Package ‘automap’

October 12, 2022

Version 1.0-16
Date 2022-04-04
Title Automatic Interpolation Package
Author Paul Hiemstra <p.h.hiemstra@gmail.com>
Maintainer Jon Olav Skoien <jon.skoien@gmail.com>
Description Performs an automatic interpolation by automatically estimating the variogram and then calling gstat.
Depends R (>= 2.10.0), sp (>= 0.9-55)
Imports gstat, lattice, reshape, methods, ggplot2, maptools
License GPL
NeedsCompilation no
Repository CRAN
Date/Publication 2022-04-05 09:30:02 UTC

**autofitVariogram**  
*Automatically fitting a variogram*

**Description**

Automatically fitting a variogram to the data on which it is applied. The automatic fitting is done through `fit.variogram`. In `fit.variogram` the user had to supply an initial estimate for the sill, range etc. `autofitVariogram` provides this estimate based on the data and then calls `fit.variogram`.

**Usage**

```r
autofitVariogram(formula,  
input_data,  
model = c("Sph", "Exp", "Gau", "Ste"),  
kappa = c(0.05, seq(0.2, 2, 0.1), 5, 10),  
fix.values = c(NA,NA,NA),  
verbose = FALSE,  
GLS.model = NA,  
start_vals = c(NA,NA,NA),  
miscFitOptions = list(),  
...)  
```

**Arguments**

- **formula**  
  formula that defines the dependent variable as a linear model of independent variables; suppose the dependent variable has name 'z', for ordinary and simple kriging use the formula 'z~1'; for simple kriging also define 'beta' (see below); for universal kriging, suppose 'z' is linearly dependent on 'x' and 'y', use the formula 'z~x+y'.

- **input_data**  
  An object of `SpatialPointsDataFrame-class`.

- **model**  
  The list of variogram models that will be tested.

- **kappa**  
  Smoothing parameter of the Matern model. Provide a list if you want to check more than one value.

- **fix.values**  
  Can be used to fix a variogram parameter to a certain value. It consists of a list with a length of three. The items describe the fixed value for the nugget, range and sill respectively. They need to be given in that order. Setting the value to NA means that the value is not fixed.

- **verbose**  
  logical, if TRUE the function will give extra feedback on the fitting process

- **GLS.model**  
  If a variogram model is passed on through this parameter a Generalized Least Squares sample variogram is calculated.

- **start_vals**  
  Can be used to give the starting values for the variogram fitting. The items describe the fixed value for the nugget, range and sill respectively. They need to be given in that order. Setting the value to NA means that the value will be automatically chosen.
miscFitOptions A list with named arguments that provide additional control over the fitting process. For example: `list(merge.small.bins = TRUE)`. If the list is empty, `autofitVariogram` uses default values. The following parameters can be set:

- `merge.small.bins`: logical, when TRUE, the function checks if there are bins with less than 5 points. If so, the first two bins are merged and the check is repeated. This is done until all bins have more than `min.np.bin` points.
- `min.np.bin`: integer, the minimum number of points allowed in a bin before we start merging bins. See also `merge.small.bins`.

... parameters that are passed on to `variogram` when calculating the sample variogram.

Details

Geostatistical routines are used from package `gstat`.

A few simple choices are made when estimating the initial guess for `fit.variogram`. The initial sill is estimated as the mean of the max and the median of the semi-variance. The initial range is defined as 0.10 times the diagonal of the bounding box of the data. The initial nugget is defined as the min of the the semi-variance.

There are five different types of models that are often used:

- **Sph** A spherical model.
- **Exp** An exponential model.
- **Gau** A gaussian model.
- **Mat** A model of the Matern family
- **Ste** Matern, M. Stein’s parameterization

A list of all permitted variogram models is available by typing `vgm()` into the R console. `autofitVariogram` iterates over the variogram models listed in `model` and picks the model that has the smallest residual sum of squares with the sample variogram. For the Matern model, all the kappa values in `kappa` are tested.

Note that when using the power model, and not specifying starting values yourself, the sill is set to 1, the range to 1 and the nugget to 0. This is because the normal initial values for those parameters don’t work well with the power model. I consider this a temporary solution, any suggestions are appreciated.

