

# Package ‘bit’

May 15, 2018

**Type** Package

**Title** A Class for Vectors of 1-Bit Booleans

**Version** 1.1-13

**Date** 2018-04-11

**Author** Jens Oehlschlägel <Jens.Oehlschlaegel@truecluster.com>

**Maintainer** Jens Oehlschlägel <Jens.Oehlschlaegel@truecluster.com>

**Depends** R (>= 2.9.2)

**Description** True boolean datatype (no NAs),

coercion from and to logicals, integers and integer subscripts;

fast boolean operators and fast summary statistics.

With 'bit' vectors you can store true binary booleans {FALSE,TRUE} at the expense of 1 bit only, on a 32 bit architecture this means factor 32 less RAM and ~ factor 32 more speed on boolean operations. Due to overhead of R calls, actual speed gain depends on the size of the vector: expect gains for vectors of size > 10000 elements. Even for one-time boolean operations it can pay-off to convert to bit, the pay-off is obvious, when such components are used more than once.

Reading from and writing to bit is approximately as fast as accessing standard logicals - mostly due to R's time for memory allocation. The package allows to work with pre-allocated memory for return values by calling .Call() directly: when evaluating the speed of C-access with pre-allocated vector memory, copying from bit to logical requires only 70% of the time for copying from logical to logical; and copying from logical to bit comes at a performance penalty of 150%. the package now contains further classes for representing logical selections: 'bitwhich' for very skewed selections and 'ri' for selecting ranges of values for chunked processing. All three index classes can be used for subsetting 'ff' objects (ff-2.1-0 and higher).

**License** GPL-2

**LazyLoad** yes

**ByteCompile** yes

**Encoding** UTF-8

**URL** <http://ff.r-forge.r-project.org/>

**NeedsCompilation** yes

**Repository** CRAN

**Date/Publication** 2018-05-15 20:57:57 UTC

**Description**

Package 'bit' provides bitmapped vectors of booleans (no NAs), coercion from and to logicals, integers and integer subscripts; fast boolean operators and fast summary statistics.

With bit vectors you can store true binary booleans {FALSE,TRUE} at the expense of 1 bit only, on a 32 bit architecture this means factor 32 less RAM and factor 32 more speed on boolean operations. With this speed gain it even pays-off to convert to bit in order to avoid a single boolean operation on logicals or a single set operation on (longer) integer subscripts, the pay-off is dramatic when such components are used more than once.

Reading from and writing to bit is approximately as fast as accessing standard logicals - mostly due to R's time for memory allocation. The package allows to work with pre-allocated memory for return values by calling `.Call()` directly: when evaluating the speed of C-access with pre-allocated vector memory, coping from bit to logical requires only 70% of the time for copying from logical to logical; and copying from logical to bit comes at a performance penalty of 150%.

Since bit objects cannot be used as subscripts in R, a second class 'bitwhich' allows to store selections as efficiently as possible with standard R types. This is usefull either to represent parts of bit objects or to represent very asymmetric selections.

Class 'ri' (range index) allows to select ranges of positions for chunked processing: all three classes 'bit', 'bitwhich' and 'ri' can be used for subsetting 'ff' objects (ff-2.1.0 and higher).

**Usage**

```
bit(length)
## S3 method for class 'bit'
print(x, ...)
```

**Arguments**

length	length of vector in bits
x	a bit vector
...	further arguments to print

**Details**

Package:	bit
Type:	Package
Version:	1.1.0
Date:	2012-06-05
License:	GPL-2
LazyLoad:	yes
Encoding:	latin1

summary.bit	summary.bitwhich	summary.ri	tabulate	aggregate c(nFALSE, nTRUE, min)
regtest.bit				regressiontests for the package

**Value**

`bit` returns a vector of integer sufficiently long to store `'length'` bits (but not longer) with an attribute `'n'` and class `'bit'`

**Note**

Currently operations on bit objects have some overhead from R-calls. Do expect speed gains for vectors of length  $\sim 10000$  or longer.

Since this package was created for high performance purposes, only positive integer subscripts are allowed: All R-functions behave as expected - i.e. they do not change their arguments and create new return values. If you want to save the time for return value memory allocation, you must use `.Call` directly (see the `dontrun` example in `sum.bit`).

