Package ‘archivist’

April 24, 2018

Version 2.3.1
Type Package
Title Tools for Storing, Restoring and Searching for R Objects
Description Data exploration and modelling is a process in which a lot of data artifacts are produced. Artifacts like: subsets, data aggregates, plots, statistical models, different versions of data sets and different versions of results. The more projects we work with the more artifacts are produced and the harder it is to manage these artifacts. Archivist helps to store and manage artifacts created in R. Archivist allows you to store selected artifacts as a binary files together with their metadata and relations. Archivist allows to share artifacts with others, either through shared folder or github. Archivist allows to look for already created artifacts by using it's class, name, date of the creation or other properties. Makes it easy to restore such artifacts. Archivist allows to check if new artifact is the exact copy that was produced some time ago. That might be useful either for testing or caching.

Tools for Storing, Restoring and Searching for R Objects

**Description**

Data exploration and modelling is a process in which a lot of data artifacts are produced. Artifacts like: subsets, data aggregates, plots, statistical models, different versions of data sets and different versions of results. The more projects we work on, the more artifacts are produced and the harder it is to manage these artifacts.

Archivist helps to store and manage artifacts created in R.

Archivist allows you to store selected artifacts as binary files along with their metadata and relations. Archivist allows you to share artifacts with others, either through a shared folder or github. Archivist allows you to look for artifacts by using its class, name, date of creation or other properties. It also facilitates restoring such artifacts. Archivist allows you to check if a new artifact is the exact copy of the one that was produced some time ago. This might be useful either for testing or caching.

The list of main use cases is available here [https://github.com/pbiecek/archivist](https://github.com/pbiecek/archivist).

Extensions of archivist are

- Tools for Archiving, Managing and Sharing R Objects via GitHub: [archive marcinkosinski.github.io/archivist.github/](https://archive marcinkosinski.github.io/archivist.github/)

**Details**

addHooksToPrint: Add archivist Hooks to rmarkdown Reports

Description

addHooksToPrint adds an overloaded version of the print function for objects of selected class. The overloaded function will add all objects of selected class to the Repository and then will add hooks (to the Remote or Local Repository) to the HTML report (generated in rmarkdown) for these objects (artifacts - archivist-package). The great example can be seen in this blogpost http://www.r-bloggers.com/why-should-you-backup-your-r-objects/.

Usage

addHooksToPrint(class = "ggplot", repoDir = aoptions("repoDir"), repo = aoptions("repo"), user = aoptions("user"), branch = "master", subdir = aoptions("subdir"), format = "markdown")

Arguments

class: A character with a name of class (one or more) that should be archived.
repoDir: A character containing a name of a Local Repository.
repo: A character with a name of a Remote repository on which the Repository is archived. If repo = NULL then hooks will be added to files in local directories.
user: A character with a name of a Remote-repository user on whose account the repo is created.
branch: A character with a name of Remote-repository’s branch on which the Repository is archived. Default branch is master.
subdir: A character with a name of a subdirectory on a Remote repository on which the Repository is stored. If the Repository is stored in main folder on a Remote repository, this should be set to subdir = "/" as default.
format: A character denoting format as in alink.

**addTagsRepo**

**Note**

One can specify `userTags` as in `saveToLocalRepo` for artifacts by adding "tags" attribute. See note section about that in `saveToLocalRepo`.

**Author(s)**

Przemyslaw Biecek, <przemyslaw.biecek@gmail.com>

**References**

**See Also**

Other archivist: `Repository`, `Tags`, `%a%`, `addTagsRepo`, `aformat`, `ahistory`, `alink`, `aoptions`, `archivist-package`, `areadLocal`, `aread`, `asearchLocal`, `asearch`, `asession`, `atrace`, `cache`, `copyLocalRepo`, `createLocalRepo`, `createMDGallery`, `deleteLocalRepo`, `getRemoteHook`, `getTagsLocal`, `loadFromLocalRepo`, `md5hash`, `removeTagsRepo`, `restoreLibs`, `rmFromLocalRepo`, `saveToLocalRepo`, `searchInLocalRepo`, `setLocalRepo`, `shinySearchInLocalRepo`, `showLocalRepo`, `splitTagsLocal`, `summaryLocalRepo`, `zipLocalRepo`

**Examples**

```{r}
## Not run:
# only in Rmd report, links to github repository
addHooksToPrint(class="ggplot", repoDir = "arepo",
repog = "graphGallery", user="pbiecek")
# only in Rmd report, links to local files
addHooksToPrint(class="ggplot", repoDir = "arepo",
repog = NULL)
## End(Not run)
```

---

**Description**

`addTagsRepo` adds new `Tags` to the existing `Repository`.

**Usage**

`addTagsRepo(md5shashes, repoDir = NULL, FUN = NULL, tags = NULL, ...)`
`addTagsRepo`

**Arguments**

- **mdUhashes**: a character vector of md5hashes specifying to which corresponding artifacts new Tags should be added. See Note to get to know about the length of tags and mdUhashes parameters.
- **repoDir**: A character that specifies the directory of the Repository to which new Tags will be added. If it is set to NULL (by default), it uses the repoDir specified in `setLocalRepo`.
- **FUN**: A function which is evaluated on the artifacts for which mdUhashes are given. The result of this function evaluation are Tags which will be added to the local Repository.
- **tags**: A character vector which specifies what kind of Tags should be added to artifacts corresponding to given md5hashes. See Note to get to know about the length of tags and md5hashes parameters. One can specify either FUN or tags.
- **...**: Other arguments that will be passed to FUN.

**Details**

`addTagsRepo` function adds new Tags to artifacts that are already stored in the repository. One can add new Tags either explicitly with `tags` parameter or by passing a function which extracts Tags from selected artifacts corresponding to md5hashes. To learn more about artifacts visit `archivist-package`.

**Contact**

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

**Note**

One should remember that `length(tags) modulo length(md5hashes)` must be equal to 0 or `length(md5hashes) modulo length(tags)` must be equal to 0.

Other archivist: Repository, Tags, %a%, addHooksToPrint, aformat, ahistory, alink, aoptions, archivist-package, areadLocal, aread, asearchLocal, asearch, asession, atrace, cache, copyLocalRepo, createLocalRepo, createMDGallery, deleteLocalRepo, getRemoteHook, getTagsLocal, loadFromLocalRepo, md5Hash, removeTagsRepo, restoreLibs, rmFromLocalRepo, saveToLocalRepo, searchInLocalRepo, setLocalRepo, shinySearchInLocalRepo, showLocalRepo, splitTagsLocal, summaryLocalRepo, zipLocalRepo
Examples

## Not run:

## We take all artifacts of lm class from repository, extract R^2 for them and store as R^2:number tags

```r
# Creating empty repository
easyRepoDir <- tempfile()
createLocalRepo(easyRepoDir, force=TRUE)

# Saving lm artifacts into repository
m1 <- lm(Sepal.Length ~ Species, iris)
saveToLocalRepo(m1, easyRepoDir)
m2 <- lm(Sepal.Width ~ Species, iris)
saveToLocalRepo(m2, easyRepoDir)

# We may see what kind of Tags are related to "m1" artifact corresponding to
# "9e66edd297c2f291446f3503c01d443a" md5Hash
getTagsLocal("9e66edd297c2f291446f3503c01d443a", easyRepoDir, ""

# We may see what kind of Tags are related to "m2" artifact corresponding to
# "da1bca68752c146903f700c1a458438" md5Hash
getTagsLocal("da1bca68752c146903f700c1a458438", easyRepoDir, ""

# We take all objects of lm class from repository
md5hashes <- searchInLocalRepo(repoDir=easyRepoDir, "class:lm")

# Adding new tag "test" explicitly
addTagsRepo(md5hashes, easyRepoDir, tags = "test")

# Adding new tag "R^2: " using FUN parameter
addTagsRepo(md5hashes, easyRepoDir, function(x) paste0("R^2: ",summary(x)$r.square))

# And now: Tags related to "m1" artifact are
getTagsLocal("9e66edd297c2f291446f3503c01d443a", easyRepoDir, ""

# And now: Tags related to "m2" artifact are
getTagsLocal("da1bca68752c146903f700c1a458438", easyRepoDir, ""

# One more look at our Repo
showLocalRepo(easyRepoDir, method = "tags")

# Deleting example repository
deleteLocalRepo(easyRepoDir, deleteRoot=TRUE)
rm(easyRepoDir)
```

## End(Not run)
Description

aformat extracts artifact’s formats. Having formats one may decide which should he read. Currently only rda format is supported for artifact and txt/png for miniatures.

Usage

aformat(mdHash = NULL)

Arguments

mdHash One of the following (see aread):
A character vector which elements are consisting of at least three components separated with '/': Remote user name, Remote repository and name of the artifact (MD5 hash) or it’s abbreviation.
MD5 hashes of artifacts in current local default directory or its abbreviations.

Value

A vector of characters.

Other archivist: Repository, Tags, %a%, addHooksToPrint, addTagsRepo, ahistory, alink, aoptions, archivist-package, areadLocal, aread, asearchLocal, asearch, aseession, atrace, cache, copyLocalRepo, createLocalRepo, createMDgallery, deleteLocalRepo, getRemoteHook, getTagsLocal, loadFromLocalRepo, mdHash, removeTagsRepo, restoreLibs, rmFromLocalRepo, saveToLocalRepo, searchInLocalRepo, setLocalRepo, shinySearchInLocalRepo, showLocalRepo, splitTagsLocal, summaryLocalRepo, zipLocalRepo

Examples

```r
# Not run:
setLocalRepo(system.file("graphGallery", package = "archivist"))
aformat("2a6e492cb6982f230e48cf46023e2e4f")
# old
```
ahistory

```r
aformat("pbiecek/graphGallery/2a6e492cb6982f230e48cf46023e2e4f")
# png
aformat("pbiecek/graphGallery/7f3453331910e3f321ef97d87adb5bad")

## End(Not run)
```

## ahistory

Show Artifact's History

**Description**

ahistory extracts artifact's history and creates a data frame with history of calls and md5hashes of partial results. The overloaded print.ahistory function prints this history in a concise way. The overloaded print.ahistoryKable function prints this history in the same way as kable. When alink=TRUE one can create history table/kable with hooks to partial results (artifacts) as in the alink function.

