Package ‘bayesdfa’

February 26, 2024

Type Package

Title Bayesian Dynamic Factor Analysis (DFA) with 'Stan'

Version 1.3.3

Description Implements Bayesian dynamic factor analysis with 'Stan'. Dynamic factor analysis is a dimension reduction tool for multivariate time series. 'bayesdfa' extends conventional dynamic factor models in several ways. First, extreme events may be estimated in the latent trend by modeling process error with a student-t distribution. Second, alternative constraints (including proportions are allowed). Third, the estimated dynamic factors can be analyzed with hidden Markov models to evaluate support for latent regimes.

**dfa_cv**

Apply cross validation to DFA model

**Description**

Apply cross validation to DFA model

**Usage**

dfa_cv(
  stanfit,
  cv_method = c("loocv", "lfocv"),
  fold_ids = NULL,
  n_folds = 10,
  estimation = c("sampling", "optimizing", "vb"),
  iter = 2000,
  chains = 4,
  thin = 1,
  ...
)

**Arguments**

- **stanfit** A stanfit object, to preserve the model structure from a call to fit_dfa()
- **cv_method** The method used for cross validation. The options are 'loocv', where time is ignored and each data point is assigned randomly to a fold. The method 'lfocv' is leave time out cross validation, and time slices are iteratively held out out. Finally the method 'lfocv' implements leave future out cross validation to do one-step ahead predictions.
- **fold_ids** A vector whose length is the same as the number of total data points. Elements are the fold id of each data point. If not all data points are used (e.g. the lfocv or lfocv approach might only use 10 time steps) the value can be something other than a number, e.g. NA.
- **n_folds** Number of folds, defaults to 10
- **estimation** Character string. Should the model be sampled using rstan::sampling() ("sampling", default), rstan::optimizing() ("optimizing"), variational inference rstan::vb() ("vb").
- **iter** Number of iterations in Stan sampling, defaults to 2000.
- **chains** Number of chains in Stan sampling, defaults to 4.
- **thin** Thinning rate in Stan sampling, defaults to 1.
- **...** Any other arguments to pass to rstan::sampling().
### Examples

```
## Not run:
set.seed(42)
s <- sim_dfa(num_trends = 1, num_years = 20, num_ts = 3)
obs <- c(s$y_sim[1, ], s$y_sim[2, ], s$y_sim[3, ])
long <- data.frame("obs" = obs, "ts" = sort(rep(1:3, 20)),
                  "time" = rep(1:20, 3))
m <- fit_dfa(y = long, data_shape = "long", estimation="none")
# random folds
fit_cv <- dfa_cv(m, cv_method = "loocv", n_folds = 5, iter = 50,
                  chains = 1, estimation="sampling")

# folds can also be passed in
fold_ids <- sample(1:5, size = nrow(long), replace = TRUE)
m <- fit_dfa(y = long, data_shape = "long", estimation="none")
fit_cv <- dfa_cv(m, cv_method = "loocv", n_folds = 5, iter = 50, chains = 1,
                  fold_ids = fold_ids, estimation="sampling")

# do an example of leave-time-out cross validation where years are dropped
fold_ids <- long$time
m <- fit_dfa(y = long, data_shape = "long", estimation="none")
fit_cv <- dfa_cv(m, cv_method = "loocv", iter = 100, chains = 1,
                  fold_ids = fold_ids)

# example with covariates and long format data
obs_covar <- expand.grid("time" = 1:20, "timeseries" = 1:3,
                        "covariate" = 1:2)
obs_covar$value <- rnorm(nrow(obs_covar), 0, 0.1)
s <- sim_dfa(num_trends = 1, num_years = 20, num_ts = 3)
sfit <- fit_dfa(y = long, obs_covar = obs_covar,
                data_shape = "long", estimation="none")
fit_cv <- dfa_cv(m, cv_method = "loocv", n_folds = 5,
                 iter = 50, chains = 1, estimation="sampling")
```

## End(Not run)

**dfa_fitted**  
*Get the fitted values from a DFA as a data frame*

### Description

Get the fitted values from a DFA as a data frame

### Usage

`dfa_fitted(modelfit, conf_level = 0.95, names = NULL)`
Arguments

modelfit  Output from fit_dfa.
conf_level  Probability level for CI.
names  Optional vector of names for time series labels. Should be same length as the number of time series.

Value

A data frame with the following columns: ID is an identifier for each time series, time is the time step, y is the observed values standardized to mean 0 and unit variance, estimate is the mean fitted value, lower is the lower CI, and upper is the upper CI.

