Package ‘atable’

February 21, 2022

Type Package
Title Create Tables for Reporting Clinical Trials
Version 0.1.11
Author Armin Ströbel [aut, cre] (<https://orcid.org/0000-0002-6873-5332>),
        Alan Haynes [aut] (<https://orcid.org/0000-0003-1374-081X>)
Maintainer Armin Ströbel <arminstroebel@web.de>
Description Create Tables for Reporting Clinical Trials.
        Calculates descriptive statistics and hypothesis tests,
        arranges the results in a table ready for reporting with LaTeX, HTML or Word.

R topics documented:

    add_observation_column ...................................... 2
    atable ..................................................................... 3
**add_observation_column**

*Adds a column to a data.frame*

**Description**

The new column has name `atable_options('colname_for_observations')` and class 'count_me'.

**Usage**

```r
add_observation_column(DD)
```

**Arguments**

- `DD` A data.frame.

**Details**

Throws an error if a column of that name is already present in `DD`. 
atable

Value
As DD now with one more column.

atable

Create Tables for Reporting of Clinical Trials

Description
Applies descriptive statistics and hypothesis tests to data, and arranges the results for printing.

Usage
atable(x, ...)

## S3 method for class 'data.frame'
atable(
x,
target_cols,
group_col = NULL,
split_cols = NULL,
format_to = atable_options("format_to"),
drop_levels = TRUE,
add_levels_for_NA = FALSE,
blocks = NULL,
add_margins = atable_options("add_margins"),
indent_character = NULL,
indent = atable_options("indent"),
...
)

## S3 method for class 'formula'
atable(formula, data, ...)

Arguments

x  An object. If x is a data.frame, it must have unique and syntactically valid colnames, see is_syntactically_valid_name. If x is a formula, then its format must be target_cols ~ group_col | split_cols. See other arguments for more details.

... Passed from and to other methods. You can use the ellipsis ... to modify atable: For example the default-statistics for numeric variables are mean and sd. To change these statistics pass a function to argument statistics.numeric, that calculates the statistics you prefer for your data. See examples below how to modify atable by ....

Actually statistics.numeric is passed to statistics and thus documented there, but for convenience it also documented here.

Here is a list of the statistics and hypothesis tests that can be modified by ...:
• statistics.numeric: Either NULL or a function. Default is NULL. If a function, then it will replace atable:::statistics.numeric when atable is called. The function must mimic statistics: see the help there.
• statistics.factor: Analog to argument statistics.numeric.
• statistics.ordered: Analog to argument statistics.numeric.
• two_sample_htest.numeric: Either NULL or a function. Default is NULL. If a function, then it will replace atable:::two_sample_htest.numeric when atable is called. The function must mimic two_sample_htest: see the help there.
• two_sample_htest.factor: Analog to argument two_sample_htest.numeric
• two_sample_htest.ordered: Analog to argument two_sample_htest.numeric
• multi_sample_htest.numeric: Either NULL or a function. Default is NULL. If a function, then it will replace atable:::multi_sample_htest.numeric when atable is called. The function must mimic multi_sample_htest: see the help there.
• multi_sample_htest.factor: Analog to argument multi_sample_htest.numeric
• multi_sample_htest.ordered: Analog to argument multi_sample_htest.numeric
• format_statistics.statistics_numeric: Either NULL or a function. Default is NULL. If a function, then it will replace atable:::format_statistics.statistics_numeric when atable is called. The function must mimic format_statistics: see the help there.
• format_statistics.statistics_factor: Analog to argument format_statistics.statistics_numeric
• format_tests.htest: Either NULL or a function. Default is NULL. If a function, then it will replace format_tests.htest. The function must mimic format_tests: see the help there.
• format_tests.htest_with_effect_size: Analog to argument format_tests.htest

**target_cols**
A character vector containing some column names of x.
Descriptive statistics and hypothesis test are applied to these columns depending on their class. The descriptive statistics are defined by statistics: their representation and format by format_statistics.
Hypothesis test are defined by two_sample_htest or multi_sample_htest (depending on the number of levels of group_col); their representation and format by format_tests. Note that atable always adds one name to target.cols to count the number of observations. This name is stored in atable_options(’colname_for_observations’).

**group_col**
A character of length 1 containing a column of x or NULL. This column defines the groups that are compared by the hypothesis tests. as.factor is applied to this column before further processing. Default is NULL, meaning that no hypothesis tests are applied.

**split_cols**
A character vector containing some of colnames(x) or NULL. x is splitted by these columns before descriptive statistics and hypothesis test are applied. as.factor is applied to this column before further processing. Default is NULL, meaning that no splitting is done.

**format_to**

**drop_levels**
A logical. If TRUE then droplevels is called on group_col and split_cols before further processing. Default is TRUE.
add_levels_for_NA
If TRUE then addNA is called on group_col and split_cols before further processing. Default is FALSE.

blocks
NULL or a list. If blocks is a list, then the names of the list must be non-NA characters. The elements of the list must be some of target_cols, retaining the order of target_cols. Also in this case split_cols must be NULL as simultaneous blocking and splitting is not supported. Default is NULL, meaning that no blocking is done. Variables of a block are additionally indented. Blocking has no effect on the statistics, it only affects the indentation of the resulting table. See Examples.

add_margins
A logical with length one, TRUE or FALSE. Default is defined in atable_options as FALSE. When add_margins is TRUE and group_col is not NULL, a column containing the results of an ungrouped atable-call is added to the results. See Examples.

indent_character
A character with length 1 or NULL (default). This character is used for indentation in the resulting table. If NULL, then the value stored in atable_options is taken instead, depending on format_to. indent_data_frame does the indentation. See help there.

indent
A logical with length one, TRUE or FALSE. Default is defined in atable_options. Decides if indentation is done or not. The resulting table will have a different layout. If FALSE, then blocks is ignored.

formula
A formula of the form target_cols ~ group_col | split_cols. The | separates the group_col from the split_cols. Read the | as 'given' as in a conditional probability \( P(\text{target_cols} | \text{split_cols}) \). target_cols and split_cols may contain multiple names separated by +. group_col must be a single name if given. group_col and split_cols may be omitted and can be replaced by 1 in this case. The | may also be omitted if no split_cols are given.

data
Passed to atable(x = data,...).