**Usage**

```r
ahistory(artifact = NULL, md5hash = NULL, repoDir = aoptions("repoDir"),
          format = "regular", alink = FALSE, ...)
```

**Arguments**

- **artifact** An artifact which history is supposed to be reconstructed. It will be converted into md5hash.
- **md5Hash** If artifact is not specified then md5hash is used.
- **repoDir** A character denoting an existing directory in which an artifact will be saved.
- **format** A character denoting whether to print history in either a "regular" (default) way or like in a "kable" function. See Notes.
- **alink** Whether to provide hooks to objects like in alink. See examples.
- **...** Further parameters passed to alink function. Used when format = "kable" and alink = TRUE.

**Details**

All artifacts created with %a% operator are archivised with detailed information about it's source (both call and md5hash of the input). The function ahistory reads all artifacts that precede artifact and create a description of the input flow. The generic print.ahistory function plots the history in a human readable way.

**Value**

A data frame with two columns - names of calls and md5hashes of partial results.
## ahistory

**Contact**

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

**Demonstration**

This function is well explained on this http://r-bloggers.com/r-hero-saves-backup-city-with-archivist-and-github blog post.

**Note**

There are provided functions (\texttt{print.ahistory} and \texttt{print.ahistoryKable}) to print the artifact's history. History can be printed either in a regular way which is friendly for the console output or in a kable format which prints the artifact's history in a way \texttt{kable} function would. This is convenient when one prints history in .Rmd files using \texttt{rmarkdown}.

Moreover when user passes \texttt{format} = 'kable' and \texttt{alink} = TRUE then one can use links for remote Repository. Then mdhashes are taken from Local Repository, so user has to specify repo, user and repoDir even though they are set globally, because repo is a substring of repodir and during evluation of ... R treats repo as repodir.

**Author(s)**

Przemyslaw Biecek, <przemyslaw.biecek@gmail.com>

Marcin Kosinski, <m.p.kosinski@gmail.com>

**References**

**See Also**

Other archivist: \texttt{Repository, Tags, %a%, addHooksToList, addTagsRepo, aformat, alink, aoptions, archivist-package, areadLocal, aread, asearchLocal, asearch, asession, atrace, cache, copypLocalRepo, createLocalRepo, createMDGallery, deleteLocalRepo, getRemoteHook, getTagsLocal, loadFromLocalRepo, md5hash, removeTagsRepo, restoreLibs, rmFromLocalRepo, saveToLocalRepo, searchInLocalRepo, setLocalRepo, shinySearchInLocalRepo, showLocalRepo, splitTagsLocal, summaryLocalRepo, zipLocalRepo}

**Examples**

```r
createLocalRepo("ahistory_check", default = TRUE)
library(dplyr)
iris %>%
filter(Sepal.Length < 6) %>%
lm(Petal.Length~Species, data=.) %>%
summary() -> artifact
```
Return a Link To Download an Artifact Stored on Remote Repository

Description

`alink` returns a link to download an artifact from the Remote Repository. Artifact has to be already archived on GitHub, e.g. with `archivist::github::archive` function (recommended) or `saveToRepo` function and traditional Git manual synchronization. To learn more about artifacts visit `archivist-package`.

Usage

```r
alink(mdUhash, repo = aoptions("repo"), user = aoptions("user"),
  subdir = aoptions("subdir"), branch = "master",
  repoType = aoptions("repoType"), format = "markdown", rawLink = FALSE)
```

Arguments

- **mdUhash**: A character assigned to the artifact through the use of a cryptographical hash function with MD5 algorithm. If it is specified in a format of `repo/user/md5hash` then `user` and `repo` parameters are omitted.
- **repo**: The Remote Repository on which the artifact that we want to download is stored.
- **user**: The name of a user on whose Repository the artifact that we want to download is stored.
- **subdir**: A character containing a name of a directory on the Remote repository on which the Repository is stored. If the Repository is stored in the main folder on the Remote repository, this should be set to `subdir = "/"` as default.
- **branch**: A character containing a name of the Remote Repository's branch on which the Repository is archived. Default branch is `master`.
- **repoType**: A character containing a type of the remote repository. Currently it can be 'github' or 'bitbucket'.
- **format**: In which format the link should be returned. Possibilities are `markdown` (default) or `latex`.
- **rawLink**: A logical denoting whether to return raw link or a link in the format convention. Default value is `FALSE`.
Details

For more information about md5hash see md5hash.

Value

This function returns a link to download artifact that is archived on GitHub.

Examples

```r
## Not run:
# link in markdown format
alink('pbiecek/archivist/134ecbbe2a8814d98f0c2758000c408e')
# link in markdown format with additional subdir
alink(user='BetaAndBit',repo='PieczaraPietraszki',
      md5Hash = '1569cc44e8450439ac52c11ccac35138',
      subdir = 'UniwersytetDzieciarepo')
# link in latex format
alink(user = 'MarcinKosinski', repo = 'Museum',
      md5Hash = '1651caac499a2b07a3bda3896a2fc717', format = 'latex')
# link in raw format
alink('pbiecek/graphGallery/f5185c458bff721f0faa8e1332f01e0f', rawLink = TRUE)
alink('pbiecek/graphgallerygit/02aaf4f99e440324b9e329faa293a9394', repoType='bitbucket')
```

## End(Not run)
Description

The function `aoptions` sets and gets default options for other archivist functions.

Usage

```
aoptions(key, value = NULL, unset = FALSE)
```

Arguments

- `key` A character denoting name of the parameter.
- `value` New value for the `key` parameter.
- `unset` Set to TRUE if want to set parameter to NULL, i.e. when unsetting Repository `aoptions('repoDir', NULL, T)`.

Details

The function `aoptions` with two parameters sets default value of key parameter for other archivist functions. The function `aoptions` with one parameter returns value (stored in an internal environment) of the given key parameter.

Value

The function returns value that corresponds to a selected key.

Other archivist: Repository, Tags, %a%, addHooksToPrint, addTagsRepo, aformat, ahistory, aNlink, archivist-package, areadLocal, aread, asearchLocal, asearch, aseession, atrace, acache, copyLocalRepo, createLocalRepo, createMDGallery, deleteLocalRepo, getRemoteHook, getTagsLocal, loadFromLocalRepo, md5Hash, removeTagsRepo, restoreLibs, rmFromLocalRepo, saveToLocalRepo, searchInLocalRepo, setLocalRepo, shinySearchInLocalRepo, showLocalRepo, splittagsLocal, summaryLocalRepo, zipLocalRepo

Examples

## Not run:
# data.frame object
# data(iris)

## EXAMPLE 1 : SET default local repository using aoptions() function.

# creating example repository
eampleRepoDir <- tempfile()
createLocalRepo(exampleRepoDir)

"repoDir" parameter in each archivist function will be default and set to exampleRepoDir.
aoptions(key = "repoDir", value = exampleRepoDir)

data(iris)
data(swiss)
# From this moment repoDir parameter may be ommitted in the following functions
saveToLocalRepo(iris)
saveToLocalRepo(swiss)
showLocalRepo()
showLocalRepo(method = "tags")
zipLocalRepo()
file.remove(file.path(getwd(), "repository.zip"))
iris2 <- loadFromLocalRepo( "ff575c2", value = TRUE)
searchInLocalRepo("name:i", fixed = F)
getTagsLocal("ff575c261c949d073b2895b05d1097c3")
rmFromLocalRepo("4c43f")
showLocalRepo()
summaryLocalRepo()

# REMEMBER that in deleteRepo you MUST specify repoDir parameter!
# deleteLocalRepo doesn't take setLocalRepo's settings into consideration
deleteLocalRepo( exampleRepoDir, deleteroot = TRUE)
rm( exampleRepoDir )

## EXAMPLE 2 : SET default Github repository using aoptions() function.
aoptions(key = "user", value = "pbiecek")
aoptions(key = "repo", value = "archivist")

# From this moment user and repo parameters may be ommitted in the following functions:
showRemoteRepo()
loadFromRemoteRepo( "ff575c261c949d073b2895b05d1097c3" )
this <- loadFromRemoteRepo( "ff", value = T)
file.remove(file.path(getwd(), "repository.zip")) # We can remove this zip file
searchInRemoteRepo( "name":, fixed= FALSE)
getTagsGithub("ff575c261c949d873b2895b05d1097c3")
summaryRemoteRepo( )
searchInRemoteRepo( pattern="varname:Sepal.Width", "class:lm", "name:myplot123",
                 intersect = FALSE )
## EXAMPLE 3 : SET default Github repository using aoptions() function.
showRemoteRepo('Museum', 'MarcinKosinski', subdir = 'ex1')
aoptions('repo', 'Museum')
aoptions('user', 'MarcinKosinski')
aoptions('subdir', 'ex1')
aoptions('branch', 'master')
showRemoteRepo()
showRemoteRepo(subdir = 'ex2')
aoptions('subdir')

## EXAMPLE 4 : SET sha256 as a hasing algorithm
aoptions("hashFunction", value = "sha256")
extampleRepoDir <- tempfile()
createLocalRepo(exampleRepoDir)
aoptions(key = "repoDir", value = exampleRepoDir)

data(iris)
saveToLocalRepo(iris)
getTagsLocal(digest::digest(iris, algo = "sha256"))

## End(Not run)

---

**aread**  
*Read Artifacts Given as md5hashes from the Repository*

## Description

*aread* reads the artifact from the *Repository*. It's a wrapper around *loadFromLocalRepo* and *loadFromRemoteRepo*.

## Usage

```
aread(md5hash)
```

## Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>md5hash</code></td>
<td>One of the following: A character vector which elements are consisting of at least three components separated with <code>/</code>: Remote user name, Remote repository and name of the artifact (MD5 hash) or it’s abbreviation. MD5 hashes of artifacts in current local default directory or its abbreviations.</td>
</tr>
</tbody>
</table>
Function `aread` reads artifacts (by md5shashes) from Remote Repository. It uses `loadFromLocalRepo` and `loadFromRemoteRepo` functions with different parameter’s specification.

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

Note

Before you start using this function, remember to set local or Remote repository to default by using `setLocalRepo()` or `setRemoteRepo` functions.

# as this is stated in asession("7f3453331910e3f321ef97d87adb5bad")
# The state of R libraries can be restored to the same state in
# which 7f3453331910e3f321ef97d87adb5bad was created with the restoreLibs function.