See Also

predicted plot_fitted fit_dfa

Examples

```r
y <- sim_dfa(num_trends = 2, num_years = 20, num_ts = 4)
m <- fit_dfa(y = y$y_sim, num_trends = 2, iter = 50, chains = 1)
fitted <- dfa_fitted(m)
```

---

dfa_loadings  

Get the loadings from a DFA as a data frame

Description

Get the loadings from a DFA as a data frame

Usage

dfa_loadings(rotated_modelfit, names = NULL, summary = TRUE, conf_level = 0.95)

Arguments

  rotated_modelfit  Output from rotate_trends.
  names  An optional vector of names for plotting the loadings.
  summary  Logical. Should the full posterior densities be returned? Defaults to TRUE.
  conf_level  Confidence level for credible intervals. Defaults to 0.95.
Get the trends from a DFA as a data frame

**Value**

A data frame with the following columns: name is an identifier for each loading, trend is the trend for the loading, median is the posterior median loading, lower is the lower CI, upper is the upper CI, and prob_diff0 is the probability the loading is different than 0. When summary = FALSE, there is no lower or upper columns and instead there are columns chain and draw.

**See Also**

plot_loadings fit_dfa rotate_trends

**Examples**

```r
set.seed(42)
s <- sim_dfa(num_trends = 2, num_ts = 4, num_years = 10)
# only 1 chain and 180 iterations used so example runs quickly:
m <- fit_dfa(y = s$y_sim, num_trends = 2, iter = 50, chains = 1)
r <- rotate_trends(m)
loadings <- dfa_loadings(r, summary = TRUE)
loadings <- dfa_loadings(r, summary = FALSE)
```

---

**Description**

Get the trends from a DFA as a data frame

**Usage**

dfa_trends(rotated_modelfit, years = NULL)

**Arguments**

rotated_modelfit  
Output from `rotate_trends`.

years  
Optional numeric vector of years.

**Value**

A data frame with the following columns: time is the time step, trend_number is an identifier for each trend, estimate is the trend mean, lower is the lower CI, and upper is the upper CI.

**See Also**

plot_trends fit_dfa rotate_trends
Examples

```r
set.seed(1)
s <- sim_dfa(num_trends = 1)
m <- fit_dfa(y = s$y_sim, num_trends = 1, iter = 50, chains = 1)
r <- rotate_trends(m)
trends <- dfa_trends(r)
```

find_dfa_trends  
Find the best number of trends according to LOOIC

Description

Fit a DFA with different number of trends and return the leave one out (LOO) value as calculated by the loo package.

Usage

```r
find_dfa_trends(
  y = y,
  kmin = 1,
  kmax = 5,
  iter = 2000,
  thin = 1,
  compare_normal = FALSE,
  convergence_threshold = 1.05,
  variance = c("equal", "unequal"),
  ...
)
```

Arguments

- **y**: A matrix of data to fit. Columns represent time element.
- **kmin**: Minimum number of trends, defaults to 1.
- **kmax**: Maximum number of trends, defaults to 5.
- **iter**: Iterations when sampling from each Stan model, defaults to 2000.
- **thin**: Thinning rate when sampling from each Stan model, defaults to 1.
- **compare_normal**: If TRUE, does model selection comparison of Normal vs. Student-t errors
- **convergence_threshold**: The maximum allowed value of Rhat to determine convergence of parameters
- **variance**: Vector of variance arguments for searching over large groups of models. Can be either or both of ("equal", "unequal")
- **...**: Other arguments to pass to fit_dfa()
Examples

```r
set.seed(42)
s <- sim_dfa(num_trends = 2, num_years = 20, num_ts = 3)
# only 1 chain and 180 iterations used so example runs quickly:
m <- find_dfa_trends(
y = s$y_sim, iter = 50,
kmin = 1, kmax = 2, chains = 1, compare_normal = FALSE,
variance = "equal", convergence_threshold = 1.1,
control = list(adapt_delta = 0.95, max_treedepth = 20)
)
m$summary
m$best_model
```

---

**find_inverted_chains**  
*Find which chains to invert*

**Description**

Find which chains to invert by checking the sum of the squared deviations between the first chain and each other chain.