Value
Results depend on format_to:

- 'Raw': A list with two elements called 'statistics_result' and 'tests_result', that contain all results of the descriptive statistics and the hypothesis tests. This format useful, when extracting a specific result unformatted (when format_to is not 'Raw' all numbers are also returned, but as rounded characters for printing and squeezed into a data.frame).
  - 'statistics_result': contains a data.frame with colnames c(split_cols, group_col, target_cols. split_cols and group_col retain their original values (now as factor). target_cols contain lists with the results of function statistics. As the result of function statistics is also a list, target_cols contain lists of lists.
  - 'tests_result': has the same structure as 'statistics_result', but contains the results of two_sample_htest and multi_sample_htest. Note that tests_result only exists if split_cols is not NULL.
- 'Word': A data.frame. Column atable_options('colname_for_group') contains all combinations of the levels of split cols and the names of the results of function format_statistics.
Further columns are the levels of `group_col` the names of the results of `format_tests`.
The levels of `split_cols` and the statistics are arranged vertically. The hypothesis test are
arranged horizontally.

- 'HTML': Same as for `format_to = 'Word'` but a different character indents the first column.
- 'Console': Meant for printing in the R console for interactive analysis. Same as for `format_to = 'Word'` but a different character indents the first column.
- 'Latex': Same as for `format_to = 'Word'` but a different character indents the first column and with `translate_to_LaTeX` applied afterwards.

Methods (by class)

- `data.frame`: applies descriptive statistics and hypothesis tests, arranges the results for printing.
- `formula`: parses the formula and passes its parts to `atable`.

Examples

```r
# See vignette for more examples:
# utils::vignette('atable_usage', package = 'atable')

# Analyse datasets::ToothGrowth:
# Length of tooth for each dose level and delivery method:
atable::atable(datasets::ToothGrowth,
   target_cols = 'len',
   group_col = 'supp',
   split_cols = 'dose',
   format_to = 'Word')
# Print in .docx with e.g. flextable::regulartable and officer::body_add_table

# Analyse datasets::ChickWeight:
# Weight of chickens for each time point and diet:
atable(weight ~ Diet | Time, datasets::ChickWeight, format_to = 'Latex')
# Print as .pdf with e.g. Hmisc::latex

# Analyse atable::test_data:
atable(Numeric + Logical + Factor + Ordered ~ Group | Split1 + Split2, atable::test_data, format_to = 'HTML')
# Print as .html with e.g. knitr::kable and options(knitr.kable.NA = '')

# Modify atable: calculate median and MAD for numeric variables
new_stats <- function(x, ...){list(Median = median(x, na.rm = TRUE),
MAD = mad(x, na.rm = TRUE))}
atable::atable(test_data,
   target_cols = c('Numeric', 'Numeric2'),
   statistics.numeric = new_stats,
   format_to = 'Console')
# Print in Console with format_to = 'Console'.

# Analyse mtcars and add labels and units of via package Hmisc
```
mtcars <- within(datasets::mtcars, {gear <- factor(gear)})
# Add labels and units.
attr(mtcars$mpg, 'alias') = 'Consumption [Miles (US)/ gallon]
Hmisc::label(mtcars$qsec) = 'Quarter Mile Time'
units(mtcars$qsec) = 's'

# apply atable
atable::atable(mpg + hp + gear + qsec ~ cyl | vs,
  mtcars,
  format_to = 'Console')

# Blocks
# In datasets::mtcars the variables cyl, disp and mpg are related to the engine and am and gear are
# related to the gearbox. So grouping them together is desirable.
atable::atable(datasets::mtcars,
  target_cols = c("cyl", "disp", "hp", "am", "gear", "qsec") ,
  blocks = list("Engine" = c("cyl", "disp", "hp"),
                "Gearbox" = c("am", "gear")),
  format_to = "Console")
# Note that Variable qsec is not blocked and thus not indented.

# addMargins
atable::atable(atable::test_data,
  target_cols = "Numeric",
  group_col = "Group",
  split_cols = "Split1",
  add_margins = TRUE,
  format_to = "Console")
# The column 'Total' contains the results of the ungrouped atable-call:
# The number of observations is the sum of observations of the groups.
# The default of add_margins can be changed via atable_options.

---

**atable_compact**

More compact formatting than atable()

**Description**

This is a wrapper for atable(), calculating the same statistics, but with different format.

**Usage**

atable_compact(x, ...)

## S3 method for class 'data.frame'
atable_compact(
  x,
  target_cols,
etable_compact

```r

group_col = NULL,
indent_character = atable_options("indent_character_compact"),
blocks = NULL,
format_factor = atable_options("format_statistics_compact.statistics_factor"),
format_numeric = atable_options("format_statistics_compact.statistics_numeric"),
```

Arguments

- **x** object passed to `atable`.
- **...** Passed to `atable`.
- **target_cols** character. Some of `colnames(x)`.
- **group_col** character or NULL. If character then, one of `colnames(x)`.
- **indent_character** character length 1. Default is defined in `table_options("indent_character_compact")`. For Latex-Format use e.g. `indent_character="\quad"`. For Word-Format use e.g. `indent_character=paste0(rep(intToUtf8(160),5),collapse = "")` and e.g. Package officer and its functions officer::read_docx(), officer::body_add_table and print-methods.
- **blocks** NULL or a list, passed to `atable`, see help there.
- **format_factor** a function that defines the format of factor variables. Default is defined in `atable_options`. See `check_format_statistics` for the return-value of this function.
- **format_numeric** a function that defines the format of numeric variables. Analog to `format_factor`.

Details

The compact formatting is:

- Numeric `target_cols` get one line in the table; the line contains the mean and SD of the variable.
- Factor `target_cols` also get one line in the table, when they have only two levels and only the first level is displayed in the table and the name of the variable is omitted. This is intended for item like "Sex at birth: Female/Male". Knowing the percentage of Female is sufficient in this case (when NAas are not counted). Be careful with items like "Pregnant: Yes/No". Here only the level "Yes" will be printed and the name of the item (Pregnant) is omitted, making the table uninformative. Factors with three or more levels get one line per level, the levels are intended and a header line containing the name of the variable is added.

Arguments in `...` are passed to `atable`. See the help there. `atable_compact` is not designed for splitted atables, so argument `split_cols` must be omitted or NULL. Also argument `format_to` is ignored. Other features of `atable` (blocking, add_margins, alias) are available, see examples.

Value

data.frame
Methods (by class)

- `data.frame`: a compact version of `atable`.

