Package ‘arkdb’

January 16, 2024

Version 0.0.18
Title Archive and Unarchive Databases Using Flat Files
Description Flat text files provide a robust, compressible, and portable way to store tables from databases. This package provides convenient functions for exporting tables from relational database connections into compressed text files and streaming those text files back into a database without requiring the whole table to fit in working memory.

Description

Flat text files provide a more robust, compressible, and portable way to store tables. This package provides convenient functions for exporting tables from relational database connections into compressed text files and streaming those text files back into a database without requiring the whole table to fit in working memory.

Details

It has two functions:

- `ark()`: archive a database into flat files, chunk by chunk.
- `unark()`: Unarchive flat files back into a database connection.

arkdb will work with any DBI supported connection. This makes it a convenient and robust way to migrate between different databases as well.

---

Description

Archive tables from a database as flat files

Usage

```r
ark(
  db_con,
  dir,
  streamable_table = streamable_base_tsv(),
  lines = 50000L,
  compress = c("bzip2", "gzip", "xz", "none"),
  tables = list_tables(db_con),
  method = c("keep-open", "window", "window-parallel", "sql-window"),
  overwrite = "ask",
  filter_statement = NULL,
  filenames = NULL,
  callback = NULL
)
```

Arguments

- `db_con`: a database connection
- `dir`: a directory where we will write the compressed text files output
- `streamable_table`: interface for serializing/deserializing in chunks
- `lines`: the number of lines to use in each single chunk
- `compress`: file compression algorithm. Should be one of "bzip2" (default), "gzip" (faster write times, a bit less compression), "xz", or "none", for no compression.
- `tables`: a list of tables from the database that should be archived. By default, will archive all tables. Table list should specify schema if appropriate, see examples.
- `method`: method to use to query the database, see details.
- `overwrite`: should any existing text files of the same name be overwritten? default is "ask", which will ask for confirmation in an interactive session, and overwrite in a non-interactive script. TRUE will always overwrite, FALSE will always skip such tables.
filter_statement

Typically an SQL "WHERE" clause, specific to your dataset. (e.g., `WHERE year = 2013`)

filenames

An optional vector of names that will be used to name the files instead of using the tablename from the tables parameter.

callback

An optional function that acts on the data.frame before it is written to disk by streamable_table. It is recommended to use this on a single table at a time. Callback functions must return a data.frame.

Details

ark will archive tables from a database as (compressed) tsv files. Or other formats that have a streamtable_table method, like parquet. ark does this by reading only chunks at a time into memory, allowing it to process tables that would be too large to read into memory all at once (which is probably why you are using a database in the first place!) Compressed text files will likely take up much less space, making them easier to store and transfer over networks. Compressed plain-text files are also more archival friendly, as they rely on widely available and long-established open source compression algorithms and plain text, making them less vulnerable to loss by changes in database technology and formats.

In almost all cases, the default method should be the best choice. If the `DBI::dbSendQuery()` implementation for your database platform returns the full results to the client immediately rather than supporting chunking with `n` parameter, you may want to use "window" method, which is the most generic. The "sql-window" method provides a faster alternative for databases like PostgreSQL that support windowing natively (i.e. BETWEEN queries). Note that "window-parallel" only works with streamable_parquet.

Value

the path to dir where output files are created (invisibly), for piping.