**Usage**

```r
find_inverted_chains(model, trend = 1, plot = FALSE)
```

**Arguments**

- `model`: A Stan model, `rstanfit` object
- `trend`: Which trend to check
- `plot`: Logical: should a plot of the trend for each chain be made? Defaults to FALSE

**See Also**

- `invert_chains`

**Examples**

```r
set.seed(2)
s <- sim_dfa(num_trends = 2)
set.seed(1)
m <- fit_dfa(y = s$y_sim, num_trends = 1, iter = 30, chains = 2)
# chains were already inverted, but we can redo that, as an example, with:
find_inverted_chains(m$model, plot = TRUE)
```
## find_regimes

**Fit multiple models with differing numbers of regimes to trend data**

### Description

Fit multiple models with differing numbers of regimes to trend data

### Usage

```r
find_regimes(
  y, 
  sds = NULL, 
  min_regimes = 1, 
  max_regimes = 3, 
  iter = 2000, 
  thin = 1, 
  chains = 1, 
  ... 
)
```

### Arguments

- **y**: Data, time series or trend from fitted DFA model.
- **sds**: Optional time series of standard deviations of estimates. If passed in, residual variance not estimated.
- **min_regimes**: Smallest of regimes to evaluate, defaults to 1.
- **max_regimes**: Biggest of regimes to evaluate, defaults to 3.
- **iter**: MCMC iterations, defaults to 2000.
- **thin**: MCMC thinning rate, defaults to 1.
- **chains**: MCMC chains; defaults to 1 (note that running multiple chains may result in a "label switching" problem where the regimes are identified with different IDs across chains).
- **...**: Other parameters to pass to `rstan::sampling()`.

### Examples

```r
data(Nile)
find_regimes(log(Nile), iter = 50, chains = 1, max_regimes = 2)
```
**find_swans**

**Find outlying "black swan" jumps in trends**

**Description**

Find outlying "black swan" jumps in trends

**Usage**

```
find_swans(rotated_modelfit, threshold = 0.01, plot = FALSE)
```

**Arguments**

- `rotated_modelfit` 
  - Output from `rotate_trends()`.
- `threshold` 
  - A probability threshold below which to flag trend events as extreme
- `plot` 
  - Logical: should a plot be made?

**Value**

Prints a ggplot2 plot if `plot = TRUE`; returns a data frame indicating the probability that any given point in time represents a "black swan" event invisibly.

**References**

**Examples**

```r
set.seed(1)
s <- sim_dfa(num_trends = 1, num_ts = 3, num_years = 30)
s$y_sim[1, 15] <- s$y_sim[1, 15] - 6
plot(s$y_sim[1, ], type = "o")
abline(v = 15, col = "red")
# only 1 chain and 250 iterations used so example runs quickly:
m <- fit_dfa(y = s$y_sim, num_trends = 1, iter = 50, chains = 1, nu_fixed = 2)
r <- rotate_trends(m)
p <- plot_trends(r) #+ geom_vline(xintercept = 15, colour = "red")
print(p)
# a 1 in 1000 probability if was from a normal distribution:
find_swans(r, plot = TRUE, threshold = 0.001)
```
fit_dfa

Fit a Bayesian DFA

Description

Fit a Bayesian DFA

Usage

fit_dfa(
  y = y,
  num_trends = 1,
  varIndx = NULL,
  scale = c("zscore", "center", "none"),
  iter = 2000,
  chains = 4,
  thin = 1,
  control = list(adapt_delta = 0.99, max_treedepth = 20),
  nu_fixed = 101,
  est_correlation = FALSE,
  estimate_nu = FALSE,
  estimate_trend_ar = FALSE,
  estimate_trend_ma = FALSE,
  estimate_process_sigma = FALSE,
  equal_process_sigma = TRUE,
  estimation = c("sampling", "optimizing", "vb", "none"),
  data_shape = c("wide", "long"),
  obs_covar = NULL,
  pro_covar = NULL,
  offset = NULL,
  z_bound = NULL,
  z_model = c("dfa", "proportion"),
  trend_model = c("rw", "bs", "ps", "gp"),
  n_knots = NULL,
  knot_locs = NULL,
  par_list = NULL,
  family = "gaussian",
  verbose = FALSE,
  inv_var_weights = NULL,
  likelihood_weights = NULL,
  gp_theta_prior = c(3, 1),
  expansion_prior = FALSE,
  ...
)
Arguments

y
A matrix of data to fit. See data_shape option to specify whether this is long or wide format data. Wide format data (default) is a matrix with time across columns and unique time series across rows, and can only contain 1 observation per time series - time combination. In contrast, long format data is a data frame that includes observations ("obs"), time ("time") and time series ("ts") identifiers – the benefit of long format is that multiple observations per time series can be included. Correlation matrix currently not estimated if data shape is long.

num_trends
Number of trends to fit.