Examples

```r
# For Console:
atable_compact(
    atable::test_data,
    target_cols = c("Numeric", "Numeric2", "Split2", "Factor", "Ordered"),
    group_col = "Group2",
    blocks = list("Primary Endpoint" = "Numeric",
                  "Secondary Endpoints" = c("Numeric2", "Split2", "Factor")),
    add_margins = TRUE)
```

# The target_cols are "Numeric", "Numeric2", "Split2", "Factor", "Ordered".
# The group_col is "Group2".
# The data.frame is grouped by group_col and the summary statistics of the target_cols are
# calculated: mean, sd for numeric, counts and percentages for factors.
# Some target_cols are blocked: the first block 'Primary Endpoint' contains the variable Numeric.
# The second block 'Secondary Endpoints' contains the variables "Numeric2", "Split2", "Factor".
# The blocks are intended.
# For variable Split2 only the first level is reported, as the variable has only two levels and
# the name 'Split2' does not appear in the table.
# The variable Factor has more than two levels, so all of them are
# reported and appropriately intended.
# The variable Ordered is not part of a block and thus not intended.

# For Latex:
# Same as for Console, but with different indent_character:

```r
tab = atable_compact(atable::test_data,
    target_cols = c("Numeric", "Numeric2", "Logical", "Factor", "Ordered"),
    group_col = "Group2",
    indent_character = \quad"
)
```

# Then call e.g. Hmisc::latex(tab, ...)

# Example for Word format:
## Not run:
```
# The argument indent_character has the value intToUtf8(160) (non breakable space).
```
# This is the important part:
# Spaces at the beginning of a cell of a data.frame are somehow lost on the way to the docx.
# Other indent_characters may also do the job.

# doc = officer::read_docx()
# doc = officer::body_add_table(doc,tab)

# print(doc, target = "atable_Word.docx")

# Other packages may exist for Word-export.

## End(Not run)

---

atable_longitudinal  A longitudinal version of atable

**Description**

This is a wrapper for atable(), calculating the same statistics, but with different format.

**Usage**

atable_longitudinal(x, ...)

## S3 method for class 'data.frame'
atable_longitudinal(  
  x,  
  target_cols,  
  split_cols,  
  group_col = NULL,  
  format_numeric = atable_options("format_statistics_longitudinal.statistics_numeric"),  
  format_factor = atable_options("format_statistics_longitudinal.statistics_factor"),  
  ...  
)

**Arguments**

- **x**: object passed to atable. Currently x must be a data.frame.
- **...**: Passed to atable.
- **target_cols**: character. Exactly one of colnames(x).
- **split_cols**: character. Exactly one of colnames(x).
- **group_col**: character or NULL. If character then, one of colnames(x).
- **format_numeric**: a function that defines the format of numeric variables. Analog to format_factor.
- **format_factor**: a function that defines the format of factor variables. Default is defined in atable_options. See check_format_statistics for the return-value of this function.
Details

The intention is to report longitudinal data, i.e. data measured on the same objects on multiple times points.

This function allows only one target_col and only one split_col (the time point of the measurement). The longitudinal formatting is:

The names of the target_col and split_col do not show up in the table. The names should thus be written in the caption of the table.

Numeric target_cols get one line in the table; the format of the statistics is: mean (sd), N, missing.

Factor target_cols also get one line in the table, when it has only two levels and only the first level is displayed in the table and the name of the variable is omitted. This is intended for item like "Sex at birth: Female/Male". Knowing the percentage of Female is sufficient in this case (when NAs are not counted). The name of the target_cols and its first level should be stated in the caption of the table, otherwise the table is uninformative. The format of the statistics is: percent

Factors with three or more levels get one line per level and the name of the variable is omitted. The format of the statistics is: percent

Argument block must omitted, as there is only one target_col and nothing to block.

See examples.

Value

data.frame

Methods (by class)

• data.frame: a longitudinal version of atable.

Examples

# create data with a time-variable
x = atable::test_data
set.seed(42)
x = within(x, {time = sample(paste0("time_", 1:5), size=nrow(x), replace = TRUE)})
split_cols = "time"
group_col = "Group2"

# table for a factor with two levels
atable_longitudinal(x,
  target_cols = "Split2",
  group_col = group_col,
  split_cols = split_cols,
  add_margins = TRUE)

# table for a factor with three levels
atable_longitudinal(x,
  target_cols = "Split1",
  group_col = group_col,
  split_cols = split_cols,
  add_margins = TRUE)
atable_options

Set or get options

### Description

Set or get options for the atable-package via the settings package.

### Usage

atable_options(...)

### Arguments

...  

Option names to retrieve option values or [key]=[value] pairs to set options.

### Details

These options control some aspects of the atable package.

For restoring the default values see atable_options_reset.

### Supported options

The following options are supported:

- **addMargins**: A logical with length 1, TRUE of FALSE. This is the default-value of atable’s argument addMargins. See the help there.

- **colname_for_total**: A character with length 1. Default is 'Total'. This character will show up in the results of atable when addMargins is TRUE and group_col is not NULL.

- **replaceNA_by**: A character with length 1, or NULL. Default is 'missing'. Used in function replaceNA. This character will show up in the results of atable, so it can be modified.
• **colname_for_variable**: A character with length 1. Default is 'variable__\textunderscore\textunderscore\textunderscore'. Used in function `add_name_to_tests` and `add_name_to_statistics`. This character will not show up in the results and is only used internally for intermediate data.frames. There may be name clashes with user-supplied data.frames; so modification may be necessary.

• **colname_for_observations**: A character with length 1. Default is 'Observations'. Used in function `add_observation_column`. This character will show up in the results of `atable`, so it can be modified. There may be name clashes with user-supplied data.frames; so modification may be necessary.

• **colname_for_blocks**: A character with length 1. Default is 'block_name__\textunderscore\textunderscore\textunderscore'. Used in function `indent_data_frame_with_blocks`. This character will not show up in the results and is only used internally for intermediate data.frames. There may be name clashes with user-supplied data.frames; so modification may be necessary.

• **labels_TRUE_FALSE**: A character of length 2. Default is `c('yes', 'no')`. Currently used in function `statistics.logical` (see `statistics`) to cast logical to factor. TRUE is mapped to `labels_TRUE_FALSE[1]` and FALSE to `labels_TRUE_FALSE[2]`. This characters may show up in the results of `atable`, so it can be modified.

• **labels_Mean_SD**: A character length 1. Default is 'Mean (SD)'. Currently used in function `format_statistics` as a name for the mean and standard deviation of numeric variables. This character may show up in the results of `atable`, so it can be modified.

• **labels_valid_missing**: A character length 1. Default is 'valid (missing)'. Currently used in function `format_statistics` as a name for the number of valid and missing values of numeric variables. This character may show up in the results of `atable`, so it can be modified.