## End(Not run)

```

## Description

Coercing to bit vector

## Usage

```
as.bit(x, ...)  
## S3 method for class 'bit'  
as.bit(x, ...)  
## S3 method for class 'logical'  
as.bit(x, ...)  
## S3 method for class 'integer'  
as.bit(x, ...)  
## S3 method for class 'bitwhich'  
as.bit(x, ...)  
## S3 method for class 'which'  
as.bit(x, length, ...)  
## S3 method for class 'ri'  
as.bit(x, ...)
```

## Arguments

x	an object of class <a href="#">bit</a> , <a href="#">logical</a> , <a href="#">integer</a> , <a href="#">bitwhich</a> or an integer from <a href="#">as.which</a> or a boolean <a href="#">ff</a>
length	the length of the new bit vector
...	further arguments

## Details

Coercing to bit is quite fast because we use a double loop that fixes each word in a processor register

## Value

`is.bit` returns FALSE or TRUE, `as.bit` returns a vector of class 'bit'

## Note

Zero is coerced to FALSE, all other numbers including NA are coerced to TRUE. This differs from the NA-to-FALSE coercion in package `ff` and may change in the future.

## Author(s)

Jens Oehlschlägel

## See Also

[bit](#), [as.logical](#)

**Examples**

```
x <- as.bit(c(FALSE, NA, TRUE))
as.bit(x)
as.bit.which(c(1,3,4), 12)
```

as.bitwhich

*Coercing to bitwhich***Description**

Functions to coerce to bitwhich

**Usage**

```
as.bitwhich(x, ...)
## S3 method for class 'bitwhich'
as.bitwhich(x, ...)
## S3 method for class 'ri'
as.bitwhich(x, ...)
## S3 method for class 'bit'
as.bitwhich(x, range=NULL, ...)
## S3 method for class 'which'
as.bitwhich(x, maxindex, ...)
## S3 method for class 'integer'
as.bitwhich(x, ...)
## S3 method for class 'double'
as.bitwhich(x, ...)
## S3 method for class 'logical'
as.bitwhich(x, ...)
```

**Arguments**

x	An object of class 'bitwhich', 'integer', 'logical' or 'bit' or an integer vector as resulting from 'which'
maxindex	the length of the new bitwhich vector
range	a <a href="#">ri</a> or an integer vector of length==2 giving a range restriction for chunked processing
...	further arguments

**Value**

a value of class [bitwhich](#)

**Author(s)**

Jens Oehlschlägel

**See Also**[bitwhich](#), [as.bit](#)**Examples**

```

as.bitwhich(c(FALSE, FALSE, FALSE))
as.bitwhich(c(FALSE, FALSE, TRUE))
as.bitwhich(c(FALSE, TRUE, TRUE))
as.bitwhich(c(TRUE, TRUE, TRUE))

```

---

`as.logical.bit`*Coercion from bit, bitwhich and ri to logical, integer, double*

---

**Description**

Coercing from bit to logical, integer, which.

**Usage**

```

## S3 method for class 'bit'
as.logical(x, ...)
## S3 method for class 'bitwhich'
as.logical(x, ...)
## S3 method for class 'ri'
as.logical(x, ...)
## S3 method for class 'bit'
as.integer(x, ...)
## S3 method for class 'bitwhich'
as.integer(x, ...)
## S3 method for class 'ri'
as.integer(x, ...)
## S3 method for class 'bit'
as.double(x, ...)
## S3 method for class 'bitwhich'
as.double(x, ...)
## S3 method for class 'ri'
as.double(x, ...)

```

**Arguments**

<code>x</code>	an object of class <a href="#">bit</a> , <a href="#">bitwhich</a> or <a href="#">ri</a>
<code>...</code>	ignored

**Details**

Coercion from bit is quite fast because we use a double loop that fixes each word in a processor register.

**Value**

`as.logical` returns a vector of FALSE, TRUE, `as.integer` and `as.double` return a vector of 0, 1.

**Author(s)**

Jens Oehlschlägel

**See Also**

`as.bit`, `as.which`, `as.bitwhich`, `as.ff`, `as.hi`

**Examples**

```
x <- ri(2, 5, 10)
y <- as.logical(x)
y
stopifnot(identical(y, as.logical(as.bit(x))))
stopifnot(identical(y, as.logical(as.bitwhich(x))))

y <- as.integer(x)
y
stopifnot(identical(y, as.integer(as.logical(x))))
stopifnot(identical(y, as.integer(as.bit(x))))
stopifnot(identical(y, as.integer(as.bitwhich(x))))

y <- as.double(x)
y
stopifnot(identical(y, as.double(as.logical(x))))
stopifnot(identical(y, as.double(as.bit(x))))
stopifnot(identical(y, as.double(as.bitwhich(x))))
```

---

as.which

*Coercion to (positive) integer positions*

---

**Description**

Coercing to something like the result of which [which](#)

**Usage**

```
as.which(x, ...)
## Default S3 method:
as.which(x, ...)
## S3 method for class 'ri'
as.which(x, ...)
## S3 method for class 'bit'
as.which(x, range = NULL, ...)
## S3 method for class 'bitwhich'
as.which(x, ...)
```

**Arguments**

`x` an object of classes `bit`, `bitwhich`, `ri` or something on which `which` works  
`range` a `ri` or an integer vector of length==2 giving a range restriction for chunked processing  
`...` further arguments (passed to `which` for the default method, ignored otherwise)

**Details**

`as.which.bit` returns a vector of subscripts with class 'which'

**Value**

a vector of class 'logical' or 'integer'

**Author(s)**

Jens Oehlschlägel

**See Also**

[as.bit](#), [as.logical](#), [as.integer](#), [as.which](#), [as.bitwhich](#), [as.ff](#), [as.hi](#)

**Examples**