# read the object from Remote
pl <- aread("pbiecek/graphGallery/7f3453331910e3f321ef97d87adb5bad")
# To plot it remember to have ggplot2 in version 2.1.0
# as this is stated in asession("pbiecek/graphGallery/7f3453331910e3f321ef97d87adb5bad")
# The state of R libraries can be restored to the same state in
# which 7f3453331910e3f321ef97d87adb5bad was created with the restoreLibs function.
```
areadLocal  

*Read Artifacts Given as md5hashes from the Repository*

**Description**

`areadLocal` reads the artifact from the Local Repository. It’s a wrapper around `loadFromLocalRepo`.

**Usage**

`areadLocal(mdShash, repo)`

**Arguments**

- `mdShash` A character vector which elements are consisting name of the repository and name of the artifact (MD5 hash) or it’s abbreviation.
- `repo` A character with path to local repository.

**Details**

Function `areadLocal` reads artifacts (by mdShashes) from Local Repository.

**Contact**

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

**Author(s)**

Przemyslaw Biecek, <przemyslaw.biecek@gmail.com>

**References**

**See Also**

Other archivist: Repository, Tags, %a%, addHooksToPrint, addTagsRepo, aformat, ahistory, alink, aoptions, archivist-package, aread, asearchLocal, asearch, asession, atrace, cache, copyLocalRepo, createLocalRepo, createMDGallery, deleteLocalRepo, getRemoteHook, getTagsLocal, loadFromLocalRepo, mdShash, removeTagsRepo, restoreLibs, rmFromLocalRepo, saveToLocalRepo, searchInLocalRepo, setLocalRepo, shinySearchInLocalRepo, showLocalRepo, splitTagsLocal, summaryLocalRepo, zipLocalRepo
asearch

*Read Artifacts Given as a List of Tags*

**Description**

asearch searches for artifacts that contain all specified Tags and reads all of them from a default or Remote Repository. It’s a wrapper around searchInLocalRepo and loadFromLocalRepo and their Remote versions.

**Usage**

```r
asearch(patterns, repo = NULL)
```

**Arguments**

- `patterns`: A character vector of Tags. Only artifacts that contain all Tags are returned.
- `repo`: One of following:
  - A character with Remote user name and Remote repository name separated by `/`.
  - NULL in this case search will be performed in the default repo, either local or Remote

**Details**

Function asearch reads all artifacts that contain given list of Tags from default or Remote Repository. It uses both loadFromLocalRepo and searchInLocalRepo functions (or their Remote versions) but has shorter name and different parameter’s specification.

**Value**

This function returns a list of artifacts (by their values).

**Contact**

Bug reports and feature requests can be sent to [https://github.com/pbiecek/archivist/issues](https://github.com/pbiecek/archivist/issues)

**Note**

Remember that if you want to use local repository you should set it to default.

Examples

## Not run:
### default LOCAL version
### objects preparation

# data.frame object
data(iris)

# ggplot/gg object
library(ggplot2)
df <- data.frame(gp = factor(rep(letters[1:3], each = 10), y = rnorm(30))
library(plyr)
ds <- ddply(df, .(gp), summarise, mean = mean(y), sd = sd(y))
myplot123 <- ggplot(df, aes(x = gp, y = y)) +
  geom_point() + geom_point(data = ds, aes(y = mean),
                             colour = 'red', size = 3)

# lm object
model <- lm(Sepal.Length~ Sepal.Width + Petal.Length + Petal.Width, data = iris)
model2 <- lm(Sepal.Length~ Sepal.Width + Petal.Width, data = iris)
model3 <- lm(Sepal.Length~ Sepal.Width, data = iris)

## creating example default local repository
exampleRepoDir <- tempfile()
createLocalRepo(repoDir = exampleRepoDir)
## setting default local repository
setLocalRepo( repoDir = exampleRepoDir )
saveToLocalRepo(myplot123)
saveToLocalRepo(iris)
saveToLocalRepo(model)
saveToLocalRepo(model2)
saveToLocalRepo(model3)

## Searching for objects of class:lm
lm <- asearch(patterns = "class:lm")
# Searching for objects of class:lm with coefname:Petal.Width

```r
lm_c_PW <- asearch(patterns = c("class:lm","coefname:Petal.Width"))
```

# Note that we searched for objects. Then loaded them from repository by their value.

### Deleting example repository

```r
deleteLocalRepo(repoDir = exampleRepoDir, deleteRoot = TRUE)
```

### Default GitHub version

### Setting default GitHub repository

```r
setRemoteRepo(user = "pbiecek", repo = "archivist")
```

### Searching for objects of class:lm

```r
asearch(patterns = c("class:lm"))
```

### Searching for objects of class:gg

```r
ggplot_objects <- asearch(patterns = c("class:gg"))
```

### Names of ggplot objects

# To plot them remember to have ggplot2 in version 2.1.0
# as this is stated in `session("pbiecek/archivist:13b272413eb2c62578b4dab0d7b2cea")` or
# `session("pbiecek/archivist:7f3453331910e3f82ef97d87adb5bad")`.
# The state of R libraries can be restored to the same state in
# which those objects were created with the `restoreLibs` function.

### Remote version

### Note that repo argument is passed in the following way to `asearch`:
```r
repo = "GitHub user name/GitHub repository name"
```

### Searching for objects of class:gg

```r
asearch("pbiecek/graphGallery",
    patterns = c("class:gg",
                 "labelx:Sepal.Length")) -> ggplots_objects_v2
```

### End(Not run)

---

**asearchLocal**

*Read Artifacts Given as a List of Tags*

**Description**

`asearchLocal` searches for artifacts that contain all specified tags and reads all of them from a local repository. It's a wrapper around `searchInLocalRepo` and `loadFromLocalRepo`. 
**asearchLocal**

**Usage**

```
asearchLocal(patterns, repo = NULL)
```

**Arguments**

- `patterns`: A character vector of Tags. Only artifacts that contain all Tags are returned.
- `repo`: A character with path to local repository.

**Details**

Function `asearchLocal` reads all artifacts that contain given list of Tags from the selected Local Repository.

**Value**

This function returns a list of artifacts (by their values).

asession

Show Artifact's Session Info

Description

asession extracts artifact's session info. This allows to check in what conditions the artifact was created.

Usage

asession(mdShash = NULL)

Arguments

mdShash

One of the following (see aread):

A character vector which elements are consisting of at least three components separated with '/': Remote user name, Remote repository and name of the artifact (MD5 hash) or its abbreviation.

MD5 hashes of artifacts in current local default directory or its abbreviations.

Value

An object of the class session_info.

```r
## Not run:
setLocalRepo(system.file("graphGallery", package = "archivist"))
asession("2a6e492cb6982f230e48cf46023e2e4f")

# no session info
asession("pbiecek/graphGallery/2a6e492cb6982f230e48cf46023e2e4f")
# nice session info
asession("pbiecek/graphGallery/7f3453331910e3f321ef97d87adb5bad")

## End(Not run)
```

```r
atrace
Add Tracing For All Objects Created By Given Function
```

**Description**

atrace add call to `saveToLocalRepo` at the end of a given function.

**Usage**

`atrace(FUN = "lm", object = "z")`

**Arguments**

- `FUN` name of a function to be traced (character)
- `object` name of an object that should be traced (character)

**Details**

Function `atrace` calls the `trace` function.

Examples

# read the object from local directory
createLocalRepo("arepo_test", default=TRUE)
atrace("lm", "z")
lm(Sepal.Length-Sepal.Width, data=iris)
asearch("class:lm")
untrace("lm")

Description

cache function stores all results of function calls in local Repository. All results are stored together with md5 hashes of the function calls. If a function is called with the same arguments, then its results can be loaded from the repository.

One may specify expiration date for live objects. It may be useful for objects that can be changed externally (like queries to database).

Usage

cache(cacheRepo = NULL, FUN, ..., notOlderThan = NULL)

Arguments

cacheRepo A repository used for storing cached objects.
FUN A function to be called.
... Arguments of FUN function.
notOlderThan load an artifact from the database only if it was created after notOlderThan.

Details

cache function stores all results of function calls in local Repository specified by the cacheRepo argument. The md5 hash of FUN and it’s arguments is added as a Tag to the repository. This Tag has the following structure "cached:md5hash". Note that cache is a good solution if objects are not that big but calculations are time consuming (see Examples). If objects are big and calculations are easy, then disk input-output operations may take more time than calculations itself.
Value

Result of the function call with additional attributes: tags - md5 hash of the function call and call - "".

Other archivist: Repository, Tags, %a%, addHooksToPrint, addTagsRepo, aformat, ahistory, alink, aoptions, archivist-package, areadLocal, aread, asearchLocal, asearch, asession, atrace, copyLocalRepo, createLocalRepo, createMDGallery, deleteLocalRepo, getRemoteHook, getTagsLocal, loadFromLocalRepo, mdShash, removeTagsRepo, restoreLibs, rmFromLocalRepo, saveToLocalRepo, searchInLocalRepo, setLocalRepo, shinySearchInLocalRepo, showLocalRepo, splitTagsLocal, summaryLocalRepo, zipLocalRepo

Examples

```r
## Not run:

# objects preparation
library("lubridate")
cacheRepo <- tempfile()
createLocalRepo( cacheRepo )

## Example 1:
# cache is useful when objects used by FUN are not that big but calculations
# are time-consuming. Take a look at this example:
fun <- function(n) {replicate(n, summary(lm(Sepal.Length~Species, iris))$r.squared)}

# let's check time of two evaluations of cache function
system.time( res <- cache(cacheRepo, fun, 1000) )
system.time( res <- cache(cache Repo, fun, 1000) )
# The second call is much faster. Why is it so? Because the result of fun
# function evaluation has been stored in local cacheRepo during the first evaluation
# of cache. In the second call of cache we are simply loading the result of fun
# from local cacheRepo Repository.
```
## Example 2:

```r
testFun <- function(x) {cat(x); x}
```

# testFun will be executed and saved to cacheRepo
tmp <- cache(cacheRepo, testFun, "Say hallo!")

# testFun execution will be loaded from repository
tmp <- cache(cacheRepo, testFun, "Say hallo!")

# testFun will be executed once again as it fails with expiration date. It will
# be saved to cacheRepo.
tmp <- cache(cacheRepo, testFun, "Say hallo!", notOlderThan = now())

# testFun execution will be loaded from repository as it
# passes with expiration date [within hour]
tmp <- cache(cacheRepo, testFun, "Say hallo!", notOlderThan = now() - hours(1))

deleteLocalRepo( cacheRepo, TRUE)
rm( cacheRepo )

## End(Not run)

---

### copyLocalRepo

**Copy an Existing Repository into Another Repository**

#### Description

`copyLocalRepo` copies artifacts from one Repository into another Repository. It adds new files to existing gallery folder in repoTo Repository. `copyLocalRepo` copies local Repository while `copyRemoteRepo` copies remote Repository.

#### Usage

```r
copyLocalRepo(repoFrom = NULL, repoTo, md5hashes)
```

`copyRemoteRepo(repoTo, md5hashes, repo = aoptions("repo"),
user = aoptions("user"), branch = aoptions("branch"),
subdir = aoptions("subdir"), repoType = aoptions("repoType"))`

#### Arguments

- `repoFrom` While copying local repository. A character that specifies the directory of the Repository from which artifacts will be copied. If it is set to NULL (by default), it will use the repoDir specified in `setLocalRepo`.

- `repoTo` A character that specifies the directory of the Repository into which artifacts will be copied.
copyLocalRepo

mdShashes A character vector containing mdShashes of artifacts to be copied.

repo While coping the remote repository. A character containing a name of the remote repository on which the "repoFrom" - Repository is archived. By default set to NULL - see Note.

user While coping the remote repository. A character containing a name of the remote user on whose account the "repoFrom" - Repository is created. By default set to NULL - see Note.

branch While coping with the remote repository. A character containing a name of Remote Repository’s branch on which the "repoFrom" - Repository is archived. Default branch is master.

subdir While working with the remote repository. A character containing a name of a directory on the remote repository on which the "repoFrom" - Repository is stored. If the Repository is stored in the main folder on the remote repository, this should be set to FALSE as default.

repoType A character containing a type of the remote repository. Currently it can be 'Remote' or 'bitbucket'.

Details

Functions copyLocalRepo and copyRemoteRepo copy artifacts from the archivist’s Repositories stored in a local folder or on the Remote. Both of them use mdShashes of artifacts which are to be copied in mdShashes parameter. For more information about mdShash see mdShash.

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

Note

If repo and user are set to NULL (as default) in remote mode then global parameters set in setRemoteRepo function are used. If one would like to copy whole Repository we suggest to extract all mdShashes in this way unique(showLocalRepo(repoDir)[,1]).

## Not run:

## Using archivist remote Repository to copy artifacts
# creating example Repository

```r
exampleRepoDir <- tempfile()
createLocalRepo( exampleRepoDir )
```

# Searching for md5hashes of artifacts (without data related to them)
# in the archivist remote Repository

```r
hashes <- searchInRemoteRepo( pattern="name", user="pbiecek", repo="archivist", fixed=FALSE )
```

# Copying selected artifacts from archivist Remote Repository into exampleRepoDir Repository

```r
copyRemoteRepo( repoTo = exampleRepoDir, md5hashes = hashes, user="pbiecek", repo="archivist" )
```

# See how the gallery folder in our exampleRepoDir Repository
# with copies of artifacts from archivist Remote Repository looks like

```r
list.files( path = file.path( exampleRepoDir, "gallery" ) )
```

# See how the backpack database in our exampleRepoDir Repository looks like

```r
showLocalRepo( repoDir = exampleRepoDir )
```

# removing an example Repository

```r
deleteLocalRepo( exampleRepoDir, deleteRoot=TRUE )
```

```r
rm( exampleRepoDir )
```

# many archivist-like Repositories on one Remote repository

```r
dir <- paste0(getwd(), "/ex1")
createLocalRepo( dir )
copyRemoteRepo( repoTo = dir, md5hashes = "ff575c261c949d073b2895b05d1097c3", user="MarcinKosinski", repo="Museum", branch="master", subdir="ex2")
```

# Check if the copied artifact is on our dir Repository

```r
showLocalRepo( repoDir = dir ) # It is in backpack database indeed
list.files( path = file.path( dir, "gallery" ) ) # it is also in gallery folder
```

# removing an example Repository

```r
deleteLocalRepo( dir, TRUE )
```

```r
rm(dir)
```
## Using graphGallery Repository attached to the archivist package to copy artifacts

# creating example Repository

declare exampleRepoDir <- tempfile()
display createLocalRepo(exampleRepoDir)

# searching for md5 hashes of artifacts (without data related to them)
# in the graphGallery Repository
archivistRepo <- system.file( "graphGallery", package = "archivist"
# You may use:
# hashes <- unique(showLocalRepo(repoDir)[,1])
# to extract all artifacts from repository
hashes <- searchInLocalRepo(pattern="name",
repodir = archivistRepo,
fixed=FALSE)

# copying selected artifacts from archivist Remote Repository into examplerepodir Repository

copyLocalRepo(repoFrom = archivistRepo, repoTo = examplerepodir, md5hashes= hashes)

# see how the backpack database in our examplerepodir Repository looks like
showLocalRepo(repoDir = examplerepodir)

# removing an example Repository

deleteLocalRepo(exampleRepoDir, deleteRoot=TRUE)

display rm(exampleRepoDir)
display rm(archivistRepo)

## End(Not run)

createLocalRepo  
Create an Empty Repository

### Description

createLocalRepo creates an empty Repository in the given directory in which archived artifacts will be stored.

### Usage

createLocalRepo(repoDir, force = FALSE, default = FALSE)
createPostgresRepo(repoDir, connector, force = FALSE, default = FALSE)
createEmptyRepo(...)

createLocalRepo

Arguments

- **repoDir**: A character that specifies the directory for the Repository which is to be made.
- **force**: If `force = TRUE` and `repoDir` parameter specifies the directory that contains `backpack.db` file, then function call will force to recreate new `backpack.db` database set to `force = FALSE`. If `default = TRUE` then `repoDir` is set as default Local Repository.
- **connector**: If user want to use some external database instead of SQLite, then the connector shall be the function that create a DBI connection with the database. Within every transaction the connection is opened and closed, thus the connector function will be executed often and shall not be computationally heavy. See the Examples section for some examples. Note that it's an experimental feature.

... All arguments are being passed to `createLocalRepo`.

Details

At least one Repository must be initialized before using other functions from the `archivist` package. While working in groups, it is highly recommended to create a Repository on a shared Dropbox/GitHub folder.

All artifacts which are desired to be archived are going to be saved in the local Repository, which is an SQLite database stored in a file named `backpack.db`. After calling `saveToRepo` function, each artifact will be archived in a `md5hash.rda` file. This file will be saved in a folder (under `repoDir` directory) named `gallery`. For every artifact, `md5hash` is a unique string of length 32 that is produced by `digest` function, which uses a cryptographically MD5 hash algorithm.

To learn more about artifacts visit `archivist-package`.

Created `backpack` database is a useful and fundamental tool for remembering artifact's name, class, archiving date etc. (the so called Tags) or for keeping artifact's `md5hash`.

Besides the `backpack` database, `gallery` folder is created in which all artifacts will be archived.

After every `saveToRepo` call the database is refreshed. As a result, the artifact is available immediately in `backpack.db` database for other collaborators.

Other archivist: Repository, Tags, %a, addHooksToPrint, addTagsRepo, aformat, ahistory, alink, aoptions, archivist-package, areadLocal, aread, asearchLocal, asearch, asession, atrace, cache, copyLocalRepo, createMDGallery, deleteLocalRepo, getRemoteHook, getTagsLocal, loadFromLocalRepo, mdShash, removeTagsRepo, restoreLibs, rmFromLocalRepo, saveToLocalRepo, searchInLocalRepo, setLocalRepo, shinySearchInLocalRepo, showLocalRepo, splitTagsLocal, summaryLocalRepo, zipLocalRepo

Examples

```r
## Not run:
exampleRepoDir <- tempfile()
createLocalRepo( repoDir = exampleRepoDir, default = TRUE )
data(iris)
saveToLocalRepo(iris)
showLocalRepo()
showLocalRepo( method = "tags")
deleteLocalRepo( repoDir = exampleRepoDir, unset = TRUE, deleteRoot = TRUE)

# example with external database
# create a connector
require("rPostgreSQL")
drv <- dbDriver("PostgreSQL")
connector <- function() {
  dbConnect(drv, dbname = "postgres",
         host = "localhost", port = 5432,
         user = "user", password = pw)
}
# Now you can create an empty repository with postgress database
exampleRepoDir <- tempfile()
createPostgresRepo( repoDir = exampleRepoDir, connector)
data(iris)
saveToLocalRepo(iris)
showLocalRepo()
showLocalRepo( method = "tags")
deleteLocalRepo( repoDir = exampleRepoDir, unset = TRUE, deleteRoot = TRUE)
```
createMDGallery  

Create the Summary for Each Artifact in a Markdown Format

Description

createMDGallery creates a summary for each artifact from Repository stored on a GitHub. For each artifact the function creates a markdown file with: the download link, artifact’s Tags (when addTags = TRUE) and miniature (addMiniature = TRUE) if the artifact was archived with it’s miniature and Tags. The miniature is a print or head over an artifact or it’s png when it was a plot. But this function only supports png miniatures.

Usage

createMDGallery(output, repo = aoptions("repo"), user = aoptions("user"), branch = aoptions("branch"), subdir = aoptions("subdir"), repoType = aoptions("repoType"), addTags = FALSE, addMiniature = FALSE, maxTags = 100)

Arguments

output  A name of the file in which artifacts should be summarized.
repo  A character containing a name of the Remote repository on which the Repository is stored. By default set to NULL - see Note.
user  A character containing a name of the Github user on whose account the repo is created. By default set to NULL - see Note.
branch  A character containing a name of the Remote Repository’s branch on which the Repository is stored. Default branch is master.
subdir  A character containing a name of a directory on the Remote repository on which the Repository is stored. If the Repository is stored in the main folder of the Remote repository, this should be set to subdir = "/" as default.
repoType  A character containing a type of the remote repository. Currently it can be ’github’ or ’bitbucket’.
addTags  Logical, whether to add artifact’s Tags to the output.
addMiniature  Logical, whether to add artifact’s miniature/plots to the output.
maxTags  Integer. The maximal length of chunks output when describing Tags of artifact.

Details

To learn more about artifacts visit archivist-package.

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues
**Note**

If repo and user are set to NULL (as default) in the Remote mode then global parameters set in `setRemoteRepo` (or via `aoptions`) function are used.

## Not run:
createMDGallery(user = 'MarcinKosinski', repo = 'Museum', 'README_test1.md', addTags = TRUE)
createMDGallery('graphGallery', 'pbiecek', addMiniature = TRUE, 'README_test2.md', addTags = TRUE)

## End(Not run)
```

---

**deleteLocalRepo**

*Delete the Existing Repository from the Given Directory*

**Description**

deleteLocalRepo deletes the existing Repository from the given directory. As a result all artifacts from gallery folder are removed and database backpack.db is deleted.
Usage

deleteLocalRepo(repoDir, deleteRoot = FALSE, unset = FALSE)
deleteRepo(...)  