It is possible to pass anisotropy parameters to `autofitVariogram`. However, `autofitVariogram` does not fit anisotropic variogram models. The function sees the anisotropic sample variogram as one big sample variogram. So it fits an average isotropic variogram model from the anisotropic sample variogram. A warning is issued when a users passes `alpha` to `autofitVariogram`.

Value

An object of type `autofitVariogram` is returned. This object contains the experimental variogram, the fitted variogram model and the sums of squares (`sserr`) between the sample variogram and the fitted variogram model.
Note

autofitVariogram is mostly used indirectly through the function autoKrige

Examples

data(meuse)
coordinates(meuse) =~ x+y
variogram = autofitVariogram(zinc~1,meuse)
plot(variogram)

# Residual variogram
data(meuse)
coordinates(meuse) =~ x+y
variogram = autofitVariogram(zinc ~ soil + ffreq + dist, meuse)
plot(variogram)

# Settings additional fitting options
variogram = autofitVariogram(zinc ~ soil + ffreq + dist, meuse,
   miscFitOptions = list(merge.small.bins = FALSE))
plot(variogram)

# Settings the minimum number of pairs per bin quite high
# to see the effect of merging bins
variogram = autofitVariogram(zinc ~ soil + ffreq + dist, meuse,
   miscFitOptions = list(min.np.bin = 500))
plot(variogram)

# ...and disable the merging, note the difference between the two plots
variogram = autofitVariogram(zinc ~ soil + ffreq + dist, meuse,
   miscFitOptions = list(min.np.bin = 500, merge.small.bins = FALSE))
plot(variogram)

## Not run:
# An example of autofitVariogram with anisotropic sample variogram.
# This is not supported, see details section.

vm.isotropic = autofitVariogram(log(zinc) ~ dist, meuse)
vm.anisotropic = autofitVariogram(log(zinc) ~ dist, meuse, alpha = c(0,45,90,135))

## End(Not run)
**autoKriging**

Performs an automatic interpolation

---

**Description**

This function performs automatic kriging on the given dataset. The variogram is generated automatically using `autofitVariogram`.

**Usage**

```r
autoKriging(formula, 
  input_data, 
  new_data, 
  data_variogram = input_data, 
  block = 0, 
  model = c("Sph", "Exp", "Gau", "Ste"), 
  kappa = c(0.05, seq(0.2, 2, 0.1), 5, 10), 
  fix.values = c(NA,NA,NA), 
  remove_duplicates = TRUE, 
  verbose = FALSE, 
  GLS.model = NA, 
  start_vals = c(NA,NA,NA), 
  miscFitOptions = list(), 
  ...) 
```

**Arguments**

- **formula**: formula that defines the dependent variable as a linear model of independent variables; suppose the dependent variable has name 'z', for ordinary and simple kriging use the formula 'z~1'; for simple kriging also define 'beta' (see below); for universal kriging, suppose 'z' is linearly dependent on 'x' and 'y', use the formula 'z~x+y'.
- **input_data**: An object of the `SpatialPointsDataFrame`-class containing the data to be interpolated.
- **new_data**: A `sp` object containing the prediction locations. `new_data` can be a points set, a grid or a polygon. Must not contain NA's. If this object is not provided a default is calculated. This is done by taking the convex hull of `input_data` and placing around 5000 gridcells in that convex hull.
- **data_variogram**: An optional way to provide a different dataset for the building of the variogram then for the spatial interpolation.
- **block**: Use this parameter to pass on a specification for the block size. e.g. `c(1000,1000)`
- **model**: List of models that will be tested during automatic variogram fitting.
- **kappa**: List of values for the smoothing parameter of the Matern model that will be tested during automatic variogram fitting.
autoKrige

fix.values Can be used to fix a variogram parameter to a certain value. It consists of a list with a length of three. The items describe the fixed value for the nugget, range and sill respectively. Setting the value to NA means that the value is not fixed. Is passed on to autofitVariogram.

remove_duplicates

logical, remove duplicate points from the input_data. This can take some time on large datasets.

verbose

logical, if TRUE autoKrige will give extra information on the fitting process

GLS.model

If a variogram model is passed on through this parameter a Generalized Least Squares sample variogram is calculated.

start_vals

Can be used to give the starting values for the variogram fitting. The items describe the fixed value for the nugget, range and sill respectively. They need to be given in that order. Setting the value to NA means that the value will be automatically chosen.

miscFitOptions

Additional options to set the behavior of autofitVariogram. For details see the documentation of autofitVariogram. For details see the documentation of autofitVariogram.