• **format_to**: A character length 1. Default is 'Latex'. Currently used in function `atable`.

• **colname_for_group**: A character of length 1. Default is 'Group'. This character will show up in the results of `atable`. This column will contain all values of `DD[split_cols]` and `DD[target_cols]`.

• **colname_for_value**: A character of length 1. Default is 'value'. This character shows up in the results of `atable` when `group_col` is NULL. The column will contain the results of the `statistics`.

• **colname_for_variable_compact**: A character of length 1. Default is `intToUtf8(160)`, a non-breaking space. This character will show up in the results of `atable_compact` as name of the first column.

• **statistics.numeric**: Either NULL or a function. Default is NULL. If a function, then it will replace `atable:::statistics.numeric` when `atable` is called. The function must mimic `statistics`: see the help there.

• **statistics.factor**: Analog to argument `statistics.numeric`.

• **statistics.ordered**: Analog to argument `statistics.numeric`.

• **two_sample_htest.numeric**: Either NULL or a function. Default is NULL. If a function, then it will replace `atable:::two_sample_htest.numeric` when `atable` is called. The function must mimic `two_sample_htest`: see the help there.

• **two_sample_htest.factor**: Analog to argument `two_sample_htest.numeric`

• **two_sample_htest.ordered**: Analog to argument `two_sample_htest.numeric`
• **multi_sample_hptest.numeric**: Either NULL or a function. Default is NULL. If a function, then it will replace `atable:::multi_sample_hptest.numeric` when `atable` is called. The function must mimic `multi_sample_hptest`; see the help there.

• **multi_sample_hptest.factor**: Analog to argument `multi_sample_hptest.numeric`

• **multi_sample_hptest.ordered**: Analog to argument `multi_sample_hptest.numeric`

• **format_statistics.statistics_numeric**: Either NULL or a function. Default is NULL. If a function, then it will replace `atable:::format_statistics.statistics_numeric`. The function must mimic `format_statistics`; see the help there.

• **format_statistics.statistics_factor**: Analog to argument `format_statistics.statistics_numeric`

• **format_tests.htest**: Either NULL or a function. Default is NULL. If a function, then it will replace `format_tests.htest`. The function must mimic `format_tests`; arguments are `x` and the ellipsis `...`. Result is a data.frame with 1 rows and unique colnames.

• **format_tests.htest_with_effect_size**: Analog to argument `format_tests.htest`

• **format_p_values**: A function with one argument returning a character with same length as the argument. This functions is called by `format_tests` to produce printable p-values.

• **format_percent**: A function with one argument returning a character with same length as the argument. This functions is called by `format_statistics` for factors to produce printable percentages.

• **format_numbers**: A function with one argument returning a character with same length as the argument. This functions is called by `format_statistics` and `format_tests` for number, that are not p-values or percentages.

• **digits**: 2. How many digits a number should have in the table. Used by `format_percent` and `format_percent` and passed to `format`

• **get_alias.default**: A function with one argument `x` and ... returning a character or NULL. This functions is called by `get_alias` and `create_alias_mapping` to retrieve alternative Variable names to print in the table.

• **get_alias.labelled**: A function with one argument `x` and ..., that must return a character. This functions is called by `get_alias` on the columns that have class labelled.

• **modify_colnames_without_alias**: A function with one argument `x` and ... returning a character. This functions is called by `create_alias_mapping` on the columns that have is.NULL(get_alias(x)). Replaces underscores by blanks and then calls `trimws`.

• **indent_character**: A Character with length 1. Passed to `indent_data_frame`. Every option of `format_to` has a corresponding `indent_character`. See the help of `atable` for these options.

• **indent_character_compact**: A Character with length 1. Passed to `atable_compact`. Value is " " for viewing in the console. Use \"quad\" for Latex and `intToUtf8(160)` for Word.

• **indent**: A logical with length 1. Passed to `atable`. Controls, if `indent_data_frame` is called.

• **format_statistics_compact.statistics_factor**: A function with the same Properties as `format_statistics`. Used as a default value for `atable_compact`

• **format_statistics_compact.statistics_numeric**: A function with the same Properties as `format_statistics`. Used as a default value for `atable_compact`

• **format_statistics_longitudinal.statistics_factor**: A function with the same Properties as `format_statistics`. Used as a default value for `atable_longitudinal`

• **format_statistics_longitudinal.statistics_numeric**: A function with the same Properties as `format_statistics`. Used as a default value for `atable_longitudinal`
atable_options_reset

Examples

atable_options() # show all options
atable_options('replace_NA_by' = 'no value') # set a new value
atable_options('replace_NA_by') # return the new value

atable_options_reset  Reset atable_options to default

Description

Does as the name implies. See also atable_options.

Usage

atable_options_reset()

Examples

atable_options('replace_NA_by') # show options
atable_options('replace_NA_by' = 'foo bar') # set a new value
atable_options('replace_NA_by') # show options
atable_options_reset() # restore all defaults
atable_options('replace_NA_by') # as before

atable_package  atable: Create Tables for Reporting Clinical Trials

Description

The packages provides functions for descriptive statistics and hypothesis tests, and arranging the results for printing.

Details

The main function is atable. See documentation there.
check_alias_mapping  Checks the output of function create_alias_mapping

Description
Checks the output of function create_alias_mapping.

Usage
check_alias_mapping(Alias_mapping)

Arguments
Alias_mapping  Result of function create_alias_mapping.

Value
TRUE if x has the following properties: Alias_mapping is a non-empty data.frame with character columns 'old' and 'new', without NA and ''. Column 'new' has no duplicates. Else throws an error. Prints the duplicates of column 'new', if available.

check_format_statistics  Checks the output of function format_statistics

Description
Checks the output of function format_statistics.

Usage
check_format_statistics(x)

Arguments
x  Result of function format_statistics.

Value
TRUE if x has the following properties: x is a non-empty data.frame with 2 columns called 'tag' and 'value'. Column 'tag' has class factor and no duplicates. Column 'value' is a character. Else throws an error.
check_format_tests

| check_format_tests | Checks the output of functions format_tests |

**Description**

Checks the output of function `format_tests`.

**Usage**

`check_format_tests(x)`

**Arguments**

- `x` Result of function `format_tests`.

**Value**

TRUE if `x` has the following properties: `x` is a data.frame with exactly one row and with unique colnames. Else throws an error.

check_statistics

| check_statistics | Checks the output of function statistics |

**Description**

Checks the output of function `statistics`.