Arguments

repoDir A character that specifies the directory for the Repository which is to be deleted.
deleteRoot A logical value that specifies if the repository root directory should be deleted for Local Repository.
unset A logical. If deleted repoDir was set to be default Local Repository and unset is TRUE, then repoDir is unset as a default Local Repository (aoptions('repoDir/repo', NULL, T)).
...
All arguments are being passed to deleteLocalRepo.

Contact

Bug reports and feature requests can be sent to https://github.com/pbieck/archivist/issues

Note

Remember that using tempfile() instead of tempdir() in examples section is crucial. tempdir() is existing directory in which R works so calling deleteLocalRepo(exampleRepoDir, deleteRoot=TRUE) removes important R files. You can find out more information about this problem at stackoverflow webpage.

getRemoteHook  

*Get http Hook for Remote Repo*

**Description**

getRemoteHook returns http adress of the remote Repository. Then it can be used to download artifacts from the remote Repository.

**Usage**

getRemoteHook(repo = aoptions("repo"), user = aoptions("user"),  
branch = aoptions("branch"), subdir = aoptions("subdir"), 
repoType = aoptions("repoType"))

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>repo</td>
<td>A character containing a name of a Git repository on which the Repository is archived.</td>
</tr>
<tr>
<td>user</td>
<td>A character containing a name of a Git user on whose account the repo is created.</td>
</tr>
<tr>
<td>branch</td>
<td>A character containing a name of Git Repository’s branch on which the Repository is archived. Default branch is master.</td>
</tr>
<tr>
<td>subdir</td>
<td>A character containing a name of a directory on Git repository on which the Repository is stored. If the Repository is stored in main folder on Git repository, this should be set to subdir = &quot;/&quot; as default.</td>
</tr>
<tr>
<td>repoType</td>
<td>A character containing a type of the remote repository. Currently it can be 'github' or 'bitbucket'.</td>
</tr>
</tbody>
</table>

getRemoteHook("graphGallery", "pbiecek")

## End(Not run)
```

getTagsLocal  

Return Tags Corresponding to md5Hash

Description

getTagsLocal and getTagsRemote return Tags (see Tags) related to md5Hash of an artifact. To learn more about artifacts visit archivist-package.

Usage

getTagsLocal(md5Hash, repodir = aoptions("repodir"), tag = "name")

getTagsRemote(md5Hash, repo = aoptions("repo"), user = aoptions("user"),
  branch = aoptions("branch"), subdir = aoptions("subdir"),
  repotype = aoptions("repotype"), tag = "name")

Arguments

- **md5Hash**: A character containing md5Hash of artifacts which Tags are desired to be returned.
- **repodir**: A character denoting an existing directory in which artifacts are stored.
- **tag**: A regular expression denoting type of a Tag that we search for (see Examples). Default tag = "name".
- **repo**: While working with the Remote repository. A character containing a name of the Remote repository on which the Repository is stored. By default set to NULL - see Note.
- **user**: While working with the Remote repository. A character containing a name of the Remote user on whose account the repo is created. By default set to NULL - see Note.
getTagsLocal

branch
While working with the Remote repository. A character containing a name of the Remote repository’s branch on which the Repository is stored. Default branch is master.

subdir
While working with the Remote repository. A character containing a name of a directory on the Remote repository on which the Repository is stored. If the Repository is stored in main folder on the Remote repository, this should be set to subdir = "/" as default.

repoType
A character containing a type of the remote repository. Currently it can be 'github' or 'bitbucket'.

Details

getTagsLocal and getTagsRemote return Tags, of a specific type described by tag parameter, related to md5Hash of an artifact. To learn more about artifacts visit archivist-package.

Value
The character vector of Tags (see Tags) related to md5Hash of an artifact.

Contact
Bug reports and feature requests can be sent to https://github.com/pbieck/archivist/issues

Note
If repo and user are set to NULL (as default) in Remote mode then global parameters set in setRemoteRepo function are used.

summarise(avgmpg = mean(mpg), avgwt = mean(wt)) %a%
filter(avgmpg > 20) %a%
savetoRepo( exampleRepoDir )

showLocalRepo(exampleRepoDir)
showLocalRepo(exampleRepoDir, method = "tags")

# We search for a Tag with default "name" regular expression corresponding to
# hash mdShash.
getTagsLocal( mdShash = hash, exampleRepoDir )

# Deleting example respository
deleteLocalRepo( exampleRepoDir, TRUE)
rm( exampleRepoDir )

## EXAMPLE with data iris
eexampleRepoDir <- tempfile()
createlocalrepo( exampleRepoDir )

data(iris)
savetoRepo(iris, repodir = exampleRepoDir )
showLocalRepo(exampleRepoDir)
showLocalRepo(exampleRepoDir, method = "tags")

# We can notice that there is only one mdShash
# (and second for archiveSessionInfo) in repo so we will use it
hash <- showLocalRepo(exampleRepoDir)[1,1]

# We search for a Tag with "varname" regular expression corresponding to
# hash mdShash.
getTagsLocal( mdShash = hash, exampleRepoDir, tag = "varname" )
# There are 5 different Tags with "varname" regular expression
```
### Description

`loadFromLocalRepo` loads an artifact from a local **Repository** into the workspace. `loadFromRemoteRepo` loads an artifact from a github / git / mercurial **Repository** into the workspace. To learn more about artifacts visit [archivist-package](https://github.com/archivist-package).

### Usage

```c
loadFromLocalRepo(md5hash, repoDir = aoptions("repoDir"), value = FALSE)

loadFromRemoteRepo(md5hash, repo = aoptions("repo"),
                   user = aoptions("user"), branch = aoptions("branch"),
                   subdir = aoptions("subdir"), repoType = aoptions("repoType"),
                   value = FALSE)
```

### Arguments

- **md5Hash**: A character assigned to the artifact through the use of a cryptographical hash function with MD5 algorithm, or its abbreviation.
- **repoDir**: A character denoting an existing directory from which an artifact will be loaded.
loadFromLocalRepo

value
If FALSE (default) then artifacts are loaded into the Global Environment with their original names, if TRUE then artifacts are returned as a list of values (if there is more than one artifact) or as a single value (if there is only one artifact that matches md5Hash).

repo
While working with a Remote repository. A character containing a name of a Remote repository on which the Repository is archived. By default set to NULL - see Note.

user
While working with a Remote repository. A character containing a name of a Remote user on whose account the repo is created. By default set to NULL - see Note.

branch
While working with a Remote repository. A character containing a name of Remote Repository’s branch on which the Repository is archived. Default branch is master.

subdir
While working with a Remote repository. A character containing a name of a directory on Remote repository on which the Repository is stored. If the Repository is stored in main folder on Remote repository, this should be set to subdir = “/” as default.

repoType
A character containing a type of the remote repository. Currently it can be 'Remote' or 'bitbucket'.

Details
Functions loadFromLocalRepo and loadFromRemoteRepo load artifacts from the archivist Repositories stored in a local folder or on git. Both of them take md5hash as a parameter, which is a result of saveToRepo function. For each artifact, md5hash is a unique string of length 32 that is produced by digest function, which uses a cryptographical MD5 hash algorithm. For more information see md5hash.

Important: instead of giving the whole md5hash character, the user can simply give first few characters of the md5hash. For example, a09dd instead of a09ddjdfk9kj33dcjdnfjgos9jd9jkcvm. All artifacts with the same md5hash abbreviation will be loaded from Repository.

Note that user and repo should be used only when working with a git repository and should be omitted in the local mode. subdir should only be used when working on a local Repository and should be omitted in the git mode.

One may notice that loadFromRemoteRepo and loadFromLocalRepo load artifacts to the Global Environment with their original names. Alternatively, a parameter value = TRUE can be specified so that these functions may return artifacts as a value. As a result loaded artifacts can be attributed to new names. Note that, when an abbreviation of md5hash was given then a list of artifacts corresponding to this abbreviation will be loaded.

Contact
Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

Note
You can specify one md5hash (or its abbreviation) per function call.
If repo and user are set to NULL (as default) in Remote mode then global parameters set in setRemoteRepo function are used.

You should remember while using loadFromRepo wrapper that repodir is a parameter used only in loadFromLocalRepo while repo, user, branch and subdir are used only in loadFromRemoteRepo. When you mix those parameters you will receive an error message.

---

**mdShash**

**Description**

Repository stores specific values of an artifact, different for various artifact’s classes, and artifact themselves. Artifacts are archived with a special attribute named mdShash. To learn more about artifacts visit archivist-package.

**Details**

For each artifact, mdShash is a unique string of length 32 that is produced by digest function which uses a cryptographical MD5 hash algorithm. The mdShash of each artifact that is archived in the Repository is also saved on the Repository along with the artifact’s Tags - see Tags. It enables to distinguish artifacts in the Repository and facilitates searching and loading them.

Other archivist: Repository, Tags, %a%, addHooksToPrint, addTagsRepo, aformat, ahistory, alink, aoptions, archivist-package, areadLocal, aread, asearchLocal, asearch, asession, atrace, cache, copyLocalRepo, createLocalRepo, createMDGallery, deleteLocalRepo, getRemoteHook, getTagsLocal, loadFromLocalRepo, removeTagsRepo, restoreLibs, rmFromLocalRepo, saveToLocalRepo, searchInLocalRepo, setLocalRepo, shinySearchInLocalRepo, showLocalRepo, splitTagsLocal, summaryLocalRepo, zipLocalRepo
**Description**

`removeTagsRepo` removes selected Tags from selected objects in Repository.

