Package ‘archivist’

August 31, 2019

Version  2.3.4
Type    Package
Title   Tools for Storing, Restoring and Searching for R Objects
Description  Data exploration and modelling is a process in which a lot of data artifacts are produced. Artifacts like: subsets, data aggregates, plots, statistical models, different versions of data sets and different versions of results. The more projects we work with the more artifacts are produced and the harder it is to manage these artifacts. Archivist helps to store and manage artifacts created in R. Archivist allows you to store selected artifacts as a binary files together with their metadata and relations. Archivist allows to share artifacts with others, either through shared folder or github. Archivist allows to look for already created artifacts by using it's class, name, date of the creation or other properties. Makes it easy to restore such artifacts. Archivist allows to check if new artifact is the exact copy that was produced some time ago. That might be useful either for testing or caching.

Repository  CRAN
License  GPL-2
LazyLoad  yes
LazyData  yes
Depends  R (>= 3.2.0)
Imports  RCurl, digest, httr, DBI, lubridate, RSQLite, magrittr, flock
Suggests  shiny, dplyr, testthat, ggplot2, devtools, knitr

Description

Data exploration and modelling is a process in which a lot of data artifacts are produced. Artifacts like: subsets, data aggregates, plots, statistical models, different versions of data sets and different versions of results. The more projects we work on, the more artifacts are produced and the harder it is to manage these artifacts.

Archivist helps to store and manage artifacts created in R.

Archivist allows you to store selected artifacts as binary files along with their metadata and relations. Archivist allows you to share artifacts with others, either through a shared folder or github. Archivist allows you to look for artifacts by using its class, name, date of creation or other properties. It also facilitates restoring such artifacts. Archivist allows you to check if a new artifact is the exact copy of the one that was produced some time ago. This might be useful either for testing or caching.

The list of main use cases is available here https://github.com/pbiecek/archivist.

Details

Other archivist: Repository, Tags, %a%, addHooksToPrint, addTagsRepo, aformat, ahistory, alink, aoptions, areadLocal, aread, asearchLocal, asearch, asession, atrace, cache, copyLocalRepo, createLocalRepo, createMDGallery, deleteLocalRepo, getRemoteHook, getTagsLocal, loadFromLocalRepo, md5Hash, removeTagsRepo, restoreLibs, rmFromLocalRepo, saveToLocalRepo, searchInLocalRepo, setLocalRepo, shinySearchInLocalRepo, showLocalRepo, splitTagsLocal, summaryLocalRepo, zipLocalRepo

---

**addHooksToPrint**

*Add archivist Hooks to rmarkdown Reports*

**Description**

`addHooksToPrint` adds an overloaded version of the print function for objects of selected class. The overloaded function will add all objects of selected class to the Repository and then will add hooks (to the Remote or Local Repository) to the HTML report (generated in *rmarkdown*) for these objects (*artifacts - archivist-package*). The great example can be seen in this blogpost [http://www.r-bloggers.com/why-should-you-backup-your-r-objects/](http://www.r-bloggers.com/why-should-you-backup-your-r-objects/).

**Usage**

```r
addHooksToPrint(class = "ggplot", repoDir = aoptions("repoDir"),
repo = aoptions("repo"), user = aoptions("user"),
branch = "master", subdir = aoptions("subdir"),
format = "markdown")
```

**Arguments**

- `class`: A character with a name of class (one or more) that should be archived.
- `repoDir`: A character containing a name of a Local Repository.
- `repo`: A character with a name of a Remote repository on which the Repository is archived. If `repo = NULL` then hooks will be added to files in local directories.
- `user`: A character with a name of a Remote-repository user on whose account the repo is created.
- `branch`: A character with a name of Remote-repository’s branch on which the Repository is archived. Default branch is `master`.
- `subdir`: A character with a name of a subdirectory on a Remote repository on which the Repository is stored. If the Repository is stored in main folder on a Remote repository, this should be set to `subdir = "/"` as default.
- `format`: A character denoting format as in `alink`.

**Contact**

Bug reports and feature requests can be sent to [https://github.com/pbiecek/archivist/issues](https://github.com/pbiecek/archivist/issues)
Note

One can specify userTags as in saveToLocalRepo for artifacts by adding "tags" attribute. See note section about that in saveToLocalRepo.

Author(s)

Przemyslaw Biecek, <przemyslaw.biecek@gmail.com>

References

See Also

Other archivist: Repository, Tags, %a%, addTagsRepo, aformat, ahistory, alink, aoptions, archivist-package, areadLocal, aread, asearchLocal, asearch, asession, atrace, cache, copyLocalRepo, createLocalRepo, createMDGallery, deleteLocalRepo, getRemoteHook, getTagsLocal, loadFromLocalRepo, md5hash, removeTagsRepo, restoreLibs, rmFromLocalRepo, saveToLocalRepo, searchInLocalRepo, setLocalRepo, shinySearchInLocalRepo, showLocalRepo, splitTagsLocal, summaryLocalRepo, zipLocalRepo

Examples

```r
## Not run:
# only in Rmd report, links to github repository
addHooksToPrint(class="ggplot", repoDir = "arepo",
repo="graphGallery", user="pbiecek")

# only in Rmd report, links to local files
addHooksToPrint(class="ggplot", repoDir = "arepo",
repo=NULL)

## End(Not run)
```

addTagsRepo

Add new Tags to the Existing Repository

Description

addTagsRepo adds new Tags to the existing Repository.

Usage

addTagsRepo(md5hashes, repoDir = NULL, FUN = NULL, tags = NULL, ...)
Arguments

- **md5hashes**: A character vector of md5hashes specifying to which corresponding artifacts new Tags should be added. See Note to get to know about the length of tags and md5hashes parameters.

- **repoDir**: A character that specifies the directory of the Repository to which new Tags will be added. If it is set to NULL (by default), it uses the repoDir specified in `setLocalRepo`.

- **FUN**: A function which is evaluated on the artifacts for which md5hashes are given. The result of this function evaluation are Tags which will be added to the local Repository.

- **tags**: A character vector which specifies what kind of Tags should be added to artifacts corresponding to given md5hashes. See Note to get to know about the length of tags and md5hashes parameters. One can specify either FUN or tags.

- **...**: Other arguments that will be passed to FUN.

Details

`addTagsRepo` function adds new Tags to artifacts that are already stored in the repository. One can add new Tags either explicitly with tags parameter or by passing a function which extracts Tags from selected artifacts corresponding to md5hashes. To learn more about artifacts visit `archivist-package`.

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

Note

One should remember that \( \text{length(tags)} \) modulo \( \text{length(md5hashes)} \) must be equal to 0 or \( \text{length(md5hashes)} \) modulo \( \text{length(tags)} \) must be equal to 0.

Examples

## Not run:

## We Take all artifacts of `lm` class from repository, 
## extract $R^2$ for them and store as $R^2$:number Tags

# Creating empty repository
exampleRepoDir <- tempfile()
createLocalRepo(exampleRepoDir, force=TRUE)

# Saving lm artifacts into repository
m1 <- lm(Sepal.Length~Species, iris)
saveToLocalRepo(m1, exampleRepoDir)
m2 <- lm(Sepal.Width~Species, iris)
saveToLocalRepo(m2, exampleRepoDir)

# We may see what kind of Tags are related to "m1" artifact corresponding to
# "9e66edd297c2f291446f3503c01d443a" md5hash
getTagsLocal("9e66edd297c2f291446f3503c01d443a", exampleRepoDir, "")

# We may see what kind of Tags are related to "m2" artifact corresponding to
# "da1bcaf68752c146903f700c1a458438" md5hash
getTagsLocal("da1bcaf68752c146903f700c1a458438", exampleRepoDir, "")

# We Take all objects of lm class from repository
md5hashes <- searchInLocalRepo(repoDir=exampleRepoDir, "class:lm")

# Adding new tag "test" explicitly
addTagsRepo(md5hashes, exampleRepoDir, tags = "test")

# Adding new tag "$R^2:" using FUN parameter
addTagsRepo(md5hashes, exampleRepoDir, function(x) paste0("$R^2: ", summary(x)$r.square))

# And now: Tags related to "m1" artifact are
getTagsLocal("9e66edd297c2f291446f3503c01d443a", exampleRepoDir, "")

# And now: Tags related to "m2" artifact are
getTagsLocal("da1bcaf68752c146903f700c1a458438", exampleRepoDir, "")

# One more look at our Repo
showLocalRepo(exampleRepoDir, method = "tags")

# Deleting example repository
deleteLocalRepo(exampleRepoDir, deleteRoot=TRUE)
rm(exampleRepoDir)

## End(Not run)
Description

`aformat` extracts artifact's formats. Having formats one may decide which should he read. Currently only rda format is supported for artifact and txt/png for miniatures.

Usage

```r
aformat(md5hash = NULL)
```

Arguments

- `md5hash` One of the following (see `aread`):
  - A character vector which elements are consisting of at least three components separated with '/': Remote user name, Remote repository and name of the artifact (MD5 hash) or it's abbreviation.
  - MD5 hashes of artifacts in current local default directory or its abbreviations.

Value

A vector of characters.