**Usage**

`check_statistics(x)`

**Arguments**

- `x` Result of function `statistics`.

**Value**

TRUE if `x` has the following properties: `x` is a named list with length > 0. The names of the list must not have duplicates. The names may contain NA. Else an error.
check_tests

Checks the output of functions two_sample_h test and multi_sample_h test.

Description

Checks the output of function two_sample_h test and multi_sample_h test.

Usage

check_tests(x)

Arguments

x Result of function two_sample_h test or multi_sample_h test.

Value

TRUE if x has the following properties: x is a named list with length > 0. The names of the list must not have duplicates. The names may contain NA. Else an error.

Most hypothesis-test-functions in R like t.test or chisq.test return an object of class htest. This object passes this checks. Additional fields can be added to these objects and they will still pass this check.

create_alias_mapping

Get Aliases of column names

Description

Column names of data.frame in atable must have syntactically valid colnames, see is_syntactically_valid_name. So no blanks or special characters allowed. But Reporting in human readable language needs special characters. These functions here allow atable to handle arbitrary character for pretty printing.

Usage

create_alias_mapping(DD, ...)

Arguments

DD A data.frame

... Passed from and to other methods.
Details

We use attributes here, to assign alternative names to columns. Also class labelled created by Hmisc’s label is supported.

See create_alias_mapping for the function that does the actual work.

If no aliases are found, then underscores in the column names of DD will be replaced by blanks. See Examples in ?atable.

Value

create_alias_mapping returns a data.frame with two columns old and new and as many rows as DD has columns. Column old contains the original column names of DD and column new their aliases.

Value

create_alias_mapping returns a data.frame with two columns old and new and as many rows as DD has columns. Column old contains the original column names of DD and column new their aliases.

Description

The results of function statistics must be formated before printing. format_statistics does this.

Usage

format_statistics(x, ...)

## S3 method for class 'statistics_numeric'
format_statistics(x, format_statistics.statistics_numeric = NULL, ...)

## S3 method for class 'statistics_factor'
format_statistics(x, format_statistics.statistics_factor = NULL, ...)

## S3 method for class 'statistics_count_me'
format_statistics(x, ...)

## Default S3 method:
format_statistics(x, ...)

Arguments

x An object.

... Passed from and to other methods.

format_statistics.statistics_numeric

Either NULL or a function. Default is NULL. If a function, then it will replace atable:::format_statistics.statistics_numeric. The function must mimic format_statistics: arguments are x and the ellipsis ... . Result is a non-empty data.frame with 2 columns called 'tag' and 'value'.

format_statistics.statistics_factor

Analog to argument format_statistics.statistics_numeric
Details
This function defines which statistics are printed in the final table and how they are formated.
The format depends on the class \textit{x}. See section methods.
If you are not pleased with the current format you may alter these functions. But you must keep
the original output-format, see section Value. Function \texttt{check\_format\_statistics} checks if the
output of statistics is suitable for further processing.

Value
A non-empty data.frame with 2 columns called 'tag' and 'value'. Column 'tag' has class factor
and no duplicates. Column 'value' is a character. See also function \texttt{check\_format\_statistics}.

Methods (by class)
- \texttt{statistics\_numeric}: Defines how to format class \texttt{statistics\_numeric}. Returns a data.frame
  with 2 rows. Column 'tag' contains 'Mean\_SD' and 'valid\_missing'. Column 'value' contains two values:
  first value is the rounded mean and standard deviation, pasted together. The standard deviation is bracketed.
  Second value is the number of non-missing and missing values pasted together. The number of missing values is bracketed.
- \texttt{statistics\_factor}: Defines how to format class \texttt{statistics\_factor}. Returns a data.frame. Column 'tag' contains all names of \textit{x}. Column 'value' contains the percentages and the total number of values in brackets.
- \texttt{statistics\_count\_me}: Defines how to format class \texttt{statistics\_count\_me}. Returns a data.frame. Column 'tag' contains the empty character. The empty character is choosen because \texttt{colname\_for\_observations} already appears in the final table. Column 'value' contains the number of observations. See also 'colname\_for\_observations' in \texttt{atable\_options}.
- \texttt{default}: Returns a data.frame. Column 'tag' contains all names of \textit{x}. Column 'value' contains all elements of \textit{x}, rounded by \texttt{format}.

---

\texttt{format\_tests} \hspace{1cm} \textit{Formats hypothesis test results}

Description
The results of function \texttt{two\_sample\_htest} and \texttt{multi\_sample\_htest} must be formated before printing. \texttt{format\_tests} does this.

Usage
\texttt{format\_tests(x, ...)}

## S3 method for class 'htest'
\texttt{format\_tests(x, format\_tests\_htest = NULL, ...)}

## S3 method for class 'htest\_with\_effect\_size'
get_alias

format_tests(x, format_tests.htest_with_effect_size = NULL, ...)

## Default S3 method:
format_tests(x, ...)

Arguments

x                An object.
...
format_tests.htest
Either NULL or a function. Default is NULL. If a function, then it will replace
format_tests.htest. The function must mimic format_tests: arguments
are x and the ellipsis ... . Result is a data.frame with 1 rows and unique colnames.

format_tests.htest_with_effect_size
Analog to argument format_tests.htest

Details

This function defines which test results are printed in the final table and how they are formated.
The format depends on the class x. See section methods.

If you are not pleased with the current format you may alter these functions. But you must keep the
original output-format, see section Value. Function check_format_tests checks if the output of
format_tests is suitable for further processing.

Value

A non-empty data.frame with one row. See also function check_format_tests.

Methods (by class)

• htest: Defines how to format class htest. Returns a data.frame with 1 rows. Column p
contains the p-value of the x.
• htest_with_effect_size: Defines how to format class htest_with_effect_size. Returns
a data.frame with 1 rows. Column p contains the p-value of the x. Column stat contains the
teststatistic. Column Effect Size (CI) contains a effect size and its 95% Confidence interval.
• default: Tries to cast to data.frame with one row. Uses the names of the list as colnames.

get_alias

GetAliases of column names

Description

Retrieves attributes label and units of class labelled and attribute alias otherwise.
Usage

get_alias(x, ...)

## S3 method for class 'labelled'
get_alias(x, ...)

## Default S3 method:
get_alias(x, ...)

## S3 method for class 'data.frame'
get_alias(x, ...)

## S3 method for class 'list'
get_alias(x, ...)

Arguments

x An object. Aliases will be retrieved of x.