**Usage**

```r
removeTagsRepo(md5hashes, repoDir = NULL, tags = NULL)
```

**Arguments**

- `md5hashes`: a character vector of md5hashes specifying to which corresponding artifacts Tags should be removed.
- `repoDir`: A character that specifies the directory of the Repository to which new Tags will be added. If it is set to `NULL` (by default), it uses the `repoDir` specified in `setLocalRepo`.
- `tags`: A character vector which specifies what Tags should be removed.

**Details**

The `removeTagsRepo` function removes all Tags from all listed objects. Note that some hashes are required for keeping erlations between objects in the repository. Be careful what are you removing.

### Description

Repository stores specific values of an artifact, different for various artifact’s classes and artifacts themselves. To learn more about artifacts visit archivist-package.

### Details

Repository is a folder with an SQLite database stored in a file named `backpack` and a subdirectory named `gallery`. `backpack` contains two tables: `artifact` and `tag`. `artifact` table consists of three columns:

- `md5Hash`
- `name`
- `createdDate`

while `tag` table consists of the following three columns:

- `artifact`
- `tag`
- `createdDate`

`gallery` collects the following objects:

- artifacts and artifacts’ data saved as `.rda` files,
- artifacts’ miniatures saved as `.txt` and `.png` files.

---

**restoreLibs**

### Description

Function **restoreLibs** gets either session info or artifact’s md5hash and restore libraries/packages to versions attached when the object was saved in the repo. Typical use case is following. We have saved an object and now we are restoring it, but with current version of packages something is not working. The function **restoreLibs()** reverts all libraries that were attached previously to their previous versions.

### Usage

```
restoreLibs(md5hash, session_info = NULL, lib.loc = NULL)
```

### Arguments

- **md5hash**: One of the following (see aread):
  - A character vector which elements are consisting of at least three components separated with ‘/’: Remote user name, Remote repository and name of the artifact (MD5 hash) or its abbreviation.
  - MD5 hashes of artifacts in current local default directory or its abbreviations.

- **session_info**: Object with versions of packages to be installed. If not supplied then it will be extracted from md5hash

- **lib.loc**: A character vector describing the location of R library trees to restore archived libraries, or NULL. The default value of NULL corresponds to all libraries currently known to .libPaths(). Non-existent library trees are silently ignored.

## End(Not run)
```

---

### rmFromLocalRepo

**Remove an Artifact Given as a md5hash from the Repository**

**Description**

rmFromLocalRepo removes an artifact given as a md5hash from the Repository. To learn more about artifacts visit archivist-package.

**Usage**

```r
rmFromLocalRepo(md5hash, repoDir = aoptions("repoDir"), removeData = FALSE, removeMiniature = FALSE, force = FALSE, many = FALSE)

rmFromRepo(...)```
Arguments

**md5hash**
A character assigned to the artifact through the use of a cryptographical hash function with MD5 algorithm, or its abbreviation. This object will be removed. If `many` parameter is set to TRUE then md5hash will be a character vector.

**repoDir**
A character denoting an existing directory from which an artifact will be removed.

**removeData**
A logical value denoting whether to remove data along with the artifact specified by the md5hash. Default FALSE.

**removeMiniature**
A logical value denoting whether to remove a miniature along with the artifact specified by the md5hash. Default FALSE.

**force**
A logical value denoting whether to remove data related to more than one artifact. Default FALSE.

**many**
A logical value. To accelerate the speed of removing many objects, you can set this parameter to TRUE and pass a vector of artifacts’ md5hashes to a md5hash parameter. It is not possible to use a vector of artifacts’ md5hashes abbreviations - see Note. By default, set to FALSE.

...All arguments are being passed to `rmFromLocalRepo`.

Details

`rmFromLocalRepo` removes an artifact given as a `md5hash` from the Repository. To be more precise, an artifact is removed both from `backpackNdb` file (the SQLite database) and `gallery` subdirectory, where the artifacts are stored as `md5hashNrda` files.

Important: instead of giving the whole md5hash character, a user can simply give its first few characters. For example, "a09dd" instead of "a09ddjdf9k3j33cjdncjgos9jd9kcv". All artifacts with the same md5hash abbreviation will be removed from the repository.

`rmFromLocalRepo` provides functionality that enables us to delete miniatures of the artifacts (.txt or .png files) while removing .rda files. To delete miniature of the artifact use `removeMiniature = TRUE` argument. Moreover, if the data from the artifact is archived then there is a possibility to delete this data while removing the artifact. Simply use `removeData = TRUE` argument.

If one wants to remove all artifacts created between two dates, it is suggested to perform:

```
  • obj2rm <- searchInLocalRepo( tag = list(dateFrom, dateTo), repoDir = )
  • sapply(obj2rm, rmFromLocalRepo, repoDir = )
```

Contact

Bug reports and feature requests can be sent to [https://github.com/pbiecek/archivist/issues](https://github.com/pbiecek/archivist/issues)

Note

md5hash can be a result of the `searchInLocalRepo` function called by `tag = NAME` argument, where NAME is a Tag that describes the property of the artifacts to be deleted.
It is not possible to use a vector of artifacts’ md5hashes abbreviations while using many = TRUE argument. This assumption was made to protect a user from removing, by accident, too many artifacts from the Repository.

For more information about Tags check Tags.

# Again we receive a warning as Artifacts are no longer in the repository but ...
list.files(file.path(exampleRepoDir, "gallery"))
# gallery folder is empty now! Artifact's miniature's were removed.
saveToLocalRepo

Save an Artifact into a Repository

Description

The `saveToLocalRepo` function saves desired artifacts to the local Repository in a given directory. To learn more about artifacts visit [archivist-package](#).

Usage

```r
saveToLocalRepo(artifact, repodir = aoptions("repodir"), archivedata = TRUE, 
archiveTags = TRUE, archiveMiniature = TRUE, archiveSessionInfo = TRUE, 
force = TRUE, value = FALSE, ..., userTags = c(),
use_flocks = aoptions("use_flocks"), silent = aoptions("silent"), 
ascii = FALSE, artifactName = deparse(substitute(artifact)))
```

```r
saveToRepo(artifact, repodir = aoptions("repodir"), archivedata = TRUE, 
archiveTags = TRUE, archiveMiniature = TRUE, archiveSessionInfo = TRUE, 
force = TRUE, value = FALSE, ..., userTags = c(),
use_flocks = aoptions("use_flocks"), silent = aoptions("silent"), 
ascii = FALSE, artifactName = deparse(substitute(artifact)))
```

```r
asave(artifact, repodir = aoptions("repodir"), archivedata = TRUE, 
archiveTags = TRUE, archiveMiniature = TRUE, archiveSessionInfo = TRUE, 
force = TRUE, value = FALSE, ..., userTags = c(),
use_flocks = aoptions("use_flocks"), silent = aoptions("silent"), 
ascii = FALSE, artifactName = deparse(substitute(artifact)))
```

Arguments

- **artifact**: An arbitrary R artifact to be saved. For supported artifacts see details.
- **repopDir**: A character denoting an existing directory in which an artifact will be saved.
- **archivedata**: A logical value denoting whether to archive the data from the artifact.
- **archiveTags**: A logical value denoting whether to archive Tags from the artifact.
saveToLocalRepo

archiveMiniature
A logical value denoting whether to archive a miniature of the artifact.

archiveSessionInfo
A logical value denoting whether to archive the session info that describes the context in which this given artifact was created.

force
A logical value denoting whether to archive artifact if it was already archived in a Repository.

value
A logical value. Should the result be (default value = FALSE) the md5hash of a stored artifact or should the result be an input artifact (value = TRUE), so that valueing code can be used. See examples.

... Graphical parameters denoting width and height of a miniature. See details. Further arguments passed to head. See Details section about firstrows parameter

userTags
A character vector with Tags. These Tags will be added to the repository along with the artifact.

use_flocks
A logical value. If TRUE then flock package is used to lock access to a database. By default it's FALSE.

silent
If TRUE produces no warnings.

ascii
A logical value. An ascii argument is passed to save function.

artifactName
The name of the artifact with which it should be archived. If NULL then object’s MD5 hash will be used instead.

Details

callToLocalRepo function saves desired artifacts to the local Repository in a given directory. Artifacts are saved in the local Repository, which is a SQLite database named backpack. After every call toLocalRepo call the database is refreshed, so the artifact is available immediately in the database for other collaborators. Each artifact is archived in a md5hash.rda file. This file will be saved in a folder (under repoDir directory) named gallery. For each artifact, md5hash is a unique string of length 32 that is produced by digest function, which uses a cryptographical MD5 hash algorithm.

By default, a miniature of an artifact and (if possible) a data set needed to compute this artifact are extracted. They are also going to be saved in a file named by their md5hash in the gallery folder that exists in the directory specified in the repoDir argument. Moreover, a specific Tag-relation is going to be added to the backpack dataset in case there is a need to load the artifact with it’s related data set - see loadFromLocalRepo or loadFromRemoteRepo. Default settings may be changed by using the archiveData, archiveTag or archiveMiniature arguments with the FALSE value.

Tags are artifact’s attributes, different for various artifact’s classes. For more detailed information check Tags

Archived artifact can be searched in the backpack dataset by using the searchInLocalRepo or searchInRemoteRepo functions. Artifacts can be searched by their Tags, names, classes or archiving date. firstRows parameter.

If the artifact is of class data.frame or user set archiveData = TRUE for artifact that stores data within it, it is possible to specify how many rows of that data (or that data.frame) should be archived in a miniature. This can be done by adding the argument firstRows with the n
saveToLocalRepo

corresponding to the number of rows (as in head). Note that, the data can be extracted only from
the artifacts that are supported by the archivist package; see Tags.

Graphical parameters.
If the artifact is of class lattice or ggplot, and archiveMiniature = TRUE, then it is possible
to set the miniature’s width and height parameters. By default they are set to width = 800,
height = 600.

Supported artifact’s classes are listed here Tags.

Value

As a result of calling this function a character string is returned, which determines the md5hash
of the artifact. If archiveData is TRUE, the result will also have an attribute, named data, which
determines md5hash of the data needed to compute the artifact.