varIndx
Indices indicating which timeseries should have shared variances.

scale
Character string, used to standardized data. Can be "zscore" to center and standardize data, "center" to just standardize data, or "none". Defaults to "zscore".

iter
Number of iterations in Stan sampling, defaults to 2000. Used for both rstan::sampling() and rstan::vb()

counts
Number of chains in Stan sampling, defaults to 4.

thin
Thinning rate in Stan sampling, defaults to 1.

control
A list of options to pass to Stan sampling. Defaults to list(adapt_delta = 0.99, max_treedepth = 20).

nu_fixed
Student t degrees of freedom parameter. If specified as greater than 100, a normal random walk is used instead of a random walk with a t-distribution. Defaults to 101.

est_correlation
Boolean, whether to estimate correlation of observation error matrix R. Defaults to FALSE. Currently can’t be estimated if data are in long format.

estimate_nu
Logical. Estimate the student t degrees of freedom parameter? Defaults to FALSE.

estimate_trend_ar
Logical. Estimate AR(1) parameters on DFA trends? Defaults to ‘FALSE”, in which case AR(1) parameters are set to 1

estimate_trend_ma
Logical. Estimate MA(1) parameters on DFA trends? Defaults to ‘FALSE“, in which case MA(1) parameters are set to 0.

estimate_process_sigma
Logical. Defaults FALSE, whether or not to estimate process error sigma. If not estimated, sigma is fixed at 1, like conventional DFAs.

equal_process_sigma
Logical. If process sigma is estimated, whether or not to estimate a single shared value across trends (default) or estimate equal values for each trend

estimation
Character string. Should the model be sampled using rstan::sampling() ("sampling", default), rstan::optimizing() ("optimizing"), variational inference rstan::vb() ("vb"), or no estimation done ("none"). No estimation may be useful for debugging and simulation.
data_shape
If `wide` (the current default) then the input data should have rows representing the various timeseries and columns representing the values through time. This matches the MARSS input data format. If `long` then the long format data is a data frame that includes observations ("obs"), time ("time") and time series ("ts") identifiers – the benefit of long format is that multiple observations per time series can be included.

obs_covar
Optional dataframe of data with 4 named columns ("time", "timeseries", "covariate", "value"), representing: (1) time, (2) the time series affected, (3) the covariate number for models with more than one covariate affecting each trend, and (4) the value of the covariate.

pro_covar
Optional dataframe of data with 4 named columns ("time", "trend", "covariate", "value"), representing: (1) time, (2) the trend affected, (3) the covariate number for models with more than one covariate affecting each trend, and (4) the value of the covariate.

offset
A string argument representing the name of the offset variable to be included. The variable name is in the data frame passed in, e.g. "offset". This only works when the data shape is "long". All transformations (such as log transformed effort) to the offset must be done before passing in the data.

z_bound
Optional hard constraints for estimated factor loadings – really only applies to model with 1 trend. Passed in as a 2-element vector representing the lower and upper bound, e.g. (0, 100) to constrain positive.

z_model
Optional argument allowing for elements of Z to be constrained to be proportions (each time series modeled as a mixture of trends). Arguments can be "dfa" (default) or "proportion".

trend_model
Optional argument to change the model of the underlying latent trend. By default this is set to 'rw', where the trend is modeled as a random walk - as in conventional DFA. Alternative options are 'bs', where B-splines are used to model the trends, "ps" where P-splines are used to model the trends, or 'gp', where gaussian predictive processes are used. If models other than 'rw' are used, there are some key points. First, the MA and AR parameters on these models will be turned off. Second, for B-splines and P-splines, the process_sigma becomes an optional scalar on the spline coefficients, and is turned off by default. Third, the number of knots can be specified (more knots = more wiggliness, and n_knots < N). For models with > 2 trends, each trend has their own spline coefficients estimated though the knot locations are assumed shared. If knots aren’t specified, the default is N/3. By default both the B-spline and P-spline models use 3rd degree functions for smoothing, and include an intercept term. The P-spline model uses a difference penalty of 2.

n_knots
The number of knots for the B-spline, P-spline, or Gaussian predictive process models. Optional, defaults to round(N/3).

knot_locs
Locations of knots (optional), defaults to uniform spacing between 1 and N.

par_list
A vector of parameter names of variables to be estimated by Stan. If NULL, this will default to c("x", "Z", "sigma", "log_lik", "psi", "xstar") for most models – though if AR / MA, or Student-t models are used additional parameters will be monitored. If you want to use diagnostic tools in rstan, including moment_matching, you will need to pass in a larger list. Setting this argument...
to "all" will monitor all parameters, enabling the use of diagnostic functions – but making the models a lot larger for storage. Finally, this argument may be a custom string of parameters to monitor, e.g. `c("x","sigma")`

**family**

String describing the observation model. Default is "gaussian", but included options are "gamma", "lognormal", negative binomial ("nbinom2"), "poisson", or "binomial". The binomial family is assumed to have logit link, gaussian family is assumed to be identity, and the rest are log-link.

