` style of line that splits groups
- `break.style` style of group boundaries: "line", "arrow", "both"
- `arrow.offset` vertical offset for "arrow" style boundaries, single numeric value or vector of offsets
- `arrow.length` value passed to `arrows` to define arrow head size
- ... further arguments to `plotSPC`

**Details**

The left-right ordering of groups can be adjusted by converting groups into a factor and explicitly setting factor levels. Alpha-numeric ordering is used for all other types.

groupedProfilePlot(loafercreek, groups='hillslopeprof', group.name.cex = 0.5, group.name.offset = -10, break.style = 'arrow', group.line.lty = 1, group.line.lwd = 1)

# both
groupedProfilePlot(loafercreek, groups='hillslopeprof', group.name.cex = 0.5, group.name.offset = -10, break.style = 'both', group.line.lty = 1, group.line.lwd = 1)

## End(Not run)
**groupSPC**  
*(EXPERIMENTAL)* Store groupings within a profile collection.

**Description**  
*(EXPERIMENTAL)* Store groupings within a profile collection.

**Usage**  
groupSPC(object, ...)

**Arguments**
- `object` *SoilProfileCollection.*
- `...` One or more expressions evaluated within the context of `object` that resolve to vectors that can be coerced to factor "groups."

---

**guessGenHzLevels**  
Guess Appropriate Ordering for Generalized Horizon Labels

**Description**  
This function makes an (educated) guess at an appropriate set of levels for generalized horizon labels using the median of horizon depth mid-points.

**Usage**  
guessGenHzLevels(x, hz = "genhz")

**Arguments**
- `x` *a SoilProfileCollection object*
- `hz` name of horizon-level attribute containing generalized horizon labels, see details

**Details**  
This function is useful when groups of horizons have been generalized via some method other than `generalize.hz`. For example, it may be useful to generalize horizons using labels derived from slice depths. The default sorting of these labels will not follow a logical depth-wise sorting when converted to a factor. `guessGenHzLevels` does a good job of "guessing" the proper ordering of these labels based on median horizon depth mid-point.
Value

a list:

- **levels** a vector of levels sorted by median horizon depth mid-point
- **median.depths** a vector of median horizon mid-points

generalize.hz

Examples

```r
# load some example data
data(sp1, package='aqp')

# upgrade to SoilProfileCollection
depths(sp1) <- id ~ top + bottom

# generalize horizon names
n <- c('O', 'A', 'B', 'C')
p <- c('O', 'A', 'B', 'C')
sp1$genhz <- generalize.hz(sp1$name, n, p)

# note: levels are in the order in which originally defined:
levels(sp1$genhz)

# generalize horizons by depth slice
s <- slice(sp1, c(5, 10, 15, 25, 50, 100, 150) ~ .)
s$slice <- paste0(s$top, ' cm')
# not a factor
levels(s$slice)

# the proper ordering of these new labels can be guessed from horizon depths
guessGenHzLevels(s, 'slice')

# convert to factor, and set proper order
s$slice <- factor(s$slice, levels=guessGenHzLevels(s, 'slice')$levels)

# that is better
levels(s$slice)
```
guessHzAttrName

Description

guessHzAttrName(): Guess the horizon column name where possible/preferred formative elements are known. There is a preference for records where more optional requirements are met to handle cases where there will be many matches. For example, working with soil data one might have "low, RV and high" total clay, as well as clay fractions. One could distinguish between these different measurements using standard formative elements for column names from the database of interest. Result is the first match in horizonNames(x) with the most required plus optional patterns matched.

e.g. guessHzAttrName(x, attr="clay", optional=c("total","_r")) matches (claytotal_r == totalclay_r) over (clay_r == claytotal == totalclay) over clay.

guessHzDesgnName(): This follows the historic convention used by aqp::plotSPC() looking for "hzname" or other column names containing the regular expression "name". If the pattern "name" is not found, the pattern "desgn" is searched as a fallback, as "hzdesgn" or "hz_desgn" are other common column naming schemes for horizon designation name.

guessHzTexClName(): This function is used to provide a texture class attribute column name to functions. It will use regular expressions to match "texcl" which is typically the texture of the fine earth fraction, without modifiers or in-lieu textures. Alternately, it will match "texture" for cases where "texcl" is absent (e.g. in NASIS Component Horizon).

Usage

guessHzAttrName(x, attr, optional = NULL, verbose = TRUE, required = FALSE)

guessHzDesgnName(x, required = FALSE)

guessHzTexClName(x, required = FALSE)

Arguments

x A SoilProfileCollection

attr A regular expression containing required formative element of attribute name.

optional A character vector of regular expression(s) containing optional formative elements of attribute name.

verbose A boolean value for whether to produce message output about guesses.

required logical Default: FALSE. Is this attribute required? If it is, set to TRUE to trigger error on invalid value.

Value

Character containing horizon attribute column name. Result is the first match in horizonNames(x) with the most required plus optional patterns matched.
Examples

# a has the required attr pattern, but none of the optional
a <- data.frame(id = 1, top = c(0,10), bottom=c(10,40),
  clay=c(18,19))
depths(a) <- id ~ top + bottom

guessHzAttrName(a, attr="clay", optional=c("total", "_r"))

# b has required attr pattern, and one of the optional patterns
# notice that it also contains "clay" but preferentially matches more optional patterns
b <- data.frame(id = 1, top = c(0,10), bottom=c(10,40),
  clay=c(0.18,0.19), clay_r=c(18,19))
depths(b) <- id ~ top + bottom

guessHzAttrName(b, attr="clay", optional=c("total", "_r"))

# c has total and _r (both optional) on either side of clay
# having all of the optional patterns plus required is best evidence, and first
# column containing that combination will be returned
# a <- data.frame(id = 1, top = c(0,10), bottom=c(10,40),
#  totalclay_r=c(18,19), claytotal_r=c(0.18,0.19))
depths(c) <- id ~ top + bottom

guessHzAttrName(c, attr="clay", optional=c("total", "_r"))

a <- data.frame(id = 1, top = c(0,10), bottom=c(10,40), horizonname=c("A","Bw"))
depths(a) <- id ~ top + bottom

# store guess in metadata
hzdesgnname(a) <- guessHzDesgnName(a)

# inspect result
hzdesgnname(a)

a <- data.frame(id = 1, top = c(0,10), bottom=c(10,40), texture=c("A","Bw"))
depths(a) <- id ~ top + bottom

# store guess in metadata
hztexclname(a) <- guessHzTexClName(a)

# inspect result
hztexclname(a)
**harden.melanization**  

**Harden (1982) Melanization**

---

**Description**

Calculate Melanization component of Profile Development Index after Harden (1982) "A quantitative index of soil development from field descriptions: Examples from a chronosequence in central California". Accepts vectorized inputs for value and reference value to produce vector output. A convenient use case would be to apply this on a profile-specific basis, where the value_ref has a single value, and value is a vector of length equal to the number of horizons within the upper 100 cm.

**Usage**

```r
harden.melanization(value, value_ref)
```

**Arguments**

- `value` numeric vector containing Munsell values
- `value_ref` A numeric vector containing Munsell value(s) for reference material

**Details**

In Harden (1982), melanization is calculated relative to a reference parent material for all horizons within 100cm of the soil surface. In addition, several other non-color components are normalized relative to a maximum value and summed to obtain the overall Profile Development Index.

**Value**

A numeric vector reflecting horizon darkening relative to a reference (e.g. parent) material.

**Author(s)**

Andrew G. Brown

**References**

**Examples**

```r
library(aqp)
data("jacobs2000", package="aqp")
# LEFT JOIN hue, value, chroma matrix color columns
horizons(jacobs2000) <- cbind(horizons(jacobs2000)[,c(idname(jacobs2000), hzidname(jacobs2000))],
```

parseMunsell(jacobs2000$matrix_color_munsell, convertColors = FALSE))

# calculate a mixed 150-200cm color —"parent material"

jacobs2000$c_horizon_color <- profileApply(jacobs2000, function(p) {

  # and derive the parent material from the 150-200cm interval
  p150_200 <- glom(p, 150, 200, truncate = TRUE)
p150_200$thickness <- p150_200$bottom - p150_200$top

  # mix colors
  clrs <- na.omit(horizons(p150_200)[,c('matrix_color_munsell','thickness')])
mixMunsell(clrs$matrix_color_munsell, w = clrs$thickness)$munsell
})

# segment profile into 1cm slices (for proper depth weighting)

jacobs2000$melan <- profileApply(jacobs2000, function(p) {

  # sum the melanization index over the 0-100cm interval
  p0_100 <- segment(p, 0:100)

  ccol <- parseMunsell(p$c_horizon_color, convertColors = FALSE)

  sum(harden.melanization(
      value = as.numeric(p0_100$value),
      value_ref = as.numeric(ccol$value)), na.rm = TRUE)
})

jacobs2000$melanorder <- order(jacobs2000$melan)

# Plot in order of increasing Melanization index

plotSPC(jacobs2000, axis.line.offset = -1,
        color = "matrix_color",
        label = "melan",
        plot.order = jacobs2000$melanorder)

abline(h = c(0,100,150,200), lty = 2)

# Add [estimated] parent material color swatches
lapply(seq_along(jacobs2000$c_horizon_color), function(i) {

  rect(i - 0.15, 250, i + 0.15, 225,
       col = parseMunsell(jacobs2000$c_horizon_color[jacobs2000$melanorder[i]]))
})
Description

Calculate Rubification component of Profile Development Index after Harden (1982) "A quantitative index of soil development from field descriptions: Examples from a chronosequence in central California". Accepts vectorized inputs for hue and chroma to produce vector output.

In Harden (1982) rubification is calculated relative to a reference parent material. Several other non-color components are normalized relative to a maximum value and summed to obtain the overall Profile Development Index.

Usage

harden.rubification(hue, chroma, hue_ref, chroma_ref)

Arguments

- **hue**: A character vector containing Munsell hues (e.g. "7.5YR")
- **chroma**: A numeric vector containing Munsell chromas
- **hue_ref**: A character vector containing Munsell hue(s) (e.g. "10YR") for reference material
- **chroma_ref**: A numeric vector containing Munsell chroma(s) for reference material

Value

A numeric vector reflecting horizon redness increase relative to a reference (e.g. parent) material.

harmonize,SoilProfileCollection-method

*Harmonize a property by profile-level denormalization for convenient visualization or analysis of ranges*
Description

It is sometimes convenient to be able to "denormalize" to a SoilProfileCollection with fewer attributes but more profiles. This is helpful wherever calculations are made on a profile basis and ranges or repeated measures are depicted with multiple attributes per soil horizon.

harmonize is most commonly used for creating "comparison" soil profile sketches with plotSPC—where the thematic attribute is derived from multiple data sources or summary statistics (such as quantiles of a property for Low-RV-High). However, the method more generally applies wherever one wants to alias between multiple columns containing "similar" data as input to an algorithm.

Data are "harmonized" to a common attribute names specified by the names of list elements in x.names. Profiles are essentially duplicated. In order to satisfy uniqueness constraints of the SoilProfileCollection, the label from the sub-elements of x.names are used to disambiguate profiles. A new column in the site table is calculated to reflect these groupings and facilitate filtering. See examples below.

Usage

```r
## S4 method for signature 'SoilProfileCollection'
harmonize(x, x.names, keep.cols = NULL, grp.name = "hgroup")
```

Arguments

- `x`: A SoilProfileCollection.
- `x.names`: a named list of character vectors specifying target names, profile ID suffixes and source attribute names for harmonization
- `keep.cols`: a character vector of column names to keep unaltered from the horizon data
- `grp.name`: a character vector with column name to store grouping variable in site table (default: "hgroup")

Details

If attributes reflecting the same or similar property within a soil layer have different names (e.g. `socQ95`, `socQ50`, `socQ95`) it is sometimes inconvenient to work with them as multiple attributes within the same profile. These similar attributes may need to be analyzed together, or in sequence by profile, displayed using the same name or using a common scale. It is also useful to be able to alias different data sources that have the same attributes with different names.

Each list element in x.names specifies a single "harmonization," which is comprised of one or more mappings from new to old. Each named "sub-element" of x.names specifies the name and attribute to use for updating the profile ID and site table of the duplicated profiles.

Value

A (redundant) SoilProfileCollection, with one profile for each set of harmonizations specified by x.names.

Author(s)

Andrew G. Brown
Examples

### single source "harmonization" of single-profile with range -> single attribute, multi-profile

# make some test data
spc <- pbindlist(lapply(1:10, random_profile, SPC = TRUE))

# assume that p1, p2 and p3 are the low RV and high quantiles for a hypothetical property "foo"
h1 <- harmonize(spc, x.names = list(foo = c(q05 = "p1", q50 = "p2", q95 = "p3")))

# inspect result
plot(h1, color = "foo")

# filter with calculated "harmonized group" to get just RV profiles
plot(subset(h1, hgroup == "q50"), color="foo")

### single source, two properties at once; with common labels: "method1" "method2"

# assume that p1, p2 are measurements by two (!=) methods for a hypothetical property "foo"
# p3, p4 are measurements by same two methods for a hypothetical property "bar"
h3 <- harmonize(spc, x.names = list(foo = c(method1 = "p1", method2 = "p2"),
                                    bar = c(method1 = "p3", method2 = "p4")))

plot(h3, color = "foo")
plot(h3, color = "bar")
head(horizons(h3))

# a slight modification, "method 1" only used for "foo" and "method 3" for "bar"
h3 <- harmonize(spc, x.names = list(foo = c(method1 = "p1", method2 = "p2"),
                    bar = c(method1 = "p3", method2 = "p4")))

plot(h3, color = "foo") # note the pattern of values missing for foo (*_method3)
plot(h3, color = "bar") # likewise for bar (*_method1)

# the new labels need not match across harmonizations -- not sure how useful this is but it works
h3 <- harmonize(spc, x.names = list(foo = c(method1 = "p1", method2 = "p2"),
                                     bar = c(method3 = "p3", method4 = "p4")))

plot(h3, color = "foo") # note the pattern of values missing for foo (*_method 3 + 4)
plot(h3, color = "bar") # likewise for bar (*_method 1 + 2)

### two-source harmonization

# make test data
spc1 <- pbindlist(lapply(LETTERS[1:5], random_profile, SPC = TRUE))
spc2 <- pbindlist(lapply(letters[1:5], random_profile, SPC = TRUE))

h4 <- pbindlist(list(harmonize(spc1, list(foo = c(transect1 = "p4"))),
                      harmonize(spc2, list(foo = c(transect2 = "p2"))))) # foo is p4 in dataset 1

# same property with different name in two different datasets
plot(h4, color = "foo")

### many source harmonization
hasDarkColors

Find horizons with colors darker than a Munsell hue, value, chroma threshold

Description

hasDarkColors returns a boolean value by horizon representing whether darkness thresholds are met. The code is fully vectorized and deals with missing data and optional thresholds. Default arguments are set up for "5-3-3 colors" – the basic criteria for Mollic/Umbirc epipedon/mineral soil darkness. Any of the thresholds or column names can be altered. Any thresholds that are set equal to NA will be ignored.

Usage

```r
hasDarkColors(
p,
  d_hue = NA,
  m_hue = NA,
  d_value = 5,
  d_chroma = NA,
  m_value = 3,
  m_chroma = 3,
  dhuenm = "d_hue",
  dvalnm = "d_value",
  dchrnm = "d_chroma",
)```
hasDarkColors

mhuenm = "m_hue",
mvalnm = "m_value",
mchrnm = "m_chroma"
)

Arguments

p               A SoilProfileCollection.
d_hue           Optional: character vector of dry hues to match (default: NA)
m_hue           Optional: character vector of moist hues to match (default: NA)
d_value         Maximum value of dry value (default: 5)
d_chroma        Optional: Maximum value of dry chroma (default: NA)
m_value         Maximum value of moist value (default: 3)
m_chroma        Maximum value of moist chroma (default: 3)
dhuenm          Column name containing dry hue.
dvalnm          Column name containing dry value.
dchrnm          Column name containing dry chroma.
mhuenm          Column name containing moist hue.
mvalnm          Column name containing moist value.
mchrnm          Column name containing moist chroma.

Value

Boolean value (for each horizon in p) reflecting whether "darkness" criteria are met.

Author(s)

Andrew G. Brown

Examples

# construct a fake profile
spc <- data.frame(id=1, taxsubgrp = "Lithic Haploxeralfs",
   hzdesgn = c("A","AB","Bt","Bt","R"),
   hzdept = c(0, 20, 32, 42, 49),
   hzdepb = c(20, 32, 42, 49, 200),
   d_value = c(5, 5, 5, 6, NA),
   m_value = c(2.5, 3, 3, 4, NA),
   m_chroma = c(2, 3, 4, 4, NA))

# promote to SoilProfileCollection
depths(spc) <- id ~ hzdept + hzdepb

# print results in table
data.frame(id = spc[[idname(spc)]],
   hz_design = spc$hzdesgn,  
   has_dark_colors = hasDarkColors(spc))
horizonColorIndices

Description
Calculate basic horizon-level color indices for a SoilProfileCollection. Basic indices do not require
aggregation over the whole profile or comparison to a "reference" (e.g. parent material) color.
Includes Hurst (1977) Redness Index, Barron-Torrent Redness Index (1986) and Buntley-Westin
Index (1965). This is a wrapper method around several horizon-level indices. See the individual
functions for more details.

Usage
horizonColorIndices(p, hue = "m_hue", value = "m_value", chroma = "m_chroma")

Arguments
p A SoilProfileCollection
hue Column name containing moist hue; default: "m_hue"
value Column name containing moist value; default: "m_value"
chroma Column name containing moist chroma; default: "m_chroma"

Value
A data.frame containing unique pedon and horizon IDs and horizon-level color indices.

Author(s)
Andrew G. Brown

Examples
data(sp1)

# promote sp1 data to SoilProfileCollection
depths(sp1) <- id ~ top + bottom

# move site data
site(sp1) <- ~ group

# compute indices
# merged into `sp1` with left-join on hzidname(sp1)
horizons(sp1) <- horizonColorIndices(sp1, hue="hue", value="value", chroma="chroma")
# visualize
par(mar=c(0, 1, 3, 1))
plot(sp1, color='hurst_redness')
plot(sp1, color='barron_torrent_redness')
plot(sp1, color='buntley_westin')

horizonDepths<-

Set horizon depth column names

Description
Set column name containing horizon ID
Get column names containing horizon depths

Usage
horizonDepths(object) <- value

## S4 method for signature 'SoilProfileCollection'
horizonDepths(object)

Arguments
object  
a SoilProfileCollection
value  
a character vector of length two with names of columns containing numeric top
and bottom depths

horizonNames<-

Set horizon column names

Description
Set horizon column names
Get names of columns in horizon table.

Usage
horizonNames(object) <- value

## S4 method for signature 'SoilProfileCollection'
horizonNames(object)

Arguments
object  
a SoilProfileCollection
value  
a unique vector of equal length to number of columns in horizons length(horizonNames(object))
horizons,SoilProfileCollection-method

Retrieve horizon data from SoilProfileCollection

Description

Get horizon data from SoilProfileCollection. Result is returned in the same data.frame class used to initially construct the SoilProfileCollection.

Horizon data in an object inheriting from data.frame can easily be added via merge (LEFT JOIN). There must be one or more same-named columns (with at least some matching data) on the left and right hand side to facilitate the join: `horizons(spc) <- newdata`

Usage

```r
## S4 method for signature 'SoilProfileCollection'
horizons(object)

horizons(object) <- value
```

Arguments

- `object`: A SoilProfileCollection
- `value`: An object inheriting data.frame

Examples

```r
# load test data
data(sp2)

# promote to SPC
depths(sp2) <- id ~ top + bottom

# assign true to surface horizon
newdata <- data.frame(top = 0,
                      newvalue = TRUE)

# do left join
horizons(sp2) <- newdata

# inspect site table: newvalue TRUE only for horizons
# with top depth equal to zero
horizons(sp2)
```
huePosition

Munsell Hue Reference and Position Searching

Description

The 40 Munsell hues are typically arranged from 5R to 2.5R moving clock wise on the unit circle. This function matches a vector of hues to positions on that circle, with options for setting a custom origin or search direction.

This function is fully vectorized.

Usage

huePosition(
  x,  
  returnHues = FALSE,  
  includeNeutral = FALSE,  
  origin = "5R",  
  direction = c("cw", "ccw")
)

Arguments

  x character vector of hues, e.g. c('10YR', '5YR'), optional if returnHues = TRUE
  returnHues logical, should the full set of Munsell hues be returned? See details.
  includeNeutral logical, add 'N' to the end of the full set of Munsell hues
  origin hue to be used as the starting point for position searches (position 1)
  direction indexing direction, should be cw (clock wise) or ccw (counter-clock wise)

Value

A vector of integer hue positions is returned, of the same length and order as x. If returnHues = TRUE, then all hue names and ordering are returned and x is ignored.

huePositionCircle  Visual Description of Munsell Hue Ordering

Description

Munsell hues are arranged on the unit circle with "neutral" at the center.

Usage

huePositionCircle(
  hues = huePosition(returnHues = TRUE),
  value = 6,
  chroma = 10,
  chip.cex = 5.5,
  label.cex = 0.66,
  seg.adj = 0.8,
  seg.col = "grey",
  plot = TRUE,
  simulateCVD = NULL,
  CVDseverity = 1
)
Arguments

- **hues**: vector of Munsell hues, commonly derived from `huePosition()`
- **value**: single integer, Munsell value used to create an actual color
- **chroma**: single integer, Munsell chroma used to create an actual color
- **chip.cex**: numeric, scaling for color chips
- **label.cex**: numeric, scaling labels
- **seg.adj**: numeric, scaling for line segment cues
- **seg.col**: single color, color used for line segment cues
- **plot**: logical, generate output on the current graphics device
- **simulateCVD**: simulate color vision deficiencies with the colorspace package, should be the character representation of a function name, one of: 'deutan', 'protan', or 'tritan'.
- **CVDseverity**: numeric value between 0 (none) and 1 (total), describing the severity of the color vision deficiency

Value

- an invisible `data.frame` of data used to create the figure

Note

The best results are obtained when setting margins to zero, and inverting foreground / background colors. For example: `par(mar = c(0, 0, 0, 0), fg = 'white', bg = 'black').`

References

Examples