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

Note

In the following way one can specify his own Tags for artifacts by setting artifact’s attribute before
call of the saveToLocalRepo function: attr(x, "tags") = c( "name1", "name2" ), where x
is an artifact and name1, name2 are Tags specified by a user. It can be also done in a new, simpler
way by using userTags parameter like this:

- saveToLocalRepo(model, repodir, userTags = c("my_model", "do not delete"));

Specifying additional Tags by attributes can be beneficial when one uses addHooksToPrint.
Important: if one wants to archive data from artifacts which is one of: survfit, glmnet, qda, lda, trellis, htest
class, and this dataset is transformed within the artifact’s formula then saveToLocalRepo will not
archive this dataset. saveToLocalRepo only archives datasets that already exist in any of R envi-
ronments.

Example: The data set will not be archived here.

- z <- lda(Sp ~ ., Iris, prior = c(1,1,1)/3, subset = train[,,-8])
- saveToLocalRepo( z, repodir )

Example: The data set will be archived here.

- train2 <- train[,,-8]
- z <- lda(Sp ~ ., Iris, prior = c(1,1,1)/3, subset = train2)
- saveToLocalRepo( z, repodir )

**searchInLocalRepo**

*Search for an Artifact in the Repository Using Tags*

Description

searchInRepo searches for an artifact in the Repository using its Tags. To learn more about artifacts visit archivist-package.
Usage

searchInLocalRepo(pattern, repoDir = aoptions("repoDir"), fixed = TRUE,
intersect = TRUE)

searchInRemoteRepo(pattern, repo = aoptions("repo"),
user = aoptions("user"), branch = "master", subdir = aoptions("subdir"),
repoType = aoptions("repoType"), fixed = TRUE, intersect = TRUE)

multiSearchInLocalRepo(...)  
multiSearchInRemoteRepo(...)  

Arguments

pattern If fixed = TRUE: a character denoting a Tag which is to be searched for in
the Repository. It is also possible to specify pattern as a list of length 2 with
dateFrom and dateTo; see details. If fixed = FALSE: a regular expression
specifying the beginning of a Tag, which will be used to search for artifacts. If
of length more than one and if intersect = TRUE then artifacts that match all
conditions are returned. If intersect = FALSE then artifacts that match any
condition are returned. See examples.

repoDir A character denoting an existing directory in which artifacts will be searched
for.

fixed A logical value specifying how artifacts should be searched for. If fixed = TRUE
(default) then artifacts are searched for by using pattern = "Tag" argument. If
fixed = FALSE then artifacts are searched for by using pattern = "regular expression"
argument. The latter is wider and more flexible method, e.g., using pattern = "name", fixed = FALSE
arguments enables to search for all artifacts in the Repository.

intersect A logical value. Used only when length(pattern) > 1 & is.character(pattern).
See pattern for more details.

repo While working with the Remote repository. A character containing a name of
the Remote repository on which the Repository is stored. By default set to NULL
- see Note.

user While working with the Remote repository. A character containing a name of
the Remote user on whose account the repo is created. By default set to NULL -
see Note.

branch While working with the Remote repository. A character containing a name of
the Remote Repository’s branch on which the Repository is stored. Default
branch is master.

subdir While working with the Remote repository. A character containing a name of
a directory on the Remote repository on which the Repository is stored. If the
Repository is stored in the main folder of the Remote repository, this should be
set to subdir = "/" as default.

repoType A character containing a type of the remote repository. Currently it can be
'github' or 'bitbucket'.

... Used for old deprecated functions.
**searchInLocalRepo**

### Details

`searchInRepo` searches for an artifact in the Repository using its tag (e.g., name, class or archiving date). Tags are used in a pattern parameter. For various artifact classes different Tags can be searched for. See **Tags**. If a pattern is a list of length 2 then md5hashes of all artifacts created from date `dateFrom` to date `dateTo` are returned. The date should be formatted according to the YYYY-MM-DD format, e.g., "2014-07-31".

Tags, used in a pattern parameter, should be determined according to the format: "TagKey:TagValue" - see examples.

### Value

`searchInRepo` returns character vector of md5hashes of artifacts that were searched for. Those are hashes assigned to artifacts while they were saved in the Repository by the `saveToLocalRepo` function. If the artifact is not in the Repository then a logical value FALSE is returned.

### Contact

Bug reports and feature requests can be sent to [https://github.com/pbiecek/archivist/issues](https://github.com/pbiecek/archivist/issues)

### Note

If `repo`, `user`, `subdir` and `repoType` are not specified in the Remote mode then global parameters set in `setRemoteRepo` function are used.

Bug reports and feature requests can be sent to [https://github.com/pbiecek/archivist/issues](https://github.com/pbiecek/archivist/issues)

## End(Not run)

setLocalRepo Set Repository’s Global Path

Description

setLocalRepo sets local Repository’s global path. setRemoteRepo similarly sets Remote Repository’s path. See examples.

Usage

setLocalRepo(repoDir)

setPostgresRepo(repoDir, connector = NULL)

setRemoteRepo(user, repo, branch = "master", subdir = "/",
  repoType = "github")

Arguments

repoDir A character denoting a directory of a Repository that we want to make dafault.
connector If user want to use some external database instead of SQLite, then the connector
  shall be the function that create a DBI connection with the database. Within every
  transaction the connection is opened and closed, thus the connector function
  will be executed often and shall not be computationally heavy. See examples
  for createLocalRepo for some applications. If connector=NULL then informa-
  tion about connectors to an external database will be removed. Note that it’s an
  experimental feature.
user While working with the Remote repository. A character containing a name of
  the Remote user that we want to make default.
repo While working with the Remote repository. A character containing a name of
  the Remote repository that we want to make default.
branch While working with the Remote repository. A character containing a name of
  the Remote Repository’s branch that we want to make default. Default branch
  is master.
subdir While working with the Remote repository. A character containing a name of the
  Repository’s directory on Remote that we want to make default. If the Reposi-
  tory is stored in the main folder on the Remote repository, this should be set to
  subdir = "/" as default.
setLocalRepo

repoType A character containing a type of the remote repository. Currently it can be 'github' or 'bitbucket'.

Details

If you are working on a local Repository and you are tired of specifying repodir parameter in every function call that uses this parameter, you can set Repository’s path globally using setLocalRepo function and omit repodir parameter in future function calls.

If you are working on the Remote Repository and you are tired of specifying user, repo, branch and subdir parameters in every function call that uses these parameters, you can set Remote Repository’s path globally using setRemoteRepo function and omit user, repo, branch and subdir parameters in future function calls. See examples.

For local repositories, in this way, in the following function calls: loadFromLocalRepo, searchInLocalRepo, rmFromLocalRepo, zipLocalRepo, addTagsRepo, shinySearchInLocalRepo, getTagsLocal, showLocalRepo, summaryLocalRepo repodir parameter may be omitted. For remote repositories, in this way, in the following function calls: zipRemoteRepo, loadFromRemoteRepo, searchInRemoteRepo, getTagsRemote, showRemoteRepo, summaryRemoteRepo, copyRemoteRepo parameters user, repo, branch, subdir may be omitted.

## Not run:
## Local version
exampleRepoDir <- tempfile()
createLocalRepo(repoDir = exampleRepoDir)
setLocalRepo(exampleRepoDir)

data(iris)
data(swiss)

# From this moment repoDir parameter may be ommitted in the following functions
saveToRepo(iris)
saveToRepo(swiss)
showLocalRepo()
showLocalRepo(method = "tags")
iris2 <- loadFromLocalRepo("ff575c2", value = TRUE)
searchInLocalRepo("name:i", fixed = FALSE)
getTagsLocal("ff575c261c949d073b2895b05d1097c3")
rmFromLocalRepo("4c43f")
showLocalRepo()
summaryLocalRepo()

# REMEMBER that in deleteLocalRepo you MUST specify repoDir parameter!
# deleteRepo doesn't take setLocalRepo's settings into consideration
deleteLocalRepo(exampleRepoDir, deleteRoot=TRUE)
rm(exampleRepoDir)

## Github version
setRemoteRepo( user="MarcinKosinski", repo="Museum", branch="master", subdir="ext" )

# From this moment user, repo, branch, subdir parameters may be ommitted
# in the following functions:
showRemoteRepo()
loadFromRemoteRepo("ff575c261c949d073b2895b05d1097c3")
this <- loadFromRemoteRepo("ff", value = TRUE)
zipRemoteRepo()
file.remove(file.path(getwd(), "repository.zip")) # We can remove this zip file
searchInRemoteRepo("name:", fixed = FALSE)
getTagsRemote("ff575c261c949d073b2895b05d1097c3")
summaryRemoteRepo()
```
shinySearchInLocalRepo

Description

shinySearchInLocalRepo searches for an artifact in a Repository using Tags. To create an application one needs to point the name of artifacts' repository. The application is generated on the run. As for now there are two controllers exposed. A text input field and a slider. Tags that are typed into text field are used for searching in repository. Objects that have the same Tags are presented on the right panel. These object might be also downloaded just by click. To learn more about artifacts visit archivist-package.

Usage

shinySearchInLocalRepo(repoDir = NULL, host = "0.0.0.0")

Arguments

repoDir
A character denoting an existing directory in which artifacts will be searched. If set to NULL (by default), uses the repoDir specified in setLocalRepo.

host
A host IP adress, see the host argument in shiny::runApp.

Details

shinySearchInLocalRepo searches for artifacts in a Repository using their Tags (e.g., name, class or archiving date). Tags are submitted in a text input in a shiny application. Many Tags may be specified, they should be comma separated. User can specify more Tags like phase, project, author etc. when artifact is created.

In the search query one can add Tags starting with sort: or sort:-. As a result, miniatures will be sorted appropriately. For example sort:class will sort class Tags, while sort:-class will sort class tags backwards. sort:createdDate will sort createdDate Tag and sort:-createdDate will sort createdDate Tag backwards.

Tags, submitted in the text field, should be given according to the format: "TagKey:TagValue" - see examples.
showLocalRepo

Value

shinySearchInLocalRepo runs a shiny application.

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

shiny

This function uses tools from the fantastic shiny package, so you’ll need to make sure to have it installed.

showLocalRepo  View the List of Artifacts from the Repository

Description

showLocalRepo and showRemoteRepo functions produce the data.frame of the artifacts from the Repository saved in a given repoDir (directory). showLocalRepo shows the artifacts from the Repository that exists on the user’s computer whereas showRemoteRepo shows the artifacts of the Repository existing on the remote repository. To learn more about artifacts visit archivist-package.
Usage