**verbose**

Whether to print iterations and information from Stan, defaults to FALSE.

**inv_var_weights**

Optional name of inverse variance weights argument in data frame. This is only implemented when data are in long format. If not entered, defaults to `inv_var_weights = 1` for all observations. The implementation of `inv_var_weights` relies on inverse variance weightings, so that if you have standard errors associated with each observation, the inverse variance weights are calculated as `inv_var_weights <- 1 / (standard_errors^2)` . The observation error sigma in the likelihood then becomes `sigma / sqrt(inv_var_weights)`

**likelihood_weights**

Optional name of likelihood weights argument in data frame. These are used in the same way weights are implemented in packages glmmTMB, brms, sdmTMB, etc. Weights are used as multipliers on the log-likelihood, with higher weights allowing observations to contribute more. Currently only implemented with univariate distributions, when data is in long format

**gp_theta_prior**

A 2-element vector controlling the prior on the Gaussian process parameter in `cov_exp_quad`. This prior is a half-Student t prior, with the first argument of `gp_theta_prior` being the degrees of freedom (nu), and the second element being the standard deviation

**expansion_prior**

Defaults to FALSE, if TRUE uses the parameter expansion prior of Ghosh & Dunson 2009

... Any other arguments to pass to `rstan::sampling()`.

**Details**

Note that there is nothing restricting the loadings and trends from being inverted (i.e. multiplied by -1) for a given chain. Therefore, if you fit multiple chains, the package will attempt to determine which chains need to be inverted using the function `find_inverted_chains()`.

# example of Gaussian process model with wide format data
s <- sim_dfa(num_trends = 1, num_years = 20, num_ts = 3)
m <- fit_dfa(y = s$y_sim, iter = 50, chains = 1, trend_model = "gp", n_knots = 5)

# example of long format data
s <- sim_dfa(num_trends = 1, num_years = 20, num_ts = 3)
obs <- c(s$y_sim[, 1], s$y_sim[, 2], s$y_sim[3, ])
long <- data.frame("obs" = obs, "ts" = sort(rep(1:3, 20)), 
"time" = rep(1:20, 3), "offset" = rep(0.1, length(obs)))
m <- fit_dfa(y = long, data_shape = "long", offset = "offset", iter = 50, chains = 1)
fit_regimes  

Fit models with differing numbers of regimes to trend data

Description

Fit models with differing numbers of regimes to trend data

Usage

fit_regimes(
  y,
  sds = NULL,
  n_regimes = 2,
  iter = 2000,
  thin = 1,
  chains = 1,
  ...
)

Arguments

- **y**: Data, time series or trend from fitted DFA model.
- **sds**: Optional time series of standard deviations of estimates. If passed in, residual variance not estimated. Defaults to NULL.
- **n_regimes**: Number of regimes to evaluate, defaults 2
- **iter**: MCMC iterations, defaults to 2000.
- **thin**: MCMC thinning rate, defaults to 1.
- **chains**: MCMC chains, defaults to 1 (note that running multiple chains may result in a label switching problem where the regimes are identified with different IDs across chains).
- **...**: Other parameters to pass to `rstan::sampling()`.

Examples

```r
data(Nile)
fit_regimes(log(Nile), iter = 50, n_regimes = 1)
```
hmm_init

Create initial values for the HMM model.

**Description**
Create initial values for the HMM model.

**Usage**
hmm_init(K, x_t)

**Arguments**
- **K**
  The number of regimes or clusters to fit. Called by `rstan::sampling()`.
- **x_t**
  A matrix of values. Called by `rstan::sampling()`.

**Value**
list of initial values (mu, sigma)

invert_chains

**Description**
Invert chains

**Usage**
invert_chains(model, trends = 1, print = FALSE, ...)

**Arguments**
- **model**
  A Stan model, rstanfit object
- **trends**
  The number of trends in the DFA, defaults to 1
- **print**
  Logical indicating whether the summary should be printed. Defaults to FALSE.
- **...**
  Other arguments to pass to `find_inverted_chains()`.