Other archivist: `Repository`, `Tags`, `%a%`, `addHooksToPrint`, `addTagsRepo`, `ahistory`, `alink`, `aoptions`, `archivist-package`, `areadLocal`, `aread`, `asearchLocal`, `asearch`, `asession`, `atrace`, `cache`, `copyLocalRepo`, `createLocalRepo`, `createMDGallery`, `deleteLocalRepo`, `getRemoteHook`, `getTagsLocal`, `loadFromLocalRepo`, `md5hash`, `removeTagsRepo`, `restoreLibs`, `rmFromLocalRepo`, `saveToLocalRepo`, `searchInLocalRepo`, `setLocalRepo`, `shinySearchInLocalRepo`, `showLocalRepo`, `splitTagsLocal`, `summaryLocalRepo`, `zipLocalRepo`

Examples

```r
## Not run:
setLocalRepo(system.file("graphGallery", package = "archivist"))
aformat("2a6e492cb6982f230e48cf46023e2e4f")

# old
```
ahistory extracts artifact’s history and creates a data frame with history of calls and md5hashes of partial results. The overloaded print.ahistory function prints this history in a concise way. The overloaded print.ahistoryKable function prints this history in the same way as kable. When alink=TRUE one can create history table/kable with hooks to partial results (artifacts) as in the alink function.

### Usage

```r
ahistory(artifact = NULL, md5hash = NULL, 
repoDir = aoptions("repoDir"), format = "regular", alink = FALSE, 
...)
```

### Arguments

- **artifact**: An artifact which history is supposed to be reconstructed. It will be converted into md5hash.
- **md5hash**: If artifact is not specified then md5hash is used.
- **repoDir**: A character denoting an existing directory in which an artifact will be saved.
- **format**: A character denoting whether to print history in either a "regular" (default) way or like in a "kable" function. See Notes.
- **alink**: Whether to provide hooks to objects like in alink. See examples.
- **...**: Further parameters passed to alink function. Used when format = "kable" and alink = TRUE.

### Details

All artifacts created with `%a%` operator are archivised with detailed information about it’s source (both call and md5hash of the input). The function ahistory reads all artifacts that precede artifact and create a description of the input flow. The generic print.ahistory function plots the history in a human readable way.

### Value

A data frame with two columns - names of calls and md5hashes of partial results.
Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

Demonstration

This function is well explained on this http://r-bloggers.com/r-hero-saves-backup-city-with-archivist-and-github blog post.

Note

There are provided functions (print.ahistory and print.ahistoryKable) to print the artifact's history. History can be printed either in a regular way which is friendly for the console output or in a kable format which prints the artifact's history in a way kable function would. This is convenient when one prints history in .Rmd files using rmarkdown.

Moreover when user passes format = 'kable' and alink = TRUE then one can use links for remote Repository. Then mdhashes are taken from Local Repository, so user has to specify repo, user and repoDir even though they are set globally, because repo is a substring of repoDir and during evulation of ... R treats repo as repoDir.

References

See Also

Other archivist: Repository, Tags, %a%, addHooksToPrint, addTagsRepo, aformat, alink, aoptions, archivist-package, areadLocal, aread, asearchLocal, asearch, asession, atrace, cache, copyLocalRepo, createLocalRepo, createMDGallery, deleteLocalRepo, getRemoteHook, getTagsLocal, loadFromLocalRepo, md5hash, removeTagsRepo, restoreLibs, rmFromLocalRepo, saveToLocalRepo, searchInLocalRepo, setLocalRepo, shinySearchInLocalRepo, showLocalRepo, splitTagsLocal, summaryLocalRepo, zipLocalRepo

Examples

```r
createLocalRepo("ahistory_check", default = TRUE)
library(dplyr)
iris %>%
  filter(Sepal.Length < 6) %>%
  lm(Petal.Length~Species, data=.) %>%
  summary() -> artifact
```
Return a Link To Download an Artifact Stored on Remote Repository

Description

`alink` returns a link to download an artifact from the Remote Repository. Artifact has to be already archived on GitHub, e.g. with `archivist::archive` function (recommended) or `saveToRepo` function and traditional Git manual synchronization. To learn more about artifacts visit archivist-package.

Usage

```r
alink(md5hash, repo = aoptions("repo"), user = aoptions("user"),
    subdir = aoptions("subdir"), branch = "master",
    repoType = aoptions("repoType"), format = "markdown",
    rawLink = FALSE)
```

Arguments

- **md5hash**  
  A character assigned to the artifact through the use of a cryptographical hash function with MD5 algorithm. If it is specified in a format of `repo/user/md5hash` then user and repo parameters are omitted.

- **repo**  
  The Remote Repository on which the artifact that we want to download is stored.

- **user**  
  The name of a user on whose Repository the artifact that we want to download is stored.

- **subdir**  
  A character containing a name of a directory on the Remote repository on which the Repository is stored. If the Repository is stored in the main folder on the Remote repository, this should be set to `subdir = "/"` as default.

- **branch**  
  A character containing a name of the Remote Repository’s branch on which the Repository is archived. Default branch is master.

- **repoType**  
  A character containing a type of the remote repository. Currently it can be ‘github’ or ‘bitbucket’.
importancesformat In which format the link should be returned. Possibilities are markdown (default) or latex.

rawLink A logical denoting whether to return raw link or a link in the format convention. Default value is FALSE.

Details
For more information about md5hash see md5hash.

Value
This function returns a link to download artifact that is archived on GitHub.

## End(Not run)
```
aoptions

---

**aoptions**

Default Options for Archivist

---

**Description**

The function `aoptions` sets and gets default options for other archivist functions.

**Usage**

```r
aoptions(key, value = NULL, unset = FALSE)
```

**Arguments**

- `key` A character denoting name of the parameter.
- `value` New value for the 'key' parameter.
- `unset` Set to `TRUE` if want to set parameter to `NULL`, i.e. when unsetting Repository

```r
aoptions('repoDir',NULL,T).
```

**Details**

The function `aoptions` with two parameters sets default value of key parameter for other archivist functions. The function `aoptions` with one parameter returns value (stored in an internal environment) of the given key parameter.

**Value**

The function returns value that corresponds to a selected key.

Examples

## Not run:
# data.frame object
# data(iris)

## EXAMPLE 1 : SET default local repository using aoptions() function.

# creating example repository
eampleRepoDir <- tempfile()
createLocalRepo(exampleRepoDir)

# "repoDir" parameter in each archivist function will be default and set to exampleRepoDir.
aoptions(key = "repoDir", value = exampleRepoDir)

data(iris)
data(swiss)
# From this moment repoDir parameter may be ommitted in the following functions
saveToLocalRepo(iris)
saveToLocalRepo(swiss)
showLocalRepo()
showLocalRepo(method = "tags")
zipLocalRepo()
file.remove(file.path(getwd(), "repository.zip"))
iris2 <- loadFromLocalRepo("ff575c2", value = TRUE)
s searchInLocalRepo("name:i", fixed = F)
getTagsLocal("ff575c261c949d073b2895b05d1097c3")
rmFromLocalRepo("4c43f")
showLocalRepo()
summaryLocalRepo()

# REMEMBER that in deleteRepo you MUST specify repoDir parameter!
# deleteLocalRepo doesn't take setLocalRepo's settings into consideration
deleteLocalRepo( exampleRepoDir, deleteRoot = TRUE)
rm( exampleRepoDir )

## EXAMPLE 2 : SET default Github repository using aoptions() function.
aoptions(key = "user", value = "pbiecek")
aoptions(key = "repo", value = "archivist")

# From this moment user and repo parameters may be ommitted in the following functions:
showRemoteRepo()
loadFromRemoteRepo("ff575c261c949d073b2895b05d1097c3")
aread

**Description**

aread reads the artifact from the Repository. It’s a wrapper around `loadFromLocalRepo` and `loadFromRemoteRepo`.

**Usage**

```r
aread(md5hash)
```

**Arguments**

- `md5hash`
  
  One of the following:
  
  A character vector which elements are consisting of at least three components separated with `/`: Remote user name, Remote repository and name of the artifact (MD5 hash) or its abbreviation.

  MD5 hashes of artifacts in current local default directory or its abbreviations.
Details

Function `aread` reads artifacts (by md5hashes) from Remote Repository. It uses `loadFromLocalRepo` and `loadFromRemoteRepo` functions with different parameter's specification.

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

Note

Before you start using this function, remember to set local or Remote repository to default by using `setLocalRepo()` or `setRemoteRepo` functions.

# To plot it remember to have ggplot2 in version 2.1.0
# as this is stated in asession("pbiecek/graphGallery/7f3453331910e3f321ef97d87adb5bad")
# The state of R libraries can be restored to the same state in
# which 7f3453331910e3f321ef97d87adb5bad was created with the restoreLibs function.
**readLocal**

Read Artifacts Given as md5hashes from the Repository

**Description**

readLocal reads the artifact from the Local Repository. It's a wrapper around loadFromLocalRepo.

**Usage**

readLocal(md5hash, repo)

**Arguments**

- **md5hash**  
  A character vector which elements are consisting name of the repository and name of the artifact (MD5 hash) or it's abbreviation.

- **repo**  
  A character with path to local repository.

**Details**

Function readLocal reads artifacts (by md5hashes) from Local Repository.

**Contact**

asearch

Read Artifacts Given as a List of Tags

Description

asearch searches for artifacts that contain all specified Tags and reads all of them from a default or Remote Repository. It’s a wrapper around searchInLocalRepo and loadFromLocalRepo and their Remote versions.

Usage

asearch(patterns, repo = NULL)

Arguments

patterns A character vector of Tags. Only artifacts that contain all Tags are returned.
repo One of following:
A character with Remote user name and Remote repository name separated by '/'.
NULL in this case search will be performed in the default repo, either local or Remote

Details

Function asearch reads all artifacts that contain given list of Tags from default or Remote Repository. It uses both loadFromLocalRepo and searchInLocalRepo functions (or their Remote versions) but has shorter name and different parameter’s specification.

Value

This function returns a list of artifacts (by their values).

# names(ggplot_objects)

# To plot them remember to have ggplot2 in version 2.1.0  
# as this is stated in asession("pbiecek/archivist/13b2724139eb2c6257b84da0d7b2cea") or  
# asession("pbiecek/archivist/7f345331910e3f321ef97d87ab5b5ad") .  
# The state of R libraries can be restored to the same state in  
# which those objects were created with the restoreLibs function.

### Remote version

## Note that repo argument is passed in the following way to asearch:  
## repo = "GitHub user name/GitHub repository name"

## Searching for objects of class:gg

asearch("pbiecek/graphGallery",  
patterns = c("class:gg",  
"labelx:Sepal.Length") -> ggplots_objects_v2

## End(Not run)

---

### asearchLocal

**Read Artifacts Given as a List of Tags**

**Description**

asearchLocal searches for artifacts that contain all specified Tags and reads all of them from a local Repository. It’s a wrapper around searchInLocalRepo and loadFromLocalRepo.

**Usage**

asearchLocal(patterns, repo = NULL)
asession

Arguments

- **patterns**: A character vector of Tags. Only artifacts that contain all Tags are returned.
- **repo**: A character with path to local repository.

Details

Function `asearchLocal` reads all artifacts that contain given list of Tags from the selected Local Repository.

Value

This function returns a list of artifacts (by their values).

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

asession

Show Artifact’s Session Info

Description

asession extracts artifact’s session info. This allows to check in what conditions the artifact was created.

Usage

asession(md5hash = NULL)
Arguments

md5hash One of the following (see aread):
A character vector which elements are consisting of at least three components
separated with '/': Remote user name, Remote repository and name of the artifact (MD5 hash) or it's abbreviation.
MD5 hashes of artifacts in current local default directory or its abbreviations.

Value
An object of the class session_info.

Examples
```r
## Not run:
setLocalRepo(system.file("graphGallery", package = "archivist"))
asession("2a6e492cb6982f230e48cf46023e2e4f")