```r
# better graphics defaults
op <- par(mar = c(0, 0, 0, 0), fg = 'white', bg = 'black')

# full set of hues, as generated by huePosition(returnHues = TRUE)
huePositionCircle()

# subset
huePositionCircle(hues = c('5R', '5Y', '5G', '5B', '5P'))

# reset graphics state
par(op)
```
The text is already in natural format. No further conversion is necessary.
Arguments

- **x**: A `SoilProfileCollection`
  - Comma-separated set of R expressions that evaluate as `TRUE` or `FALSE` in context of horizon data frame. Length for individual expressions matches number of horizons, in `x`.

- **offset**: Integer offset in terms of `SoilProfileCollection[,j]` (horizon/slice) index

- **SPC**: Return a `SoilProfileCollection`? Default `TRUE` for horizon_* methods.

- **simplify**: If `TRUE` return a vector (all elements combined), or a list (1 element per profile). If SPC is `TRUE` then `simplify` is `TRUE`.

- **hzid**: A vector of target horizon IDs. These are calculated from ... for horizon_*() methods

Details

To minimize likelihood of issues with non-standard evaluation context, especially when using `hzAbove()`/`hzBelow()` inside another function, all expressions used in ... should be in terms of variables that are in the horizon data frame.

Value

- A `SoilProfileCollection` (when SPC = `TRUE`) or a vector of horizon row indices (when SPC = `FALSE` and simplify = `TRUE`) or a list (when SPC = `FALSE` and simplify = `FALSE`).

Examples

```r
data(sp4)
depths(sp4) <- id ~ top + bottom

# get the horizon above the last horizon (j-index of bottom horizon minus 1)
hzAbove(sp4, hzID(sp4) %in% getLastHorizonID(sp4))

# get horizons below the last horizon (none; j-index of bottom horizon plus 1)
hzBelow(sp4, hzID(sp4) %in% getLastHorizonID(sp4))
```

Description

This function removes profiles or horizons from a `SoilProfileCollection` that are flagged as having invalid horizon depth logic by `checkHzDepthLogic`. Invalid profiles may be created when setting `byhz = TRUE`; use caution as some functions may not work properly in the presence of gaps. Consider using `fillHzGaps` to fill these gaps.
hzDepthTests

Usage

```
HzDepthLogicSubset(x, byhz = FALSE)
```

Arguments

- `x`: a `SoilProfileCollection` object
- `byhz`: logical, evaluate horizon depth logic at the horizon level (profile level if FALSE)

Value

a `SoilProfileCollection` object

hzDepthTests  

Tests of horizon depth logic

Description

Function used internally by `checkHzDepthLogic()`, `glom()` and various other functions that operate on horizon data from single soil profiles and require a priori depth logic checks. Checks for bottom depths less than top depth / bad top depth order ("depthLogic"), bottom depths equal to top depth ("sameDepth"), overlaps/gaps ("overlapOrGap") and missing depths ("missingDepth"). Use `names(res)[res]` on result `res` of `hzDepthTest()` to determine type of logic error(s) found – see examples below.

Usage

```
hzDepthTests(top, bottom = NULL)
```

Arguments

- `top`: A numeric vector containing horizon top depths. Or a `data.frame` with two columns (first containing top depths, second containing bottom)
- `bottom`: A numeric vector containing horizon bottom depths.

Value

A named logical vector containing TRUE for each type of horizon logic error found in the given data.

Author(s)

Andrew G. Brown & Dylan E. Beaudette
Examples

# no logic errors
res <- hzDepthTests(top = c(0,10,20,30), bottom = c(10,20,30,50))
names(res)[res]

# bottom < top
hzDepthTests(top = c(10,20,30,50), bottom = c(0,10,20,30))
names(res)[res]

# bottom == top
hzDepthTests(top = c(10,20,30,50), bottom = c(0,20,20,30))
names(res)[res]

# overlap
hzDepthTests(top = c(0,5,20,30), bottom = c(10,20,30,50))
names(res)[res]

# gap
hzDepthTests(top = c(0,15,20,30), bottom = c(10,20,30,50))
names(res)[res]

# missing
hzDepthTests(c(0,15,NA,30),c(10,NA,30,50))
names(res)[res]

hzDesgn,SoilProfileCollection-method

Get horizon designation column name

Description
Get horizon designation names

Usage
## S4 method for signature 'SoilProfileCollection'
hzDesgn(object)

Arguments
  object a SoilProfileCollection
hzdesgnname

Get or Set Horizon Designation Column Name

Description

hzdesgnname(): Get column name containing horizon designations
hzdesgnname<-: Set horizon designation column name

Usage

## S4 method for signature 'SoilProfileCollection'
hzdesgnname(object, required = FALSE)

## S4 replacement method for signature 'SoilProfileCollection'
hzdesgnname(object, required = FALSE) <- value

Arguments

object a SoilProfileCollection
required logical, is this attribute required? If it is, set to TRUE to trigger error on invalid value.
value character, name of column containing horizon designations

Details

Store the column name containing horizon designations or other identifiers in the metadata slot of the SoilProfileCollection.

Convert Horizon Boundary Distinctness to Vertical Offset

Description

This function will convert USDA-NCSS horizon boundary distinctness codes into vertical (+/-) offsets in cm, based on the Field Book for Describing and Sampling Soils, version 3.0.

Usage

`hzDistinctnessCodeToOffset(x, codes = c("very abrupt", "abrupt", "clear", "gradual", "diffuse"), offset = c(0.5, 2, 5, 15, 20)/2)

Arguments

- `x`: vector of boundary distinctness codes to be converted
- `codes`: character vector of distinctness terms ('clear') or codes ('C'), case insensitive, see details
- `offset`: vertical offset factors (cm), approximating 1/2 of the transitional zone thickness, see details

Details

The default offsets are based on the high-end of ranges presented in "transitional zone thickness criteria" from the Field Book version 3.0 (page 2-6). Offsets are returned as 1/2 of the transitional zone thickness so that horizon boundaries can be adjusted up/down from horizon depths. See `plotSPC`, specifically the `hz.distinctness.offset` argument for visualization ideas. Missing data in `x` (NA) or codes that are not defined in `codes` are returned as 0 offsets.

Either format (or mixture) are accepted, case insensitive:

- terms: `c('very abrupt', 'abrupt', 'clear', 'gradual', 'diffuse')`
- coded values: `c('v', 'a', 'c', 'g', 'd')`

Additional examples are available in the Visualization of Horizon Boundaries tutorial.

Value

vector of offsets with same length as `x`

hzidname(sp1) <- "hzIDrev"  

# get horizon designation column  
hzidname(sp1)
**hztexclname**

Get or Set Horizon Texture Class Column Name

**Description**

hztexclname(): Get column name containing horizon designation name
hztexclname<-: Set horizon texture class column name for a SoilProfileCollection

**Usage**

```r
## S4 method for signature 'SoilProfileCollection'
hztexclname(object, required = FALSE)

## S4 replacement method for signature 'SoilProfileCollection'
hztexclname(object, required = FALSE) <- value
```

**Arguments**

- `object`: a SoilProfileCollection
- `required`: logical, is this attribute required? If it is, set to TRUE to trigger error on invalid value.
- `value`: character, name of column containing horizon texture classes

**Details**

Store the column name containing horizon texture classes or other identifiers in the metadata slot of the SoilProfileCollection.

**Examples**

```r
data(sp1)

# promote to SPC
depths(sp1) <- id ~ top + bottom

# set horizon texture class column
hztexclname(sp1) <- "texture"

# get horizon texture class column
hztexclname(sp1)
```
hzTopographyCodeToLineType

Convert Horizon Boundary Topography to Line Type

Description

This function will convert USDA-NCSS horizon boundary topography codes into line types, based on the Field Book for Describing and Sampling Soils, version 3.0.

Usage

hzTopographyCodeToLineType(
  x,
  codes = c("smooth", "wavy", "irregular", "broken"),
  lty = c(1, 2, 3, 4)
)

Arguments

x vector of boundary topography codes to be converted
codes character vector of topography terms (‘smooth’) or codes (‘S’), case insensitive, see details
lty line types

Details

Visualization of horizon boundary topography can be difficult, line type offers an additional visual cue. See hzTopographyCodeToOffset for an offset-based approach. Additional examples are available in the Visualization of Horizon Boundaries tutorial. Missing data in x (NA) or codes that are not defined in codes are returned as line type 1.

Either format (or mixture) are accepted, case insensitive:

- terms: c('smooth','wavy','irregular','broken')
- coded values: c('s','w','i','b')

Value

vector of line types with same length as x

hzTopographyCodeToOffset

Convert Horizon Boundary Topography to Vertical Offset

Description
This function will convert USDA-NCSS horizon boundary topography codes into a vertical offset, suitable for use in plotSPC. Default values are reasonable starting points for encoding smooth, wavy, irregular, or broken style horizon boundary topography as defined in Field Book for Describing and Sampling Soils, version 3.0.

Usage
hzTopographyCodeToOffset(
  x,
  codes = c("smooth", "wavy", "irregular", "broken"),
  offset = c(0, 4, 8, 12)
)

Arguments
- x: vector of boundary topography codes to be converted
- codes: character vector of topography terms ('smooth') or codes ('S'), case insensitive, see details
- offset: vertical offset (depth units) used to create "chevron" effect

Details
Additional examples are available in the Visualization of Horizon Boundaries tutorial. Missing data in x (NA) or codes that are not defined in codes are returned with an offset of 0.

Either format (or mixture) are accepted, case insensitive:

- terms: c('smooth', 'wavy', 'irregular', 'broken')
- coded values: c('s', 'w', 'i', 'b')

Value
vector of vertical offsets with same length as x

hzTransitionProbabilities

*Horizon Transition Probabilities*

Description

Functions for creating and working with horizon (sequence) transition probability matrices.

Usage

hzTransitionProbabilities(x, name, loopTerminalStates = FALSE)

Arguments

- **x**: A SoilProfileCollection object.
- **name**: A horizon level attribute in x that names horizons.
- **loopTerminalStates**: should terminal states loop back to themselves? This is useful when the transition probability matrix will be used to initialize a markovchain object. See examples below.

Details

See the following tutorials for some ideas:

**horizon designation TP** [http://ncss-tech.github.io/AQP/aqp/hz-transition-probabilities.html](http://ncss-tech.github.io/AQP/aqp/hz-transition-probabilities.html)

**soil color TP** [http://ncss-tech.github.io/AQP/aqp/series-color-TP-graph.html](http://ncss-tech.github.io/AQP/aqp/series-color-TP-graph.html)

Value

The function hzTransitionProbabilities returns a square matrix of transition probabilities. See examples.

The function genhzTableToAdjMat returns a square adjacency matrix. See examples.

The function mostLikelyHzSequence returns the most likely sequence of horizons, given a markovchain object initialized from horizon transition probabilities and an initial state, t0. See examples.

Note

These functions are still experimental and subject to change.

invertLabelColor

Get profile ID column name

Description
Get column name containing unique profile IDs

Usage
## S4 method for signature 'SoilProfileCollection'
idname(object)

Arguments
object a SoilProfileCollection

invertLabelColor Make High Contrast Label Colors

Description
Generate a vector of white or black label colors conditioned on a vector of colors to maximize label contrast.

Usage
invertLabelColor(colors, threshold = 0.65)

Arguments
colors vector of colors
threshold black | white threshold

Value
vector of label colors

Author(s)
D.E. Beaudette
Examples

# test with shades of grey
s <- seq(0, 1, by = 0.05)
cols <- grey(s)
soilPalette(cols, lab = as.character(s))

# test with 10YR x/3
m <- sprintf('10YR %s/3', 1:8)
cols <- parseMunsell(m)
soilPalette(cols, lab = m)

Description

Select soil morphologic data from "Redoximorphic Features as Indicators of Seasonal Saturation, Lowndes County, Georgia". This is a useful sample dataset for testing the analysis and visualization of redoximorphic features.

Usage

data(jacobs2000)

Format

A SoilProfileCollection object.

References

Examples

# load
data(jacobs2000)

# basic plot
par(mar=c(0,1,3,3))

cc <- unique(cc)
par(bg='black', fg='white')
colorContrastPlot(cc$m1, cc$m2, labels = c('depletion', 'concentration'))

---

**L1_profiles**  
*Create Representative Soil Profiles via L1 Estimator*

**Description**

The L1 estimator, or geometric median, is a multivariate generalization of the (univariate) median concept. This function performs a multivariate aggregation (via L1 estimator) according to a suite of ratio-scale soil properties. The L1 estimator is applied to soil profile data that have been sliced to a 1-depth-unit basis.

See the [L1 Profiles Tutorial](#) for additional examples.

**Usage**

L1_profiles(
    x,
    fm,
    basis = 1,
method = c("regex", "simple", "constant"),
maxDepthRule = c("max", "min"),
maxDepthConstant = NULL
)

Arguments

x SoilProfileCollection object
fm formula, for example: `group ~ p1 + p2 + p3`, where "group" is a site-level grouping variable, and "p1", "p2", and "p3" are horizon level variables
basis positive integer, aggregation basis (e.g. 1 for 1-depth-unit intervals). Values other than 1 are not currently supported.
method soil depth evaluation method: "regex" for regular expression, "simple", or "constant". See details.
maxDepthRule maximum depth rule: "max" or "min" See details.
maxDepthConstant positive integer, maximum depth when maxDepthRule = 'constant'

Details

See this related tutorial for additional examples. The method, maxDepthRule, and maxDepthConstant arguments set the maximum depth (over the entire collection) of analysis used to build "L1 profiles". The following rules are available:

- method = 'regex' uses pattern matching on horizon designations (note that `hzdesgnname` metadata must be set with `hzdesgnname(x) <- 'columnname'`)
- method = 'simple' uses min or max as applied to x, no accounting for non-soil horizons (e.g. Cr or R)
- method = 'constant' uses a fixed depth value supplied by maxDepthConstant

The maxDepthRule argument sets depth calculation constraint, applied to soil depths computed according to method (min or max).

Value

a SoilProfileCollection object

Note

This function requires the Gmedian package.

References

length, SoilProfileCollection-method

*Get the number of profiles in a SoilProfileCollection*

**Description**

Get the number of profiles in a SoilProfileCollection

**Usage**

```r
## S4 method for signature 'SoilProfileCollection'
length(x)
```

**Arguments**

- `x` a SoilProfileCollection

**lunique**

*Eliminate duplicate instances of profile IDs in a list of SoilProfileCollections*

**Description**

@description Experimental function to "clean" list input where duplicates exist (that would otherwise prevent `pbindlist`). Useful for queries that may have overlapping instances of the same data, for instance a list of SoilProfileCollections where each list element contains profiles gathered from a set of (potentially overlapping) extents.

**Usage**

```r
lunique(l)
```

**Arguments**

- `l` A list of SoilProfileCollections.

**Value**

A list of SoilProfileCollections, with duplicate profile IDs removed.

**Author(s)**

Andrew G. Brown
Examples

data(sp5)

# EXAMPLE #1 -- resolving overlap
# 6 profiles in four sets, and 5,6,7 are missing
input <- lapply(list(c(1,3,4), c(2,2,3), NA, c(8,9,1)), function(idx) {
  if(!all(is.na(idx)))
    sp5[idx,]
})

output <- lunique(input)

# 6 profiles are in final SPC; 5,6,7 are missing
match(profile_id(pbindlist(output)), profile_id(sp5))

# EXAMPLE #2 -- exact duplicates
# deliberately duplicate an SPC
sp5_2 <- sp5
res <- lunique(list(sp5, sp5_2))

# the number of profiles in first element is equal to number in sp5
length(res[[1]]) == length(sp5)

# second list element contains NA b/c all uniques are in #1
res[[2]]
### metadata, SoilProfileCollection-method

Retrieve metadata from *SoilProfileCollection*

---

**Description**

Get metadata from *SoilProfileCollection*. Result is a list. Two entries (*aqp_df_class, depth_units*) should not be edited in the metadata list directly. There are methods that facilitate changing them -- and propagating their changes throughout the collection. Otherwise, metadata list is a free-form slot used to store arbitrary information about the data, how it was collected, citations, etc.

**Usage**

```r
## S4 method for signature 'SoilProfileCollection'
metadata(object)
```

```r
## S4 replacement method for signature 'SoilProfileCollection'
metadata(object) <- value
```

**Arguments**

- **object**: A *SoilProfileCollection*
- **value**: A named list (see examples)

**Examples**

```r
data(sp5)

# replace default metadata with itself
metadata(sp5) <- metadata(sp5)

# set new metadata attribute value
metadata(sp5)$newvalue <- 'foo'

# get metadata attribute
metadata(sp5)$newvalue
```

---

### min, SoilProfileCollection-method

*Get the minimum bottom depth in a SoilProfileCollection*

---

**Description**

Get the shallowest depth of description out of all profiles in a *SoilProfileCollection*. Data missing one or more of: bottom depth, profile ID, or any optional attribute are omitted using `complete.cases`. 
Usage

```r
## S4 method for signature 'SoilProfileCollection'
min(x, v = NULL, na.rm = TRUE)
```

Arguments

- `x`: a SoilProfileCollection
- `v`: optional: a vector of horizon attribute names to refine calculation
- `na.rm`: remove NA? default: TRUE

---

**missingDataGrid**

### Missing Data Grid

Generate a levelplot of missing data from a SoilProfileCollection object.

**Usage**

```r
missingDataGrid(
  s,
  max_depth,
  vars,
  filter.column = NULL,
  filter.regex = NULL,
  cols = NULL,
  ...
)
```

**Arguments**

- `s`: a SoilProfileCollection object
- `max_depth`: integer specifying the max depth of analysis
- `vars`: character vector of column names over which to evaluate missing data
- `filter.column`: a character string naming the column to apply the filter REGEX to
- `filter.regex`: a character string with a regular expression used to filter horizon data OUT of the analysis
- `cols`: a vector of colors
- `...`: additional arguments passed on to levelplot

**Details**

This function evaluates a missing data fraction based on slice-wise evaluation of named variables in a SoilProfileCollection object.
Value

A data.frame describing the percentage of missing data by variable.

Note

A lattice graphic is printed to the active output device.

Author(s)

D.E. Beaudette

See Also

slice

Examples

```r
# 10 random profiles
set.seed(10101)
s <- lapply(as.character(1:10), random_profile)
s <- do.call("rbind", s)

# randomly sprinkle some missing data
s[sample(nrow(s), 5), , 'p1'] <- NA
s[sample(nrow(s), 5), , 'p2'] <- NA
s[sample(nrow(s), 5), , 'p3'] <- NA

# set all p4 and p5 attributes of 'soil 1' to NA
s[which(s$id == '1'), , 'p5'] <- NA
s[which(s$id == '1'), , 'p4'] <- NA

# upgrade to SPC
depths(s) <- id ~ top + bottom

# plot missing data via slicing + levelplot
missingDataGrid(
  s,
  max_depth = 100,
  vars = c('p1', 'p2', 'p3', 'p4', 'p5'),
  main='Missing Data Fraction'
)
```
Description

Simulate mixing of colors in Munsell notation, similar to the way in which mixtures of pigments operate.

Usage