... arguments that are passed on to the gstat function krige.

Details

call the function autofitVariogram that fits a variogram model to the given dataset. This variogram model and the data are used to make predictions on the locations in new_data. The only compulsory argument is input_data. So the most simple call would of the form:

autoKrige(meuse)

autoKrige now assumes that you want to perform ordinary kriging on the first column of input_data.

autoKrige performs some checks on the coordinate systems of input_data and new_data. If one of both is NA, it is assigned the projection of the other. If they have different projections, an error is raised. If one of both has a non-projected system (i.e. latitude-longitude), an error is raised. This error is raised because ’gstat does use spherical distances when data are in geographical coordinates, however the usual variogram models are typically not non-negative definite on the sphere, and no appropriate models are available’ (Edzer Pebesma on r-sig-geo).

When the user specifies the power model (Pow) as the model, the initial range is set to one. Note that when using the power model, the initial range is the initial power.

Value

This function returns an autoKrige object containing the results of the interpolation (prediction, variance and standard deviation), the sample variogram, the variogram model that was fitted by autofitVariogram and the sums of squares between the sample variogram and the fitted variogram model. The attribute names are krige_output, exp_var, var_model and sserr respectively.

# Dealing with duplicate observations
data(meuse)
meuse.dup = rbind(meuse, meuse[1,]) # Create duplicate
coordinates(meuse.dup) =~ x+y
kr = autoKrige(zinc~dist, meuse.dup, meuse.grid)

# Extracting parts from the autoKrige object
prediction_spdf = kr$krige_output
sample_variogram = kr$exp_var
variogram_model = kr$var_model

## End(Not run)
Description

Uses `autofitVariogram` to fit a variogram model to the data and then calls `krige.cv` to perform cross-validation.

Usage

```r
autoKrive.cv(formula, input_data, data_variogram = input_data, model = c("Sph", "Exp", "Gau", "Ste"), kappa = c(0.05, seq(0.2, 2, 0.1), 5, 10), fix.values = c(NA,NA,NA), verbose = c(FALSE,TRUE), GLS.model = NA, start_vals = c(NA,NA,NA), miscFitOptions = list(), ...)
```

Arguments

- **formula**: formula that defines the dependent variable as a linear model of independent variables; suppose the dependent variable has name ‘z’, for ordinary and simple kriging use the formula ‘z~1’; for simple kriging also define ‘beta’ (see below); for universal kriging, suppose ‘z’ is linearly dependent on ‘x’ and ‘y’, use the formula ‘z~x+y’.
- **input_data**: An object of the `SpatialPointsDataFrame-class` containing the data to be interpolated.
- **data_variogram**: An optional way to provide a different dataset for the building of the variogram.
- **model**: List of models that will be tested during automatic variogram fitting.
- **kappa**: List of values for the smoothing parameter of the Matern model that will be tested during automatic variogram fitting.
- **fix.values**: Can be used to fix a variogram parameter to a certain value. It consists of a list with a length of three. The items describe the fixed value for the nugget, range and sill respectively. Setting the value to NA means that the value is not fixed. Is passed on to autofitVariogram.
- **verbose**: vector of 2 logicals. The first element sets the verbosity of autofitVariogram, see its documentation for more information. The second element sets the verbosity level of krige.cv, see its documentation for more information.
- **GLS.model**: If a variogram model is passed on through this parameter a Generalized Least Squares sample variogram is calculated.
- **start_vals**: Can be used to give the starting values for the variogram fitting. The items describe the fixed value for the nugget, range and sill respectively. They need to be given in that order. Setting the value to NA means that the value will be automatically chosen.
- **miscFitOptions**: Additional options to set the behavior of autofitVariogram. For details see the documentation of autofitVariogram.
- **...**: arguments passed to `krige.cv`
Value

autoKrige.cv returns an object of class autoKrige.cv. This is a list containing one object of class SpatialPointsDataFrame with the results of the cross-validation, see krig.cv for more details. The attribute name is krig.cv_output.