```
r <- ri(5, 20, 100)
x <- as.which(r)
x

stopifnot(identical(x, as.which(as.logical(r))))
stopifnot(identical(x, as.which(as.bitwhich(r))))
stopifnot(identical(x, as.which(as.bit(r))))
```

---

bbatch

*Balanced Batch sizes*

---

**Description**

`bbatch` calculates batch sizes so that they have rather balanced sizes than very different sizes

**Usage**

```
bbatch(N, B)
```

**Arguments**

`N` total size  
`B` desired batch size

**Details**

Tries to have  $rb=0$  or  $rb$  as close to  $b$  as possible while guaranteeing that  $rb < b$  &&  $(b - rb) \leq \min(nb, b)$

**Value**

a list with components

<code>b</code>	the batch size
<code>nb</code>	the number of batches
<code>rb</code>	the size of the rest

**Author(s)**

Jens Oehlschlägel

**See Also**

[repleft](#), [ffvecapply](#)

**Examples**

```
bbatch(100, 24)
```

---

bitwhich

*A class for vectors representing asymmetric selections*

---

**Description**

A bitwhich object like the result of [which](#) and [as.which](#) does represent integer subscript positions, but bitwhich objects represent some subscripts rather with negative integers, if this needs less space. The extreme cases of selecting all/none subscripts are represented by TRUE/FALSE. This needs less RAM compared to [logical](#) (and often less than [as.which](#)). Logical operations are fast if the selection is asymmetric (only few or almost all selected).

**Usage**

```
bitwhich(maxindex, poslength = NULL, x = NULL)
```

**Arguments**

<code>maxindex</code>	the length of the vector (sum of all TRUEs and FALSEs)
<code>poslength</code>	Only use if <code>x</code> is not NULL: the sum of all TRUEs
<code>x</code>	Default NULL or FALSE or unique negative integers or unique positive integers or TRUE

**Details**

class 'bitwhich' represents a boolean selection in one of the following ways

- FALSE to select nothing
- TRUE to select everything
- unique positive integers to select those
- unique negative integers to exclude those

**Value**

An object of class 'bitwhich' carrying two attributes

maxindex        see above  
 poslength      see above

**Author(s)**

Jens Oehlschlägel

**See Also**

[as.bitwhich](#), [as.which](#), [bit](#)

**Examples**

```
bitwhich(12, x=c(1,3), poslength=2)
bitwhich(12, x=-c(1,3), poslength=10)
```

---

bit_init	<i>Initializing bit masks</i>
----------	-------------------------------

---

**Description**

Functions to allocate (and de-allocate) bit masks

**Usage**

```
bit_init()
bit_done()
```

**Details**

The C-code operates with bit masks. The memory for these is allocated dynamically. `bit_init` is called by `.First.lib` and `bit_done` is called by `.Last.lib`. You don't need to care about these under normal circumstances.

**Value**

NULL

**Author(s)**

Jens Oehlschlägel

**See Also**

[bit](#)

**Examples**

```
bit_done()
bit_init()
```

---

c.bit

*Concatenating bit and bitwhich vectors*

---

**Description**

Creating new bit by concatenating bit vectors

**Usage**

```
## S3 method for class 'bit'
c(...)
## S3 method for class 'bitwhich'
c(...)
```

**Arguments**

... bit objects

**Value**

An object of class 'bit'

**Author(s)**

Jens Oehlschlägel

**See Also**

[c](#), [bit](#), [bitwhich](#)

**Examples**

```
c(bit(4), bit(4))
```

---

chunk	<i>Chunked range index</i>
-------	----------------------------

---

### Description

creates a sequence of range indexes using a syntax not completely unlike 'seq'

### Usage

```
chunk(...)
## Default S3 method:
chunk(from = NULL, to = NULL, by = NULL, length.out = NULL, along.with = NULL
, overlap = 0L, method = c("bbatch", "seq"), maxindex = NA, ...)
```

### Arguments

from	the starting value of the sequence.
to	the (maximal) end value of the sequence.
by	increment of the sequence
length.out	desired length of the sequence.
along.with	take the length from the length of this argument.
overlap	number of values to overlap (will lower the starting value of the sequence, the first range becomes smaller)
method	default 'bbatch' will try to balance the chunk size, see <a href="#">bbatch</a> , 'seq' will create chunks like <a href="#">seq</a>
maxindex	passed to <a href="#">ri</a>
...	ignored

### Details

chunk is generic, the default method is described here, other methods that automatically consider RAM needs are provided with package 'ff', see for example [chunk.ffdf](#)

### Value

chunk.default returns a list of [ri](#) objects representing chunks of subscripts

### available methods

chunk.default, [chunk.bit](#), [chunk.ff\\_vector](#), [chunk.ffdf](#)

### Author(s)

Jens Oehlschlägel

**See Also**

[ri](#), [seq](#), [bbatch](#)

**Examples**