```r
mixMunsell(
x,  
w = rep(1, times = length(x))/length(x),  
mixingMethod = c("reference", "exact", "estimate", "adaptive", "spectra"),  
n = 1,  
keepMixedSpec = FALSE,  
distThreshold = 0.025,  
...
)
```

Arguments

- `x` vector of colors in Munsell notation
- `w` vector of proportions, can sum to any number
- `mixingMethod` approach used to simulate a mixture:
  - `reference`: simulate a subtractive mixture of pigments, selecting `n` closest reference spectra from `munsell.spectra.wide`
  - `exact`: simulate a subtractive mixture of pigments, color conversion via CIE1931 color-matching functions (see details)
  - `estimate`: closest Munsell chip to a weighted mean of CIELAB coordinates
  - `adaptive`: use reference spectra when possible, falling-back to weighted mean of CIELAB coordinates
- `n` number of closest matching color chips (mixingMethod = reference only)
- `keepMixedSpec` keep weighted geometric mean spectra, final result is a list (mixingMethod = reference only)
- `distThreshold` spectral distance used to compute `scaledDistance`, default value is based on an analysis of spectral distances associated with adjacent Munsell color chips. This argument is only used with `mixingMethod = 'reference'`.
- `...` additional arguments to `spec2Munsell`
Details

An accurate simulation of pigment mixtures ("subtractive" color mixtures) is incredibly complex due to factors that aren’t easily measured or controlled: pigment solubility, pigment particle size distribution, water content, substrate composition, and physical obstruction to name a few. That said, it is possible to simulate reasonable, subtractive color mixtures given a reference spectra library (350-800nm) and some assumptions about pigment qualities and lighting. For the purposes of estimating a mixture of soil colors (these are pigments after all) we can relax these assumptions and assume a standard light source. The only missing piece is the spectral library for all Munsell chips in our color books.

Thankfully, Scott Burns has outlined the entire process, and Paul Centore has provided a Munsell color chip reflectance spectra library. The estimation of a subtractive mixture of soil colors can proceed as follows:

1. look up the associated spectra for each color in x
2. compute the weighted (w argument) geometric mean of the spectra
3. convert the spectral mixture to the closest Munsell color via:
   - search for the closest n matching spectra in the reference library (mixtureMethod = 'reference')
   - direct conversion of spectra to closest Munsell color via spec2Munsell ((mixtureMethod = 'exact'))

1. suggest resulting Munsell chip(s) as the best candidate for a simulated mixture

Key assumptions include:

- similar particle size distribution
- similar mineralogy (i.e. pigmentation qualities)
- similar water content.

For the purposes of estimating (for example) a "mixed soil color within the top 18cm of soil" these assumptions are usually valid. Again, these are estimates that are ultimately "snapped" to the nearest chip and not do not need to approach the accuracy of paint-matching systems.

A message is printed when scaledDistance is larger than 1.

Value

A data.frame with the closest matching Munsell color(s):

- munsell: Munsell notation of the n-closest spectra
- distance: spectral (Gower) distance to the n-closest spectra
- scaledDistance: spectral distance scaled by distThreshold
- mixingMethod: method used for each mixture

When keepMixedSpec = TRUE then a list:

- mixed: a data.frame containing the same elements as above
- spec: spectra for the 1st closest match
Calculate the minimum thickness requirement for Mollic epipedon

Utilize horizon depths, designations and textures in a profile to estimate the thickness requirement for the Mollic or Umbric epipedon, per criterion 6 in the U.S. Keys to Soil Taxonomy (12th Edition).

Usage

```r
mollic.thickness.requirement(
  p,
  texcl.attr = guessHzTexClName(p),
  clay.attr = guessHzAttrName(p, "clay", c("total", "_r")),
  truncate = TRUE
)
```
Arguments

- **p**: A single-profile SoilProfileCollection.
- **texcl.attr**: Column in horizon table containing texture classes. Default: `guessHzTexClName(p)`
- **clay.attr**: Column in horizon table containing clay contents. Default: `guessHzAttrName(p, 'clay', c('total', '_r'))`
- **truncate**: Should sliding scale (Criterion 6C) results be truncated to 18 to 25 cm interval? (Experimental; Default: TRUE)

Value

A unit length numeric vector containing Mollic or Umbric epipedon minimum thickness requirement.

Author(s)

Andrew G. Brown

Examples

```r
# construct a fake profile
spc <- data.frame(id=1, taxsubgrp = "Lithic Haploxeralfs", hzname = c("A","AB","Bt","Bt","R"), hzdept = c(0, 20, 32, 42, 49), hzdepb = c(20, 32, 42, 49, 200), prop = c(18, 22, 28, 24, NA), texcl = c("l","l","cl", "l","br"), d_value = c(5, 5, 5, 6, NA), m_value = c(2.5, 3, 3, 4, NA), m_chroma = c(2, 3, 4, 4, NA))

# promote to SoilProfileCollection
depths(spc) <- id ~ hzdept + hzdepb
hzdesgnname(spc) <- 'hzname'
hztexclname(spc) <- 'texcl'

# print results in table
data.frame(id = spc[[idname(spc)]],
    thickness_req = mollic.thickness.requirement(spc, clay.attr='prop'),
    thickness_req_nobound = mollic.thickness.requirement(spc, clay.attr='prop', truncate=FALSE))
```

---

munsell

**Munsell to sRGB Lookup Table for Common Soil Colors**

Description

A lookup table of interpolated Munsell color chips for common soil colors.
Usage

data(munsell)

Format

A data frame with 8825 rows.

- **hue**  Munsell Hue, upper case
- **value**  Munsell Value
- **chroma**  Munsell Chroma
- **r**  sRGB "red" value (0-1)
- **g**  sRGB "green" value (0-1)
- **b**  sRGB "blue" value (0-1)
- **L**  CIE LAB "L" coordinate
- **A**  CIE LAB "A" coordinate
- **B**  CIE LAB "B" coordinate

Details

See munsell2rgb for conversion examples. Note that this table does not currently have entries for values of 2.5—common in most soil color books. These chips should be added in the next major release of aqp. Values are referenced to the D65 standard illuminant.

Source

Color chip XYZ values: http://www.rit.edu/cos/colorscience/rc_munsell_renotation.php

References

- http://dx.doi.org/10.1016/j.cageo.2012.10.020  Methods used to generate this table

Examples

data(munsell)
Description

The original database "SpectralReflectancesOf2007MunsellBookOfColorGlossy.txt" was provided by Paul Centore and downloaded July, 2020. Reflectance values for odd chroma have been interpolated from adjacent chips. See aqp/misc/utils/Munsell/ for the entire set of processing steps.

Munsell value typically ranges from 2-9, and chroma from 1-12. Ranges vary by hue. Run aqp:::.summarizeMunsellSpectraRanges() for a detailed listing by hue.

The original database contains the following description:

This file contains spectral reflectance measurements of X-Rite’s 2007 Munsell Book of Color (Glossy Finish). The measurements were made in 2012 with a ColorMunki spectrophotometer. The first column is the Munsell name. The remaining columns give reflectance values for 380 nm to 730 nm, in steps of 10 nm. The reflectance is a value between 0 (indicating that no light at that wavelength is reflected) and 1 (indicating that all the light at that wavelength is reflected). Occasionally an entry is slightly greater than 1. The likely cause is random variability, and those entries can be adjusted to 1 with negligible loss. In all, 1485 colour samples were measured. Researchers are invited to analyze the data in this file.

Usage

data(munsell.spectra)

Format

A data frame with 89496 rows and 10 variables:

- **munsell**: munsell color
- **hue**: hue component
- **value**: value component
- **chroma**: chroma component
- **wavelength**: wavelength (nm)
- **reflectance**: reflectance

References

munsell2rgb

Convert Munsell Color Notation to other Color Space Coordinates (sRGB and CIELAB)

Description

Color conversion based on a look-up table of common soil colors.

Usage

```r
munsell2rgb(
  the_hue,
  the_value,
  the_chroma,
  alpha = 1,
  maxColorValue = 1,
  return_triplets = FALSE,
  returnLAB = FALSE
)
```

Arguments

- **the_hue**: a vector of one or more hues, upper-case (e.g. '10YR')
- **the_value**: a vector of one or more values (e.g. '4')
- **the_chroma**: a vector of one or more chromas (e.g. '6'), may be NA for neutral hues
- **alpha**: numeric, transparency setting used when `return_triplets = FALSE` and `returnLAB = FALSE`
- **maxColorValue**: maximum sRGB color value, typically 1 (see `rgb`)
- **return_triplets**: logical, return sRGB coordinates (range 0-1) instead of standard hex notation of sRGB (e.g. '#8080B')
- **returnLAB**: logical, return CIELAB coordinates (D65 illuminant)

Details

This function is vectorized without recycling: i.e. the length of each argument must be the same. Both functions will pad output with NA if there are any NA present in the inputs.

Neutral hues are approximated by greyscale shades ranging from 20\%

Gley soil colors that are missing a chroma will not be correctly interpreted. Consider using a chroma of 1. Values of "2.5" (common in soil color descriptions) are silently truncated to "2". Non-standard Munsell notation (e.g. '7.9YR 2.7/2.0') can be matched (nearest-neighbor, no interpolation) to the closest color within the munsell sRGB/CIELAB look-up table via `getClosestMunsellChip()`.

A more accurate estimate of sRGB values from non-standard notation can be achieved with the `munsellinterpol` package.

See examples below.
Value

A vector of R colors is returned that is the same length as the input data. When return_triplets = TRUE and/or returnLAB = TRUE, then a data.frame (of sample length as input) is returned.

Note

Care should be taken when using the resulting sRGB values; they are close to their Munsell counterparts, but will vary based on your monitor and ambient lighting conditions. Also, the value used for maxColorValue will affect the brightness of the colors. The default value (1) will usually give acceptable results, but can be adjusted to force the colors closer to what the user thinks they should look like.

mutate_profile

\textit{Transform a SPC (by profile) with a set of expressions}

Description

\texttt{mutate_profile()} is a function used for transforming SoilProfileCollections. Each expression is applied to site or horizon level attributes of individual profiles. This distinguishes this function from \texttt{mutate}, which is applied to all values in a collection, regardless of which profile they came from.

Usage

\texttt{mutate_profile(object, \ldots, horizon\_level = NULL)}

Arguments

- \texttt{object}: A SoilProfileCollection
- \texttt{\ldots}: A set of comma-delimited R expressions that resolve to a transformation to be applied to a single profile e.g. \texttt{mutate\_profile(hzdept = max(hzdept) - hzdept)}
- \texttt{horizon\_level}: logical. If TRUE results of expressions are added to the SoilProfileCollection’s horizon slot, if FALSE the results are added to the site slot. If NULL (default) the results are stored in the site or horizon slot based on the number of rows in each slot compared to the length of the result calculated from the first and last profile in the collection.
Details

If the length an expression’s result matches the number of horizons, the result is stored as a horizon-level variable. If the result has length 1, it is stored as a site-level variable. In the ambiguous case where the first and last profile have only one horizon, the results are stored in the horizon slot by default. To force results into site slot use `horizon_level = FALSE`.

Value

A SoilProfileCollection.

Author(s)

Andrew G. Brown.

names,SoilProfileCollection-method

Get names of columns in site and horizons table

Description

Get names of columns in site and horizons table of a SoilProfileCollection.

Usage

```r
## S4 method for signature 'SoilProfileCollection'
names(x)
```

Arguments

- `x` : a SoilProfileCollection

nrow,SoilProfileCollection-method

Get the number of horizons in a SoilProfileCollection

Description

Get the number of horizons in a SoilProfileCollection.

Usage

```r
## S4 method for signature 'SoilProfileCollection'
nrow(x)
```

Arguments

- `x` : a SoilProfileCollection
overlapMetrics

**Find and Quantify Overlap within a 1D Sequence**

**Description**

Desc.

**Usage**

overlapMetrics(x, thresh)

**Arguments**

- **x**: vector of relative horizontal positions, one for each profile
- **thresh**: threshold defining "overlap", typically < 1

@return a list:

- **idx**: unique index to overlapping elements in x
- **ov**: normalized overlap (see details)

**Examples**

```r
x <- c(1, 2, 3, 3.4, 3.5, 5, 6, 10)
overlapMetrics(x, thresh = 0.5)
```

panel.depth_function

**Lattice Panel Function for Soil Profiles**

**Description**

Panel function for plotting grouped soil property data, along with upper and lower estimates of uncertainty.

This function can be used to replace `panel.superpose` when plotting depth function data. When requested, contributing fraction data are printed using colors the same color as corresponding depth function lines unless a single color value is given via `cf.col`.

This function is not able to apply transformations (typically `log = 10`) applied in the `scales` argument to `xyplot` to upper/lower bounds. These will have to be manually applied. See examples.
panel.depth_function

Usage

panel.depth_function(
  x,
  y,
  id,
  upper = NA,
  lower = NA,
  subscripts = NULL,
  groups = NULL,
  sync.colors = FALSE,
  cf = NA,
  cf.col = NA,
  cf.interval = 20,
  ...
)

Arguments

x  x values (generated by calling lattice function)
y  y values (generated by calling lattice function)
id  vector of id labels, same length as x and y–only required when plotting segments (see Details section)
upper  vector of upper confidence envelope values
lower  vector of lower confidence envelope values
subscripts  paneling indices (generated by calling lattice function)
groups  grouping data (generated by calling lattice function)
sync.colors  optionally sync the fill color within the region bounded by (lower–upper) with the line colors
cf  optionally annotate contributing fraction data at regular depth intervals see slab
cf.col  optional color for contributing fraction values, typically used to override the line color
cf.interval  number of depth units to space printed contributing fraction values
...  further arguments to lower-level lattice plotting functions, see below

```
parseMunsell

**Parse Munsell Color Notation**

**Description**

Split Munsell color notation into "hue", "value", and "chroma", with optional conversion to sRGB hex notation, sRGB coordinates, and CIELAB coordinates. Conversion is performed by `munsell2rgb`.

**Usage**

```
parseMunsell(munsellColor, convertColors = TRUE, delim = NA, ...)
```

**Arguments**

- `munsellColor` character vector of Munsell colors (e.g. `c('10YR 3/4', '5YR 4/6')`)
- `convertColors` logical, convert colors to sRGB hex notation, sRGB coordinates, CIELAB coordinates
- `delim` optional, specify the type of delimiter used between value and chroma parts of the Munsell code. By default ":", ":", ":", and ":" are supported.
- `...` additional arguments to `munsell2rgb`

**Value**

a `data.frame` object

**Author(s)**

P. Roudier and D.E. Beaudette

**Examples**

```
# just sRGB
parseMunsell("10YR 3/5", return_triplets = TRUE)

# sRGB + CIELAB (D65 illuminant)
parseMunsell("10YR 3/5", return_triplets = TRUE, returnLAB = TRUE)
```
pbindlist

Combine a list of SoilProfileCollection objects

Description

See combine(...) for a connotative short-hand method that does not require that SoilProfileCollection be in a list. Profiles will be sorted based on character sorting of profile ID.

Usage

pbindlist(l, new.idname = NULL, verbose = TRUE)

Arguments

- `l`: a list of SoilProfileCollection objects
- `new.idname`: Optional: a character referring to a new column name to put unique profile IDs in; default: NULL to attempt with existing idname in first element
- `verbose`: Produce warnings and messages regarding results? default: TRUE

Details

Input data must share a common depth unit, and if spatial data are present, a common CRS and coordinate names. In the case of non-conformal @idname and/or @depthcols, the first SoilProfileCollection is used as a template. If one or more subsequent list elements has non-unique values in a site level attribute of that name, the ID name from the second list element is attempted, and so on. Non-conforming spatial data are dropped from the final result (returns default empty SpatialPoints).

Value

- a SoilProfileCollection object

Author(s)

D.E. Beaudette and A.G. Brown
Examples

```r
# example data
data(sp2, package = 'aqp')
depths(sp2) <- id ~ top + bottom
site(sp2) <- ~ surface

# copy pieces
x <- sp2[1:5, ]
y <- sp2[6:10, ]

# reset IDs and combine
profile_id(y) <- sprintf("%s-copy", profile_id(y))

# this should work
z <- pbindlist(list(x, y))

# check
plot(z)
```

---

**pc**

*Numerical Soil Profile Comparison*

**Description**

Performs a numerical comparison of soil profiles using named properties, based on a weighted, summed, depth-segment-aligned dissimilarity calculation. If `s` is a `SoilProfileCollection`, site-level variables (2 or more) can also be used. The site-level and horizon-level dissimilarity matrices are then re-scaled and averaged.

**Usage**

```r
pc(
  s,
  vars,
  max_d,
  k,
  filter = NULL,
  sample_interval = NA,
  replace_na = TRUE,
  add_soil_flag = TRUE,
  return_depth_distances = FALSE,
  strict_hz_eval = FALSE,
  progress = "none",
  plot.depth.matrix = FALSE,
  rescale.result = FALSE,
  verbose = FALSE
)
```
Arguments

- **s**: a dataframe with at least 2 columns of soil properties, and an 'id' column for each profile. Horizon depths must be integers and self-consistent, or a SoilProfileCollection object.
- **vars**: A vector with named properties that will be used in the comparison. These are typically column names describing horizon-level attributes (2 or more), but can also contain site-level attributes (2 or more) if `s` is a SoilProfileCollection.
- **max_d**: depth-slices up to this depth are considered in the comparison.
- **k**: a depth-weighting coefficient, use '0' for no depth-weighting (see examples below).
- **filter**: an index used to determine which horizons (rows) are included in the analysis.
- **sample_interval**: use every n-th depth slice instead of every depth slice, useful for working with > 1000 profiles at a time.
- **replace_na**: if TRUE, missing data are replaced by maximum dissimilarity (TRUE).
- **add_soil_flag**: The algorithm will generate a 'soil'/non-soil' matrix for use when comparing soil profiles with large differences in depth (TRUE). See details section below.
- **return_depth_distances**: return intermediate, depth-wise dissimilarity results (FALSE).
- **strict_hz_eval**: should horizons be strictly checked for internal self-consistency? (FALSE).
- **progress**: 'none' (default): argument passed to dply and related functions, see create_progress_bar for all possible options; 'text' is usually fine.
- **plot.depth.matrix**: should a plot of the 'soil'/non-soil' matrix be returned (FALSE).
- **rescale.result**: should the result be rescaled by dividing by max(D) (FALSE).
- **verbose**: extra debug output (FALSE).

Details

Variability in soil depth can interfere significantly with the calculation of between-profile dissimilarity--what is the numerical “distance” (or dissimilarity) between a slice of soil from profile A and the corresponding, but missing, slice from a shallower profile B? Gower’s distance metric would yield a NULL distance, despite the fact that intuition suggests otherwise: shallower soils should be more dissimilar from deeper soils. For example, when a 25 cm deep profile is compared with a 50 cm deep profile, numerical distances are only accumulated for the first 25 cm of soil (distances from 26 - 50 cm are NULL). When summed, the total distance between these profiles will generally be less than the distance between two profiles of equal depth. Our algorithm has an option (setting replace_na=TRUE) to replace NULL distances with the maximum distance between any pair of profiles for the current depth slice. In this way, the numerical distance between a slice of soil and a corresponding slice of non-soil reflects the fact that these two materials should be treated very differently (i.e. maximum dissimilarity).

This alternative calculation of dissimilarities between soil and non-soil slices solves the problem of comparing shallow profiles with deeper profiles. However, it can result in a new problem: distances calculated between two shallow profiles will be erroneously inflated beyond the extent of either...
profile's depth. Our algorithm has an additional option (setting add_soil_flag=TRUE) that will preserve NULL distances between slices when both slices represent non-soil material. With this option enabled, shallow profiles will only accumulate mutual dissimilarity to the depth of the deeper profile.

Note that when the add_soil_flag option is enabled (default), slices are classified as 'soil' down to the maximum depth to which at least one of variables used in the dissimilarity calculation is not NA. This will cause problems when profiles within a collection contain all NAs within the columns used to determine dissimilarity. An approach for identifying and removing these kind of profiles is presented in the examples section below.

A notice is issued if there are any NA values within the matrix used for distance calculations, as these values are optionally replaced by the max dissimilarity.

Our approach builds on the work of (Moore, 1972) and the previously mentioned depth-slicing algorithm.

**Value**

A dissimilarity matrix object of class 'dissimilarity, dist', optionally scaled by max(D).