# no session info
asession("pbiecek/graphGallery/2a6e492cb6982f230e48cf46023e2e4f")
# nice session info
asession("pbiecek/graphGallery/7f3453331910e3f321ef97d87adb5bad")

## End(Not run)
```
**Description**

`atrace` add call to `saveToLocalRepo` at the end of a given function.

**Usage**

```r
atrace(FUN = "lm", object = "z")
```

**Arguments**

- **FUN**: name of a function to be traced (character)
- **object**: name of an object that should be traced (character)

**Details**

Function `atrace` calls the `trace` function.

Examples

```r
# read the object from local directory
createLocalRepo("arepo_test", default=TRUE)
atrace("lm", "z")
lm(Sepal.Length~Sepal.Width, data=iris)
asearch("class:lm")
untrace("lm")
deleteLocalRepo("arepo_test", deleteRoot = TRUE)
```

Description

The `cache` function stores all results of function calls in a local repository. All results are stored together with md5 hashes of the function calls. If a function is called with the same arguments, then its results can be loaded from the repository.

One may specify expiration date for live objects. It may be useful for objects that can be changed externally (like queries to database).

Usage

```r
cache(cacheRepo = NULL, FUN, ..., notOlderThan = NULL)
```

Arguments

- `cacheRepo` A repository used for storing cached objects.
- `FUN` A function to be called.
- `...` Arguments of `FUN` function.
- `notOlderThan` load an artifact from the database only if it was created after `notOlderThan`.

Details

The `cache` function stores all results of function calls in a local repository specified by the `cacheRepo` argument. The md5 hash of `FUN` and its arguments is added as a Tag to the repository. This Tag has the following structure "cached:md5hash". Note that `cache` is a good solution if objects are not that big but calculations are time consuming (see Examples). If objects are big and calculations are easy, then disk input-output operations may take more time than calculations itself.

Value

Result of the function call with additional attributes: `tags` - md5 hash of the function call and `call` - "".

Examples

```r
## Not run:

# objects preparation
library("lubridate")
cacheRepo <- tempfile()
createLocalRepo( cacheRepo )

## Example 1:
# cache is useful when objects used by FUN are not that big but calculations
# are time-consuming. Take a look at this example:
fun <- function(n) {replicate(n, summary(lm(Sepal.Length~Species, iris))$r.squared)}

# let's check time of two evaluations of cache function
system.time( res <- cache(cacheRepo, fun, 1000) )
system.time( res <- cache(cacheRepo, fun, 1000) )
# The second call is much faster. Why is it so? Because the result of fun
# function evaluation has been stored in local cacheRepo during the first evaluation
# of cache. In the second call of cache we are simply loading the result of fun
# from local cacheRepo Repository.

## Example 2:

testFun <- function(x) {cat(x);x}

testFun will be executed and saved to cacheRepo
tmp <- cache(cacheRepo, testFun, "Say hallo!"

# testFun execution will be loaded from repository
tmp <- cache(cacheRepo, testFun, "Say hallo!"

# testFun will be executed once again as it fails with expiration date. It will
```
## copyLocalRepo

*Copy an Existing Repository into Another Repository*

### Description

copy*Repo* copies artifacts from one Repository into another Repository. It adds new files to existing gallery folder in repoTo Repository. `copyLocalRepo` copies local Repository while `copyRemoteRepo` copies remote Repository.

### Usage

```
copyLocalRepo(repoFrom = NULL, repoTo, md5hashes)
copyRemoteRepo(repoTo, md5hashes, repo = aoptions("repo"),
  user = aoptions("user"), branch = aoptions("branch"),
  subdir = aoptions("subdir"), repoType = aoptions("repoType"))
```

### Arguments

- **repoFrom**: While copying local repository. A character that specifies the directory of the Repository from which artifacts will be copied. If it is set to NULL (by default), it will use the repoDir specified in `setLocalRepo`.
- **repoTo**: A character that specifies the directory of the Repository into which artifacts will be copied.
- **md5hashes**: A character vector containing md5hashes of artifacts to be copied.
- **repo**: While coping the remote repository. A character containing a name of the remote repository on which the "repoFrom" - Repository is archived. By default set to NULL - see Note.
- **user**: While coping the remote repository. A character containing a name of the remote user on whose account the "repoFrom" - Repository is created. By default set to NULL - see Note.
copyLocalRepo

branch While coping with the remote repository. A character containing a name of Remote Repository’s branch on which the "repoFrom" - Repository is archived. Default branch is master.

subdir While working with the remote repository. A character containing a name of a directory on the remote repository on which the "repoFrom" - Repository is stored. If the Repository is stored in the main folder on the remote repository, this should be set to FALSE as default.

repoType A character containing a type of the remote repository. Currently it can be 'Remote' or 'bitbucket'.

Details
Functions copyLocalRepo and copyRemoteRepo copy artifacts from the archivist’s Repositories stored in a local folder or on the Remote. Both of them use md5hashes of artifacts which are to be copied in md5hashes parameter. For more information about md5hash see md5hash.

Contact
Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

Note
If repo and user are set to NULL (as default) in remote mode then global parameters set in setRemoteRepo function are used. If one would like to copy whole Repository we suggest to extract all md5hashes in this way unique(showLocalRepo(repoDir)[,1]).

Examples

```r
## Not run:
## Using archivist remote Repository to copy artifacts
# creating example Repository

eexampleRepoDir <- tempfile()
createLocalRepo( exampleRepoDir )

# Searching for md5hashes of artifacts (without data related to them)
# in the archivist remote Repository
hashes <- searchInRemoteRepo( pattern="name", user="pbiecek", repo="archivist", fixed=FALSE )

# Copying selected artifacts from archivist Remote Repository into exampleRepoDir Repository
copyRemoteRepo( repoTo = exampleRepoDir , md5hashes= hashes, user="pbiecek", repo="archivist" )

# See how the gallery folder in our exampleRepoDir Repository
# with copies of artifacts from archivist Remote Repository looks like
list.files( path = file.path( exampleRepoDir, "gallery" ) )

# See how the backpack database in our exampleRepoDir Repository looks like
showLocalRepo( repoDir = exampleRepoDir )

# removing an example Repository
deleteLocalRepo( exampleRepoDir, deleteRoot=TRUE )
rm( exampleRepoDir )

# many archivist-like Repositories on one Remote repository
dir <- paste0(getwd(), "/ex1")
createLocalRepo( dir )
copyRemoteRepo( repoTo = dir , md5hashes = "ff575c261c949d073b2895b05d1097c3",
user="MarcinKosinski", repo="Museum",
branch="master", subdir="ex2"
)

# Check if the copied artifact is on our dir Repository
showLocalRepo( repoDir = dir ) # It is in backpack database indeed
list.files( path = file.path( dir, "gallery" ) ) # it is also in gallery folder