Examples

```r
# setup
library(dplyr)
dir <- tempdir()
db <- dbplyr::nycflights13_sqlite(tempdir())

## And here we go:
ark(db, dir)

## Not run:

## For a Postgres DB with schema, we can append schema names first
## to each of the table names, like so:
schema_tables <- dbGetQuery(db, sqlInterpolate(db,
  "SELECT table_name FROM information_schema.tables
  WHERE table_schema = ?schema",
  schema = "schema_name"
))```
arkdb_delete_db

delete the local arkdb database

Description

delete the local arkdb database

Usage

arkdb_delete_db(db_dir = arkdb_dir(), ask = interactive())

Arguments

db_dir  
neon database location

ask  
Ask for confirmation first?

Details

Just a helper function that deletes the database files. Usually unnecessary but can be helpful in resetting a corrupt database.

Examples

# Create a db
dir <- tempfile()
db <- local_db(dir)

# Delete it
arkdb_delete_db(dir, ask = FALSE)

local_db

Connect to a local stand-alone database

Description

This function will provide a connection to the best available database. This function is a drop-in replacement for [DBI::dbConnect] with behaviour that makes it more subtle for R packages that need a database backend with minimal complexity, as described in details.
Usage

`local_db(`
  `dbdir = arkdb_dir(),`
  `driver = Sys.getenv("ARKDB_DRIVER", "duckdb"),`
  `readonly = FALSE,`
  `cache_connection = TRUE,`
  `memory_limit = getOption("duckdb_memory_limit", NA),`
  `...`
``)

Arguments

dbdir Path to the database.
driver Default driver, one of "duckdb", "MonetDBLite", "RSQLite". It will select the first one of those it finds available if a driver is not set. This fallback can be overwritten either by explicit argument or by setting the environmental variable ARKDB_DRIVER.
readonly Should the database be opened read-only? (duckdb only). This allows multiple concurrent connections (e.g. from different R sessions)
cache_connection should we preserve a cache of the connection? allows faster load times and prevents connection from being garbage-collected. However, keeping open a read-write connection to duckdb or MonetDBLite will block access of other R sessions to the database.
memory_limit Set a memory limit for duckdb, in GB. This can also be set for the session by using options, e.g. options(duckdb_memory_limit=10) for a limit of 10GB. On most systems duckdb will automatically set a limit to 80% of machine capacity if not set explicitly.
... additional arguments (not used at this time)

Details

This function provides several abstractions to `DBI::dbConnect` to provide a seamless backend for use inside other R packages.

First, this provides a generic method that allows the use of a `RSQLite::SQLite` connection if nothing else is available. An argument or environmental variable can be used to override this to manually set a database endpoint for testing purposes.

Second, this function will cache the database connection in an R environment and load that cache. That means you can call `local_db()` as fast/frequently as you like without causing errors that would occur by rapid calls to `DBI::dbConnect`

Third, this function defaults to persistent storage location set by `tools::R_user_dir` and configurable by setting the environmental variable ARKDB_HOME. This allows a package to provide persistent storage out-of-the-box, and easily switch that storage to a temporary directory (e.g. for testing purposes, or custom user configuration) without having to edit database calls directly.
Value

Returns a [DBIconnection] connection to the default database

Examples

## OPTIONAL: you can first set an alternative home location, such as a temporary directory:
Sys.setenv(ARKDB_HOME = tempdir())

## Connect to the database:
db <- local_db()
process_chunks  

Description

process a table in chunks

Usage

```r
process_chunks(
  file,
  process_fn,
  streamable_table = NULL,
  lines = 50000L,
  encoding = Sys.getenv("encoding", "UTF-8"),
  ...
)
```

Arguments

- `file`  
  path to a file
- `process_fn`  
  a function of a chunk
- `streamable_table`  
  interface for serializing/deserializing in chunks
- `lines`  
  number of lines to read in a chunk.
- `encoding`  
  encoding to be assumed for input files.
- `...`  
  additional arguments to `streamable_table$read` method.

Examples

```r
con <- system.file("extdata/mtcars.tsv.gz", package = "arkdb")
dummy <- function(x) message(paste(dim(x), collapse = " x "))
process_chunks(con, dummy, lines = 8)
```

streamable_base_csv  

Description

streamable csv using base R functions

Usage