Examples

data(meuse)
coordinates(meuse) = ~x+y
data(meuse.grid)
gridded(meuse.grid) = ~x+y

kr.cv = autoKrige.cv(log(zinc)-1, meuse, model = c("Exp"), nfold = 10)
kr_dist.cv = autoKrige.cv(log(zinc)-sqrt(dist), meuse, model = c("Exp"), nfold = 10)
kr_dist_ffreq.cv = autoKrige.cv(log(zinc)-sqrt(dist)+ffreq, meuse, model = c("Exp"), nfold = 10)

Description

This function wraps around spplot and creates a blue-to-whitish colorscale instead of the standard bpy colorscale.

Usage

automapPlot(plot_data, zcol, col.regions, ...)

Arguments

plot_data A spatial object that is to be plotted
zcol The name of the column from plot_data you want to use. Can also be a list.
col.regions Choose a colors that specify the fill colours.
... arguments that are passed on to spplot. A sp.layout object for example.
Details

A good function to calculate the position of the colorbreaks the `classIntervals` function from the `classInt` package.

Author(s)

Paul Hiemstra, <paul@numbertheory.nl>

See Also

`spplot`, `plot.autoKrige`, `plot.posPredictionInterval`

Examples

```r
# Ordinary kriging
data(meuse)
coordinates(meuse) <- x+y
data(meuse.grid)
gridded(meuse.grid) <- x+y

kriging_result = autoKrige(zinc~1, meuse, meuse.grid)

# Adding the sp.layout parameter shows the locations of the measurements
automapPlot(kriging_result$krige_output, "var1.pred",
          sp.layout = list("sp.points", meuse))
```
**Arguments**

...  
  autoKrige.cv objects that are compared to each other. Also accepts the output form krig.cv, these objects are transformed to autoKrige.cv objects.

col.names  
  Names for the different objects in ... This defaults to the names of the objects in ....

bubbleplots  
  logical, if TRUE then bubble plots of the objects in ... are drawn using the same value for the color breaks.

zcol  
  Which column in the objects in ... is going to be drawn in the bubbleplots. Options are: var1.pred, var1.var, observed, residual and zscore.

layout  
  Layout of the bubbleplot, e.g. c(2,2). The argument gives the number of rows and columns in which the set of bubbleplots is to be drawn. Useful defaults are selected.

key.entries  
  A list of numbers telling what the key entries in the bubbleplots are. See bubble for more details.

reference  
  An integer telling which of the objects should be taken as a reference if plot.diff equals TRUE. reference equal to 1 means that the first object is the reference, reference equal to 2 means that the second object is the reference etc.

plot.diff  
  logical, if plot.diff is TRUE the number specified in reference defines the CV object that is taken as a reference What is shown in the plot is reference data squared minus the other data squared. So the color red means that the CV is doing worse than the reference, vice-versa for green. This is very useful to see where the differences between the results are spatially and if there is a pattern.

digits  
  The number of significant digits in the resulting data.frame.

ggplot  
  logical, determines if spplot or ggplot2 is used to make the spatial plot of the cross-validation residuals. Note that the plot.diff and reference arguments are obsolete when ggplot equals TRUE.

addPoly  
  if this object contains a SpatialPolygons* object, it is added to the plot as layout. Note that this only works when ggplot equals TRUE.

**Value**

A data.frame with for each cross-validation result a number of diagnostics:

mean_error  
  The mean of the cross-validation residual. Ideally small.

me_mean  
  mean error divided by the mean of the observed values, measure for how large the mean_error is in contrast to the mean of the dataset

MSE  
  Mean Squared error.