# removing an example Repository
deleteLocalRepo( dir, TRUE)
rm(dir)

## Using graphGallery Repository attached to the archivist package to copy artifacts
# creating example Repository
```
createLocalRepo <- tempfile()
createLocalRepo( exampleRepoDir )

# Searching for md5hashes of artifacts (without data related to them)
# in the graphGallery Repository
archivistRepo <- system.file( "graphGallery", package = "archivist"
# You may use:
# hashes <- unique(showLocalRepo(repoDir)[,1])
# to extract all artifacts from repository
hashes <- searchInLocalRepo( pattern="name",
   repoDir = archivistRepo,
   fixed=FALSE )

# Copying selected artifacts from archivist Remote Repository into exampleRepoDir Repository
copyLocalRepo( repoFrom = archivistRepo, repoTo = exampleRepoDir , md5hashes= hashes )

# See how the backpack database in our exampleRepoDir Repository looks like
showLocalRepo( repoDir = exampleRepoDir )

# removing an example Repository
deleteLocalRepo( exampleRepoDir, deleteRoot=TRUE )

rm( exampleRepoDir )
rm( archivistRepo )

## End(Not run)

createLocalRepo   Create an Empty Repository

Description

createLocalRepo creates an empty Repository in the given directory in which archived artifacts
will be stored.

Usage

createLocalRepo(repoDir, force = FALSE, default = FALSE)
createPostgresRepo(repoDir, connector, force = FALSE, default = FALSE)
createEmptyRepo(...
createLocalRepo

Arguments

repoDir A character that specifies the directory for the Repository which is to be made.
force If force = TRUE and repoDir parameter specifies the directory that contains backpack.db file, then function call will force to recreate new backpack.db. Default set to force = FALSE.
default If default = TRUE then repoDir is set as default Local Repository.
connector If user want to use some external database instead of SQLite, then the connector shall be the function that create a DBI connection with the database. Within every transaction the connection is opened and closed, thus the connector function will be executed often and shall not be computationally heavy. See the Examples section for some examples. Note that it’s an experimental feature.

... All arguments are being passed to createLocalRepo.

Details

At least one Repository must be initialized before using other functions from the archivist package. While working in groups, it is highly recommended to create a Repository on a shared Dropbox/GitHub folder.

All artifacts which are desired to be archived are going to be saved in the local Repository, which is an SQLite database stored in a file named backpack. After calling saveToRepo function, each artifact will be archived in a md5hash.rda file. This file will be saved in a folder (under repoDir directory) named gallery. For every artifact, md5hash is a unique string of length 32 that is produced by digest function, which uses a cryptographical MD5 hash algorithm.

To learn more about artifacts visit archivist-package.

Created backpack database is a useful and fundamental tool for remembering artifact’s name, class, archiving date etc. (the so called Tags) or for keeping artifact’s md5hash.

Besides the backpack database, gallery folder is created in which all artifacts will be archived.

After every saveToRepo call the database is refreshed. As a result, the artifact is available immediately in backpack.db database for other collaborators.

Other archivist: Repository, Tags, %a%, addHooksToPrint, addTagsRepo, aformat, ahistory, alink, aoptions, archivist-package, areadLocal, aread, asearchLocal, asearch, asession, atrace, cache, copyLocalRepo, createMDGallery, deleteLocalRepo, getRemoteHook, getTagsLocal, loadFromLocalRepo, md5hash, removeTagsRepo, restoreLibs, rmFromLocalRepo, saveToLocalRepo, searchInLocalRepo, setLocalRepo, shinySearchInLocalRepo, showLocalRepo, splitTagsLocal, summaryLocalRepo, zipLocalRepo

Other archivist: Repository, Tags, %a%, addHooksToPrint, addTagsRepo, aformat, ahistory, alink, aoptions, archivist-package, areadLocal, aread, asearchLocal, asearch, asession, atrace, cache, copyLocalRepo, createMDGallery, deleteLocalRepo, getRemoteHook, getTagsLocal, loadFromLocalRepo, md5hash, removeTagsRepo, restoreLibs, rmFromLocalRepo, saveToLocalRepo, searchInLocalRepo, setLocalRepo, shinySearchInLocalRepo, showLocalRepo, splitTagsLocal, summaryLocalRepo, zipLocalRepo

Examples

```r
## Not run:
exampleRepoDir <- tempfile()
createLocalRepo( repoDir = exampleRepoDir, default = TRUE )
data(iris)
saveToLocalRepo(iris)
showLocalRepo()
showLocalRepo(method = "tags")
deleteLocalRepo( repoDir = exampleRepoDir, unset = TRUE, deleteRoot = TRUE )

# example with external database
# create a connector
require("RPostgreSQL")
drv <- dbDriver("PostgreSQL")
connector <- function() {
  dbConnect(drv, dbname = "postgres",
            host = "localhost", port = 5432,
            user = "user", password = pw)
}
# Now you can create an empty repository with postgres database
exampleRepoDir <- tempfile()
createPostgresRepo( repoDir = exampleRepoDir, connector)
data(iris)
saveToLocalRepo(iris)
showLocalRepo()
showLocalRepo(method = "tags")
deleteLocalRepo( repoDir = exampleRepoDir, unset = TRUE, deleteRoot = TRUE)
```
createMDGallery

Create the Summary for Each Artifact in a Markdown Format

Description

createMDGallery creates a summary for each artifact from Repository stored on a GitHub. For each artifact this function creates a markdown file with: the download link, artifact’s Tags (when addTags = TRUE) and miniature (addMiniature = TRUE) if the artifact was archived with it’s miniature and Tags. The miniature is a print or head over an artifact or it’s png when it was a plot. But this function only supports png miniatures.

Usage

createMDGallery(output, repo = aoptions("repo"),
               user = aoptions("user"), branch = aoptions("branch"),
               subdir = aoptions("subdir"), repoType = aoptions("repoType"),
               addTags = FALSE, addMiniature = FALSE, maxTags = 100)

Arguments

output A name of the file in which artifacts should be summarized.
repo A character containing a name of the Remote repository on which the Repository is stored. By default set to NULL – see Note.
user A character containing a name of the Github user on whose account the repo is created. By default set to NULL – see Note.
branch A character containing a name of the Remote Repository’s branch on which the Repository is stored. Default branch is master.
subdir A character containing a name of a directory on the Remote repository on which the Repository is stored. If the Repository is stored in the main folder of the Remote repository, this should be set to subdir = "/" as default.
repoType A character containing a type of the remote repository. Currently it can be ’github’ or ’bitbucket’.
addTags Logical, whether to add artifact’s Tags to the output.
addMiniature Logical, whether to add artifact’s miniature/plots to the output.
maxTags Integer. The maximal length of chunks output when describing Tags of artifact.

Details

To learn more about artifacts visit archivist-package.

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues
**deleteLocalRepo**

**Description**

`deleteLocalRepo` deletes the existing `Repository` from the given directory. As a result all artifacts from gallery folder are removed and database `backpack.db` is deleted.

**Note**

If `repo` and `user` are set to NULL (as default) in the Remote mode then global parameters set in `setRemoteRepo` (or via `aoptions`) function are used.

**Author(s)**

Marcin Kosinski, <m.p.kosinski@gmail.com>

**References**

**See Also**

Markdown example: https://github.com/pbiecek/archivist/issues/144#issuecomment-174192366

Other archive: Repository, Tags, %a%, addHooksToPrint, addTagsRepo, aformat, ahistory, alink, aoptions, archivist-package, areadLocal, aread, asearchLocal, asearch, asession, atrace, cache, copyLocalRepo, createLocalRepo, deleteLocalRepo, getRemoteHook, getTagsLocal, loadFromLocalRepo, mdShash, removeTagsRepo, restoreLibs, rmFromLocalRepo, saveToLocalRepo, searchInLocalRepo, setLocalRepo, shinySearchInLocalRepo, showLocalRepo, splitTagsLocal, summaryLocalRepo, zipLocalRepo

**Examples**

```r
## Not run:
createMDGallery(user = 'MarcinKosinski', repo = 'Museum', 'README_test1.md', addTags = TRUE)
createMDGallery('graphGallery', 'pbiecek', addMiniature = TRUE, 'README_test2.md', addTags = TRUE)
## End(Not run)
```

```r
deleteLocalRepo  Delete the Existing Repository from the Given Directory
```
Usage

```r
deleteLocalRepo(repoDir, deleteRoot = FALSE, unset = FALSE)

deleteRepo(...)```

Arguments

- `repoDir`: A character that specifies the directory for the Repository which is to be deleted.
- `deleteRoot`: A logical value that specifies if the repository root directory should be deleted for Local Repository.
- `unset`: A logical. If deleted `repoDir` was set to be default Local Repository and `unset` is TRUE, then `repoDir` is unset as a default Local Repository (`options('repoDir/repo', NULL, T)`).
- `...`: All arguments are being passed to `deleteLocalRepo`.

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

Note

Remember that using `tempfile()` instead of `tempdir()` in examples section is crucial. `tempdir()` is existing directory in which R works so calling `deleteLocalRepo(exampleRepoDir, deleteRoot=TRUE)` removes important R files. You can find out more information about this problem at stackoverflow webpage.

## End(Not run)
```

getTagsLocal

Return Tags Corresponding to md5Hash

Description

getTagsLocal and getTagsRemote return Tags (see Tags) related to md5Hash of an artifact. To learn more about artifacts visit archivist-package.

Usage