## 1. check out the influence depth-weight coef:
library(lattice)

z <- rep(1:100,4)
k <- rep(c(0,0.1,0.05,0.01), each=100)
w <- 100*exp(-k*z)

xyplot(z ~ w, groups=k, ylim=c(105,-5), xlim=c(-5,105), type='l',
      ylab='Depth', xlab='Weighting Factor', asp=1.5,
      auto.key=list(columns=4, lines=TRUE, points=FALSE, title="k", cex=0.8, size=3),
      panel=function(...) {
```
# more soil properties

data(sp2)
depths(sp2) <- id ~ top + bottom

d.1 <- profile_compare(sp2, vars=c('prop','field_ph','hue','value'),
                       max_d=100, k=0.01, plot.depth.matrix=TRUE)

# add some missing data:
sp2$prop[1:2] <- NA
d.2 <- profile_compare(sp2, vars=c('prop','field_ph','hue','value'),
                       max_d=100, k=0.01, plot.depth.matrix=TRUE)

# note small changes in D:
cor(d.1, d.2)

## 3. identify profiles within a collection that contain all NAs
set.seed(1010101)
s <- pbindlist(lapply(letters[1:10], random_profile, SPC=TRUE))

# replace first profile’s data with NA
na.required <- nrow(s[1,])
s$p1[1:na.required] <- NA
s$p2[1:na.required] <- NA

# attempt profile comparison: this won’t work, throws an error
d <- profile_compare(s, vars=c('p1','p2'), max_d=100, k=0)

# check for soils that are missing all clay / total RF data
f.check.NA <- function(i) length(which(is.na(i$p1) | is.na(i$p2))) / nrow(i) == 1
missing.too.much.data.idx <- which(profileApply(s, f.check.NA))

# remove bad profiles and try again: works
s.no.na <- profile_compare(s[-missing.too.much.data.idx, ],
                           vars=c('p1','p2'),
                           max_d=100, k=0, plot.depth.matrix=TRUE)

## 4. better plotting of dendrograms with ape package:
if(require(ape) & require(cluster) & require(MASS)) {
  data(sp2)
depths(sp2) <- id ~ top + bottom
  site(sp2) <- ~ surface

  d <- profile_compare(sp2, vars=c('prop','field_ph','hue','value'),
                       max_d=100, k=0)
  h <- diana(d)
p <- as.phylo(as.hclust(h))
perturb

Perturb soil horizon depths using boundary distinctness

Description

"Perturbs" the **boundary between horizons** or the **thickness of horizons** using a standard deviation specified as a horizon-level attribute. This is selected using either `boundary.attr` or `thickness.attr` to specify the column name.

The boundary standard deviation corresponds roughly to the concept of "horizon boundary distinctness." In contrast, the **horizon thickness** standard deviation corresponds roughly to the "variation in horizon thickness" so it may be determined from several similar profiles that have a particular layer "in common."
perturb

Usage

```r
perturb(
  p,
  n = 100,
  id = NULL,
  thickness.attr = NULL,
  boundary.attr = NULL,
  min.thickness = 1,
  max.depth = NULL,
  new.idname = "pID"
)
```

Arguments

- **p**: A single-profile SoilProfileCollection
- **n**: Number of new profiles to generate (default: 100)
- **id**: a vector of profile IDs with length equal to (n). Overrides use of `seq_len(n)` as default profile ID values.
- **thickness.attr**: Horizon variance attribute containing numeric "standard deviations" reflecting horizon thickness
- **boundary.attr**: Horizon variance attribute containing numeric "standard deviations" reflecting boundary transition distinctness
- **min.thickness**: Minimum thickness of permuted horizons (default: 1)
- **max.depth**: Depth below which horizon depths are not perturbed (default: NULL)
- **new.idname**: New column name to contain unique profile ID (default: pID)

Details

Imagine a Normal curve with mean centered on the vertical (depth axis) at a representative value (RV) horizon bottom depth or thickness. By the Empirical Rule for Normal distribution, two "standard deviations" above or below that "central" mean value represent 95% of the "typical volume" of that horizon or boundary.

perturb can leverage semi-quantitative (ordered factor) levels of boundary distinctness/topography for the upper and lower boundary of individual horizons. A handy function for this is `hzDistinctnessCodeToOffset()`. The `boundary.attr` is arguably easier to parameterize from a single profile description or "Form 232" where horizon boundary distinctness classes (based on vertical distance of transition) are conventionally recorded for each layer.

Alternately, perturb can be parameterized using standard deviation in thickness of layers derived from a group. Say, the variance parameters are defined from a set of pedons correlated to a particular series or component, and the template "seed" profile is, for example, the Official Series Description or the Representative Component Pedon.

Value

a SoilProfileCollection with n realizations of p

plotColorMixture  

Visualize Spectral Mixing of Munsell Colors

Description

Lattice visualization demonstrating subtractive mixtures of colors in Munsell notation and associated spectra.

Usage

plotColorMixture(
  x,
  w = rep(1, times = length(x))/length(x),
  mixingMethod = c("reference", "exact"),
  n = 1,
  swatch.cex = 6,
  label.cex = 0.85,
  showMixedSpec = FALSE,
  overlapFix = TRUE
)

Arguments

x  vector of colors in Munsell notation, should not contain duplicates
w  vector of weights, can sum to any number
mixingMethod  approach used to simulate a mixture:
  • reference: simulate a subtractive mixture of pigments, selecting n closest reference spectra
  • exact: simulate a subtractive mixture of pigments, color conversion via CIE1931 color-matching functions (see mixMunsell)
n  number of closest mixture candidates when mixingMethod = 'reference' (see mixMunsell), results can be hard to interpret when n > 2

swatch.cex  scaling factor for color swatch

label.cex  scaling factor for swatch labels

showMixedSpec  show weighted geometric mean (mixed) spectra as dotted line (only when mixingMethod = 'reference')

overlapFix  attempt to "fix" overlapping chip labels via fixOverlap

Details

If present, names attribute of x is used for the figure legend.

Value

a lattice graphics object

Author(s)

D.E. Beaudette

Examples

# color chips
chips <- c('5B 5/10', '5Y 8/8')
names(chips) <- chips

# weights
wt <- c(1, 1)

plotColorMixture(
  x = chips,
  w = wt,
  swatch.cex = 4,
  label.cex = 0.65,
  showMixedSpec = TRUE,
  mixingMethod = 'reference'
)

plotColorMixture(
  x = chips,
  w = wt,
  swatch.cex = 4,
  label.cex = 0.65,
  mixingMethod = 'exact'
)
plotColorQuantiles  Visualize Color Quantiles

Description

This function creates a visualization of the output from `colorQuantiles` using lattice graphics.

Usage

```r
plotColorQuantiles(res, pt.cex = 7, lab.cex = 0.66)
```

Arguments

- `res`: list returned by `colorQuantiles`
- `pt.cex`: scaling factor for color chips
- `lab.cex`: chip label scaling factor

Details

Marginal percentiles and L1 median CIELAB values from `colorQuantiles` are combined into a single plot, arranged in panels according to L, A, and B coordinates. Munsell "chips" (colors and labels) are based on the closest Munsell color found via `rgb2Munsell`.

Value

- a lattice graphics object

Author(s)

D.E. Beaudette

plotMultipleSPC  Plot Multiple SoilProfileCollection Objects

Description

Plot Multiple SoilProfileCollection Objects
plotMultipleSPC

Usage

plotMultipleSPC(
  spc.list,
  group.labels,
  args = rep(list(NA), times = length(spc.list)),
  merged.legend = NULL,
  merged.colors = c("#5E4FA2", "#3288BD", "#66C2A5", "#ABDDA4", "#E6F598", "#FEE08B",
                    "#FDAE61", "#F46D43", "#D53E4F", "#9E0142"),
  merged.legend.title = merged.legend,
  arrow.offset = 2,
  bracket.base.depth = 95,
  label.offset = 2,
  label.cex = 0.75,
  ...
)

Arguments

spc.list a list of SoilProfileCollection objects
group.labels a vector of group labels, one for each SoilProfileCollection object
args a list of arguments passed to plotSPC, one for each SoilProfileCollection object
merged.legend name of a horizon level attribute from which to create thematic sketches and merged legend
merged.colors vector of colors used to create thematic sketches from a shared horizon level attribute
merged.legend.title legend title
arrow.offset vertical offset in depth from base of start / end profiles and group bracket arrows
bracket.base.depth baseline depth used for group brackets
label.offset vertical offset of group labels from baseline
label.cex label size
... additional arguments to the first call to plotSPC

Details

Combine multiple SoilProfileCollection objects into a single profile sketch, with annotated groups.
See examples below for usage.

Note

For thematic sketches, use the merged.legend argument instead of color argument to plotSPC
Author(s)

D.E. Beaudette and Ben Marshall

Examples

```r
##
## Simple Example
##

# using default arguments to plotSPC()

# load sample data
data(sp3)
data(sp4)

# promote to SoilProfileCollection
depths(sp3) <- id ~ top + bottom
depths(sp4) <- id ~ top + bottom

# combine into a list
spc.list <- list(sp3, sp4)

# argument list
arg.list <- list(
  list(name='name', id.style='top'),
  list(name='name', id.style='side')
)

# plot multiple SPC objects,
# with list of named arguments for each call to plotSPC
par(mar=c(1,1,3,3))
plotMultipleSPC(
  spc.list,
  group.labels = c('Collection 1', 'Collection 2'),
  args = arg.list,
  bracket.base.depth = 120, label.cex = 1
)

# specify a different max.depth
plotMultipleSPC(
  spc.list,
  group.labels = c('Collection 1', 'Collection 2'),
  args = arg.list,
  bracket.base.depth = 120, label.cex = 1,
  max.depth = 250
)
```
## Merged Legend Example

# merged legend based on hz attribute 'clay'

# reset sample data
data(sp3)
data(sp4)

# promote to SoilProfileCollection
depths(sp3) <- id ~ top + bottom
depths(sp4) <- id ~ top + bottom

# combine into a list
spc.list <- list(sp3, sp4)

# argument list
arg.list <- list(
  list(name='name', id.style='top'),
  list(name='name', id.style='side')
)

par(mar=c(1,1,3,3))
plotMultipleSPC(
  spc.list,
  group.labels = c('Collection 1', 'Collection 2'),
  args = arg.list,
  label.cex = 1,
  merged.legend = 'clay', merged.legend.title = 'Clay (%)'
)

## Complex Merged Legend Example

# create a merged legend from "clay" in sp4 and jacobs2000
# use "soil_color" from sp3

# reset sample data
data(sp3)
data(sp4)
data(jacobs2000)

# promote to SoilProfileCollection
depths(sp3) <- id ~ top + bottom
depths(sp4) <- id ~ top + bottom

# remove 'clay' column from sp3
sp3$clay <- NULL

# combine into a list
spc.list <- list(sp3, sp4, jacobs2000)

# try some variations on the default arguments
# `clay` is missing in the first SPC, safe to specify another column for colors
arg.list <- list(  
  list(color = 'soil_color', id.style='top', name = NA, width = 0.3, hz.depths = TRUE),  
  list(name='name', id.style='side', name.style = 'center-center'),  
  list(name='name', id.style='side', name.style = 'left-center', hz.depths = TRUE)
)

par(mar=c(1,1,3,3))
plotMultipleSPC(  
  spc.list,  
  group.labels = c('sp3', 'sp4', 'jacobs2000'),  
  label.offset = 3,  
  args = arg.list,  
  merged.legend = 'clay', merged.legend.title = 'Clay (%)',  
  axis.line.offset = 0
)

---

**plotSPC**

Create Soil Profile Sketches

**Description**

Generate a diagram of soil profile sketches from a SoilProfileCollection object. The Introduction to SoilProfileCollection Objects tutorial contains many examples and discussion of the large number of arguments to this function.

**Usage**

```r
plotSPC(
  x,  
  color = "soil_color",  
  width = ifelse(length(x) < 2, 0.15, 0.25),  
  name = hzdesgnname(x),  
  name.style = "right-center",  
  label = idname(x),  
  hz.depths = FALSE,  
  hz.depths.offset = 0,  
  hz.depths.lines = fixLabelCollisions,  
  alt.label = NULL,  
  alt.label.col = "black",  
  cex.names = 0.5,  
  cex.depth.axis = cex.names,  
  cex.id = cex.names + (0.2 * cex.names),  
  ```
font.id = 2,
print.id = TRUE,
id.style = "auto",
plot.order = 1:length(x),
relative.pos = 1:length(x),
add = FALSE,
scaling.factor = 1,
y.offset = rep(0, times = length(x)),
x.idx.offset = 0,
n = length(x),

axis.line.offset = -2.5,
plot.depth.axis = TRUE,
density = NULL,
show.legend = TRUE,
col.label = color,
col.palette = c("#5E4FA2", "#3288BD", "#66C2A5", "#ABDDA4", "#E6F598", "#FEE08B",
"#FDAE61", "#F46D43", "#D53E4F", "#9E0142"),
col.palette.bias = 1,
col.legend.cex = 1,
n.legend = 8,
lwd = 1,
lty = 1,
default.color = grey(0.95),
fixLabelCollisions = FALSE,
...
)

## S4 method for signature 'SoilProfileCollection,ANY'
## note: y argument in generic definition is not currently used
plot(x, y, ...)

Arguments

x a SoilProfileCollection object

color quoted column name containing R-compatible color descriptions, or numeric /
categorical data to be displayed thematically; see details

width scaling of profile widths (typically 0.1 - 0.4)
plotSPC

name
quoted column name of the (horizon-level) attribute containing horizon designations or labels, if missing hzdesignname(x) is used. Suppress horizon name printing by setting name = NA or name = "".

name.style
one of several possible horizon designations labeling styles: 'right-center' (aqp default), 'left-top', 'left-center'

label
quoted column name of the (site-level) attribute used to identify profile sketches

hz.depths
logical, annotate horizon top depths to the right of each sketch (FALSE)

hz.depths.offset
numeric, user coordinates for left-right adjustment for horizon depth annotation; reasonable values are usually within 0.01-0.05 (default: 0)

hz.depths.lines
logical, draw segments between horizon depth labels and actual horizon depth; this is useful when including horizon boundary distinctness and/or fixLabelCollisions = TRUE

alt.label
quoted column name of the (site-level) attribute used for secondary annotation

alt.label.col
color used for secondary annotation text

cex.names
baseline character scaling applied to all text labels

cex.depth.axis
character scaling applied to depth scale

cex.id
character scaling applied to label

font.id
font style applied to label, default is 2 (bold)

print.id
logical, print label above/beside each profile? (TRUE)

id.style
label printing style: 'auto' (default) = simple heuristic used to select from: 'top' = centered above each profile, 'side' = 'along the top-left edge of profiles'

plot.order
integer vector describing the order in which individual soil profiles should be plotted

relative.pos
vector of relative positions along the x-axis, within {1, n}, ignores plot.order; see details

add
logical, add to an existing figure

scaling.factor
vertical scaling of profile depths, useful for adding profiles to an existing figure

y.offset
numeric vector of vertical offset for top of profiles in depth units of x, can either be a single numeric value or vector of length = length(x). A vector of y-offsets will be automatically re-ordered according to plot.order.

x.idx.offset
integer specifying horizontal offset from 0 (left-hand edge)

n
integer describing amount of space along x-axis to allocate, defaults to length(x)

max.depth
suggested lower depth boundary of plot

n.depth.ticks
suggested number of ticks in depth scale

shrink
logical, reduce character scaling for 'long' horizon by 80%

shrink.cutoff
character length defining 'long' horizon names

shrink.thin
integer, horizon thickness threshold for shrinking horizon names by 80%, only activated when shrink = TRUE (NULL = no shrinkage)

abbr
logical, abbreviate label
abbr.cutoff  suggested minimum length for abbreviated label
divide.hz    logical, divide horizons with line segment? (TRUE), see details
hz.distinctness.offset
  NULL, or quoted column name (horizon-level attribute) containing vertical offsets used to depict horizon boundary distinctness (same units as profiles), see details and codeh2zDistinctnessCodeToOffset; consider setting hz.depths.lines = TRUE when used in conjunction with hz.depths = TRUE
hz.topography.offset
  NULL, or quoted column name (horizon-level attribute) containing offsets used to depict horizon boundary topography (same units as profiles), see details and codeh2zTopographyCodeToOffset
hz.boundary.lty
  quoted column name (horizon-level attribute) containing line style (integers) used to encode horizon topography
axis.line.offset
  horizontal offset applied to depth axis (default is -2.5, larger numbers move the axis to the right)
plot.depth.axis
  logical, plot depth axis? (default is TRUE)
density      fill density used for horizon color shading, either a single integer or a quoted column name (horizon-level attribute) containing integer values (default is NULL, no shading)
show.legend  logical, show legend? (default is TRUE)
col.label    thematic legend title
col.palette  color palette used for thematic sketches (default is rev(brewer.pal(10,'Spectral')))ncol.palette.bias
  color ramp bias (skew), see colorRampncol.legend.cex
  scaling of thematic legendnn.legend
  approximate number of classes used in numeric legend, max number of items per row in categorical legendnlwd      line width multiplier used for sketchesnty      line style used for sketchesndefault.color      default horizon fill color used when color attribute is NA
fixLabelCollisions
  use aqp::fixOverlap() to attempt fixing hz depth labeling collisions, will slow plotting of large collections; enabling fixes also sets hz.depths.lines = TRUE
...  other arguments passed into lower level plotting functionsny      (not used)

Details

Depth limits (max.depth) and number of depth ticks (n.depth.ticks) are suggestions to the pretty function. You may have to tinker with both parameters to get what you want.
The 'side' id.style is useful when plotting a large collection of profiles, and/or, when profile IDs are long.

If the column containing horizon designations is not specified (the name argument), a column (presumed to contain horizon designation labels) is guessed based on regular expression matching of the pattern 'name'– this usually works, but it is best to manual specify the name of the column containing horizon designations.

The color argument can either name a column containing R-compatible colors, possibly created via munsell2rgb, or column containing either numeric or categorical (either factor or character) values. In the second case, values are converted into colors and displayed along with a simple legend above the plot. Note that this functionality makes several assumptions about plot geometry and is most useful in an interactive setting.

Adjustments to the legend can be specified via col.label (legend title), col.palette (palette of colors, automatically expanded), col.legend.cex (legend scaling), and n.legend (approximate number of classes for numeric variables, or, maximum number of legend items per row for categorical variables). Currently, plotSPC will only generate two rows of legend items. Consider reducing the number of classes if two rows isn’t enough room.

Profile sketches can be added according to relative positions along the x-axis (vs. integer sequence) via relative.pos argument. This should be a vector of positions within {1,n} that are used for horizontal placement. Default values are 1:length(x). Care must be taken when both plot.order and relative.pos are used simultaneously: relative.pos specifies horizontal placement after sorting. addDiagnosticBracket and addVolumeFraction use the relative.pos values for subsequent annotation.

Relative positions that are too close will result in overplotting of sketches. Adjustments to relative positions such that overlap is minimized can be performed with fixOverlap(pos), where pos is the original vector of relative positions.

The x.idx.offset argument can be used to shift a collection of pedons from left to right in the figure. This can be useful when plotting several different SoilProfileCollection objects within the same figure. Space must be pre-allocated in the first plotting call, with an offset specified in the second call. See examples below.

Note

A new plot of soil profiles is generated, or optionally added to an existing plot.

plot_distance_graph

Between Individual Distance Plot

Description

Plot pair-wise distances between individuals as line segments.

Usage

plot_distance_graph(D, idx = 1:dim(as.matrix(D))[1])

Arguments

D distance matrix, should be of class 'dist' or compatible class
idx an integer sequence defining which individuals should be compared

Details

By default all individuals are plotting on the same axis. When there are more than about 10 individuals, the plot can become quite messy. See examples below for ideas.

Value

No value is returned.

pms.munsell.lut  Pantone Colors / Munsell Lookup Table

Description
A simple lookup table to convert Pantone spot colors into Munsell notation. Association is based on
the "closest" Munsell color via CIE2000 distance metric (dE00). This is an experimental association
between the two color systems and should not be used for precision color matching or mixing
applications.
Possible uses include rough estimation of soil colors in the field, by means of color swatches based
on the Pantone system. This type of color matching is most appropriate in an educational setting
where official soil color books may be too expensive.

Usage

data(pms.munsell.lut)

Format

code  Pantone spot color code
hex  hex representation of sRGB colorspace, suitable for on-screen use
munsell  Munsell notation of closest color "chip"
DE00  delta-E 2000 metric describing the (perceptual) distance to the closest Munsell chip
Details

Conversion from PMS to Munsell is performed by \texttt{PMS2Munsell} or manual subset of the lookup table (see examples 1 and 2 below) or implicit subset by way of a join (example 3). Conversion from Munsell to PMS will not always result in a matching color, see example 3 below.

Note

The lookup table contains entries for both coated and un-coated colors, these are identified by a `-c` or `-u` suffix. For example, PMS code `100-c` is associated with `10Y 9/9`.

Several Munsell chips are matched by multiple Pantone spot colors, e.g. `5YR 5/5`.

References

Data were sourced from:

- coated colors: \url{https://raw.githubusercontent.com/ajesma/Pantoner/gh-pages/csv/pantone-coated.csv}
- uncoated colors: \url{https://github.com/ajesma/Pantoner/raw/gh-pages/csv/pantone-uncoated.csv}

Examples

```r
# load LUT
data(pms.munsell.lut)