**See Also**
find_inverted_chains
is_converged

**Summarize Rhat convergence statistics across parameters**

**Description**

Pass in rstanfit model object, and a threshold Rhat value for convergence. Returns boolean.

**Usage**

```r
is_converged(fitted_model, threshold = 1.05, parameters = c("sigma", "x", "Z"))
```

**Arguments**

- **fitted_model**: Samples extracted (with permuted = FALSE) from a Stan model. E.g. output from `invert_chains()`.
- **threshold**: Threshold for maximum Rhat.
- **parameters**: Vector of parameters to be included in convergence determination. Defaults = c("sigma","x","Z"). Other elements can be added including "pred", "log_lik", or "lp__".

---

loos.bayesdfa

**LOO information criteria**

**Description**

Extract the LOOIC (leave-one-out information criterion) using `loo::loo()`. Note that we’ve implemented slightly different variants of loo, based on whether the DFA observation model includes correlation between time series or not (default is no correlation). Importantly, these different versions are not directly comparable to evaluate data support for including correlation or not in a DFA. If time series are not correlated, the point-wise log-likelihood for each observation is calculated and used in the loo calculations. However if time series are correlated, then each time slice is assumed to be a joint observation of all variables, and the point-wise log-likelihood is calculated as the joint likelihood of all variables under the multivariate normal distribution.

**Usage**

```r
## S3 method for class 'bayesdfa'
loo(x, ...)
```

**Arguments**

- **x**: Output from `fit_dfa()`.
- **...**: Arguments for `loo::relative_eff()` and `loo::loo.array()`. 
Examples

```r
set.seed(1)
s <- sim_dfa(num_trends = 1, num_years = 20, num_ts = 3)
m <- fit_dfa(y = s$y_sim, iter = 50, chains = 1, num_trends = 1)
loo(m)
```

---

**plot_fitted**

*Plot the fitted values from a DFA*

**Description**

Plot the fitted values from a DFA

**Usage**

```r
plot_fitted(
  modelfit,
  conf_level = 0.95,
  names = NULL,
  spaghetti = FALSE,
  time_labels = NULL
)
```

**Arguments**

- `modelfit`: Output from `fit_dfa`, a rstanfit object
- `conf_level`: Probability level for CI.
- `names`: Optional vector of names for plotting labels TODO. Should be same length as the number of time series
- `spaghetti`: Defaults to FALSE, but if TRUE puts all raw time series (grey) and fitted values on a single plot
- `time_labels`: Optional vector of time labels for plotting, same length as number of time steps

**See Also**

`plot_loadings` `fit_dfa` `rotate_trends` `dfa_fitted`

**Examples**

```r
y <- sim_dfa(num_trends = 2, num_years = 20, num_ts = 4)
m <- fit_dfa(y = y$y_sim, num_trends = 2, iter = 50, chains = 1)
p <- plot_fitted(m)
print(p)
```
p <- plot_fitted(m, spaghetti = TRUE)
print(p)

plot_loadings

Plot the loadings from a DFA

Description

Plot the loadings from a DFA

Usage

plot_loadings(
  rotated_modelfit,
  names = NULL,
  facet = TRUE,
  violin = TRUE,
  conf_level = 0.95,
  threshold = NULL
)

Arguments

rotated_modelfit
  Output from rotate_trends().

names
  An optional vector of names for plotting the loadings.

facet
  Logical. Should there be a separate facet for each trend? Defaults to TRUE.

violin
  Logical. Should the full posterior densities be shown as a violin plot? Defaults to TRUE.

conf_level
  Confidence level for credible intervals. Defaults to 0.95.

threshold
  Numeric (0-1). Optional for plots, if included, only plot loadings who have Pr(<0) or Pr(>0) > threshold. For example threshold = 0.8 would only display estimates where 80% of posterior density was above/below zero. Defaults to NULL (not used).

See Also

plot_trends fit_dfa rotate_trends
Examples

```r
set.seed(42)
s <- sim_dfa(num_trends = 2, num_ts = 4, num_years = 10)
# only 1 chain and 180 iterations used so example runs quickly:
m <- fit_dfa(y = s$y_sim, num_trends = 2, iter = 50, chains = 1)
r <- rotate_trends(m)
plot_loadings(r, violin = FALSE, facet = TRUE)
plot_loadings(r, violin = FALSE, facet = FALSE)
plot_loadings(r, violin = TRUE, facet = FALSE)
plot_loadings(r, violin = TRUE, facet = TRUE)
```