```r
getTagsLocal(md5hash, repoDir = aoptions("repoDir"), tag = "name")
getTagsRemote(md5hash, repo = aoptions("repo"),
             user = aoptions("user"), branch = aoptions("branch"),
             subdir = aoptions("subdir"), repoType = aoptions("repoType"),
             tag = "name")
```

Arguments

- `md5hash`: A character containing md5Hash of artifacts which Tags are desired to be returned.
- `repoDir`: A character denoting an existing directory in which artifacts are stored.
- `tag`: A regular expression denoting type of a Tag that we search for (see Examples). Default tag = "name".
- `repo`: While working with the Remote repository. A character containing a name of the Remote repository on which the Repository is stored. By default set to NULL - see Note.
- `user`: While working with the Remote repository. A character containing a name of the Remote user on whose account the repo is created. By default set to NULL - see Note.
getTagsLocal

**branch**
While working with the Remote repository. A character containing a name of the Remote repository’s branch on which the Repository is stored. Default branch is master.

**subdir**
While working with the Remote repository. A character containing a name of a directory on the Remote repository on which the Repository is stored. If the Repository is stored in main folder on the Remote repository, this should be set to subdir = "/" as default.

**repoType**
A character containing a type of the remote repository. Currently it can be 'github' or 'bitbucket'.

**Details**

getTagsLocal and getTagsRemote return Tags, of a specific type described by tag parameter, related to md5Hash of an artifact. To learn more about artifacts visit archivist-package.

**Value**
The character vector of Tags (see Tags) related to md5Hash of an artifact.

**Contact**
Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

**Note**
If repo and user are set to NULL (as default) in Remote mode then global parameters set in setRemoteRepo function are used.

### Local version

## Not run:

## EXAMPLE with pipe operator %a%

# Creating empty repository
```
exampleRepoDir <- tempfile()
createLocalRepo( exampleRepoDir )
```

library(dplyr)
data(mtcars)
setLocalRepo(repoDir = exampleRepoDir)
hash <- mtcars %a%
group_by(cyl, am) %a%
select(mpg, cyl, wt, am) %a%
summarise(avgmpg = mean(mpg), avgwt = mean(wt)) %a%
filter(avgmpg > 20) %a%
saveToRepo( exampleRepoDir )

showLocalRepo(exampleRepoDir)
showLocalRepo(exampleRepoDir, method = "tags")

# We search for a Tag with default "name" regular expression corresponding to
# hash md5hash.
```
getTagsLocal( md5hash = hash, exampleRepoDir )
```

# Deleting example respository
```
deleteLocalRepo( exampleRepoDir, TRUE)
```

## EXAMPLE with data iris
```
exampleRepoDir <- tempfile()
createLocalRepo( exampleRepoDir )
```

data(iris)
saveToRepo(iris, repoDir = exampleRepoDir )
showLocalRepo(exampleRepoDir)
showLocalRepo(exampleRepoDir, method = "tags")

# We can notice that there is only one md5hash
# (and second for archiveSessionInfo) in repo so we will use it
```
hash <- showLocalRepo(exampleRepoDir)[1,1]
```

# We search for a Tag with "varname" regular expression corresponding to
# hash md5hash.
```
getTagsLocal( md5hash = hash, exampleRepoDir, tag = "varname" )
```
# There are 5 different Tags with "varname" regular expression
We needn't use the whole expression "varname". We may use its abbreviation and get the same result.

```r
getTagsLocal( md5hash = hash, exampleRepoDir, tag = "varna" )
```

deleteLocalRepo( exampleRepoDir, TRUE)
rm( exampleRepoDir )

```r
### Remote version
## EXAMPLE: pbiecek archivist repository on GitHub

showRemoteRepo(user="pbiecek", repo="archivist")
```

We search for a Tag with default "name" regular expression corresponding to "cd6557c6163a6f9800f308f343e75e72" md5hash.

```r
getTagsRemote("cd6557c6163a6f9800f308f343e75e72", user="pbiecek", repo="archivist")
```

## EXAMPLE: many archivist-like Repositories on one Github repository

We search for a Tag with default "name" regular expression corresponding to "ff575c261c949d073b2895b05d1097c3" md5hash.

```r
getTagsRemote("ff575c261c949d073b2895b05d1097c3", user="MarcinKosinski", repo="Museum", branch="master", subdir="ex1")
```

## End(Not run)

---

### loadFromLocalRepo

**Load Artifact Given as a md5hash from a Repository**

#### Description

loadFromLocalRepo loads an artifact from a local **Repository** into the workspace. loadFromRemoteRepo loads an artifact from a github / git / mercurial **Repository** into the workspace. To learn more about artifacts visit **archivist-package**.

#### Usage

```r
loadFromLocalRepo(md5hash, repoDir = aoptions("repoDir"),
value = FALSE)
```

```r
loadFromRemoteRepo(md5hash, repo = aoptions("repo"),
user = aoptions("user"), branch = aoptions("branch"),
subdir = aoptions("subdir"), repoType = aoptions("repoType"),
value = FALSE)
```

#### Arguments

- **md5hash**
  
  A character assigned to the artifact through the use of a cryptographical hash function with MD5 algorithm, or it's abbreviation.
repoDir A character denoting an existing directory from which an artifact will be loaded.

value If FALSE (default) then artifacts are loaded into the Global Environment with their original names, if TRUE then artifacts are returned as a list of values (if there is more than one artifact) or as a single value (if there is only one artifact that matches md5hash).

repo While working with a Remote repository. A character containing a name of a Remote repository on which the Repository is archived. By default set to NULL - see Note.

user While working with a Remote repository. A character containing a name of a Remote user on whose account the repo is created. By default set to NULL - see Note.

branch While working with a Remote repository. A character containing a name of Remote Repository’s branch on which the Repository is archived. Default branch is master.

subdir While working with a Remote repository. A character containing a name of a directory on Remote repository on which the Repository is stored. If the Repository is stored in main folder on Remote repository, this should be set to subdir = "/" as default.

repoType A character containing a type of the remote repository. Currently it can be 'Remote' or 'bitbucket'.

Details

Functions loadFromLocalRepo and loadFromRemoteRepo load artifacts from the archivist Repositories stored in a local folder or on git. Both of them take md5hash as a parameter, which is a result of saveToRepo function. For each artifact, md5hash is a unique string of length 32 that is produced by digest function, which uses a cryptographical MD5 hash algorithm. For more information see md5hash.

Important: instead of giving the whole md5hash character, the user can simply give first few characters of the md5hash. For example, a09dd instead of a09ddjdfk9kj33dcjdnfjgos9jd9jkcv. All artifacts with the same md5hash abbreviation will be loaded from Repository.

Note that user and repo should be used only when working with a git repository and should be omitted in the local mode. repoDir should only be used when working on a local Repository and should be omitted in the git mode.

One may notice that loadFromRemoteRepo and loadFromLocalRepo load artifacts to the Global Environment with their original names. Alternatively, a parameter value = TRUE can be specified so that these functions may return artifacts as a value. As a result loaded artifacts can be attributed to new names. Note that, when an abbreviation of md5hash was given then a list of artifacts corresponding to this abbreviation will be loaded.

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues
**Note**

You can specify one md5hash (or its abbreviation) per function call.

If repo and user are set to NULL (as default) in Remote mode then global parameters set in setRemoteRepo function are used.

You should remember while using loadFromRepo wrapper that repoDir is a parameter used only in loadFromLocalRepo while repo, user, branch and subdir are used only in loadFromRemoteRepo. When you mix those parameters you will receive an error message.

**md5hash**

**md5hash**

### Description

Repository stores specific values of an artifact, different for various artifact’s classes, and artifact themselves. Artifacts are archived with a special attribute named md5hash. To learn more about artifacts visit archivist-package.

### Details

For each artifact, md5hash is a unique string of length 32 that is produced by digest function which uses a cryptographical MD5 hash algorithm. The md5hash of each artifact that is archived in the Repository is also saved on the Repository along with the artifact’s Tags - see Tags. It enables to distinguish artifacts in the Repository and facilitates searching and loading them.
md5hash

removeTagsRepo  

Description

removeTagsRepo removes selected Tags from selected objects in Repository.

Usage

removeTagsRepo(md5hashes, repoDir = NULL, tags = NULL)

Arguments

- **md5hashes**: a character vector of md5hashes specifying to which corresponding artifacts Tags should be removed
- **repoDir**: A character that specifies the directory of the Repository to which new Tags will be added. If it is set to NULL (by default), it uses the repoDir specified in setLocalRepo.
- **tags**: A character vector which specifies what Tags should be removed.

Details

removeTagsRepo function removes all Tags from all listed objects. Note that some hashes are required for keeping erlations between objects in the repository. Be careful what you are removing.

### Repository

Repository stores specific values of an artifact, different for various artifact's classes and artifacts themselves. To learn more about artifacts visit archivist-package.

### Details

Repository is a folder with an SQLite database stored in a file named `backpack` and a subdirectory named `gallery`.

`backpack` contains two tables: `artifact` and `tag`. `artifact` table consists of three columns:

- `md5hash`,
- `name`,
- `createdDate`,

while `tag` table consists of the following three columns:

- `artifact`,
- `tag`,
- `createdDate`.

`gallery` collects the following objects:

- artifacts and artifacts' data saved as `.rda` files,
- artifacts' miniatures saved as `.txt` and `.png` files.

### restoreLibs

**Restore Versions of Libraries**

**Description**

Function `restoreLibs` gets either session info or artifact’s md5hash and restore libraries/packages to versions attached when the object was saved in the repo. Typical use case is following. We have saved an object and now we are restoring it, but with current version of packages something is not working. The function `restoreLibs()` reverts all libraries that were attached previously to their previous versions.

**Usage**

```r
restoreLibs(md5hash, session_info = NULL, lib.loc = NULL)
```

**Arguments**

- `md5hash`: One of the following (see `aread`):
  - A character vector which elements are consisting of at least three components separated with `/`: Remote user name, Remote repository and name of the artifact (MD5 hash) or its abbreviation.
  - MD5 hashes of artifacts in current local default directory or its abbreviations.
- `session_info`: Object with versions of packages to be installed. If not supplied then it will be extracted from `md5hash` `md5hash`.
- `lib.loc`: A character vector describing the location of R library trees to restore archived libraries, or NULL. The default value of NULL corresponds to all libraries currently known to `.libPaths()`. Non-existent library trees are silently ignored.

---

`rmFromLocalRepo` **Remove an Artifact Given as a md5hash from the Repository**

**Description**

`rmFromLocalRepo` removes an artifact given as a md5hash from the Repository. To learn more about artifacts visit archivist-package.

**Usage**

```r
rmdirFromLocalRepo(md5hash, repoDir = aoptions("repoDir"),
                  removeData = FALSE, removeMiniature = FALSE, force = FALSE,
                  many = FALSE)
```

```r
rmdirFromRepo(...)```

Arguments

**md5hash**
A character assigned to the artifact through the use of a cryptographical hash function with MD5 algorithm, or its abbreviation. This object will be removed. If `many` parameter is set to TRUE then md5hash will be a character vector.