## 1. Munsell -> Pantone
# colors to match
colors <- c('10YR 3/3', '7.5YR 4/6')

# index / subset match
idx <- pms.munsell.lut$munsell %in% colors
m <- pms.munsell.lut[idx, ]

# simple display
colorContrastPlot(m1 = m$munsell[1], m2 = m$munsell[2], labels = m$code)

## 2. Pantone -> Munsell
codes <- c('723-c', '451-c')

# index / subset match
m <- PMS2Munsell(codes)

# simple display
colorContrastPlot(m1 = m$munsell[1], m2 = m$munsell[2], labels = m$code)

## 3. multiple Pantone colors matching a single Munsell color
# colors <- pms.munsell.lut[pms.munsell.lut$munsell == '5YR 5/5', ]
```
PMS2Munsell

Convert Pantone PMS codes to Munsell notation

Description

Convert Pantone PMS codes to Munsell notation

Usage

PMS2Munsell(codes)

Arguments

codes vector of PMS codes (e.g. ‘7630-c’), may contain NA, see pms.munsell.lut

Details

Conversion of Pantone spot colors (PMS code) is performed by look-up from pms.munsell.lut. Association is based on the “closest” Munsell color via CIE2000 distance metric (dE00) (see rgb2munsell). This is an experimental association between the two color systems and should not be used for precision color matching or paint mixing applications.
Possible uses include rough estimation of soil colors in the field, by means of color swatches based on the Pantone system. This type of color matching is most appropriate in an educational setting where official soil color books may be too expensive.

**Value**

data.frame containing closest associated Munsell color (via rgb2munsell), hex notation, and perceptual color distance (dE00) between sRGB values and closest Munsell "chip".

**Note**

Inspired by the work and outreach efforts of Dr. Karen Vaughan (UWY).

**Author(s)**

D.E. Beaudette

**Examples**

```r
# safely handles NA
codes <- c(NA, "7630-c", "102-c")
PMS2Munsell(codes)
```

**Description**

Preview colors arranged according to CIE2000 distances or manual specification.

**Usage**

```r
previewColors(
cols,
method = c("grid", "MDS", "manual"),
labels = NULL,
labels.cex = 1,
col.order = NULL,
nrow = ceiling(sqrt(length(cols))),
ncol = nrow,
border.col = "black",
pt.cex = 2,
pt.pch = 15
)
```
Arguments

- **cols**: vector of R colors
- **method**: either "grid", "MDS", or "manual", see details
- **labels**: optional vector of labels, disabled when length(cols) > 5000
- **labels.cex**: scaling factor for labels
- **col.order**: integer vector used to order colors
- **nrow**: number of rows used by "grid" method
- **ncol**: number of columns used by "grid" method
- **border.col**: border color used by "grid" method
- **pt.cex**: point scaling factor used by "MDS" method
- **pt.pch**: point symbol used by "MDS" method

Details

Color sorting is based on CIE2000 distances as calculated by `farver::compare_colour()`. The "grid" method arranges colors in a rectangular grid with ordering based on divisive hierarchical clustering of the pair-wise distances. Unique colors are used when cols contains more than 5,000 colors.

The "MDS" method arranges unique colors via classical multidimensional scaling (principal coordinates) via `cmdscale()`.

Colors can be manually arranged by supplying a vector of integers to col.order and setting method='manual'.

Value

When method = "grid" or "manual" a vector of color order is returned. When method = "MDS", the output from `MASS::cmdscale`.

Author(s)

D.E. Beaudette

Examples

```r
# example data
data(sp2)

# convert into SoilProfileCollection object
depths(sp2) <- id ~ top + bottom

previewColors(sp2$soil_color)
previewColors(sp2$soil_color, method = 'MDS', pt.cex = 3)

# create colors using HCL space
cols.hcl <- hcl(h = 0:360, c = 100, l = 50)
```
profileApply

Iterate over profiles in a SoilProfileCollection

Description

Iterate over all profiles in a SoilProfileCollection, calling FUN on a single-profile SoilProfileCollection for each step.

Usage

## S4 method for signature 'SoilProfileCollection'
profileApply(
  object,
  FUN,
  simplify = TRUE,
  frameify = FALSE,
  chunk.size = 100,
  column.names = NULL,
  ...
)

Arguments

object a SoilProfileCollection
FUN a function to be applied to each profile within the collection
simplify logical, should the result be simplified to a vector? default: TRUE; see examples
frameify logical, should the result be collapsed into a data.frame? default: FALSE; overrides simplify argument; see examples
chunk.size numeric, size of "chunks" for faster processing of large SoilProfileCollection objects; default: 100
column.names character, optional character vector to replace frameify-derived column names; should match length of colnames() from FUN result; default: NULL

... additional arguments passed to FUN
Value

When `simplify` is TRUE, a vector of length `nrow(object)` (horizon data) or of length `length(object)` (site data). When `simplify` is FALSE, a list is returned. When `frameify` is TRUE, a data.frame is returned. An attempt is made to identify `idname` and/or `hzidname` in the data.frame result, safely ensuring that IDs are preserved to facilitate merging `profileApply` result downstream.

Examples

data(sp1)
depths(sp1) <- id ~ top + bottom

# estimate soil depth using horizon designations
profileApply(sp1, estimateSoilDepth, name='name')

# scale a single property 'prop' in horizon table
# scaled = (x - mean(x)) / sd(x)
sp1$d <- profileApply(sp1, FUN=function(x) round(scale(x$prop), 2))
plot(sp1, name='d')

# compute depth-wise differencing by profile
# note that our function expects that the column 'prop' exists
f <- function(x) { c(x$prop[1], diff(x$prop)) }
sp1$d <- profileApply(sp1, FUN=f)
plot(sp1, name='d')

# compute depth-wise cumulative sum by profile
# note the use of an anonymous function
sp1$d <- profileApply(sp1, FUN=function(x) cumsum(x$prop))
plot(sp1, name='d')

# compute profile-means, and save to @site
# there must be some data in @site for this to work
site(sp1) <- ~ group
sp1$mean_prop <- profileApply(sp1, FUN=function(x) mean(x$prop, na.rm=TRUE))

# re-plot using ranks defined by computed summaries (in @site)
plot(sp1, plot.order=rank(sp1$mean_prop))

## iterate over profiles, calculate on each horizon, merge into original SPC

# example data
data(sp1)

# promote to SoilProfileCollection
depths(sp1) <- id ~ top + bottom
site(sp1) <- ~ group

# calculate horizon thickness and proportional thickness
# returns a data.frame result with multiple attributes per horizon
thicknessFunction <- function(p) {
  hz <- horizons(p)
depthnames <- horizonDepths(p)
res <- data.frame(profile_id(p), hzID(p),
  thk=(hz[[depthnames[[2]]]] - hz[[depthnames[1]]]))
res$hz_prop <- res$thk / sum(res$thk)
colnames(res) <- c(idname(p), hzidname(p), 'hz_thickness', 'hz_prop')
return(res)

# list output option with simplify=F, list names are profile_id(sp1)
list.output <- profileApply(sp1, thicknessFunction, simplify = FALSE)
head(list(output))

# data.frame output option with frameify=TRUE
df.output <- profileApply(sp1, thicknessFunction, frameify = TRUE)
head(df.output)

# since df.output contains idname(sp1) and hzidname(sp1),
# it can safely be merged by a left-join via horizons<- setter
horizons(sp1) <- df.output

plot(density(sp1$hz_thickness, na.rm=TRUE), main="Density plot of Horizon Thickness")

## iterate over profiles, subsetting horizon data

# example data
data(sp1)

# promote to SoilProfileCollection
depths(sp1) <- id ~ top + bottom
site(sp1) <- ~ group

# make some fake site data related to a depth of some importance
sp1$dep <- profileApply(sp1, function(i) {round(rnorm(n=1, mean=mean(i$top)))})

# custom function for subsetting horizon data, by profile
# keep horizons with lower boundary < site-level attribute 'dep'
fun <- function(i) {
  # extract horizons
  h <- horizons(i)
  # make an expression to subset horizons
  exp <- paste('bottom < ', i$dep, sep='')
  # subset horizons, and write-back into current SPC
  slot(i, 'horizons') <- subset(h, subset=eval(parse(text=exp)))
  # return modified SPC
  return(i)
}

# list of modified SoilProfileCollection objects
l <- profileApply(sp1, fun, simplify=FALSE)

# re-combine list of SoilProfileCollection objects into a single SoilProfileCollection
sp1.sub <- pbindlist(l)
# graphically check
par(mfrow=c(2,1), mar=c(0,0,1,0))
plot(sp1)
points(1:length(sp1), sp1$dep, col="red", pch=7)
plot(sp1.sub)

profileGroupLabels  

## Soil Profile Group Labels

Description

Labels groups of soil profiles within soil profile sketches.

See examples below for ideas.

Usage

```r
profileGroupLabels(
  x0, x1, labels, y0 = 100, y1 = 98,
  label.offset = 2, label.cex = 0.75
)
```

Arguments

- `x0`: integer indices to the first profile within each group
- `x1`: integer indices to the last profile within each group
- `labels`: vector of group labels
- `y0`: baseline depth used for group brackets
- `y1`: depth used for start and end markers for group brackets (see examples)
- `label.offset`: vertical offset of group labels from baseline
- `label.cex`: label size

Note

This function is typically called by some other convenience function such as `plotMultipleSPC`.

labels=c('Collection 1', 'Collection 2'), y0=120, y1=tick.heights)

profileInformationIndex

Soil Profile Information Index

Description

A simple index of "information" content associated with individuals in a SoilProfileCollection object. Information content is quantified by number of bytes after gzip compression via memCompress().
Usage

```r
profileInformationIndex(
  x,
  vars,
  method = c("median", "mean", "sum"),
  baseline = TRUE,
  useDepths = TRUE,
  numericDigits = 4
)
```

Arguments

- `x` SoilProfileCollection object
- `vars` character vector of site or horizon level attributes to consider
- `method` character: aggregation method, information content evaluated over `vars`: 'median', 'mean', or 'sum'
- `baseline` logical, compute ratio to "baseline" information content, see details
- `useDepths` logical, include horizon depths in `vars`
- `numericDigits` integer, number of significant digits to retain in numeric -> character conversion

Details

Information content via compression (gzip) is the central assumption behind this function: the values associated with a simple soil profile having few horizons and little variation between horizons (isotropic depth-functions) will compress to a much smaller size than a complex profile (many horizons, strong anisotropy). Information content is evaluated a profile at a time, over each site or horizon level attribute specified in `vars`. Values are aggregated to the profile level by `method`: median, mean, or sum. The `baseline` argument invokes a comparison to the simplest possible representation of each depth-function:

- **numeric**: replication of the mean value to match the number of horizons with non-NA values
- **character or factor**: replication of the most frequent value to match the number of horizons with non-NA values

The ratios computed against a "simple" baseline represent something like "information gain", ranging from 0 to 1. Larger baseline ratios suggest more complexity (more information) associated with a soil profile's depth-functions. Alternatively, the total quantity of information (in bytes) can be determined by setting `baseline = FALSE` and `method = 'sum'`.

Value

A numeric vector of the same length as `length(x)` and in the same order, suitable for direct assignment to a new site-level attribute

proj4string(obj) <- value
```

Arguments

- `obj` A SoilProfileCollection
- `value` A proj4string

random_profile Random Profile

Description

Generate a random soil profile according to set criteria, with correlated depth trends.

Usage

```r
random_profile(
    id,
    n = c(3, 4, 5, 6),
    min_thick = 5,
    max_thick = 30,
    n_prop = 5,
    exact = FALSE,
    method = "random_walk",
    HzDistinctSim = FALSE,
    SPC = FALSE,
    ...
)
```
Arguments

- **id**: a character or numeric id used for this profile
- **n**: vector of possible number of horizons, or the exact number of horizons (see below)
- **min_thick**: minimum thickness criteria for a simulated horizon
- **max_thick**: maximum thickness criteria for a simulated horizon
- **n_prop**: number of simulated soil properties (columns in the returned dataframe)
- **exact**: should the exact number of requested horizons be generated? (defaults to FALSE)
- **method**: named method used to synthesize depth function ('random_walk' or 'LPP'), see details
- **HzDistinctSim**: optionally simulate horizon boundary distinctness codes
- **SPC**: result is a SoilProfileCollection object, otherwise a data.frame object
- **...**: additional parameters passed-in to the LPP (.lpp) function

Details

The random walk method produces profiles with considerable variation between horizons and is based on values from the normal distribution seeded with means and standard deviations drawn from the uniform distribution of [0, 10].

The logistic power peak (LPP) function can be used to generate random soil property depth functions that are sharply peaked. LPP parameters can be hard-coded using the optional arguments: "lpp.a", "lpp.b", "lpp.u", "lpp.d", "lpp.e". Amplitude of the peak is controlled by ("lpp.a + "lpp.b"), depth of the peak by "lpp.u", and abruptness by "lpp.d" and "lpp.e". Further description of the method is outlined in (Brenton et al, 2011). Simulated horizon distinctness codes are based on the USDA-NCSS field description methods (https://www.nrcs.usda.gov/wps/portal/nrcs/detail/?cid=nrcs142p2_054184). Simulated distinctness codes are constrained according to horizon thickness, i.e. a gradual boundary (+/- 5cm) will not be simulated for horizons that are thinner than 3x this vertical distance

Value

A data.frame or SoilProfileCollection object.

Note

See examples for ideas on simulating several profiles at once.

**reorderHorizons**  
*Re-order corrupted horizon data*

**Description**

This is a method made available primarily to repair horizon data that have been corrupted relative to their order at time of SoilProfileCollection construction.

There is an option to specify the target order, but this will not update the corresponding metadata entry tracking the original order. Use this functionality at your own risk.

**Usage**

```r
## S4 method for signature 'SoilProfileCollection'
reorderHorizons(object, target.order = NULL)
```

**Arguments**

- `object` A SoilProfileCollection
- `target.order` A numeric vector of equal length to `object`. Default value is `NULL` which restores the internal order of the collection.

**Value**

SoilProfileCollection
repairMissingHzDepths  Repair Problematic Lower Horizon Depths

Description

Attempt a simple repair of horizon bottom depths in the presence of NA, or in cases where the horizon shares a common top and bottom depth. Both situations are common in pedon description where "contact" (Cd, Cr, R, etc.) was described without a lower depth.

Usage

repairMissingHzDepths(x, adj = 10, max.depth = 200)

Arguments

x SoilProfileCollection
adj vertical offset applied to "repair" missing bottom depths when top and bottom depth are equal or bottom depth is missing. (NA to use max.depth)
max.depth If adj is NA, or the resulting offset sum exceeds max.depth, max.depth is used.

Details

This repair is applied to the deepest horizon within a profile as identified by getLastHorizonID, as well as to bottom depths of any horizon that has a horizon below it. Horizon bottom depths are adjusted by adding adj (if non-NA). If the resulting value exceeds max.depth, the max.depth value is returned (if not NA).

Value

SoilProfileCollection with a new (logical) horizon-level attribute .repaired marking affected horizons

Examples

h <- data.frame(
    id = c(1, 1, 1, 2, 2, 2, 3, 3),
    top = c(0:2, 0:3, 0:1) * 10,
    bottom = c(rep(NA_integer_, 7), c(10, 99))
)

# NA depths result in warnings
suppressWarnings(
    depths(h) <- id - top + bottom
)

# inspect data before repairs
plot(h)
g <- repairMissingHzDepths(h)

# all depth logic now valid
all(checkHzDepthLogic(g)$valid)

# inspect
plot(g)

# no adj, max.depth only
f <- repairMissingHzDepths(h, adj = NA, max.depth = 200)
all(checkHzDepthLogic(f)$valid)
plot(f)

# max.depth defaults to max(x) if too small
f$bottom[c(3,7)] <- NA
d <- repairMissingHzDepths(f, adj = NA, max.depth = 20)
all(checkHzDepthLogic(d)$valid)
plot(d)

---

**replaceHorizons**<-

*Replace data in the horizon slot*

**Description**

Replaces horizon data with new data.frame object.

**Usage**

`replaceHorizons(object) <- value`

**Arguments**

- `object` A SoilProfileCollection
- `value` An object inheriting data.frame

**Examples**

# load test data
data(sp2)

# promote to SPC
depths(sp2) <- id ~ top + bottom

# one profile
p <- sp2[1,]

# 23 variables in horizon data
length(horizonNames(sp2))
# remove all but essential ones
replaceHorizons(p) <- horizons(p)[, c(idname(p), hzidname(p), horizonDepths(p))]

# inspect result (a clean slate)
horizons(p)

---

### restrictions, SoilProfileCollection-method

*Retrieves restriction data from SoilProfileCollection*

**Description**

Get restriction data from SoilProfileCollection. Result is returned in the same `data.frame` class used to initially construct the SoilProfileCollection.

**Usage**

```r
## S4 method for signature 'SoilProfileCollection'
restrictions(object)
```

**Arguments**

- `object` a `SoilProfileCollection`

---

### restrictions<-

*Add data to the restrictions slot*

**Description**

Restrictions data in an object inheriting from `data.frame` can easily be added via `merge` (LEFT JOIN). There must be one or more same-named profile ID columns on the left and right hand side to facilitate the join: `restrictions(spc) <- newdata`.

**Usage**

```r
restrictions(object) <- value
```

**Arguments**

- `object` A `SoilProfileCollection`
- `value` An object inheriting `data.frame`
Examples

```r
# load test data
data(sp2)

# promote to SPC
depths(sp2) <- id ~ top + bottom

# assign abrupt textural change to a profile
newdata <- data.frame(id = c("hon-21"),
                      restrkind = "abrupt textural change",
                      restrdep = 46)

# do left join
restrictions(sp2) <- newdata

# inspect site table: newvalue TRUE only for horizons
# with top depth equal to zero
restrictions(sp2)
```

---

**rgb2munsell**  
*sRGB to Munsell Color Conversion*

**Description**

Convert sRGB color coordinates to the closest n Munsell chips in the munsell lookup table.

**Usage**

```r
rgb2munsell(color, colorSpace = c("CIE2000", "LAB", "sRGB"), nClosest = 1)
```

**Arguments**

- `color`: a data.frame or matrix object containing sRGB coordinates in the range of (0,1)
- `colorSpace`: distance metric (colorspace) to use for finding the closest chip: CIE2000 is the most accurate but requires farver >= 2.0.3, Euclidean distance in CIELAB is a close second, while Euclidean distance in sRGB is not at all accurate and should only be used for demonstration purposes.
- `nClosest`: number of closest Munsell colors to return (valid range is 1-20)

**Value**

an (NA-padded) data.frame containing hue, value, chroma, and distance (dE00 when `colorSpace = ‘CIE2000’`, Euclidean distance otherwise) to nearest matching color.
Note

This function is fully vectorized and will pad output with NA-records when NA are present in color.

ROSETTA.centroids Average Hydraulic Parameters from the ROSETTA Model by USDA Soil Texture Class

Description

Average soil hydraulic parameters generated by the first stage predictions of the ROSETTA model by USDA soil texture class. These data were extracted from ROSETTA documentation and reformatted for ease of use.

Usage

data(ROSETTA.centroids)
ROSETTA.centroids

Format

A data frame:

- **texture**  soil texture class, ordered from low to high available water holding capacity
- **theta_r**  average saturated water content
- **theta_s**  average residual water content
- **alpha**  average value, related to the inverse of the air entry suction, log10-transformed values with units of cm
- **npar**  average value, index of pore size distribution, log10-transformed values with units of 1/cm
- **theta_r_sd**  1 standard deviation of theta_r
- **theta_s_sd**  1 standard deviation of theta_s
- **alpha_sd**  1 standard deviation of alpha
- **npar_sd**  1 standard deviation of npar
- **sat**  approximate volumetric water content at which soil material is saturated
- **fc**  approximate volumetric water content at which matrix potential = -33kPa
- **pwp**  approximate volumetric water content at which matrix potential = -1500kPa
- **awc**  approximate available water holding capacity: VWC(-33kPa)
  - VWC(-1500kPa)

Details

Theoretical water-retention parameters for uniform soil material of each texture class have been estimated via van Genuchten model.

See the related tutorial

rowley2019  

Soil Morphologic, Geochemical, and Mineralogy Data from Rowley et al. 2019.

Description

Data from Table 1 and Supplementary Tables 1 and 2 from "A cascading influence of calcium carbonate on the biogeochemistry and pedogenic trajectories of subalpine soils, Switzerland".
Usage

data(rowley2019)

Format

A SoilProfileCollection object:

  site-level attributes

  id  profile ID
  group  profile group

  horizon-level attributes

  sample_id  sample ID
  name  horizon name

  pH  pH
  Al_exch  cmol(+) / kg, exchangeable Al
  Ca_exch  cmol(+) / kg, exchangeable Ca
  CEC_sum  cmol(+) / kg, cation exchange capacity calculated as the sum of exchangeable cations, not including H+

  Ca_exch_saturation  percent
  Al_exch_saturation  percent
  TON  percent, total nitrogen
  SOC  percent, soil organic carbon
  C_to_N  carbon to nitrogen ratio
  Alo  g/kg, oxalate-extractable Al
  Feo  g/kg, oxalate-extractable Fe
  Ald  g/kg, dithionite-extractable Al
  Fed  g/kg, dithionite-extractable Fe
  Feo_Fed  Fe_o to Fe_d ratio

  id  profile ID

  top  horizon top (cm)
  bottom  horizon bottom (cm)

  Al  g/kg by x-ray fluorescence
  Ca  g/kg by x-ray fluorescence
  Cr  g/kg by x-ray fluorescence
  Fe  g/kg by x-ray fluorescence

### rruff.sample

#### Sample XRD Patterns

##### Description

Several sample XRD patterns from the RRUFF project site.