... Passed from and to other methods.

Details

We use attributes here, to assign alternative names to columns. Also class labelled created by Hmisc’s label is supported.

This is a workhorse function, see create_alias_mapping for the high level function

Value

For atomic vectors a character of NULL; for non-atomic vectors the results of get_alias applied to its elements.

Methods (by class)

- labelled: Retrieve attributes label and units, if available. Units are bracketed by '[ ]'. See also label and units. The user may alter this method via atable_options, see help there.
- default: Retrieve attribute alias via attr. This attribute may be an arbitrary character. If there is no attribute alias, then get_alias.default returns NULL.
- data.frame: Calls get_alias on every column.
- list: Calls get_alias on every element of the list.
indent_data_frame

Indents data.frames for printing them as tables.

Usage

indent_data_frame(
  DD,
  keys,
  values = setdiff(colnames(DD), keys),
  character_empty = "",
  numeric_empty = NA,
  indent_character = "\\quad",
  colname_indent = "Group"
)

Arguments

DD A data.frame. Should be sorted by keys with keys[1] varying slowest and keys[length(keys)] varying fastest.
keys A character. Subset of colnames(DD) with length(keys)\geq2. The combination of keys must be unique. DD[keys] must be class character or factor.
values A character. Subset of colnames(DD). DD[keys] must be class character, factor or numeric.
character_empty A character. Default ". This character will be put in the new lines in class character columns.
numeric_empty A numeric. Default NA. This character will be put in the new lines in class numeric columns.
indent_character A character. character for one indent. Default is \quad (meant for latex). Can also be ‘ ‘ for Word.
colname_indent A character. Default 'Group'. Name of the new column with the indented keys.

Details

Squeeze multiple key-columns into one column and indents the values accordingly. Adds new lines with the indented keys to the data.frame. Meant for wide tables that need to be narrower and more 'readable'. Meant for plotting with e.g. xtable::xtable or Hmisc::latex or officer::body_add_table. Look at the examples for a more precise description. Meant for left-aligned columns. That's why the indent_character is inserted to the left of the original values.
is_syntactically_valid_name

Value

A data.frame. Columns: c(colname_indent,values). Column colname_indent contains all combination of DD[keys], but now indented and squeezed in this column and casted to character. Columns 'values' contain all values of DD[values] unchanged. Number of rows is sum(cumprod(nlevels(DD[keys]))).

Examples

```r
DD <- expand.grid(Arm = paste0('Arm ', c(1,2,4)),
    Gender = c('Male', 'Female'),
    Haircolor = c('Red', 'Green', 'Blue'),
    Income = c('Low', 'Med', 'High'), stringsAsFactors = TRUE)
DD <- doBy::orderBy(~ Arm + Gender + Haircolor + Income, DD)
DD$values1 <- runif(dim(DD)[1])
DD$values2 <- 1
DD$values3 <- sample(letters[1:4], size = nrow(DD), replace = TRUE)

keys = c('Arm', 'Gender', 'Haircolor', 'Income')
values = c('values1', 'values2', 'values3')
## Not run:
DDD <- indent_data_frame(DD, keys, indent_character = '  ')

# print both:
Hmisc::latex(DD,
    file = '',
    longtable = TRUE,
    caption = 'Original table',
    rowname = NULL)

Hmisc::latex(DDD,
    file = '',
    longtable = TRUE,
    caption = 'Indented table',
    rowname = NULL)
## End(Not run)
```

is_syntactically_valid_name

Checks if valid name

Description

Checks for valid names by make.names, i.e. x is valid iff make.names does nothing with x.
multi_sample_htest

Usage

is_syntactically_valid_name(x)

Arguments

x  An object.

Value

A logical with length 1. TRUE when x is a character with length > 0 without duplicates and is valid. Else FALSE and a warning what’s wrong.

Examples

x <- c(asdf, NA,.na, '<y', 'asdf', 'asdf.1')
is_syntactically_valid_name(x)
is_syntactically_valid_name(x[FALSE]) # FALSE because empty
is_syntactically_valid_name(NA) # FALSE because not character
is_syntactically_valid_name(as.character(NA)) # FALSE because NA
is_syntactically_valid_name('NA') # FALSE. make.names changes 'NA' to 'NA.'
is_syntactically_valid_name(letters) # TRUE

multi_sample_htest  Calculates multi sample hypothesis tests

Description

Calculates multi sample hypothesis tests depending on the class of its input.

Usage

multi_sample_htest(value, group, ...)

## S3 method for class 'logical'
multi_sample_htest(value, group, ...)

## S3 method for class 'factor'
multi_sample_htest(value, group, multi_sample_htest.factor = NULL, ...)

## S3 method for class 'character'
multi_sample_htest(value, group, ...)

## S3 method for class 'ordered'
multi_sample_htest(value, group, multi_sample_htest.ordered = NULL, ...)

## S3 method for class 'numeric'
multi_sample_htest(value, group, multi_sample_htest.numeric = NULL, ...)
Arguments

value  An atomic vector.
group  A factor, same length as value.
...
Passed to methods.

multi_sample_htest.factor
  Analog to argument two_sample_htest.factor

multi_sample_htest.ordered
  Analog to argument two_sample_htest.ordered

multi_sample_htest.numeric
  Either NULL or a function. Default is NULL. If a function, then it will replace
  atable::multi_sample_htest.numeric. The function must mimic multi_sample_htest.numeric:
  arguments are value, group and the ellipsis ... . Result is a named list with
  length > 0 with unique names.

Details

Calculates multi sample hypothesis tests depending on the class of its input.
Results are passed to function format_tests for the final table.

If you are not pleased with the current hypothesis tests you may alter these functions. But you must
keep the original output-format, see section Value. Function check_tests checks if the output of
statistics is suitable for further processing.

The function multi_sample_htest is essentially a wrapper to standardize the arguments of various
hypothesis test functions.

Value

A named list with length > 0.

Most hypothesis-test-functions in R like t.test or chisq.test return an object of class 'htest'.
'htest'-objects are a suitable output for function two_sample_htest. Function check_tests
checks if the output is suitable for further processing.

Methods (by class)

- logical: Casts to factor and then calls method multi_sample_htest again.
- factor: Calls chisq.test.
- character: Casts value to factor and then calls method multi_sample_htest again.
- ordered: Calls kruskal.test.
- numeric: Calls multi_sample_htest's method on ordered(value).
replace_consecutive  

Replaces consecutive elements

Description

If \( x[i+1] = x[i] \) then \( x[i+1] \) is replaced by \( \text{by} \) for \( i = 1, \ldots, \text{length}(x)-1 \).