**repoDir**
A character denoting an existing directory from which an artifact will be removed.

**removeData**
A logical value denoting whether to remove data along with the artifact specified by the md5hash. Default FALSE.

**removeMiniature**
A logical value denoting whether to remove a miniature along with the artifact specified by the md5hash. Default FALSE.

**force**
A logical value denoting whether to remove data related to more than one artifact. Default FALSE.

**many**
A logical value. To accelerate the speed of removing many objects, you can set this parameter to TRUE and pass a vector of artifacts’ md5hashes to a md5hash parameter. It is not possible to use a vector of artifacts’ md5hashes abbreviations - see Note. By default, set to FALSE.

... All arguments are being passed to `rmFromLocalRepo`.

Details

`rmFromLocalRepo` removes an artifact given as a md5Hash from the Repository. To be more precise, an artifact is removed both from backpack.db file (the SQLite database) and gallery subdirectory, where the artifacts are stored as md5hash.rda files.

Important: instead of giving the whole md5hash character, a user can simply give its first few characters. For example, “a09dd” instead of “a09ddjdkf9kj33dcjdnfjgos9jd9jkcv”. All artifacts with the same md5hash abbreviation will be removed from the Repository.

`rmFromLocalRepo` provides functionality that enables us to delete miniatures of the artifacts (.txt or .png files) while removing .rda files. To delete miniature of the artifact use removeMiniature = TRUE argument. Moreover, if the data from the artifact is archived then there is a possibility to delete this data while removing the artifact. Simply use removeData = TRUE argument.

If one wants to remove all artifacts created between two dates, it is suggested to perform:

- `obj2rm <- searchInLocalRepo( tag = list(dateFrom, dateTo), repoDir = )`
- `sapply(obj2rm, rmFromLocalRepo, repoDir = )`

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

Note

md5hash can be a result of the `searchInLocalRepo` function called by tag = `NAME` argument, where `NAME` is a Tag that describes the property of the artifacts to be deleted.
It is not possible to use a vector of artifacts’ md5hashes abbreviations while using many = TRUE argument. This assumption was made to protect a user from removing, by accident, too many artifacts from the Repository.

For more information about Tags check Tags.

# Again we receive a warning as Artifacts are no longer in the repository but ...
list.files(file.path(exampleRepoDir, "gallery"))
# gallery folder is empty now! Artifact's miniature's were removed.
# Of course we may have done all these instructions by one simple function call.
# rmFromLocalRepo(artifacts, many = TRUE, repoDir = exampleRepoDir,
#   removeData = TRUE, removeMiniature = TRUE)
# Nevertheless, it may be instructive to see how it is done step by step.

# removing an example Repository
deleteLocalRepo(repoDir = exampleRepoDir, deleteRoot = TRUE)

rm( exampleRepoDir )

## End(Not run)

---

**saveToLocalRepo**  
*Save an Artifact into a Repository*

### Description

`saveToLocalRepo` function saves desired artifacts to the local Repository in a given directory. To learn more about artifacts visit `archivist-package`.

### Usage

```r
saveToLocalRepo(artifact, repoDir = aoptions("repoDir"),
   archiveData = TRUE, archiveTags = TRUE, archiveMiniature = TRUE,
   archiveSessionInfo = TRUE, force = TRUE, value = FALSE, ...
   userTags = c(), use_flocks = aoptions("use_flocks"),
   silent = aoptions("silent"), ascii = FALSE,
   artifactName = deparse(substitute(artifact)))
```

```r
saveToRepo(artifact, repoDir = aoptions("repoDir"), archiveData = TRUE,
   archiveTags = TRUE, archiveMiniature = TRUE,
   archiveSessionInfo = TRUE, force = TRUE, value = FALSE, ...
   userTags = c(), use_flocks = aoptions("use_flocks"),
   silent = aoptions("silent"), ascii = FALSE,
   artifactName = deparse(substitute(artifact)))
```

```r
asave(artifact, repoDir = aoptions("repoDir"), archiveData = TRUE,
   archiveTags = TRUE, archiveMiniature = TRUE,
   archiveSessionInfo = TRUE, force = TRUE, value = FALSE, ...
   userTags = c(), use_flocks = aoptions("use_flocks"),
   silent = aoptions("silent"), ascii = FALSE,
   artifactName = deparse(substitute(artifact)))
```

### Arguments

- **artifact**  
  An arbitrary R artifact to be saved. For supported artifacts see details.

- **repoDir**  
  A character denoting an existing directory in which an artifact will be saved.
saveToLocalRepo

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>archiveData</td>
<td>A logical value denoting whether to archive the data from the artifact.</td>
</tr>
<tr>
<td>archiveTags</td>
<td>A logical value denoting whether to archive Tags from the artifact.</td>
</tr>
<tr>
<td>archiveMiniature</td>
<td>A logical value denoting whether to archive a miniature of the artifact.</td>
</tr>
<tr>
<td>archiveSessionInfo</td>
<td>A logical value denoting whether to archive the session info that describes the context in this given artifact was created.</td>
</tr>
<tr>
<td>force</td>
<td>A logical value denoting whether to archive artifact if it was already archived in a Repository.</td>
</tr>
<tr>
<td>value</td>
<td>A logical value. Should the result be (default value = FALSE) the md5hash of a stored artifact or should the result be an input artifact (value = TRUE), so that valueing code can be used. See examples.</td>
</tr>
<tr>
<td>...</td>
<td>Graphical parameters denoting width and height of a miniature. See details. Further arguments passed to head. See Details section about firstRows parameter</td>
</tr>
<tr>
<td>userTags</td>
<td>A character vector with Tags. These Tags will be added to the repository along with the artifact.</td>
</tr>
<tr>
<td>use_flocks</td>
<td>A logical value. If TRUE then flock package is used to lock access to a database. By default it’s FALSE.</td>
</tr>
<tr>
<td>silent</td>
<td>If TRUE produces no warnings.</td>
</tr>
<tr>
<td>ascii</td>
<td>A logical value. An ascii argument is passed to save function.</td>
</tr>
<tr>
<td>artifactName</td>
<td>The name of the artifact with which it should be archived. If NULL then object’s MD5 hash will be used instead.</td>
</tr>
</tbody>
</table>

Details

saveToLocalRepo function saves desired artifacts to the local Repository in a given directory. Artifacts are saved in the local Repository, which is a SQLite database named backpack. After every saveToLocalRepo call the database is refreshed, so the artifact is available immediately in the database for other collaborators. Each artifact is archived in a md5hash.rda file. This file will be saved in a folder (under repoDir directory) named gallery. For each artifact, md5hash is a unique string of length 32 that is produced by digest function, which uses a cryptographical MD5 hash algorithm.

By default, a miniature of an artifact and (if possible) a data set needed to compute this artifact are extracted. They are also going to be saved in a file named by their md5hash in the gallery folder that exists in the directory specified in the repoDir argument. Moreover, a specific Tag-relation is going to be added to the backpack dataset in case there is a need to load the artifact with it’s related data set - see loadFromLocalRepo or loadFromRemoteRepo. Default settings may be changed by using the archiveData, archiveTag or archiveMiniature arguments with the FALSE value.

Tags are artifact’s attributes, different for various artifact’s classes. For more detailed information check Tags

Archived artifact can be searched in the backpack dataset by using the searchInLocalRepo or searchInRemoteRepo functions. Artifacts can be searched by their Tags, names, classes or archiving date.
firstRows parameter.

If the artifact is of class data.frame or user set archiveData = TRUE for artifact that stores data within it, it is possible to specify how many rows of that data (or that data.frame) should be archived in a miniature. This can be done by adding the argument firstRows with the n corresponding to the number of rows (as in head). Note that, the data can be extracted only from the artifacts that are supported by the archivist package; see Tags.

Graphical parameters.

If the artifact is of class lattice or ggplot, and archiveMiniature = TRUE, then it is possible to set the miniature’s width and height parameters. By default they are set to width = 800, height = 600.

Supported artifact’s classes are listed here Tags.

Value

As a result of calling this function a character string is returned, which determines the md5hash of the artifact. If archiveData is TRUE, the result will also have an attribute, named data, which determines md5hash of the data needed to compute the artifact.

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

Note

In the following way one can specify his own Tags for artifacts by setting artifact’s attribute before call of the saveToLocalRepo function: attr(x,"tags") = c("name1","name2"), where x is an artifact and name1,name2 are Tags specified by a user. It can be also done in a new, simpler way by using userTags parameter like this:

```
• saveToLocalRepo(model,repoDir,userTags = c("my_model","do not delete"));
```

Specifing additional Tags by attributes can be beneficial when one uses addHooksToPrint.

Important: if one wants to archive data from artifacts which is one of: survfit, glmnet, qda, lda, trellis, htest class, and this dataset is transformed within the artifact’s formula then saveToLocalRepo will not archive this dataset. saveToLocalRepo only archives datasets that already exist in any of R environments.