##### Usage

```r
data(rruff.sample)
```

##### Format

A data frame with 3000 observations on the following 8 variables.

- **twotheta**  twotheta values
- **nontronite**  XRD pattern for nontronite
- **montmorillonite**  XRD pattern for montmorillonite
clinoclore  XRD pattern for clinoclore
antigorite  XRD pattern for antigorite
chamosite  XRD pattern for chamosite
hematite  XRD pattern for hematite
goethite  XRD pattern for goethite

**segment**  

*Segmenting of Soil Horizon Data by Depth Interval*

**Description**

This function adds depth interval ("segment") labels to soil horizon data associated with SoilProfileCollection and data.frame objects. Additional horizon records are inserted when a segment label does not overlap with a horizon boundary. See examples.

**Usage**

`segment(object, intervals, trim = TRUE, hzdepcols = NULL)`

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object</td>
<td>either a SoilProfileCollection or data.frame</td>
</tr>
<tr>
<td>intervals</td>
<td>a vector of integers over which to slice the horizon data (e.g. c(25,100) or 25:100)</td>
</tr>
<tr>
<td>trim</td>
<td>logical, when TRUE horizons in object are truncated to the min/max specified in intervals. When FALSE, those horizons overlapping an interval are marked as such. Care should be taken when specifying more than one depth interval and trim = FALSE.</td>
</tr>
<tr>
<td>hzdepcols</td>
<td>a character vector of length 2 specifying the names of the horizon depths (e.g. c(&quot;hzdept&quot;,&quot;hzdepb&quot;)), only necessary if object is a data.frame.</td>
</tr>
</tbody>
</table>
Details

This function adds segment labels to soil horizon data according to intervals (e.g. c(25, 100) or 25:100). Compared to slice, slab, and glom, segment performs no aggregation or resampling of the source data, rather, labels are added to horizon records for subsequent aggregation. This makes it possible to process a very large number of records outside of the constraints associated with e.g. slice or slab.

Value

Either a SoilProfileCollection or data.frame with the original horizon data segmented by depth intervals. There are usually more records in the resulting object, one for each time a segment interval partially overlaps with a horizon. A new column called segment_id identifying the depth interval is added.

Author(s)

Stephen Roecker

Examples

```r
# example data
data(sp1)

# upgrade to SPC
depths(sp1) <- id ~ top + bottom

# segment and trim
z <- segment(sp1, intervals = c(0, 10, 20, 30), trim = TRUE)

# display segment labels
# note that there are new horizon boundaries at segments
par(mar = c(0, 0, 3, 1))
plotSPC(z, color = 'segment_id', width = 0.3)

# highlight new horizon records
par(mar = c(0, 0, 2, 1))
plotSPC(z, color = NA, default.color = NA, width = 0.3, lwd = 1)
plotSPC(sp1, color = NA, default.color = NA, width = 0.3, lwd = 3, add = TRUE, name = NA, print.id = FALSE)
legend('top', horiz = TRUE,
legend = c('original', 'segmented'),
lwd = c(1, 3), cex = 0.85, bty = 'n')

# same results as slab()
# 10 random profiles
s <- lapply(1:10, random_profile, n_prop = 1, SPC = TRUE, method = 'random_walk')
s <- combine(s)
a.slab <- slab(s, fm = ~ p1, slab.structure = c(0, 10, 20, 30), slab.fun = mean, na.rm = TRUE)
```
z <- segment(s, intervals = c(0, 10, 20, 30), trim = TRUE)
z <- horizons(z)
z$thick <- z$bottom - z$top

a.segment <- sapply(split(z, z$segment_id), function(i) {
  weighted.mean(i$p1, i$thick)
})

res <- data.frame(
  slab = a.slab$value,
  segment = a.segment,
  diff = a.slab$value - a.segment
)

print(res)
res$diff < 0.001

data(sp5)

# segment by upper 25-cm
test1 <- segment(sp5, intervals = c(0, 100))
print(test1)
nrow(test1)
print(object.size(test1), units = "Mb")

# segment by 1-cm increments
test2 <- segment(sp5, intervals = 0:100)
print(test2)
nrow(test2)
print(object.size(test2), units = "Mb")

# segment and aggregate

# segment and aggregate

# segment and aggregate

# segment and aggregate

test3 <- segment(horizons(sp5),
  intervals = c(0, 5, 15, 30, 60, 100, 200),
  hzdepcols = c("top", "bottom")
)
test3$hzthk <- test3$bottom - test3$top
test3_agg <- by(test3, test3$segment_id, function(x) {
  data.frame(
    hzID = x$hzID[1],
    segment_id = x$segment_id[1],
    average = weighted.mean(x$clay, w = x$hzthk)
  )
})
test3_agg <- do.call("rbind", test3_agg)

head(test3_agg)
**shannonEntropy**

**Shannon Entropy**

**Description**
A very simple implementation of Shannon entropy.

**Usage**
```
shannonEntropy(x, b = 2)
```

**Arguments**
- `x`: vector of probabilities (0,1), must sum to 1, should not contain NA
- `b`: logarithm base

**Details**
0s are automatically removed by `na.rm = TRUE`, as $0 \times \log(0) = \text{NaN}$

**Value**
A single numeric value.

**Note**
When $b = \text{length}(x)$ the result is the normalized Shannon entropy of (Kempen et al, 2009).

**References**

**Examples**
```
# a very simple example
p <- c(0.25, 0.25, 0.4, 0.05, 0.05)

shannonEntropy(p)
```
Description

Soil physical and chemical data associated with two bio-climatic sequences (granitic and andesitic parent material) from the western flank of the Sierra Nevada mountains.

Usage

data(sierraTransect)

Format

An object of class SoilProfileCollection of length 14.

Details

These data were assembled from Dahlgren et al. (1997) and Rasmussen et al. (2007), with permission granted by lead authors, by D.E. Beaudette.

Source

Original manuscripts and person communication with authors.

References

Examples

data(sierraTransect)

# tighter margins
op <- par(mar=c(0,0,0,0))

# quick sketch

# split by transect
par(mar=c(0,0,1,1))
DEPRECATED Simulate Soil Profiles

Description

Simulate a collection of soil profiles based on the horization of a single soil profile. Now deprecated: use `perturb()` for perturbations of horizon thicknesses or boundaries.
Usage

`sim(x, n = 1, iterations = 25, hz.sd = 2, min.thick = 2)`

Arguments

- **x**: a SoilProfileCollection object containing a single profile from which to draw simulated data
- **n**: the number of requested simulations
- **iterations**: sampling iterations used to determine each horizon thickness
- **hz.sd**: standard deviation used to simulate horizon thickness, can be a vector but must divide evenly into the number of horizons found in `x`
- **min.thick**: minimum horizon thickness allowed in simulation results

Details

This function generates a collection of simulated soil profiles based on the horizon thickness data associated with a single "template" profile. Simulation is based on sampling from a family of Gaussian distribution with means defined by the "template" profile and standard deviation defined by the user.

Value

A SoilProfileCollection object with `n` simulated profiles, each containing the same number of horizons and same data as `x`

Author(s)

D. E. Beaudette

See Also

`random_profile`, `perturb`

Examples

```r
# please see documentation for perturb() for examples
# the sim() function calls perturb() internally
```
**simulateColor**

*Simulate Soil Colors*

**Description**

Simulate plausible soil colors based on proportions by Munsell "chip", or using a seed Munsell chip and threshold specified via CIE2000 color contrast metric.

**Usage**

```r
simulateColor(method = c("dE00", "proportions"), n, parameters, SPC = NULL)
```

**Arguments**

- `method` : simulation method, see details
- `n` : number of simulated colors per horizon
- `parameters` : a list, format depends on method:
  - `proportions` : output from `aggregateColor`
  - `dE00` : formatted as `list(m = '7.5YR 3/3', thresh = 5, hues = c('7.5YR'))`

Where `m` is a single representative Munsell chip, `thresh` is a threshold specified in CIE2000 color contrast (dE00), and `hues` is a vector of allowed Munsell hues.

- `SPC` : `SoilProfileCollection`, attempt to modify `SPC` with simulated colors

**Value**

A list, unless `SPC` is specified, then a `SoilProfileCollection` object

**Author(s)**

D.E. Beaudette

**Examples**

```r
# m: representative or most likely color
# thresh: dE00 threshold
# hues: allowed Munsell hues

p <- list(
  'A' = list(m = '7.5YR 3/3', thresh = 5, hues = c('7.5YR')),
  'BA' = list(m = '7.5YR 4/4', thresh = 8, hues = c('7.5YR')),
  'Bt1' = list(m = '5YR 4/4', thresh = 8, hues = c('5YR', '7.5YR')),
  'Bt2' = list(m = '5YR 4/5', thresh = 8, hues = c('5YR', '7.5YR')),
  'Bt3' = list(m = '10YR 4/6', thresh = 10, hues = c('10YR', '7.5YR')),
  'Cr' = list(m = '2.5G 6/2', thresh = 15, hues = c('2.5G', '2.5GY', '2.5BG'))
)
```

# simulate
(cols <- simulateColor(method = 'dE00', n = 10, parameters = p))

# preview
previewColors(parseMunsell(unlist(cols)), method = 'MDS')

# another example, this time using a larger dE00 threshold
p <- list('A' = list(m = '7.5YR 3/3', thresh = 20, hues = c('10YR', '7.5YR', '5YR')))

# simulate
set.seed(54654)
cols <- simulateColor(method = 'dE00', n = 200, parameters = p)

# flatten
cols <- unlist(cols)

# tabulate, sort: most frequent color should be 7.5YR 3/3
sort(table(cols), decreasing = TRUE)

# review colors
previewColors(parseMunsell(cols))

# what does a dE00 threshold look like on 3 pages of hue?
contrastChart('7.5YR 3/3', hues = c('10YR', '7.5YR', '5YR'), thresh = 20)

---

**site,SoilProfileCollection-method**

*Retrieve site data from SoilProfileCollection*

**Description**

Get site data from SoilProfileCollection. Result is returned in the same data.frame class used to initially construct the SoilProfileCollection.

There are two options available via the site<- setter.

The first is a "normalization" by formula interface, whereby one specifies an attribute that is constant in horizons within profiles to be promoted to a site-level variable: site(spc) <-~ horizonvariable

The second is creation of site data from an external data.frame via merge (LEFT JOIN). There must be one or more same-named columns (with at least some matching data) on the left and right hand side to facilitate the join: site(spc) <-newdata

**Usage**

```r
## S4 method for signature 'SoilProfileCollection'
site(object)

site(object) <- value
```
Arguments

object A SoilProfileCollection
value A formula or object inheriting data.frame

Examples

# load test data
data(sp2)

# promote to SPC
depths(sp2) <- id ~ top + bottom

# normalize a horizon-level attribute to site
site(sp2) <- ~ surface

# inspect site table
site(sp2)

# make some data: classify two geomorphic surfaces with numeric value
newdata <- data.frame(surface = c("holocene", "lower riverbank"),
                      newvalue = c(1,2))

# do left join based on newly-normalized "surface" attribute
site(sp2) <- newdata

# inspect site table: holocene & lower riverbank have values
site(sp2)

sitenames<-  

Set site column names

Description

Set site column names

Get names of columns in site table.

Usage

sitenames(object) <- value

## S4 method for signature 'SoilProfileCollection'
sitenames(object)
slab-methods

Slab-Wise Aggregation of SoilProfileCollection Objects

Description

Aggregate soil properties along user-defined slabs, and optionally within groups.

Usage

## S4 method for signature 'SoilProfileCollection'
slab(
  object,
  fm,
  slab.structure = 1,
  strict = FALSE,
  slab.fun = .slab.fun.numeric.default,
  cpm = 1,
  weights = NULL,
  ...
)

Arguments

- **object**: a SoilProfileCollection
- **fm**: A formula: either groups ~ var1 + var2 + var3' where named variables are aggregated within groups' OR where named variables are aggregated across the entire collection ~ var1 + var2 + var3'. If groups' is a factor it must not contain NA.
- **slab.structure**: A user-defined slab thickness (defined by an integer), or user-defined structure (numeric vector). See details below.
- **strict**: logical: should horizons be strictly checked for self-consistency?
- **slab.fun**: Function used to process each 'slab' of data, ideally returning a vector with names attribute. Defaults to a wrapper function around stats::quantile. See details.
- **cpm**: Strategy for normalizing slice-wise probabilities, dividing by either: number of profiles with data at the current slice (cpm=1), or by the number of profiles in the collection (cpm=2). Mode 1 values will always sum to the contributing fraction, while mode 2 values will always sum to 1.
- **weights**: Column name containing weights. NOT YET IMPLEMENTED
- **...**: further arguments passed to slab.fun
Details

Multiple continuous variables OR a single categorical (factor) variable can be aggregated within a call to slab. Basic error checking is performed to make sure that top and bottom horizon boundaries make sense. User-defined aggregate functions (slab.fun) should return a named vector of results. A new, named column will appear in the results of slab for every named element of a vector returned by slab.fun. See examples below for a simple example of a slab function that computes mean, mean-1SD and mean+1SD. The default slab function wraps stats::quantile from the Hmisc package, which requires at least 2 observations per chunk. Note that if group is a factor it must not contain NAs.

Sometimes slab is used to conveniently re-arrange data vs. aggregate. This is performed by specifying identity in slab.fun. See examples below for a demonstration of this functionality.

The default slab.fun was changed 2019-10-30 from a wrapper around Hmisc::hdquantile to a wrapper around stats::quantile. See examples below for a simple way to switch to the HD quantile estimator.

Execution time scales linearly (slower) with the total number of profiles in object, and exponentially (faster) as the number of profiles / group is increased. slab and slice are much faster and require less memory if input data are either numeric or character.

There are several possible ways to define slabs, using slab.structure:

- a single integer e.g. 10: data are aggregated over a regular sequence of 10-unit thickness slabs
- a vector of 2 integers e.g. c(50, 60): data are aggregated over depths spanning 50–60 units
- a vector of 3 or more integers e.g. c(0, 5, 10, 50, 100): data are aggregated over the depths spanning 0–5, 5–10, 10–50, 50–100 units

Value

Output is returned in long format, such that slice-wise aggregates are returned once for each combination of grouping level (optional), variable described in the fm argument, and depth-wise ‘slab’.

Aggregation of numeric variables, using the default slab function:

- variable The names of variables included in the call to slab.
- groupname The name of the grouping variable when provided, otherwise a fake grouping variable named ‘all.profiles’.
- p.q5 The slice-wise 5th percentile.
- p.q25 The slice-wise 25th percentile
- p.q50 The slice-wise 50th percentile (median)
- p.q75 The slice-wise 75th percentile
- p.q95 The slice-wise 95th percentile
- top The slab top boundary.
- bottom The slab bottom boundary.
- contributing_fraction The fraction of profiles contributing to the aggregate value, ranges from 1/n_profiles to 1.

When a single factor variable is used, slice-wise probabilities for each level of that factor are returned as:
variable The names of variables included in the call to slab.

groupname The name of the grouping variable when provided, otherwise a fake grouping variable named 'all.profiles'.

A The slice-wise probability of level A
B The slice-wise probability of level B

list() n The slice-wise probability of level n
top The slab top boundary.
bottom The slab bottom boundary.

contributing_fraction The fraction of profiles contributing to the aggregate value, ranges from 1/n_profiles to 1.

Methods
data = "SoilProfileCollection" Typical usage, where input is a SoilProfileCollection.

Note
Arguments to slab have changed with aqp 1.5 (2012-12-29) as part of a code clean-up and optimization. Calculation of weighted-summaries was broken in aqp 1.2-6 (2012-06-26), and removed as of aqp 1.5 (2012-12-29). slab replaced the previously defined soil.slot.multiple function as of aqp 0.98-8.58 (2011-12-21).

Slicing of SoilProfileCollection Objects

Description

Slicing of SoilProfileCollection Objects

Usage

slice.fast(object, fm, top.down = TRUE, just.the.data = FALSE, strict = TRUE)

Arguments

- object: a SoilProfileCollection
- fm: A formula: either integer.vector ~ var1 + var2 + var3 where named variables are sliced according to integer.vector OR where all variables are sliced according to integer.vector: integer.vector ~ .
- top.down: logical, slices are defined from the top-down: 0:10 implies 0-11 depth units.
- just.the.data: Logical, return just the sliced data or a new SoilProfileCollection object.
- strict: Logical, should the horizonation be strictly checked for self-consistency?

Value

Either a new SoilProfileCollection with data sliced according to fm, or a data.frame.

Details

By default, slices are defined from the top-down: 0:10 implies 0-11 depth units.

Note

slab() and slice() are much faster and require less memory if input data are either numeric or character.

Examples

```r
library(aqp)

# simulate some data, IDs are 1:20
d <- lapply(1:20, random_profile)
d <- do.call('rbind', d)

# init SoilProfileCollection object
depths(d) <- id ~ top + bottom
head(horizons(d))

# generate single slice at 10 cm
# output is a SoilProfileCollection object
s <- slice(d, 10 ~ name + p1 + p2 + p3)

# generate single slice at 10 cm, output data.frame
s <- slice(d, 10 ~ name + p1 + p2 + p3, just.the.data=TRUE)

# generate integer slices from 0 - 26 cm
# note that slices are specified by default as "top-down"
# e.g. the lower depth will always by top + 1
s <- slice(d, 0:25 ~ name + p1 + p2 + p3)

par(mar=c(0,1,0,1))
plot(s)

# generate slices from 0 - 11 cm, for all variables
s <- slice(d, 0:10 ~ .)
print(s)

# note that pct missing is computed for each slice,
# if all vars are missing, then NA is returned
d$p1[1:10] <- NA
s <- slice(d, 10 ~ ., just.the.data=TRUE)
print(s)

## Not run:
##
## check sliced data

## test that mean of 1 cm slices property is equal to the
## hz-thickness weighted mean value of that property
data(sp1)
depths(sp1) <- id ~ top + bottom

# get the first profile
sp1.sub <- sp1[which(profile_id(sp1) == 'P009'), ]

# compute hz-thickness wt. mean
hz.wt.mean <- with(horizons(sp1.sub),
```
slicedHSD

Tukey's HSD Over Slices

Description

Apply Tukey’s HSD over 1-unit depth slices.

Usage

slicedHSD(object, fm, conf = 0.95)

Arguments

object SoilProfileCollection object

fm  a formula describing depth sequence, horizon attribute, and site (grouping) attribute. For example 0:100 ~ estimated_oc | taxonname

conf confidence applied in TukeyHSD

Author(s)

D.E. Beaudette and Sharon Perrone

soilColorSignature Soil Profile Color Signatures

Description

Generate a color signature for each soil profile in a collection.
Usage

soilColorSignature(
  spc, 
  r = "r",
  g = "g",
  b = "b",
  method = "colorBucket",
  pam.k = 3,
  RescaleLightnessBy = 1,
  useProportions = TRUE,
  pigmentNames = c(".white.pigment", ".red.pigment", ".green.pigment",
                   ".yellow.pigment", ".blue.pigment")
)

Arguments

spc a SoilProfileCollection object
r horizon level attribute containing soil color (sRGB) red values
g horizon level attribute containing soil color (sRGB) green values
b horizon level attribute containing soil color (sRGB) blue values
method algorithm used to compute color signature, colorBucket, depthSlices, or pam
pam.k number of classes to request from cluster::pam()
RescaleLightnessBy rescaling factor for CIE LAB L-coordinate
useProportions use proportions or quantities, see details
pigmentNames names for resulting pigment proportions or quantities

Details

See the related tutorial.

Value

For the colorBucket method, a data.frame object containing:
• id column: set according to idname(spc)
• .white.pigment: proportion or quantity of CIE LAB L-values
• .red.pigment: proportion or quantity of CIE LAB positive A-values
• .green.pigment: proportion or quantity of CIE LAB negative A-values
• .yellow.pigment: proportion or quantity of CIE LAB positive B-values
• .blue.pigment: proportion or quantity of CIE LAB negative B-values

Column names can be adjusted with the pigmentNames argument.

For the depthSlices method ...

For the pam method ...

soilPalette  Soil Color Palette

Description

A very simple function for generating labeled swatches of soil colors. Largely based on colorspace::swatchplot.

Usage

soilPalette(
  colors,
  lab = colors,
  lab.cex = 0.75,
  dynamic.labels = TRUE,
  x.inset = 0.01,
  y.inset = 0.01,
  ...
)

SoilProfileCollection

An S4 object representation of a group of soil profiles.

Description

In general, one should use depths() to initiate a SoilProfileCollection object from data. However, sometimes there are instances where either an empty, or very specific, object is needed. If that is the case, the general constructor SoilProfileCollection is available.

Arguments

- **colors**: vector of hex colors (e.g. #A6E46FF)
- **lab**: vector of labels
- **lab.cex**: character scaling for labels
- **dynamic.labels**: logical, adjust label colors for maximum contrast via invertLabelColor
- **x.inset**: horizontal adjustment for labels
- **y.inset**: vertical adjustment for labels
- **...**: further arguments to colorspace::swatchplot

Note

The result is a simple figure on the active plotting device.