```r
streamable_base_csv()
```
streamable_base_tsv

Details

Follows the comma-separate-values standard using utils::read.table()

Value

a streamable_table object (S3)

See Also

utils::read.table(), utils::write.table()

---

**streamable_base_tsv**  
*streamable tsv using base R functions*

Description

streamable tsv using base R functions

Usage

streamable_base_tsv()

Details

Follows the tab-separate-values standard using utils::read.table(), see IANA specification at: https://www.iana.org/assignments/media-types/text/tab-separated-values

Value

a streamable_table object (S3)

See Also

utils::read.table(), utils::write.table()
| streamable_parquet | streamable chunked parquet using arrow |

**Description**

streamable chunked parquet using arrow

**Usage**

streamable_parquet()

**Details**

Parquet files are streamed to disk by breaking them into chunks that are equal to the nlines parameter in the initial call to arrow. For each tablename, a folder is created and the chunks are placed in the folder in the form part-00000.parquet. The software looks at the folder, and increments the name appropriately for the next chunk. This is done intentionally so that users can take advantage of arrow::open_dataset in the future, when coming back to review or perform analysis of these data.

**Value**

a streamable_table object (S3)

**See Also**

arrow::read_parquet(), arrow::write_parquet()

| streamable_readr_csv | streamable csv using readr |

**Description**

streamable csv using readr

**Usage**

streamable_readr_csv()

**Value**

a streamable_table object (S3)

**See Also**

readr::read_csv(), readr::write_csv()
streamable_readr_tsv  streamable tsv using readr

Description

streamable tsv using readr

Usage

streamable_readr_tsv()

Value

a streamable_table object (S3)

See Also

readr::read_tsv(), readr::write_tsv()

streamable_table  streamable table

Description

streamable table

Usage

streamable_table(read, write, extension)

Arguments

read  read function. Arguments should be "file" (must be able to take a connection() object) and "..." (for) additional arguments.

write  write function. Arguments should be "data" (a data.frame), file (must be able to take a connection() object), and "omit_header" logical, include header (initial write) or not (for appending subsequent chunks)

extension  file extension to use (e.g. "tsv", "csv")

Details

Note several constraints on this design. The write method must be able to take a generic R connection object (which will allow it to handle the compression methods used, if any), and the read method must be able to take a textConnection object. readr functions handle these cases out of the box, so the above method is easy to write. Also note that the write method must be able to omit_header. See the built-in methods for more examples.
Value

a streamable_table object (S3)

Examples

streamable_readr_tsv <- function() {
  streamable_table(
    function(file, ...) readr::read_tsv(file, ...),
    function(x, path, omit_header) {
      readr::write_tsv(x = x, path = path, omit_header = omit_header)
    },
    "tsv"
  )
}

streamable_vroom streamable tables using vroom

Description

streamable tables using vroom

Usage

streamable_vroom()

Value

a streamable_table object (S3)

See Also

readr::read_tsv(), readr::write_tsv

unark Unarchive a list of compressed tsv files into a database

Description

Unarchive a list of compressed tsv files into a database
unark

Usage

unark(
  files,
  db_con,
  streamable_table = NULL,
  lines = 50000L,
  overwrite = "ask",
  encoding = Sys.getenv("encoding", "UTF-8"),
  tablenames = NULL,
  try_native = TRUE,
  ...
)

Arguments

files vector of filenames to be read in. Must be tsv format, optionally compressed using bzip2, gzip, zip, or xz format at present.
db_con a database src (src_dbi object from dplyr)
streamable_table interface for serializing/deserializing in chunks
lines number of lines to read in a chunk.
overwrite should any existing text files of the same name be overwritten? default is "ask", which will ask for confirmation in an interactive session, and overwrite in a non-interactive script. TRUE will always overwrite, FALSE will always skip such tables.
encoding encoding to be assumed for input files.
tablenames vector of tablenames to be used for corresponding files. By default, tables will be named using lowercase names from file basename with special characters replaced with underscores (for SQL compatibility).
try_native logical, default TRUE. Should we try to use a native bulk import method for the database connection? This can substantially speed up read times and will fall back on the DBI method for any table that fails to import. Currently only MonetDBLite connections support this.
... additional arguments to streamable_table$read method.

Details

unark will read in a files in chunks and write them into a database. This is essential for processing large compressed tables which may be too large to read into memory before writing into a database. In general, increasing the lines parameter will result in a faster total transfer but require more free memory for working with these larger chunks.

If using readr-based streamable-table, you can suppress the progress bar by using options(readr.show_progress = FALSE) when reading in large files.

Value

the database connection (invisibly)
Examples

```r
## Setup: create an archive.
library(dplyr)
dir <- tempdir()
db <- dbplyr::nycflights13_sqlite(tempdir())

## database -> .tsv.bz2
ark(db, dir)

## list all files in archive (full paths)
files <- list.files(dir, "bz2$", full.names = TRUE)

## Read archived files into a new database (another sqlite in this case)
new_db <- DBI::dbConnect(RSQLite::SQLite())
unark(files, new_db)

## Prove table is returned successfully.
tbl(new_db, "flights")
```