```
showLocalRepo(repoDir = aoptions("repoDir"), method = "mdShashes")

showRemoteRepo(repo = aoptions("repo"), user = aoptions("user"),
               branch = aoptions("branch"), subdir = aoptions("subdir"),
               repoType = aoptions("repoType"), method = "mdShashes")
```

Arguments

- **repoDir**: A character denoting an existing directory of the Repository for which metadata will be returned.
- **method**: A character specifying a method to be used to show the Repository. Available methods: mdShashes (default), tags and sets - see archivist2::saveSetToRepo.
- **repo**: While working with the Remote repository. A character containing a name of the Remote repository on which the Repository is stored. By default set to NULL - see Note.
- **user**: While working with the Remote repository. A character containing a name of the Remote user on whose account the repo is created. By default set to NULL - see Note.
- **branch**: While working with the Remote repository. A character containing a name of the Remote Repository’s branch on which the Repository is stored. Default branch is master.
- **subdir**: While working with the Remote repository. A character containing a name of a directory on the Remote repository on which the Repository is stored. If the Repository is stored in the main folder of the Remote repository, this should be set to subdir = "/" as default.
- **repoType**: A character containing a type of the remote repository. Currently it can be 'github' or 'bitbucket'.

Details

showLocalRepo and showRemoteRepo functions produce the data.frame of the artifacts from a Repository saved in a given repoDir (directory). showLocalRepo shows the artifacts from the Repository that exists on the user’s computer whereas showRemoteRepo shows the artifacts of the Repository existing on the remote repository.

Both functions show the current state of a Repository, inter alia, all archived artifacts can be seen with their unique md5Hash or a data.frame with archived Tags can be obtained.

Value

If parameter method is set as md5hashes then a data.frame with artifacts’ names and artifacts’ md5hashes will be returned.

If parameter method is set as tags then a data.frame with Tags and artifacts’ md5hashes will be returned.

Also in both cases a data.frame contains an extra column with the date of creation of the Tag or md5Hash.
To learn more about Tags or md5hashes check: Tags or md5Hash.

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

Note

If repo and user are set to NULL (as default) in the Remote mode then global parameters set in setRemoteRepo (or via aoptions) function are used.

tShowRemoteRepo( user="MarcinKosinski", repo="Museum", branch="master",
```
## splitTagsLocal

### Description

The `splitTagsLocal` function splits the `tag` column from the `tag` table placed in `backpack.db` into two separate columns: `tagKey` and `tagValue`.

### Usage

```r
splitTagsLocal(repoDir = aoptions("repoDir"))
```

### Arguments

- **repoDir**: A character denoting an existing directory of the Repository.
- **repo**: A character containing a name of the Github repository on which the Repository is stored. By default set to `NULL` - see Note.
- **user**: A character containing a name of the Github user on whose account the `repo` is created. By default set to `NULL` - see Note.
- **branch**: A character containing a name of the Github repository on which the Arrange is stored. By default set to `NULL` - see Note.
- **subdir**: A character denoting a name of a GitHub user on whose account the Arrange is created. By default set to `NULL` - see Note.
- **repotype**: A character containing a name of the Github repository on which the Arrange is stored. By default set to `NULL` - see Note.
splitTagsLocal

**branch**
While working with the Github repository. A character containing a name of the Github Repository's branch on which the Repository is stored. Default branch is `master`.

**subdir**
While working with the Github repository. A character containing a name of a directory on the Github repository on which the Repository is stored. If the Repository is stored in the main folder of the Github repository, this should be set to `subdir = "/"` as default.

**repoType**
A character containing a type of the remote repository. Currently it can be 'github' or 'bitbucket'.

**Details**

tag column from `tag` table has normally the following structure: TagKey:TagValue. `splitTagsLocal` and `splitTagsRemote` functions can be used to split `tag` column into two separate columns: `tagkey` and `tagvalue`. As a result functions from `dplyr` package can be used to easily summarize, search, and extract artifacts' Tags. See examples.

**Value**
A data.frame with 4 columns: `artifact`, `tagKey`, `tagValue` and `createdDate`, corresponding to the current state of Repository.

**Contact**
Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

**Note**
If `repo` and `user` are set to `NULL` (as default) in the Github mode then global parameters set in `setRemoteRepo` function are used.

Sometimes we can use `addTagsJ` function or `userTags` parameter in `saveToRepo` to specify a Tag which might not match TagKey:TagValue structure. It is simply Tag. In this case `tagKey = userTags` and `tagValue = Tag`. See examples.

To learn more about Tags and Repository structure check Tags and Repository.

Examples

```r
## Not run:
## LOCAL VERSION

setLocalRepo(system.file("graphGallery", package = "archivist"))
head(showLocalRepo(method = "tags"))
head(splitTagsLocal() )

## Github Version
# Let’s check how does table tag look like while we are using the
# Gitub repository.
# We will choose only special columns of data frames that show Tags
head(showRemoteRepo( user = "pbiecek", repo = "archivist", method = "tags" )[,2])
head(splitTagsRemote( user = "pbiecek", repo = "archivist" )[,2:3])

head(splitTagsRemote("PieczarPietraszki", "BetaAndBit", "master", "UniwersytetDzieci/arepo"))

## End(Not run)
```

summaryLocalRepo  View the Summary of the Repository

Description

summaryRepo summarizes the current state of the Repository.

Usage

```
summaryLocalRepo(repoDir = aoptions("repoDir"))

summaryRemoteRepo(repo = aoptions("repo"), user = aoptions("user"),
branch = "master", subdir = aoptions("subdir"),
repoType = aoptions("repoType"))
```

Arguments

- **repoDir**: A character denoting an existing directory of the Repository for which a summary will be returned.
repo While working with the Remote repository. A character containing a name of the Remote repository on which the Repository is stored. By default set to NULL - see Note.

user While working with the Remote repository. A character containing a name of the Remote user on whose account the repo is created. By default set to NULL - see Note.

branch While working with the Remote repository. A character containing a name of the Remote Repository’s branch on which the Repository is stored. Default branch is master.

subdir While working with the Remote repository. A character containing a name of a directory on the Remote repository on which the Repository is stored. If the Repository is stored in the main folder of the Remote repository, this should be set to subdir = "/" as default.

repoType A character containing a type of the remote repository. Currently it can be 'github' or 'bitbucket'.

Details

summaryRepo summarizes the current state of a Repository. Recommended to use print(summaryRepo).

See examples.

Value

An object of class repository which can be printed: print(object).

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

Note

If the same artifact was archived many times then it is counted as one artifact or database in print(summaryRepo).

If repo and user are set to NULL (as default) in the Remote mode then global parameters set in setRemoteRepo function are used.

#

x <- summaryRemoteRepo( user="pbiecek", repo="archivist")
print( x )

# many archivist-like Repositories on one Remote repository

summaryRemoteRepo(user="MarcinKosinski", repo="Museum", branch="master", subdir="ex2" )

## End(Not run)
```

---

**Description**

Tags are attributes of an artifact, i.e., a class, a name, names of artifact’s parts, etc... The list of artifact tags vary across artifact’s classes. To learn more about artifacts visit archivist-package.

**Details**

Tags are attributes of an artifact. They can be the artifact’s name, class or archiving date. Furthermore, for various artifact’s classes more different Tags are available.

A Tag is represented as a string and usually has the following structure "TagKey:TagValue", e.g., "name:iris".

Tags are stored in the Repository. If data is extracted from an artifact then a special Tag, named relationWith is created. It specifies with which artifact this data is related to.

The list of supported artifacts which are divided thematically is presented below. The newest list is also available on archivist wiki on Github.

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

Note

In the following way one can specify his own Tags for artifacts by setting artifact's attribute before call of the saveToLocalRepo function: attr(x, "tags") = c("name1", "name2"), where x is an artifact and name1, name2 are Tags specified by a user. It can be also done in a new, simpler way by using usertags parameter like this:

- saveToLocalRepo(model, repoDir, usertags = c("my_model", "do not delete")).

Specifying additional Tags by attributes can be beneficial when one uses addHooksToPrint.

# Create a zip Archive From an Existing Repository
zipLocalRepo(repodir = exampleRepoDir, value = TRUE)
repo = aoptions("repo"), branch = "master", subdir = aoptions("subdir"),
repoType = aoptions("repoType"), zipname = "repository.zip"

Arguments

repoDir A character that specifies the directory of the Repository which will be zipped.
repoTo A character that specifies the directory in which there will be created zip archive from Repository stored in repoDir or Remote directory. By default set to working directory (getwd()).
zipname A character that specifies name of the zipped repository. It is assumed that this file does not exist or does not contain backpack.db file. An attempt to override will produce an error.
user While working with the Remote repository. A character containing a name of the Remote user on whose account the repo is created. By default set to NULL - see Note.
repo While working with the Remote repository. A character containing a name of the Remote repository on which the Repository, which is to be zipped, is archived. By default set to NULL - see Note.
branch While working with the Remote repository. A character containing a name of the Remote repository’s branch on which Repository, which is to be zipped, is archived. Default branch is master.
subdir While working with a Remote repository. A character containing a name of a directory on Remote repository on which the Repository, which is to be zipped, is stored. If the Repository is stored in the main folder on the Remote repository, this should be set to FALSE as default.
repoType A character containing a type of the remote repository. Currently it can be 'Remote' or 'bitbucket'.

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

Note

The function might not work if Rtools are not installed. To solve this problem follow these Instructions.

If repo and user are set to NULL (as default) in Github mode then global parameters set in setRemoteRepo function are used.

**magrittr - a Forward-Pipe Operator for R**

**Description**

An extended pipe operator `%>%` from magrittr package version 1.0.1. Enables archiving artifacts with their chaining code - see examples and vignettes.

**Usage**

```
lhs %a% rhs
```

**Arguments**

- **lhs**: An artifact that will be used as an argument of rhs by `%a%` operator.
- **rhs**: A function call using lhs as an argument by `%a%` operator.

**Details**

The extension works as follows, the result of `%a%` operator is archived together with lhs (as an artifact) and rhs (as a Tag). This allows to present a history of an artifact. This option works only if a default repository is set.

**Contact**

Bug reports and feature requests can be sent to [https://github.com/pbiecek/archivist/issues](https://github.com/pbiecek/archivist/issues)

**Demonstration**