Author(s)

D.E. Beaudette

Examples

```r
# maybe useful for teaching about soil color
par(mfrow=c(2,1), mar=c(1,1,1,1))

# demonstrate range of Munsell value
m <- sprintf("'10YR %s/4'", 2:8)
# convert to hex representation
cols <- parseMunsell(m)
# plot
soilPalette(cols, m)

# demonstrate range of Munsell chroma
m <- sprintf("'10YR 4/%s'", 2:8)
# convert to hex representation
cols <- parseMunsell(m)
# plot
soilPalette(cols, m)
```
SoilProfileCollection

Usage

SoilProfileCollection(
  idcol = "id",
  hzidcol = "hzID",
  depthcols = c("top", "bottom"),
  metadata = list(aqp_df_class = "data.frame", aqp_group_by = "", aqp_hzdesgn = "", aqp_hztext = "", stringsAsFactors = FALSE),
  horizons = data.frame(id = character(0), hzID = character(0), top = numeric(0), bottom = numeric(0), stringsAsFactors = FALSE),
  site = data.frame(id = character(0), stringsAsFactors = FALSE),
  sp = new("SpatialPoints"),
  diagnostic = data.frame(stringsAsFactors = FALSE),
  restrictions = data.frame(stringsAsFactors = FALSE)
)

Arguments

idcol  character Profile ID Column Name
hzidcol character Horizon ID Column Name
depthcols character, length 2 Top and Bottom Depth Column Names
metadata list, metadata including data.frame class in use and depth units
horizons data.frame An object inheriting from data.frame containing Horizon data.
site data.frame An object inheriting from data.frame containing Site data.
sp SpatialPoints A SpatialPoints object. Generally initialized with coordinates(spc) <- ~ x + y.
diagnostic data.frame An object inheriting from data.frame containing diagnostic feature data. Must contain profile ID. See diagnostic_hz()
restrictions data.frame An object inheriting from data.frame containing restrictive feature data. Must contain profile ID. See restrictions()

Slots

idcol character.
hzidcol character.
depthcols character.
metadata list.
horizons data.frame.
site data.frame.
sp SpatialPoints.
diagnostic data.frame.
restrictions data.frame.

**soiltexture**  

*Lookup tables for sand, silt, clay, texture class, and textural modifiers.*

**Description**

A list that contains a snapshot of the values generated using the logic from the particle size estimator calculation in NASIS, the average values per texture class, and average rock fragment values by textural modifier.

A list that contains a snapshot of the values generated using the logic from the particle size estimator calculation in NASIS, the average values per texture class, and average rock fragment values by textural modifier.
Format

A list with 3 data frames. The first named values which contains values for sand, silt and clay by texture class. The second with average values for sand, silt and clay per texture class. The third has fragvol, low, rv and high values for texmod.

- `list("clay")` clay percentage of the fine earth fraction, a integer vector
- `list("sand")` sand percentage of the fine earth fraction, a integer vector
- `list("silt")` silt percentage of the fine earth fraction, a integer vector
- `list("texcl")` texture class, a character vector
- `list("texmod")` textural modifiers, a character vector

SoilTextureLevels  

**Ranking Systems for USDS Soil Texture Classes**

**Description**

Generate a vector of USDA soil texture codes or class names, sorted according to approximate particle size

**Usage**

`SoilTextureLevels(which = "codes")`

**Arguments**

- `which` 'codes' (texture codes) or 'names' (texture class names)
soil_minerals

Value
    an ordered factor

References
    Field Book for Describing and Sampling Soils, version 3.0

Examples

    # class codes
    SoilTextureLevels()

    # class names
    SoilTextureLevels(which = 'names')

soil_minerals    Munsell Colors of Common Soil Minerals

Description
    Munsell colors for some common soil minerals.

Usage
    data(soil_minerals)

Format
    A data frame with 20 observations on the following 5 variables.

    mineral mineral name
    color Munsell color
    hue Munsell hue
    value Munsell value
    chroma Munsell chroma

Details
    Soil color and other properties including texture, structure, and consistence are used to distinguish
    and identify soil horizons (layers) and to group soils according to the soil classification system
called Soil Taxonomy. Color development and distribution of color within a soil profile are part of
weathering. As rocks containing iron or manganese weather, the elements oxidize. Iron forms small
 crystals with a yellow or red color, organic matter decomposes into black humus, and manganese
forms black mineral deposits. These pigments paint the soil (Michigan State Soil). Color is also
affected by the environment: aerobic environments produce sweeping vistas of uniform or subtly
changing color, and anaerobic (lacking oxygen), wet environments disrupt color flow with complex, often intriguing patterns and points of accent. With depth below the soil surface, colors usually become lighter, yellower, or redder.

sp1                  Soil Profile Data Example 1

Description

Soil profile data from Pinnacles National Monument, CA.

Format

A data frame with 60 observations on the following 21 variables.

- **group** a numeric vector
- **id** a character vector
- **top** a numeric vector
- **bottom** a numeric vector
- **bound_distinct** a character vector
- **bound_topography** a character vector
- **name** a character vector
- **texture** a character vector
- **prop** a numeric vector
- **structure_grade** a character vector
- **structure_size** a character vector
- **structure_type** a character vector
- **stickiness** a character vector
- **plasticity** a character vector
- **field_ph** a numeric vector
- **hue** a character vector
- **value** a numeric vector
- **chroma** a numeric vector

Honcut Creek Soil Profile Data

Description

A collection of 18 soil profiles, consisting of select soil morphologic attributes, associated with a stratigraphic study conducted near Honcut Creek, California.

Format

A data frame with 154 observations on the following 21 variables.

- **id**: profile id
- **surface**: dated surface
top  horizon top in cm
bottom horizon bottom in cm
bound_distinct  horizon lower boundary distinctness class
bound_topography horizon lower boundary topography class
name horizon name
texture USDA soil texture class
prop field-estimated clay content
structure_grade soil structure grade
structure_size soil structure size
structure_type soil structure type
stickiness stickiness
plasticity plasticity
field_ph field-measured pH
hue Munsell hue
value Munsell value
chroma Munsell chroma
r RGB red component
g RGB green component
b RGB blue component
soil_color R-friendly encoding of soil color

**Description**

Soil samples from 10 soil profiles, taken from the Sierra Foothill Region of California.

**Format**

A data frame with 46 observations on the following 15 variables.

<table>
<thead>
<tr>
<th>id</th>
<th>soil id</th>
</tr>
</thead>
<tbody>
<tr>
<td>top</td>
<td>horizon upper boundary (cm)</td>
</tr>
<tr>
<td>bottom</td>
<td>horizon lower boundary (cm)</td>
</tr>
</tbody>
</table>
clay  clay content
ccec  CEC by ammonium acetate at pH 7
ph  pH in 1:1 water-soil mixture
tc  total carbon percent
hue  Munsell hue (dry)
value  Munsell value (dry)
chroma  Munsell chroma (dry)
mid  horizon midpoint (cm)
ln_tc  natural log of total carbon percent
L  color: l-coordinate, CIE-LAB colorspace (dry)
A  color: a-coordinate, CIE-LAB colorspace (dry)
B  color: b-coordinate, CIE-LAB colorspace (dry)
name  horizon name
soil_color  horizon color

Details
These data were collected to support research funded by the Kearney Foundation of Soil Science.

Soil Chemical Data from Serpentinitic Soils of California

Description

Soil Chemical Data from Serpentinitic Soils of California

Format

A data frame with 30 observations on the following 13 variables.

id site name
name horizon designation
top horizon top boundary in cm
bottom horizon bottom boundary in cm
K exchangeable K in cmol/kg
Mg exchangeable Mg in cmol/kg
Ca exchangeable Ca in cmol/kg
CEC_7 cation exchange capacity (NH4OAc at pH 7)
ex_Ca_to_Mg extractable Ca:Mg ratio
sand sand content by weight percentage
silt silt content by weight percentage
clay clay content by weight percentage
CF >2mm fraction by volume percentage

Details
Selected soil physical and chemical data from (McGahan et al., 2009).

Soil Physical and Chemical Data from Manganiferous Soils

Description

Soil Physical and Chemical Data from Manganiferous Soils (Bourgault and Rabenhorst, 2011)

Format

A data frame with 30 observations on the following 13 variables.

- **id** pedon name
- **name** horizon designation
- **top** horizon top boundary in cm
- **bottom** horizon bottom boundary in cm
- **color** moist soil color in Munsell notation
- **texture** USDA soil texture class
- **sand** sand content by weight percentage
- **silt** silt content by weight percentage
- **clay** clay content by weight percentage
Fe  DCB-extracted Fe in g/kg (see citation)
Mn  DCB-extracted Mn in g/kg (see citation)
C   total organic carbon as g/kg
pH  measured in 1:1 H2O slurry
Db  bulk density (g/cc), clod method

Details

Selected soil physical and chemical data from (Bourgault and Rabenhorst, 2011).

Examples

# setup environment
library(aqp)
data(sp6)

# init SPC
depths(sp6) <- id ~ top + bottom
# convert non-standard Munsell colors
sp6$soil_color <- getClosestMunsellChip(sp6$color)

# profile sketches
par(mar=c(0,0,3,0))
plot(sp6, color='soil_color')
plot(sp6, color='Mn')
plot(sp6, color='Fe')
plot(sp6, color='pH')
plot(sp6, color='texture')
Description

Facilitate safe use of just about any numeric SPC horizon attribute, from any SPC, with mpspline2::mpspline. Currently only works with a single attribute. This function will automatically filter profiles with NA in attribute of interest which may be more conservative filtering than you expect. The intention here is that a SPC of related profile instances could be splined, and then the spline results aggregated over the full interval where data was available.

Data completeness is assessed and the input SPC is filtered and truncated to create a container for the 1cm results from mpspline2::mpspline.

Usage

## S4 method for signature 'SoilProfileCollection'
spc2mpspline(
  object,
  var_name = NULL,
  pattern = "R|Cr|Cd|qm",
  hzdesgn = guessHzDesgnName(object),
  ...
)

Arguments

- **object**: A SoilProfileCollection
- **var_name**: Column name in @horizons slot of object containing numeric values to spline
- **pattern**: Regex pattern to match for bottom of profile (passed to estimateSoilDepth) default: "R|Cr|Cd|qm"
- **hzdesgn**: Column name in @horizons slot of object containing horizon designations default: aqp::guessHzDesgnName(object, required = TRUE)
- **...**: Additional arguments to mpspline2::mpspline

Value

A SoilProfileCollection with 1cm slices. Spline variables are in columns prefixed with "spline_" and RMSE/RMSE_IQR are in columns prefixed with "rmse_". If any profiles were removed from the collection, their profile IDs are stored in attr(result, 'removed').

Author(s)

Andrew G. Brown

Examples

```r
data(sp1)
depths(sp1) <- id ~ top + bottom

res <- spc2mpspline(sp1, "prop")```
spc_in_sync

```r
plotSPC(res[1:5,], color = "prop_spline", divide.hz = FALSE)
```

---

**spc_in_sync**

*Quickly assess relative state of site and horizon slots*

**Description**

Determine "state" of SoilProfileCollection before or after major modifications of site or horizon slot contents.

Two logical checks are performed on the site and horizon tables, and a third element valid returns TRUE when both checks are TRUE.

Check 1: Same number of sites in site as number of sites in horizons. No intermingling of IDs, no orphan horizons, no sites without horizons (for now)

Check 2: Site IDs match coalesced profile ID from horizons. Ensures the same relative ordering, but horizons still may be out of order within profiles

**Usage**

```r
spc_in_sync(object)
```

**Arguments**

- `object` A SoilProfileCollection

**Value**

data.frame

**Author(s)**

Andrew G. Brown

data(sp5)

```r
spc_in_sync(sp5)
```
spec2Munsell

Convert reflectance spectra to closest Munsell chip

Description

Convert reflectance spectra to closest Munsell chip

Usage

spec2Munsell(
  x,
  convert = TRUE,
  SO = c("CIE1931", "CIE1964"),
  illuminant = c("D65", "F2"),
  ...
)

Arguments

x reflectance spectra, (380nm to 730nm, 10nm resolution)
convert logical, convert sRGB coordinates to closest Munsell chip (see ?munsell)
SO CIE standard observer: these are the color matching functions defined by CIE and used to represent "average" human color perception. CIE1931 is the 2 degree standard observer more useful for describing color perception over very small areas or at distance. CIE1964 is the 10 degree standard observer, used for most industrial color matching applications.
illuminant CIE standard illuminants:
  • D65 represents average daylight
  • F2 represents typical fluorescent lighting
...
further arguments to rgb2munsell

Value

output from rgb2munsell

References

Examples

```r
# Munsell reference spectra
data("munsell.spectra.wide")

# convert to closest Munsell chip
# sRGB -> Munsell conversion via rgb2Munsell()
spec2Munsell(munsell.spectra.wide[, '10YR 3/3'])

# attempt several
cols <- c('10YR 6/2', '5YR 5/6', '10B 4/4', '5G 4/4', '2.5Y 8/2', '10YR 3/3')

# most are exact or very close
z <- do.call('rbind', lapply(cols, function(i) {
spec2Munsell(munsell.spectra.wide[, i])
}))

# format Munsell notation from pieces
z$m <- sprintf("%s %s/%s", z$hue, z$value, z$chroma)

# compare
colorContrastPlot(
m1 = cols,
m2 = z$m,
labels = c('original', 'spectral\ninterpretation')
)

# mix colors, return spectra, convert to color
cols <- c('10YR 6/2', '5YR 5/6', '10B 4/4')
res <- mixMunsell(cols, keepMixedSpec = TRUE, mixingMethod = 'reference')

# note that they are slightly different
res$mixed
spec2Munsell(res$spec)
```

spectral.reference  

**Standard Illuminants and Observers**

**Description**

D65 and F2 standard illuminant spectral power distributions, CIE1931 Standard Observer (2 degree), and CIE1964 Supplemental Standard Observer (10 degree)

**Usage**

data(spectral.reference)
spectral.reference

Format
An object of class data.frame with 71 rows and 9 columns.

References

Examples
data("spectral.reference")

)

split,SoilProfileCollection-method

\textit{Split a SoilProfileCollection object into a list of SoilProfileCollection objects.}

\textbf{Description}

This function splits a SoilProfileCollection into a list of SoilProfileCollection objects using a site-level attribute to define groups or profile ID (idname(x)).

\textbf{Usage}

## S4 method for signature 'SoilProfileCollection'
split(x, f, drop = TRUE, ...)

\textbf{Arguments}

\begin{itemize}
  \item \textbf{x} \hspace{1cm} a SoilProfileCollection object
  \item \textbf{f} \hspace{1cm} a character vector naming a single site-level attribute that defines groups, a `factor` in the sense that \texttt{as.factor(f)} defines the grouping, or a list of such factors in which case their interaction is used for the grouping.
  \item \textbf{drop} \hspace{1cm} logical indicating if levels that do not occur should be dropped (if \texttt{f} is a factor or a list).
  \item \ldots \hspace{1cm} Additional arguments are ignored
\end{itemize}

\textbf{Details}

As of aqp 1.25, omission of \texttt{f} argument is no longer possible, as the base R generic is overloaded by this SoilProfileCollection method. This used to result in an "identity" split, according to \texttt{idname(x)}, e.g. a list as long as \texttt{length(x)}, with a single-profile SoilProfileCollection per list element. Replicate this behavior using \texttt{f = idname(x)} or \texttt{f = profile_id(x)}.
splitLogicErrors

Value

A list of SoilProfileCollections or NULL for empty result.

Author(s)

D.E Beaudette

Examples

```r
data(sp2)
depths(sp2) <- id ~ top + bottom

# add a more interesting site-level attribute
site(sp2) <- ~ surface

# using identity site-level attribute (profile ID)
p1 <- split(sp2, f = idname(sp2))
names(p1)
length(p1)

# using vector equal in length to number of profiles (profile ID, again)
p2 <- split(sp2, f = profile_id(sp2))
names(p2)
length(p2)

# which are both equivalent to setting 'f' to NULL
p3 <- split(sp2, f = NULL)
names(p3)
length(p3)

# split on surface (age) site-level var
p4 <- split(sp2, f = "surface")
names(p4)
length(p4) # 5 unique "surfaces", 5 SPCs in result list
```

splitLogicErrors

Split a SoilProfileCollection into a list based on types of horizon logic errors

Description

Uses checkHzDepthLogic to identify presence of depth logic errors, same depths, missing depths, and overlaps/gaps between the horizons of each profile in a SoilProfileCollection.

Usage

```r
splitLogicErrors(object, interact = FALSE, ...)
```
subApply

Subset SPC based on result of performing function on each profile

Description

subApply() is a function used for subsetting SoilProfileCollections. It currently does NOT support for "tidy" lexical features in the ... arguments passed to profileApply(). The expectation is that the function .fun takes a single-profile SoilProfileCollection and returns a logical value of length one. The use case would be for any logical comparisons that cannot be evaluated inline by subSPC() because they require more than simple logical operations.

Usage

subApply(object, .fun, ...)

Arguments

object A SoilProfileCollection
interact Calculate interaction between the four logic errors for groups? Default: FALSE always returns 4 groups, one for each logic error type.
... Additional arguments to split.default, called when interact = TRUE

Value

A named list of SoilProfileCollections (or NULL), with names: "depthLogic", "sameDepth", "missingDepth", "overlapOrGap". If interact = TRUE then the list elements groups determined by interaction() of the error types.

Examples

data(sp4)
depths(sp4) <- id ~ top + bottom

# no errors (all four list elements return NULL)
splitLogicErrors(sp4)

# NA in top depth triggers depth logic and missing depth errors
data(sp4)
sp4$top[1] <- NA
depths(sp4) <- id ~ top + bottom

splitLogicErrors(sp4)

# interact = TRUE gets errors for profile 1 in same group
# and allows you to pass extra arguments to split.default()
splitLogicErrors(sp4, interact = TRUE, sep = "_", drop = TRUE)
Arguments

- **object**: A SoilProfileCollection
- **.fun**: A function that takes a single profile, returns *logical* of length 1.
- **...**: Additional arguments are passed to `.fun`

Value

A SoilProfileCollection.

Author(s)

Andrew G. Brown.

Description

`subset()` is a function used for extracting profiles from a SoilProfileCollection based on logical criteria. It allows the user to specify an arbitrary number of logical vectors (equal in length to site or horizon), separated by commas. The function includes some support for non-standard evaluation.

Usage

```r
## S4 method for signature 'SoilProfileCollection'
subset(x, ..., greedy = FALSE)
```

Arguments

- **x**: A SoilProfileCollection
- **...**: Comma-separated set of R expressions that evaluate as TRUE or FALSE. Length for individual expressions matches number of sites OR number of horizons, in `object`.
- **greedy**: Use "greedy" matching for combination of site and horizon level matches? `greedy = TRUE` is the union, whereas `greedy = FALSE` (default) is the intersection (of site and horizon matches).

Details

To minimize likelihood of issues with non-standard evaluation context, especially when using `subset()` inside another function, all expressions used in `...` should be in terms of variables that are in the site or horizon data frame.

Value

A SoilProfileCollection.
**Author(s)**
Andrew G. Brown.

---

**subsetHz,SoilProfileCollection-method**

*Subset the horizons in a SoilProfileCollection using logical criteria*

**Description**

`subsetHz()` is a function used for extracting horizons from a SoilProfileCollection based on logical criteria.

**Usage**

```r
## S4 method for signature 'SoilProfileCollection'
subsetHz(x, ...)
```

**Arguments**

- `x`: a SoilProfileCollection
- `...`: Comma-separated set of R expressions that evaluate as TRUE or FALSE in context of horizon data frame. Length for individual expressions matches number of horizons, in `x`.

**Details**

To minimize likelihood of issues with non-standard evaluation context, especially when using `subsetHz()` inside another function, all expressions used in `...` should be in terms of variables that are in the horizon data frame.

**Value**

a SoilProfileCollection with a subset of horizons, possibly with some sites removed

**Examples**