Example: The data set will not be archived here.

```
• z<-lda(Sp ~ .,Iris,prior = c(1,1,1)/3,subset = train[,,-8])
• saveToLocalRepo( z,repoDir )
```

Example: The data set will be archived here.

```
• train2<-train[,,-8]
• z<-lda(Sp ~ .,Iris,prior = c(1,1,1)/3,subset = train2)
• saveToLocalRepo( z,repoDir )
```
saveToLocalRepo

rm(exampleRepoDir)

## End(Not run)
```
searchInLocalRepo

Search for an Artifact in the Repository Using Tags

Description

searchInRepo searches for an artifact in the Repository using it’s Tags. To learn more about artifacts visit archivist-package.

Usage

searchInLocalRepo(pattern, repoDir = aoptions("repoDir"), fixed = TRUE, intersect = TRUE)

searchInRemoteRepo(pattern, repo = aoptions("repo"), user = aoptions("user"), branch = "master", subdir = aoptions("subdir"), repoType = aoptions("repoType"), fixed = TRUE, intersect = TRUE)

multiSearchInLocalRepo(...)

multiSearchInRemoteRepo(...)

Arguments

pattern
If fixed = TRUE: a character denoting a Tag which is to be searched for in the Repository. It is also possible to specify pattern as a list of length 2 with dateFrom and dateTo; see details. If fixed = FALSE: a regular expression specifying the beginning of a Tag, which will be used to search for artifacts. If of length more than one and if intersect = TRUE then artifacts that match all conditions are returned. If intersect = FALSE then artifacts that match any condition are returned. See examples.

repoDir
A character denoting an existing directory in which artifacts will be searched for.

fixed
A logical value specifying how artifacts should be searched for. If fixed = TRUE (default) then artifacts are searched for by using pattern = "Tag" argument. If fixed = FALSE then artifacts are searched for by using pattern = "regular expression" argument. The latter is wider and more flexible method, e.g., using pattern = "name", fixed = FALSE arguments enables to search for all artifacts in the Repository.

intersect
A logical value. Used only when length(pattern) > 1 & is.character(pattern). See pattern for more details.

repo
While working with the Remote repository. A character containing a name of the Remote repository on which the Repository is stored. By default set to NULL - see Note.
**searchInLocalRepo**

user

While working with the Remote repository. A character containing a name of the Remote user on whose account the repo is created. By default set to NULL - see Note.

branch

While working with the Remote repository. A character containing a name of the Remote Repository’s branch on which the Repository is stored. Default branch is master.

subdir

While working with the Remote repository. A character containing a name of a directory on the Remote repository on which the Repository is stored. If the Repository is stored in the main folder of the Remote repository, this should be set to subdir = ”/” as default.

repoType

A character containing a type of the remote repository. Currently it can be 'github' or 'bitbucket'.

... Used for old deprecated functions.

Details

searchInRepo searches for an artifact in the Repository using it’s Tag (e.g., name, class or archiving date). Tags are used in a pattern parameter. For various artifact classes different Tags can be searched for. See Tags. If a pattern is a list of length 2 then md5hashes of all artifacts created from date dateFrom to date dateTo are returned. The date should be formatted according to the YYYY-MM-DD format, e.g., "2014-07-31".

Tags, used in a pattern parameter, should be determined according to the format: "TagKey:TagValue" - see examples.

Value

searchInRepo returns character vector of md5hashes of artifacts that were searched for. Those are hashes assigned to artifacts while they were saved in the Repository by the saveToLocalRepo function. If the artifact is not in the Repository then a logical value FALSE is returned.

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

Note

If repo, user, subdir and repoType are not specified in the Remote mode then global parameters set in setRemoteRepo function are used.

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

                   user="pbiecek", repo="archivist", intersect = FALSE )
```

## End(Not run)

---

### setLocalRepo

**Set Repository’s Global Path**

**Description**

setLocalRepo sets local Repository’s global path. setRemoteRepo similarly sets Remote Repository’s path. See examples.

**Usage**

```r
setLocalRepo(repoDir)
```

```r
setPostgresRepo(repoDir, connector = NULL)
```

```r
setRemoteRepo(user, repo, branch = "master", subdir = "/",
               repoType = "github")
```

**Arguments**

- `repoDir` A character denoting a directory of a Repository that we want to make default.
- `connector` If user want to use some external database instead of SQLite, then the connector shall be the function that create a DBI connection with the database. Within every transaction the connection is opened and closed, thus the connector function will be executed often and shall not be computationally heavy. See examples for createLocalRepo for some applications. If connector=NULL then information about connectors to an external database will be removed. Note that it’s an experimental feature.
setLocalRepo

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user</td>
<td>While working with the Remote repository. A character containing a name of the Remote user that we want to make default.</td>
</tr>
<tr>
<td>repo</td>
<td>While working with the Remote repository. A character containing a name of the Remote repository that we want to make default.</td>
</tr>
<tr>
<td>branch</td>
<td>While working with the Remote repository. A character containing a name of the Remote Repository’s branch that we want to make default. Default branch is master.</td>
</tr>
<tr>
<td>subdir</td>
<td>While working with the Remote repository. A character containing a name of the Repository’s directory on Remote that we want to make default. If the Repository is stored in the main folder on the Remote repository, this should be set to subdir = &quot;/&quot; as default.</td>
</tr>
<tr>
<td>repoType</td>
<td>A character containing a type of the remote repository. Currently it can be 'github' or 'bitbucket'.</td>
</tr>
</tbody>
</table>

Details

If you are working on a local Repository and you are tired of specifying repoDir parameter in every function call that uses this parameter, you can set Repository’s path globally using setLocalRepo function and omit repoDir parameter in future function calls.

If you are working on the Remote Repository and you are tired of specifying user, repo, branch and subdir parameters in every function call that uses these parameters, you can set Remote Repository's path globally using setRemoteRepo function and omit user, repo, branch and subdir parameters in future function calls. See examples.

For local repositories, in this way, in the following function calls: loadFromLocalRepo, searchInLocalRepo, rmFromLocalRepo, zipLocalRepo, addTagsRepo, shinySearchInLocalRepo, getTagsLocal, showLocalRepo, summaryLocalRepo repoDir parameter may be omitted. For remote repositories, in this way, in the following function calls: zipRemoteRepo, loadFromRemoteRepo, searchInRemoteRepo, getTagsRemote, showRemoteRepo, summaryRemoteRepo, copyRemoteRepo parameters user, repo, branch, subdir may be omitted.

rmFromLocalRepo("4c43f")
showLocalRepo()
summaryLocalRepo()

# REMEMBER that in deleteLocalRepo you MUST specify repoDir parameter!
# deleteRepo doesn't take setLocalRepo's settings into consideration
deleteLocalRepo( exampleRepoDir, deleteRoot=TRUE)
rm( exampleRepoDir )
```
shinySearchInLocalRepo

**Shiny Based Live Search for an Artifact in a Repository Using Tags**

**Description**

shinySearchInLocalRepo searches for an artifact in a Repository using Tags. To create an application one needs to point the name of artifacts' repository. The application is generated on the run. As for now there are two controllers exposed. A text input field and a slider. Tags that are typed into text field are used for searching in repository. Objects that have the same Tags are presented on the right panel. These object might be also downloaded just by click. To learn more about artifacts visit archivist-package.

**Usage**

shinySearchInLocalRepo(repoDir = NULL, host = "0.0.0.0")

**Arguments**

- **repoDir**: A character denoting an existing directory in which artifacts will be searched. If set to NULL (by default), uses the repoDir specified in setLocalRepo.
- **host**: A host IP address, see the host argument in shiny::runApp.
Details

shinySearchInLocalRepo searches for artifacts in a Repository using their Tags (e.g., name, class or archiving date). Tags are submitted in a text input in a shiny application. Many Tags may be specified, they should be comma separated. User can specify more Tags like phase, project, author etc. when artifact is created.

In the search query one can add Tags starting with sort: or sort:. As a result, miniatures will be sorted appropriately. For example sort:class will sort class Tags, while sort:-class will sort class tags backwards. sort:createdDate will sort createdDate Tag and sort:-createdDate will sort createdDate Tag backwards.

Tags, submitted in the text field, should be given according to the format: "TagKey:TagValue" - see examples.

Value

shinySearchInLocalRepo runs a shiny application.

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

shiny

This function use tools from the fantastic shiny package, so you’ll need to make sure to have it installed.

showLocalRepo

View the List of Artifacts from the Repository

Description

showLocalRepo and showRemoteRepo functions produce the data.frame of the artifacts from the Repository saved in a given repoDir (directory). showLocalRepo shows the artifacts from the Repository that exists on the user's computer whereas showRemoteRepo shows the artifacts of the Repository existing on the remote repository. To learn more about artifacts visit archivist-package.

Usage

showLocalRepo(repoDir = aoptions("repoDir"), method = "md5hashes")

showRemoteRepo(repo = aoptions("repo"), user = aoptions("user"),
branch = aoptions("branch"), subdir = aoptions("subdir"),
repoType = aoptions("repoType"), method = "md5hashes")

Arguments

repoDir A character denoting an existing directory of the Repository for which metadata will be returned.
method A character specifying a method to be used to show the Repository. Available methods: md5hashes (default), tags and sets - see archivist2::saveSetToRepo.
repo While working with the Remote repository. A character containing a name of the Remote repository on which the Repository is stored. By default set to NULL - see Note.
user While working with the Remote repository. A character containing a name of the Remote user on whose account the repo is created. By default set to NULL - see Note.
branch While working with the Remote repository. A character containing a name of the Remote Repository's branch on which the Repository is stored. Default branch is master.
subdir While working with the Remote repository. A character containing a name of a directory on the Remote repository on which the Repository is stored. If the Repository is stored in the main folder of the Remote repository, this should be set to subdir = "/" as default.
repoType A character containing a type of the remote repository. Currently it can be 'github' or 'bitbucket'.

Examples

## Not run:
# assuming that there is a 'repo' dir with a valid archivist repository
shinySearchInLocalRepo( repoDir = 'repo' )

## End(Not run)
Details

showLocalRepo and showRemoteRepo functions produce the data.frame of the artifacts from a Repository saved in a given repoDir (directory). showLocalRepo shows the artifacts from the Repository that exists on the user’s computer whereas showRemoteRepo shows the artifacts of the Repository existing on the remote repository.

Both functions show the current state of a Repository, inter alia, all archived artifacts can be seen with their unique md5hash or a data.frame with archived Tags can be obtained.

Value

If parameter method is set as md5hashes then a data.frame with artifacts’ names and artifacts’ md5hashes will be returned.

If parameter method is set as tags then a data.frame with Tags and artifacts’ md5hashes will be returned.

Also in both cases a data.frame contains an extra column with the date of creation of the Tag or md5hash.

To learn more about Tags or md5hashes check: Tags or md5hash.

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

Note

If repo and user are set to NULL (as default) in the Remote mode then global parameters set in setRemoteRepo (or via aoptions) function are used.

loadFromRemoteRepo("ff575c261c", value = TRUE) -> iris123

showRemoteRepo('Museum', 'MarcinKosinski', subdir = 'ex1')
aoptions('repo', 'Museum')
aoptions('user', 'MarcinKosinski')
aoptions('subdir', 'ex1')
aoptions('branch', 'master')
showRemoteRepo()
showRemoteRepo(subdir = 'ex2')
aoptions('subdir')

## End(Not run)
```