Usage

\[
\text{replace_consecutive}(x, \text{by} = \text{""}, \text{fun_for_identical} = \text{base::identical})
\]

Arguments

- **x**: A character or factor.
- **by**: A character with length 1.
- **fun_for_identical**: A function with two arguments called \( x \) and \( y \).

Details

The equality \( = \) is defined by function \text{identical} by default. This function can be changed by argument \text{fun_for_identical}.

Value

A character, same length as \( x \), now with consecutives replaced by \( \text{by} \). If \( \text{length}(x) < 2 \), \( x \) is returned unchanged.

Examples

\[
x <- \text{rep(c('a','b','c','d'), times=c(2,4,1,3))} 
\]

\[
x
\]

## Not run: replace_consecutive(x)

# NA should not be identical. So change fun_for_identical

fun_for_identical <- function(x,y) !is.na(x) && !is.na(y) && identical(x,y)

\[
x <- \text{c(1,1,3,3,NA,NA,4)}
\]

\[
x
\]

## Not run: replace_consecutive(x, by="99")

## Not run: replace_consecutive(x, by="99", fun_for_identical = fun_for_identical)
replace_NA  

**Description**

Replaces NA in characters, factors and data.frames.

**Usage**

```r
replace_NA(x, ...)
```

```r
## S3 method for class 'character'
replace_NA(x, replacement = atable_options("replace_NA_by"), ...)
```

```r
## S3 method for class 'factor'
replace_NA(x, ...)
```

```r
## S3 method for class 'ordered'
replace_NA(x, ...)
```

```r
## S3 method for class 'data.frame'
replace_NA(x, ...)
```

```r
## S3 method for class 'list'
replace_NA(x, ...)
```

```r
## Default S3 method:
replace_NA(x, ...)
```

**Arguments**

- `x`  
  An object.

- `...`  
  Passed to methods.

- `replacement`  
  A character of length 1. Default value is defined in atable_options('replace_NA_by'), see atable_options.

**Details**

The atable package aims to create readable tables. For non-computer-affine readers NA has no meaning. So replace_NA exists.

Methods for character, factor, ordered, list and data.frame available. Default method returns x unchanged.

Gives a warning when replacement is already present in x and does the replacement.

Silently returns x unchanged when there are no NA in x.

Silently returns x unchanged when replacement is not a character of length 1 or when replacement is NA.
Value
Same class as x, now with NA replaced by replacement.

Methods (by class)
- character: replaces NA with replacement.
- factor: applies replace_NA to the levels of the factor. A factor with length > 0 without levels will get the level replacement.
- ordered: as factor.
- data.frame: applies replace_NA to all columns.
- list: applies replace_NA to all elements of the list.
- default: return x unchanged.

Examples
Character <- c(NA, letters[1:3], NA)
Factor <- factor(Character)
Ordered <- ordered(Factor)
Numeric <- rep(1, length(Factor))
Factor_without_NA <- factor(letters[1:length(Factor)])

DD <- data.frame(Character, Factor, Ordered,
                   Numeric, Factor_without_NA,
                   stringsAsFactors = FALSE)

## Not run:
DD2 <- replace_NA(DD, replacement = 'no value')

summary(DD)
summary(DD2) # now with 'no value' instead NA in column Character, Factor and Ordered

atable_options(replace_NA_by = 'not measured') # use atable_options to set replacement
DD3 <- replace_NA(DD)
summary(DD3) # now with 'not measured' instead NA

atable_options_reset() # set 'replace_NA_by' back to default

## End(Not run)

standardized_test_data

A data.frame with standardized random data of various classes

Description
A data.frame intended for testing the atable function with standardized random data and missing values in various classes.
Usage

standardized_test_data

Format

A data frame with 1080 rows and 7 variables:

Split1  A factor with 2 levels without NA. The two levels have the same frequency (540).
Split2  A factor with 2 levels with NA. The two levels and the NA have the same frequency (360).
Group   A factor with 2 levels with NA. The two levels and the NA have the same frequency (360).
Logical A logical.
Factor  A factor with 3 levels.
Ordered Class ordered with 4 levels.
Numeric Class numeric.

Details

For every subset defined by a triplet of the levels of Split1, Split2 and Group the variables have the following properties:

- 60 observations
- Logical has exactly the same number of TRUE and FALSE and NA (20).
- Factor has exactly the same number of levels taken and NA (15).
- Ordered has exactly the same number of levels taken and NA (12).
- Numeric is sampled from a normal distribution and then standardized to sd 1 and with 6 NA. Its mean is 12 when Group is 'Treatment' and 10 otherwise (up to 10^-17).

Examples

atable::atable(Logical + Numeric + Factor + Ordered ~ Group | Split1 + Split2, atable::standardized_test_data, add_levels_for_NA = TRUE, format_to = 'Word')

---

statistics

Calculates descriptive statistics

Description

Calculates descriptive statistics depending on the class of its input.
**Usage**

```r
statistics(x, ...)
```

## S3 method for class 'numeric'
```r
statistics(x, statistics.numeric = NULL, ...)
```

## S3 method for class 'factor'
```r
statistics(x, statistics.factor = NULL, ...)
```

## S3 method for class 'logical'
```r
statistics(x, labels_TRUE_FALSE = atable_options("labels_TRUE_FALSE"), ...)
```

## S3 method for class 'character'
```r
statistics(x, ...)
```

## S3 method for class 'ordered'
```r
statistics(x, statistics.ordered = NULL, ...)
```

## S3 method for class 'count_me'
```r
statistics(x, ...)
```

**Arguments**

- **x**
  An object. Statistics will be calculated of `x`.

- **...**
  Passed from and to other methods.

- **statistics.numeric**
  Either `NULL` or a function. Default is `NULL`. If a function, then it will replace `atable:::statistics.numeric`. The function must mimic `statistics`: arguments are `x` and the ellipsis `...`. Result is a named list with `length > 0` with unique names.

- **statistics.factor**
  Analog to argument `statistics.numeric`

- **labels_TRUE_FALSE**
  For relabeling logics. See also `atable_options`.

- **statistics.ordered**
  Analog to argument `statistics.numeric`

**Details**

Calculates descriptive statistics depending on the class of its input. Results are passed to function `format_statistics`. If you are not pleased with the current descriptive statistics you may alter these functions. But you must keep the original output-format, see section Value. Function `check_statistics` checks if the output of statistics is suitable for further processing.
Value

The results of statistics are passed to function `format_statistics`. So the results of statistics must have a class for which the generic `format_statistics` has a method.