```r
data(sp3)
depths(sp3) <- id ~ top + bottom

# show just horizons with 10YR hues
plot(subsetHz(sp3, hue == '10YR'))
```
subsetProfiles  

DEPRECATED use subset

Description

This function is used to subset SoilProfileCollection objects using either site-level or horizon-
level attributes, or both.

Usage

## S4 method for signature 'SoilProfileCollection'
subsetProfiles(object, s, h, ...)

Arguments

- **object**: object
- **s**: fully-quoted search criteria for matching via site-level attributes
- **h**: fully-quoted search criteria for matching via horizon-level attributes
- **...**: not used

Details

The `s` argument supplies a fully-quoted search criteria for matching via site or horizon-level at-
tributes. The `h` argument supplies a fully-quoted search criteria for matching via horizon-level
attributes. All horizons associated with a single horizon-level match (i.e. out of several, only a
single horizon matches the search criteria) are returned. See examples for usage.

Value

A SoilProfileCollection class object.

Examples

# more interesting sample data
data(sp2)
depths(sp2) <- id ~ top + bottom
site(sp2) <- ~ surface

# subset by integer index, note that this does not re-order the profiles
plot(sp2[1:5, ])

# generate an integer index via pattern-matching
idx <- grep('modesto', sp2$surface, ignore.case=TRUE)
plot(sp2[idx, ])

# generate in index via profileApply:
# subset those profiles where: min(ph) < 5.6
idx <- which(profileApply(sp2, function(i) min(i$field_ph, na.rm=TRUE) < 5.6))
plot(sp2[idx, ])

summarizeSPC(object, ...)

Arguments

object A SoilProfileCollection

... A set of (named) comma-delimited R expressions that resolve to a summary value.

e.g. `groupmean = mean(clay, na.rm = TRUE)`

Value

A data.frame with one row per level in the grouping variable, and one column for each summary.

Author(s)

Andrew G. Brown

tauW

Description

tauW: Computes: (1) unweighted naive, (2) weighted naive, (3) unweighted tau, (4) weighted tau accuracy statistics.
Usage

\texttt{tauW(}
\texttt{CM,}
\texttt{W = diag(sqrt(length(as.matrix(CM)))),}
\texttt{P = rep(1/nrow(as.matrix(CM)), nrow(as.matrix(CM)))}
\texttt{)}

Arguments

- \texttt{CM}: a square confusion (cross-classification) matrix (rows: allocation, columns: reference)
- \texttt{W}: weights: 1 on diagonals, [-1..1] off giving partial credit to this error
- \texttt{P}: prior probability vector, length = number of rows/columns in \texttt{CM} and \texttt{W}

Details

\texttt{summaryTauW}: prints a summary of the results from \texttt{tauW}
\texttt{xtableTauW}: formats a LaTeX table with results from \texttt{tauW} and saves it as a .tex file for import into a LaTeX document.

Input matrices \texttt{CM} and \texttt{W} may be in \\texttt{data.frame} format and will be converted
Weights matrix \texttt{W}: 0 = no credit; 1 = full credit; -1 = maximum penalty
If absent, default is no partial credit, i.e., unweighted.
Prior probabilities vector \texttt{P}: If absent, \texttt{P} are equal priors for each class. Special value \texttt{P = 0} is interpreted as \texttt{P = column marginals}.
Error checks: \texttt{CM} must be square; \texttt{P} must have correct number of classes and sum to 1 +/- 0.0001; \texttt{W} & \texttt{CM} must be conformable

Value

Results are returned in a list with obvious R names

Author(s)

D G Rossiter

# change in accuracy statistics weighted vs. non-weighted
(weighted$overall.weighted - weighted$overall.naive)
(weighted$user.weighted - weighted$user.naive)
(weighted$prod.weighted - weighted$prod.naive)
Description

These functions consist of several conversions between sand, silt and clay to texture class and visa versa, textural modifiers to rock fragments, and grain size composition to the family particle size class.

Usage

texcl_to_ssc(texcl = NULL, clay = NULL, sample = FALSE)

ssc_to_texcl(sand = NULL, clay = NULL, as.is = FALSE, droplevels = TRUE)
texmod_to_fragvoltot(texmod = NULL, lieutex = NULL)
texture_to_taxpartsize(
  texcl = NULL,
  clay = NULL,
  sand = NULL,
  fragvoltot = NULL
)
texture_to_texmod(texture, duplicates = "combine")

fragvol_to_texmod(
  object = NULL,
  gravel = NULL,
  cobbles = NULL,
  stones = NULL,
  boulders = NULL,
  channers = NULL,
  flagstones = NULL,
  paragravel = NULL,
  paracobbles = NULL,
  parastones = NULL,
  paraboulders = NULL,
  parachanners = NULL,
  paraflagstones = NULL,
  as.is = TRUE,
  droplevels = TRUE
)

Arguments

texcl vector of texture classes than conform to the USDA code conventions (e.g. c|C, sil|SIL, sl|SL, cos|COS)
clay vector of clay percentages
sample logical: should ssc be random sampled from the lookup table? (default: FALSE)
sand vector of sand percentages
as.is logical: should character vectors be converted to factors? (default: TRUE)
droplevels logical: indicating whether to drop unused levels in factors. This is useful when
the results have a large number of unused classes, which can waste space in
tables and figures.
texmod vector of textural modifiers that conform to the USDA code conventions (e.g.
gr|GR, grv|GRV)
lieutex vector of in lieu of texture terms that conform to the USDA code conventions
(e.g. gr|GR, pg|PG), only used when fragments or artifacts are > 90 percent by
volume (default: NULL))
fragvoltot vector of total rock fragment percentages
texture vector of combinations of texcl, texmod, and lieutex (e.g. CL, GR-CL, CBV-S,
GR)
duplicates character: specifying how multiple values should be handled, options are "combined"
(e.g. 'GR & GRV) or "max"(e.g. 'GRV')
object data.frame: containing the following column names: gravel, cobbles, stones,
boulders, channers, flagstones, paragravel, paracobbles, parastones, paraboul-
ders, parachanners, paraflagstones

Details
These functions are intended to estimate missing values or allocate particle size fractions to classes.
The ssc_to_texcl() function uses the same logic as the particle size estimator calculation in NA-
SIS to classify sand and clay into texture class. The results are stored in soiltexture and used
by texcl_to_ssc() as a lookup table to convert texture class to sand, silt and clay. The function
texcl_to_ssc() replicates the functionality described by Levi (2017). The texmod_to_fragvol() function similarly uses the logical from the Exhibit618-11_texture_modifier.xls spreadsheet to de-
determine the textural modifier from the various combinations of rock and pararock fragments (e.g.
GR and PGR).
When sample = TRUE, the results can be used to estimate within-class, marginal distributions of
sand, silt, and clay fractions. It is recommended that at least 10 samples be drawn for reasonable
estimates.
The function `texmod_to_fragvoltot` returns a data frame with multiple fragvoltot columns differentiated by tailing abbreviations (e.g. _r) which refer to the following:

1. l = low
2. r = representative
3. h = high
4. nopf = no pararock fragments (i.e. total fragments - pararock fragments)

The function `texture_to_texmod()` parses texture (e.g. GR-CL) to extract the texmod values from it in the scenario where it is missing from texmod column. If multiple texmod values are present (for example in the case of stratified textures) and `duplicates = "combine"` they will be combined in the output (e.g. GR & CBV). Otherwise if `duplicates = "max"` the texmod with the highest rock fragment (e.g. CBV) will be returned.

Unlike the other functions, `texture_to_taxpartsize()` is intended to be computed on weighted averages within the family particle size control section. Also recall from the criteria that carbonate clay should be subtracted from clay content and added to silt content. Similarly, if the percent of very fine sand is known it should be subtracted from the sand, and added to the silt content.

Unlike the other functions, `texture_to_taxpartsize()` is intended to be computed on weighted averages within the family particle size control section. Also recall from the criteria that carbonate clay should be subtracted from clay content and added to silt content. Similarly, if the percent of very fine sand is known it should be subtracted from the sand, and added to the silt content.

**Value**

- `texcl_to_ssc`: A data frame containing columns "sand","silt","clay"
- `ssc_to_texcl`: A character vector containing texture class
- `texmod_to_fragvoltot`: A data frame containing columns "fragvoltot_l","fragvoltot_r","fragvoltot_h","fragvoltot_l_nopf","fragvoltot_r_nopf","fragvoltot_h_nopf"
- `texture_to_taxpartsize`: a character vector containing "taxpartsize" classes
- `texture_to_texmod`: a character vector containing "texmod" classes
- `texmod_to_fragvol`: a data frame containing "texmod" and "lieutex" classes

Soil Texture Low-RV-High as Defined by Quantiles

**Description**

This function accepts soil texture components (sand, silt, and clay percentages) and plots a soil texture triangle with a "representative value" (point) and low-high region (polygon) defined by quantiles (estimated with Hmisc::hdquantile). Marginal quantiles of sand, silt, and clay are used to define the boundary of a low-high region. The default settings place the RV symbol at the texture defined by marginal medians of sand, silt, and clay. The default low-high region is defined by the 5th and 95th marginal percentiles of sand, silt, and clay.
textureTriangleSummary

Usage

textureTriangleSummary(
  ssc,
  p = c(0.05, 0.5, 0.95),
  delta = 1,
  rv.col = "red",
  range.border = "black",
  range.col = "RoyalBlue",
  range.alpha = 80,
  range.lty = 1,
  range.lwd = 2,
  main = "Soil Textures",
  legend.cex = 0.75,
  legend = TRUE,
  ...
)

Arguments

ssc data.frame with columns: 'SAND', 'SILT', 'CLAY', values are percentages that should add to 100. No NA allowed.

p vector of percentiles (length = 3) defining 'low', 'representative value', and 'high'

delta grid size used to form low-high region

rv.col color used for representative value (RV) symbol

range.border color used for polygon border enclosing the low-high region

range.col color used for polygon enclosing the low-high region

range.alpha transparency of the low-high range polygon (0-255)

range.lty line style for polygon enclosing the low-high region

range.lwd line weight polygon enclosing the low-high region

main plot title

legend.cex scaling factor for legend

legend logical, enable/disable automatic legend

... further arguments passed to soiltexture::TT.points

Value

an invisible matrix with marginal percentiles of sand, silt, and clay

Author(s)

D.E. Beaudette, J. Nemecek, K. Godsey

    range.alpha = 50,
    range.lwd = 1,
    col = grey(0.5),
    legend = FALSE
  )
}
```
Description

Calculate the "Profile Darkness Index" by the method of Thompson & Bell (1996) "Color index for identifying hydric conditions for seasonally saturated mollisols in Minnesota" DOI: 10.2136/ssaj1996.03615995006000060051x. The Thompson-Bell Index has been shown to reflect catenary relationships in some Mollisols of Minnesota (generally: wetter landscape positions = thicker, darker surfaces).

Usage

thompson.bell.darkness(
  p,
  name = guessHzDesgnName(p),
  pattern = "^A",
  value = "m_value",
  chroma = "m_chroma"
)

Arguments

- **p** A single-profile SoilProfileCollection (e.g. via profileApply())
- **name** Column name containing horizon designations used to find A horizons (default: first column name containing 'name')
- **pattern** Regular expression to match A horizons (default: "^A" which means horizon designation starts with A)
- **value** Column name containing horizon color values (default: "m_value")
- **chroma** Column name containing horizon color chromas (default: "m_chroma")

Value

A numeric vector reflecting horizon darkness (lower values = darker).

Author(s)

Andrew G. Brown

References

**traditionalColorNames  Traditional Soil Color Names**

**Description**

Traditional soil color names associated with select Munsell colors.

**Usage**

```r
data(traditionalColorNames)
```

**Format**

An object of class `data.frame` with 482 rows and 2 columns.

**References**

Sourced from the "colorconverter" NASIS property script.

---

**transform,SoilProfileCollection-method**

*Transform a SPC with expressions based on site or horizon level attributes*

**Description**

`transform()` is a function used for modifying columns in SoilProfileCollections.

It allows the user to specify an arbitrary number of expressions that resolve to the (re-)Calculation of one or more site or horizon level attributes. For instance: `mutate(spc, thickness = hzdepb - hzdept)`. The expressions may depend on one another, and are evaluated from left to right.

**Usage**

```r
## S4 method for signature 'SoilProfileCollection'
transform(`_data`, ...)
```

**Arguments**

- `_data` A SoilProfileCollection
- `...` Comma-separated set of R expressions e.g. `thickness = hzdepb - hzdept, hzdepm = hzdept + round(thk / 2)`

**Value**

A SoilProfileCollection
Author(s)
Andrew G. Brown.

### trunc, SoilProfileCollection-method

*Truncate a SoilProfileCollection to specified top and bottom depth*

---

**Description**

trunc is a wrapper method around glomApply for the case when the same top and bottom depth is required for all profiles in a collection. In contrast, glomApply allows for arbitrary functions to be run on each profile to calculate a unique set of depths.

**Usage**

```r
## S4 method for signature 'SoilProfileCollection'
trunc(x, z1, z2)
```

**Arguments**

- **x**: A SoilProfileCollection
- **z1**: Upper boundary
- **z2**: Lower boundary

**Value**

A SoilProfileCollection truncated to interval \([z1, z2]\)

**Examples**

```r
# load sample data
data("sp3")

# promote to SPC
depths(sp3) <- id ~ top + bottom

### TRUNCATE all profiles in sp3 to [0,25]

# set up plot parameters
par(mfrow=c(2,1), mar=c(0,0,0,0))

# full profiles
plot(sp3)

# trunc'd profiles
plot(trunc(sp3, 0, 25))
```
unique,SoilProfileCollection-method

Uniqueness within a SoilProfileCollection via MD5 Hash

Description

Unique profiles within a SoilProfileCollection using and MD5 hash of select horizon and / or site level attributes.

Usage

```r
## S4 method for signature 'SoilProfileCollection'
unique(x, vars, SPC = TRUE)
```

Arguments

- `x`: a SoilProfileCollection
- `vars`: Variables to consider in uniqueness.
- `SPC`: logical return a SoilProfileCollection when TRUE, otherwise vector of profile indices

Value

SoilProfileCollection when SPC = TRUE, otherwise a vector of integers

Examples

```r
# an example soil profile
x <- data.frame(
  id = 'A',
  name = c('A', 'E', 'Bhs', 'Bt1', 'Bt2', 'BC', 'C'),
  top = c(0, 10, 20, 30, 40, 50, 100),
  bottom = c(10, 20, 30, 40, 50, 100, 125),
  z = c(8, 5, 3, 7, 10, 2, 12)
)

# init SPC
depths(x) <- id ~ top + bottom

# horizon depth variability for simulation
horizons(x)$sd <- 2

# duplicate several times
x.dupes <- duplicate(x, times = 5)

# simulate some new profiles based on example
x.sim <- perturb(x, n = 5, thickness.attr = '.sd')
```
# graphical check
plotSPC(x.dupes, name.style = 'center-center')
plotSPC(x.sim, name.style = 'center-center')

# inspect unique results
plotSPC(unique(x.dupes, vars = c('top', 'bottom')), name.style = 'center-center')

# uniqueness is a function of variable selection
plotSPC(unique(x.sim, vars = c('top', 'bottom')), name.style = 'center-center')
plotSPC(unique(x.sim, vars = c('name')), name.style = 'center-center')

---

**unroll**  
*Unroll Genetic Horizons*

**Description**
Generate a discretized vector of genetic horizons along a user-defined pattern.

**Usage**
unroll(top, bottom, prop, max_depth, bottom_padding_value = NA, strict = FALSE)

**Arguments**
- **top**: vector of upper horizon boundaries, must be an integer
- **bottom**: vector of lower horizon boundaries, must be an integer
- **prop**: vector of some property to be "unrolled" over a regular sequence
- **max_depth**: maximum depth to which missing data is padded with NA
- **bottom_padding_value**: value to use when padding missing data
- **strict**: should horizons be strictly checked for self-consistency? defaults to FALSE

**Details**
This function is used internally by several higher-level components of the aqp package. Basic error checking is performed to make sure that bottom and top horizon boundaries make sense. Note that the horizons should be sorted according to depth before using this function. The max_depth argument is used to specify the maximum depth of profiles within a collection, so that data from any profile shallower than this depth is padded with NA.

**Value**
a vector of "unrolled" property values
us.state.soils

Author(s)

Dylan E. Beaudette

References

http://casoilresource.lawr.ucdavis.edu/

Examples

data(sp1)

# subset a single soil profile:
sp1.1 <- subset(sp1, subset=id == 'P001')

# demonstrate how this function works
x <- with(sp1.1, unroll(top, bottom, prop, max_depth=50))
plot(x, 1:length(x), ylim=c(90,0), type='b', cex=0.5)

us.state.soils   US State Soils

Description

A listing of the 50 US state soils, along with Puerto Rico and Virgin Islands.

Usage

data(us.state.soils)

Format

state  state name
abbreviated  abbreviated state name
series  soil series name
validSpatialData, SoilProfileCollection-method

Get names of columns in site table

Description

Are the contents of @sp valid: nx2 matrix? If not, then contents of @sp in the SoilProfileCollection are an empty SpatialPoints object.

Usage

```r
## S4 method for signature 'SoilProfileCollection'
validSpatialData(object)
```

Arguments

- `object`: a SoilProfileCollection

---

xtableTauW

Format a LaTeX table with results

Description

Format a LaTeX table with results

Usage

```r
xtableTauW(result.tau, file.name = "tau_results_table.tex")
```

Arguments

- `result.tau`: results returned by `tauW`
- `file.name`: name of file to write output TeX file; Default: `file.name="tau_results_table.tex"`
Description

You can access the contents of a SoilProfileCollection by profile and horizon "index", i and j, respectively: spc[i,j,...]. Subset operations are propagated to other slots (such as diagnostics or spatial) when they result in removal of sites from a collection.

- i refers to the profile position within the collection. By default the order is based on the C SORT order of the variable that you specified as your unique profile ID at time of object construction. Note that if your ID variable was numeric, then it has been sorted as a character.
- j refers to the horizon or "slice" index. This index is most useful when either a) working with slice'd SoilProfileCollection or b) working with single-profile collections. j returns the layer in the specified index positions for all profiles in a collection.
- ... is an area to specify an expression that is evaluated in the subset. Currently supported
  - .LAST (last horizon in each profile): return the last horizon from each profile. This uses i but ignores the regular j index.
  - .FIRST (first horizon in each profile): return the last horizon from each profile. This uses i but ignores the regular j index.
  - .HZID (horizon index not SoilProfileCollection result): return the horizon indices corresponding to i+j+... ("k") constraints

Usage

```r
## S4 method for signature 'SoilProfileCollection'
x[i, j, ..., drop = TRUE]
```

Arguments

- `x` a SoilProfileCollection
- `i` a numeric or logical value denoting profile indices to select in a subset
- `j` a numeric or logical value denoting horizon indices to select in a subset
- `...` non-standard expressions to evaluate in a subset
- `drop` not used
Get column of horizon or site data in a SoilProfileCollection

Description

Get the data from a column accessed by name. Column names other than profile ID are not shared between site and horizons. Bonus: [[ gives access to all site and horizon level variables in tab complete for RStudio using the magrittr pipe operator!

Usage

## S4 method for signature 'SoilProfileCollection,ANY,ANY'
x[[i, j]]

Arguments

x a SoilProfileCollection
i an expression resolving to a single column name in site or horizon table
j (not used)

Examples

data(sp2)
depths(sp2) <- id ~ top + bottom
site(sp2) <- ~ surface

# get with []
sp2[['surface']]

# get using "unknown" expression:
# "2nd + 3rd horizon column names"
for(i in horizonNames(sp2)[2:3])
  print(sp2[[i]])

data(sp5)

# some column names to work with
rgb.columns <- c("R25","G25","B25")

res <- lapply(rgb.columns, function(x) {
  # [[ allows you to access column names in a loop
  round(sp5[[x]] * 255)
})

# rename scaled results
names(res) <- paste0(rgb.columns,"_scl")
# add horizon ID to results
result <- data.frame(hzID = hzID(sp5), do.call('cbind', res))
head(result)

# join result back into horizons
horizons(sp5) <- result

Add or change column of horizon or site data in a SoilProfileCollection

Description

Add or change the data from a column accessed by name. Column names other than profile ID are not shared between site and horizons. The benefit of using double bracket setter over $ is that name can be calculated, whereas with $, it must be known a priori and hard coded.

When using the double bracket setter the length of input and output matching either the number of sites or number of horizons is used to determine which slot new columns are assigned to.

Usage

```r
## S4 replacement method for signature 'SoilProfileCollection,ANY,ANY'
x[[i]] <- value
```

Arguments

- **x**: a SoilProfileCollection
- **i**: an expression resolving to a single column name in site or horizon table-
- **value**: New value to replace – unit length or equal in length to number of sites or hori-
- **zons in the collection.**

Get data from column of horizon or site data in a SoilProfileCollection

Description

Get the data from a column accessed by name x$name. Column names other than profile ID are not shared between site and horizons.

Usage

```r
## S4 method for signature 'SoilProfileCollection'
x$name
```
Arguments

x  a SoilProfileCollection
name  a single column name in site or horizon table

Examples

data(sp1)
depths(sp1) <- id ~ top + bottom
# get data from a column by name (prop)
sp1$prop

$<-

Set data in column of horizon or site data in a SoilProfileCollection

Description

Set the data in a column accessed by name spc$name. Column names other than profile ID are not shared between site and horizons.

When using $<-, the length of input and output matching either the number of sites or number of horizons is used to determine which slot new columns are assigned to. Use site(x)$name <- value or horizons(x)$name <- value to be explicit about which slot is being accessed.

Usage

## S4 replacement method for signature 'SoilProfileCollection'
x$name <- value

Arguments

x  a SoilProfileCollection
name  a single column name in site or horizon table
value  Replacement values: unit length or equal to number of horizons or sites.