Description

Plot the state probabilities from `find_regimes()`

Usage

```r
plot_regime_model(model, 
probs = c(0.05, 0.95),
type = c("probability", "means"),
regime_prob_threshold = 0.9, 
plot_prob_indices = NULL, 
flip_regimes = FALSE)
```

Arguments

- `model` A model returned by `find_regimes()`.
- `probs` A numeric vector of quantiles to plot the credible intervals at. Defaults to `c(0.05, 0.95)`.
- `type` Whether to plot the probabilities (default) or means.
- `regime_prob_threshold` The probability density that must be above 0.5. Defaults to 0.9 before we classify a regime (only affects "means" plot).
- `plot_prob_indices` Optional indices of probability plots to plot. Defaults to showing all.
- `flip_regimes` Optional whether to flip regimes in plots, defaults to FALSE

Details

Note that the original timeseries data (dots) are shown scaled between 0 and 1.
Examples

```r
data(Nile)
m <- fit_regimes(log(Nile), n_regimes = 2, chains = 1, iter = 50)
plot_regime_model(m)
plot_regime_model(m, plot_prob_indices = c(2))
plot_regime_model(m, type = "means")
```

---

### plot_trends

**Plot the trends from a DFA**

**Description**

Plot the trends from a DFA

**Usage**

```r
plot_trends(
  rotated_modelfit,
  years = NULL,
  highlight_outliers = FALSE,
  threshold = 0.01
)
```

**Arguments**

- `rotated_modelfit`:
  Output from `rotate_trends`
- `years`:
  Optional numeric vector of years for the plot
- `highlight_outliers`:
  Logical. Should trend events that exceed the probability of occurring with a normal distribution as defined by `threshold` be highlighted? Defaults to `FALSE`
- `threshold`:
  A probability threshold below which to flag trend events as extreme. Defaults to 0.01

**See Also**

`dfa_trends`, `plot_loadings`, `fit_dfa`, `rotate_trends`

**Examples**

```r
set.seed(1)
s <- sim_dfa(num_trends = 1)
m <- fit_dfa(y = s$y_sim, num_trends = 1, iter = 50, chains = 1)
r <- rotate_trends(m)
p <- plot_trends(r)
print(p)
```
predicted

Calculate predicted value from DFA object

Description
Pass in rstanfit model object. Returns array of predictions, dimensioned number of MCMC draws x number of MCMC chains x time series length x number of time series

Usage
predicted(fitted_model)

Arguments
fitted_model Samples extracted (with permuted = FALSE) from a Stan model. E.g. output from invert_chains().

Examples
## Not run:
set.seed(42)
s <- sim_dfa(num_trends = 1, num_years = 20, num_ts = 3)
# only 1 chain and 1000 iterations used so example runs quickly:
m <- fit_dfa(y = s$y_sim, iter = 2000, chains = 3, num_trends = 1)
pred <- predicted(m)

## End(Not run)

rotate_trends

Rotate the trends from a DFA

Description
Rotate the trends from a DFA

Usage
rotate_trends(fitted_model, conf_level = 0.95, invert = FALSE)

Arguments
fitted_model Output from fit_dfa().
conf_level Probability level for CI.
invert Whether to invert the trends and loadings for plotting purposes
Examples

```r
set.seed(42)
s <- sim_dfa(num_trends = 1, num_years = 20, num_ts = 3)
# only 1 chain and 800 iterations used so example runs quickly:
m <- fit_dfa(y = s$y_sim, iter = 50, chains = 1)
r <- rotate_trends(m)
plot_trends(r)
```

---

**sim_dfa**  
Simulate from a DFA

**Description**

Simulate from a DFA

**Usage**

```r
sim_dfa(
  num_trends = 1,
  num_years = 20,
  num_ts = 4,
  loadings_matrix = matrix(nrow = num_ts, ncol = num_trends, rnorm(num_ts * num_trends, 0, 1)),
  sigma = rlnorm(1, meanlog = log(0.2), 0.1),
  varIndx = rep(1, num_ts),
  trend_model = c("rw", "bs"),
  spline_weights = matrix(ncol = 6, nrow = num_trends, data = rnorm(6 * num_trends)),
  extreme_value = NULL,
  extreme_loc = NULL,
  nu_fixed = 100,
  user_supplied_deviations = NULL
)
```

**Arguments**

- `num_trends`: The number of trends.
- `num_years`: The number of years.
- `num_ts`: The number of timeseries.
- `loadings_matrix`: A loadings matrix. The number of rows should match the number of timeseries and the number of columns should match the number of trends. Note that this loadings matrix will be internally manipulated by setting some elements to 0 and constraining some elements to 1 so that the model can be fitted. See `fit_dfa()`.