---

splitTagsLocal

**Split Tags in Repository**

**Description**

`splitTagsLocal` and `splitTagsRemote` functions split tag column from `tag` table placed in `backpack.db` into two separate columns: `tagKey` and `tagValue`. 
splitTagsLocal

Usage

splitTagsLocal(repoDir = aoptions("repoDir"))

splitTagsRemote(repo = aoptions("repo"), user = aoptions("user"),
branch = aoptions("branch"), subdir = aoptions("subdir"),
repoType = aoptions("repoType"))

Arguments

repoDir While working with the local repository. A character denoting an existing directory of the Repository.

repo While working with the Github repository. A character containing a name of the Github repository on which the Repository is stored. By default set to NULL - see Note.

user While working with the Github repository. A character containing a name of the Github user on whose account the repo is created. By default set to NULL - see Note.

branch While working with the Github repository. A character containing a name of the Github Repository’s branch on which the Repository is stored. Default branch is master.

subdir While working with the Github repository. A character containing a name of a directory on the Github repository on which the Repository is stored. If the Repository is stored in the main folder of the Github repository, this should be set to subdir = "/" as default.

repoType A character containing a type of the remote repository. Currently it can be 'github' or 'bitbucket'.

Details
tag column from tag table has normally the following structure: TagKey:TagValue. splitTagsLocal and splitTagsRemote functions can be used to split tag column into two separate columns: tagKey and tagValue. As a result functions from dplyr package can be used to easily summarize, search, and extract artifacts’ Tags. See examples.

Value

A data.frame with 4 columns: artifact, tagKey, tagValue and createdDate, corresponding to the current state of Repository.

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

Note

If repo and user are set to NULL (as default) in the Github mode then global parameters set in setRemoteRepo function are used.
Sometimes we can use addTags* function or userTags parameter in saveToRepo to specify a Tag which might not match TagKey:TagValue structure. It is simply Tag. In this case tagKey = userTags and tagValue = Tag. See examples.

To learn more about Tags and Repository structure check Tags and Repository.

Examples

```
## Not run:
## LOCAL VERSION
setLocalRepo(system.file("graphGallery", package = "archivist"))
head(showLocalRepo(method = "tags"))
head(splitTagsLocal() )

## Github Version
# Let's check how does table tag look like while we are using the
# Gitub repository.
# We will choose only special columns of data frames that show Tags
head(showRemoteRepo( user = "pbiecek", repo = "archivist", method = "tags" )[,2])
head(splitTagsRemote( user = "pbiecek", repo = "archivist" )[,2:3])

head(splitTagsRemote("PieczaraPietraszki", "BetaAndBit", "master", "UniwersytetDzieci/arepo"))

## End(Not run)
```
**summaryLocalRepo**

**View the Summary of the Repository**

**Description**

`summaryRepo` summarizes the current state of the **Repository**.

**Usage**

```r
summaryLocalRepo(repoDir = aoptions("repoDir"))

summaryRemoteRepo(repo = aoptions("repo"), user = aoptions("user"),
                   branch = "master", subdir = aoptions("subdir"),
                   repoType = aoptions("repoType"))
```

**Arguments**

- **repoDir**
  A character denoting an existing directory of the Repository for which a summary will be returned.

- **repo**
  While working with the Remote repository. A character containing a name of the Remote repository on which the Repository is stored. By default set to `NULL` - see **Note**.

- **user**
  While working with the Remote repository. A character containing a name of the Remote user on whose account the repo is created. By default set to `NULL` - see **Note**.

- **branch**
  While working with the Remote repository. A character containing a name of the Remote Repository's branch on which the Repository is stored. Default branch is `master`.

- **subdir**
  While working with the Remote repository. A character containing a name of a directory on the Remote repository on which the Repository is stored. If the Repository is stored in the main folder of the Remote repository, this should be set to `subdir = "/"` as default.

- **repoType**
  A character containing a type of the remote repository. Currently it can be 'github' or 'bitbucket'.

**Details**

`summaryRepo` summarizes the current state of a **Repository**. Recommended to use `print( summaryRepo )`. See examples.

**Value**

An object of class **repository** which can be printed: `print(object)`.

**Contact**

Bug reports and feature requests can be sent to [https://github.com/pbiecek/archivist/issues](https://github.com/pbiecek/archivist/issues)
Note

If the same artifact was archived many times then it is counted as one artifact or database in `print(summaryRepo)`. If `repo` and `user` are set to `NULL` (as default) in the Remote mode then global parameters set in `setRemoteRepo` function are used.

print( x )

# many archivist-like Repositories on one Remote repository

summaryRemoteRepo(user="MarcinKosinski", repo="Museum", branch="master", subdir="ex2" )

## End(Not run)
```
Description

Tags are attributes of an artifact, i.e., a class, a name, names of artifact’s parts, etc... The list of artifact tags vary across artifact’s classes. To learn more about artifacts visit archivist-package.

Details

Tags are attributes of an artifact. They can be the artifact’s name, class or archiving date. Furthermore, for various artifact’s classes more different Tags are available.

A Tag is represented as a string and usually has the following structure "TagKey:TagValue", e.g., "name:iris".

Tags are stored in the Repository. If data is extracted from an artifact then a special Tag, named relationWith is created. It specifies with which artifact this data is related to.

The list of supported artifacts which are divided thematically is presented below. The newest list is also available on archivist wiki on Github.

Tags

Note

In the following way one can specify his own Tags for artifacts by setting artifact’s attribute before call of the `saveToLocalRepo` function: `attr(x,"tags") = c("name1","name2")`, where `x` is an artifact and `name1`, `name2` are Tags specified by a user. It can be also done in a new, simpler way by using `userTags` parameter like this:

- `saveToLocalRepo(model,repoDir,userTags = c("my_model","do not delete")).`

Specifying additional Tags by attributes can be beneficial when one uses `addHooksToPrint`.

References

zipLocalRepo  
Create a zip Archive From an Existing Repository

Description

zipLocalRepo and zipRemoteRepo create a zip archive from an existing Repository. zipLocalRepo zips local Repository, zipRemoteRepo zips Repository stored on Github.

Usage

```r
zipLocalRepo(repoDir = aoptions("repoDir"), repoTo = getwd(),
  zipname = "repository.zip")
zipRemoteRepo(repoTo = getwd(), user = aoptions("user"),
  repo = aoptions("repo"), branch = "master",
  subdir = aoptions("subdir"), repoType = aoptions("repoType"),
  zipname = "repository.zip")
```

Arguments

- **repoDir** A character that specifies the directory of the Repository which will be zipped.
- **repoTo** A character that specifies the directory in which there will be created zip archive from Repository stored in repoDir or Remote directory. By default set to working directory (getwd()).
- **zipname** A character that specifies name of the zipped repository. It is assumed that this file does not exist or does not contain backpack.db file. An attempt to override will produce an error.
- **user** While working with the Remote repository. A character containing a name of the Remote user on whose account the repo is created. By default set to NULL - see Note.
- **repo** While working with the Remote repository. A character containing a name of the Remote repository on which the Repository, which is to be zipped, is archived. By default set to NULL - see Note.
- **branch** While working with the Remote repository. A character containing a name of the Remote repository’s branch on which Repository, which is to be zipped, is archived. Default branch is master.
zipLocalRepo

subdir While working with a Remote repository. A character containing a name of a directory on Remote repository on which the Repository, which is to be zipped, is stored. If the Repository is stored in the main folder on the Remote repository, this should be set to FALSE as default.

repoType A character containing a type of the remote repository. Currently it can be 'Remote' or 'bitbucket'.

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

Note

The function might not work if Rtools are not installed. To solve this problem follow these Instructions.
If repo and user are set to NULL (as default) in Github mode then global parameters set in setRemoteRepo function are used.

**magrittr - a Forward-Pipe Operator for R**

**Description**

An extended pipe operator `%>%` from magrittr package version 1.0.1. Enables archiving artifacts with their chaining code - see examples and vignettes.

**Usage**

`lhs %>% rhs`
Arguments

lhs  An artifact that will be used as an argument of rhs by %a% operator.
rhs  A function call using lhs as an argument by %a% operator.

Details

The extension works as follows, the result of %a% operator is archived together with lhs (as an artifact) and rhs (as a Tag). This allows to present a history of an artifact. This option works only if a default repository is set.

Contact

Bug reports and feature requests can be sent to https://github.com/pbiecek/archivist/issues

Demonstration

This function is well explained on this http://r-bloggers.com/r-hero-saves-backup-city-with-archivist-and-github blog post.