MSNE  
  Mean Squared Normalized Error, mean of the squared z-scores. Ideally small.

cor_obspred  
  Correlation between the observed and predicted values. Ideally 1.

cor_predres  
  Correlation between the predicted and the residual values. Ideally 0.

RMSE  
  Root Mean Squared Error of the residual. Ideally small.

RMSE_sd  
  RMSE divided by the standard deviation of the observed values. Provides a measure variation of the residuals vs the variation of the observed values.

URMSE  
  Unbiased Root Mean Squared Error of the residual. Ideally small.

iqr  
  Interquartile Range of the residuals. Ideally small.

Examples

# Load the data
data(meuse)
coordinates(meuse) = ~x+y
data(meuse.grid)
gridded(meuse.grid) = ~x+y

# Perform cross-validation
kr.cv = autoKrige.cv(log(zinc)-1, meuse, model = c("Exp"), nfold = 10)
kr_dist.cv = autoKrige.cv(log(zinc)-sqrt(dist), meuse,
model = c("Exp"), nfold = 10)
kr_dist_ffreq.cv = autoKrige.cv(log(zinc)-sqrt(dist)+ffreq,
meuse, model = c("Exp"), nfold = 10)

# Compare the results
compare.cv(kr.cv, kr_dist.cv, kr_dist_ffreq.cv)
compare.cv(kr.cv, kr_dist.cv, kr_dist_ffreq.cv,
bubbleplots = TRUE)
compare.cv(kr.cv, kr_dist.cv, kr_dist_ffreq.cv,
bubbleplots = TRUE, col.names = c("OK","UK1","UK2"))
compare.cv(kr.cv, kr_dist.cv, kr_dist_ffreq.cv,
bubbleplots = TRUE, col.names = c("OK","UK1","UK2"),
plot.diff = TRUE)

# I recently added a new bubble plot that uses ggplot
# I find it preferable, note that it requires ggplot2.
## Not run:
compare.cv(kr.cv, kr_dist.cv, kr_dist_ffreq.cv,
bubbleplots = TRUE, col.names = c("OK","UK1","UK2"),
ggplot = TRUE)
## End(Not run)
### Usage

```r
## S3 method for class 'autoKrige'
plot(x, sp.layout = NULL, ...)
## S3 method for class 'posPredictionInterval'
plot(x, sp.layout = NULL, justPosition = TRUE, main = "Position prediction interval", ...)
```

### Arguments

- **x**
  - the object to plot (of class autoKrige or posPredictionInterval)
- **sp.layout**
  - An object that can contain lines, points and polygons that function as extra layout.
- **justPosition**
  - logical, if FALSE: not only the plot with the position of the prediction interval is plotted, but also plots with the upper and lower limits of the prediction interval.
- **main**
  - Title of the plot for the position of the prediction interval.
- **...**
  - arguments passed to lattice functions xyplot and spplot

### Details

For a detailed description of how sp.layout is constructed see spplot.

### Author(s)

### Examples

```r
# Ordinary kriging
data(meuse)
coordinates(meuse) <- x+y
data(meuse.grid)
gridded(meuse.grid) <- x+y

kriging_result = autoKrige(log(zinc)-1, meuse, meuse.grid)
# Adding the sp.layout parameter shows the locations of the measurements
plot(kriging_result, sp.layout = list(pts = list("sp.points", meuse)))
```
posPredictionInterval

Determines the position of the p\% prediction interval

Description
This function calculates the p\% prediction interval and determines the position of this interval relative to value. This can be higher, lower or not distinguishable.

Usage
posPredictionInterval(krige_object, 
  p = 95, 
  value = median(krige_object$krige_output$var1.pred))

Arguments
krige_object  The result of from the autoKrige procedure. This is expected to be a autoKrige-object.
p  The p\% percent prediction interval is compared to value
value  The value to which the the p\% prediction interval compared

Value
The output object is of class posPredictionInterval and contains the results of the function in an Spatial-class object similar to the one in the input object. This means that if the input object contains a grid, the results are also returned on that same grid. Also included in the return object are the values for p and value.