See the outfit element `Z` in the returned list is to see the manipulated loadings matrix. If not specified, a random matrix ~ N(0, 1) is used.
**sigma**  A vector of standard deviations on the observation error. Should be of the same length as the number of trends. If not specified, random numbers are used \( \text{rlnorm}(1, \text{meanlog} = \log(0.2), 0.1) \).

**varIndx**  Indices of unique observation variances. Defaults to \( c(1, 1, 1, 1) \). Unique observation error variances would be specified as \( c(1, 2, 3, 4) \) in the case of 4 time series.

**trend_model**  The type of trend model. Random walk ("rw") or basis spline ("bs").

**spline_weights**  A matrix of basis function weights that is used if `trend_model = "bs"`. The number of columns should correspond to the number of knots and the number of rows should correspond to the number of trends.

**extreme_value**  Value added to the random walk in the extreme time step. Defaults to not included.

**extreme_loc**  Location of single extreme event in the process. The same for all processes, and defaults to \( \text{round}(n_t/2) \) where \( n_t \) is the time series length.

**nu_fixed**  Nu is the degrees of freedom parameter for the t-distribution, defaults to 100, which is effectively normal.

**user_supplied_deviations**  An optional matrix of deviations for the trend random walks. Columns are for trends and rows are for each time step.

**Value**

A list with the following elements: \( y_{\text{sim}} \) is the simulated data, \( \text{pred} \) is the true underlying data without observation error added, \( x \) is the underlying trends, \( Z \) is the manipulated loadings matrix that is fed to the model.

**Examples**

```R
x <- sim_dfa(num_trends = 2)
names(x)  # Show the names of the list elements
matplot(t(x$y_sim), type = "l")
matplot(t(x$x), type = "l")

set.seed(42)
x <- sim_dfa(extreme_value = -4, extreme_loc = 10)
matplot(t(x$x), type = "l")
abline(v = 10)
matplot(t(x$pred), type = "l")
abline(v = 10)

set.seed(42)
x <- sim_dfa()
matplot(t(x$x), type = "l")
abline(v = 10)
matplot(t(x$pred), type = "l")
abline(v = 10)
```
trend_cor

Estimate the correlation between a DFA trend and some other time-series

Description
Fully incorporates the uncertainty from the posterior of the DFA trend

Usage
trend_cor(
  rotated_modelfit,
  y,
  trend = 1,
  time_window = seq_len(length(y)),
  trend_samples = 100,
  stan_iter = 300,
  stan_chains = 1,
  ...
)

Arguments
rotated_modelfit
  Output from `rotate_trends()`.
y
  A numeric vector to correlate with the DFA trend. Must be the same length as
  the DFA trend.
trend
  A number corresponding to which trend to use, defaults to 1.
time_window
  Indices indicating a time window slice to use in the correlation. Defaults to
  using the entire time window. Can be used to walk through the timeseries and
  test the cross correlations.
trend_samples
  The number of samples from the trend posterior to use. A model will be run for
  each trend sample so this value shouldn’t be too large. Defaults to 100.
stan_iter
  The number of samples from the posterior with each Stan model run, defaults to
  300.
stan_chains
  The number of chains for each Stan model run, defaults to 1.
  Other arguments to pass to `sampling`

Details
Uses a $\sigma \sim \text{half}_t(3, 0, 2)$ prior on the residual standard deviation and a $\text{uniform}(-1, 1)$
prior on the correlation coefficient. Fitted as a linear regression of $y \sim x$, where $y$ represents the
$y$ argument to `trend_cor()` and $x$ represents the DFA trend, and both $y$ and $x$ have been scaled
by subtracting their means and dividing by their standard deviations. Samples are drawn from the
posterior of the trend and repeatedly fed through the Stan regression to come up with a combined
posterior of the correlation.
trend_cor

Value

A numeric vector of samples from the correlation coefficient posterior.

Examples

```r
set.seed(1)
s <- sim_dfa(num_trends = 1, num_years = 15)
m <- fit_dfa(y = s$y_sim, num_trends = 1, iter = 50, chains = 1)
r <- rotate_trends(m)
n_years <- ncol(r$trends[, , 1])
fake_dat <- rnorm(n_years, 0, 1)
correlation <- trend_cor(r, fake_dat, trend_samples = 25)
hist(correlation)
correlation <- trend_cor(r,
  y = fake_dat, time_window = 5:15,
  trend_samples = 25)
)
hist(correlation)
```