`format_statistics` has a default method, which accepts lists. So the results of statistics can be a named list with length > 0. The names of the list must have no duplicates.

Function `check_statistics` checks if the output of statistics is suitable for further processing.

Methods (by class)

- numeric: Descriptive statistics are: length, number of missing values, mean and standard deviation. Class of the result is 'statistics_numeric' and there is a method `format_statistics_to_latex(statistics_numeric)`. This function is meant for interval scaled variables.
- factor: Counts the numbers of occurrences of the levels of x with function `table`. This function is meant for nominal and ordinal scaled variables.
- logical: Casts x to factor, then applies statistics again. The labels for TRUE and FALSE can also be modified by setting `atable_options('labels_TRUE_FALSE')`.
- character: Casts x to factor, then applies statistics again.
- ordered: Casts x to factor, then applies statistics again.
- count_me: Returns the `length` of x. For class 'count_me' see `add_observation_column`.

---

test_data

Description

A data.frame with random data of various classes.

Usage

test_data

Format

A data frame with 129 rows and 11 variables:

- **Split1** A factor with 2 levels, drawn uniformly.
- **Split2** A factor with 3 levels, drawn uniformly.
- **Group** A factor with 2 levels, drawn uniformly.
- **Group2** A factor with 3 levels, drawn uniformly.
- **Numeric** A sample from the standard normal distribution.
- **Numeric2** A sample from the normal distribution with mean 4 and sd 3.
- **Logical** A Logical, drawn uniformly from TRUE, FALSE and NA.
Factor  A factor with 4 level drawn with weights 1:1:2:2.

Ordered  Class Ordered with 3 levels, drawn uniformly.

Character  Class character drawn uniformly from c('a', 'b', '').

Date  Class Date, generated by adding 2001-05-25 to a sample of the Poisson distribution with lambda 42.

6 Missing values were randomly added to each of Numeric, Numeric2, Factor, Ordered, Character and Date.

translate_to_LaTeX  A wrapper for latexTranslate

Description
Translate_to_LaTeX calls latexTranslate.

Usage

translate_to_LaTeX(x, ...)

## S3 method for class 'data.frame'
translate_to_LaTeX(x, ...)

## S3 method for class 'list'
translate_to_LaTeX(x, ...)

## S3 method for class 'character'
translate_to_LaTeX(
  x,
  inn = NULL,
  out = NULL,
  pb = FALSE,
  greek = FALSE,
  na = "",
  ...
)

## S3 method for class 'numeric'
translate_to_LaTeX(x, ...)

## S3 method for class 'factor'
translate_to_LaTeX(x, ...)

## S3 method for class 'logical'
translate_to_LaTeX(x, ...)
Arguments

x     An object.
in, out, pb, greek, na, ...
     As in latex.

Details

Result is suitable for print with latex.
Translate_to_LaTeX uses S3 object system. See section methods.

Value

Same length as x, now translated to latex.

Methods (by class)

• data.frame: Applies latexTranslate to rownames(x), colnames(x) and all columns of x.
• list: Translates all elements of x.
• character: As latexTranslate.
• numeric: Casts to character and then translates.
• factor: Translates the levels of the factor.
• logical: Casts to character and then translates.

two_sample_htest  Two sample hypothesis tests and effect size

Description

Calculates two sample hypothesis tests and effect size depending on the class of its input.

Usage

two_sample_htest(value, group, ...)

## S3 method for class 'character'
two_sample_htest(value, group, ...)

## S3 method for class 'factor'
two_sample_htest(value, group, two_sample_htest.factor = NULL, ...)

## S3 method for class 'logical'
two_sample_htest(value, group, ...)

## S3 method for class 'numeric'
two_sample_htest(value, group, two_sample_htest.numeric = NULL, ...)
## S3 method for class 'ordered'

two_sample_hitest(value, group, two_sample_hitest.ordered = NULL, ...)

### Arguments

- **value**: An atomic vector. These values will be tested.
- **group**: A factor with two levels and same length as `value`. Defines the two groups of `value`, that are compared by a two sample hypothesis tests.
- **...**: Passed to methods.

**two_sample_hitest.factor**
Analog to argument `two_sample_hitest.numeric`

**two_sample_hitest.numeric**
Either `NULL` or a function. Default is `NULL`. If a function, then it will replace `atable:::two_sample_hitest.numeric`. The function must mimic `two_sample_hitest.numeric`: arguments are `value`, `group` and the ellipsis `...`. Result is a named list with length > 0 with unique names.

**two_sample_hitest.ordered**
Analog to argument `two_sample_hitest.numeric`

### Details

Results are passed to function `format_tests` for the final table. So the results of `two_sample_hitest` must have a class for which the generic `format_tests` has a method.

If you are not pleased with the current hypothesis tests you may alter these functions. But you must keep the original output-format, see section Value.

Note that the various statistical test functions in R have heterogeneous arguments: for example `chisq.test` and `ks.test` do not have formula/data as arguments, whereas `wilcox.test` and `kruskal.test` do. So the function `two_sample_hitest` is essentially a wrapper to standardize the arguments of various hypothesis test functions.

As `two_sample_hitest` is only intended to be applied to unpaired two sample data, the two arguments `value` and `group` are sufficient to describe the data.

Note that e.g. for class numeric the p-value is calculated by `ks.test` and the effects size 95% CI by `cohen.d`. As these are two different functions the results may be contradicting: the p-value of `ks.test` can be smaller than 0.05 and the CI of `cohen.d` contains 0 at the same time.

### Value

A named list with length > 0, where all elements of the list are atomic and have the same length.

Most hypothesis-test-functions in R like `t.test` or `chisq.test` return an object of class `htest`. `htest`-objects are a suitable output for function `two_sample_hitest`. Function `check_tests` checks if the output is suitable for further processing.
Methods (by class)

- character: Casts value to factor and then calls method `two_sample_h test` again.
- factor: Calls `chisq.test` on value. Effect size is the odds ratio calculated by `fisher.test` (if value has two levels), or Cramer’s V by `CramerV`.
- logical: Casts value to factor and then calls `two_sample_h test` again.
- numeric: Calls `ks.test` on value. Effect size is Cohen’s d calculated by `cohen.d`.
- ordered: Calls `wilcox.test` on value. Effect size is Cliff’s delta calculated by `cliff.delta`.