```

chunk(1, 100, by=30)
chunk(1, 100, by=30, method="seq")
## Not run:
require(foreach)
m <- 10000
k <- 1000

*Cloning ff and ram objects*

---

## Description

clone physically duplicates objects and can additionally change some features, e.g. length.

## Usage

```
clone(x, ...)  
## S3 method for class 'list'  
clone(x, ...)  
## Default S3 method:  
clone(x, ...)  
still.identical(x, y)
```

## Arguments

x	x
y	y
...	further arguments to the generic

## Details

clone is generic. clone.default currently only handles atomics. clone.list recursively clones list elements. still.identical returns TRUE if the two atomic arguments still point to the same memory.

## Value

an object that is a deep copy of x

## Author(s)

Jens Oehlschlägel

## See Also

[clone.ff](#)

**Examples**

```
x <- 1:12
y <- x
still.identical(x,y)
y[1] <- y[1]
still.identical(x,y)
y <- clone(x)
still.identical(x,y)
rm(x,y); gc()
```

---

 Extract

---

*Extract or replace part of an bit vector*

---

**Description**

Operators acting on bit objects to extract or replace parts.

**Usage**

```
## S3 method for class 'bit'
x[[i]]
## S3 replacement method for class 'bit'
x[[i]] <- value
## S3 method for class 'bit'
x[i]
## S3 replacement method for class 'bit'
x[i] <- value
```

**Arguments**

x	a bit object
i	positive integer subscript
value	new logical or integer values

**Details**

Since this package was created for high performance purposes, only positive integer subscripts make sense. Negative subscripts are converted to positive ones, beware the RAM consumption. Further subscript classes allowed for '[' and '[<-' are range indices [ri](#) and [bitwhich](#). The '[' and '[<-' methods don't check whether the subscripts are positive integers in the allowed range.

**Value**

The extractors [[ and [ return a logical scalar or vector. The replacement functions return a bit object.

**Author(s)**

Jens Oehlschlägel

**See Also**[bit](#), [Extract](#)**Examples**

```
x <- as.bit(c(FALSE, NA, TRUE))
x[] <- c(FALSE, NA, TRUE)
x[1:2]
x[-3]
x[ri(1,2)]
x[as.bitwhich(c(TRUE, TRUE, FALSE))]
x[[1]]
x[] <- TRUE
x[1:2] <- FALSE
x[[1]] <- TRUE
```

---

intrle

*Hybrid Index, C-coded utilities*

---

**Description**

These C-coded utilities speed up index preprocessing considerably

**Usage**

```
intrle(x)
intisasc(x)
intisdesc(x)
```

**Arguments**

x                    an integer vector

**Details**

intrle is by factor 50 faster and needs less RAM (2x its input vector) compared to [rle](#) which needs 9x the RAM of its input vector. This is achieved because we allow the C-code of intrle to break when it turns out, that rle-packing will not achieve a compression factor of 3 or better.

intisasc is a faster version of [is.unsorted](#): it checks whether x is sorted and returns NA x contains NAs.

intisdesc checks for being sorted descending and assumes that the input x contains no NAs (is used after intisasc and does not check for NAs).

**Value**

`intrle` returns an object of class `rle` or `NULL`, if rle-compression is not efficient (compression factor  $< 3$  or  $\text{length}(x) < 3$ ).

`intisasc` returns one of `FALSE`, `NA`, `TRUE`

`intisdesc` returns one of `FALSE`, `TRUE` (if the input contains NAs, the output is undefined)

**Author(s)**

Jens Oehlschlägel

**See Also**

`hi`, `rle`, `is.unsorted`, `is.sorted`

**Examples**

```
intrle(sample(1:100))
intrle(diff(1:100))
intisasc(1:100)
intisasc(100:1)
intisasc(c(NA, 1:100))
intisdesc(1:100)
intisdesc(100:1)
```

---

is.bit

*Testing for bit, bitwhich and ri selection classes*

---

**Description**

Test whether an object inherits from `'ri'`, `'bit'` or `'bitwhich'`

**Usage**

```
is.ri(x)
is.bit(x)
is.bitwhich(x)
```

**Arguments**

`x` an R object of unknown type

**Value**

`TRUE` or `FALSE`

**Author(s)**

Jens Oehlschlägel

**See Also**

[is.logical](#), [bit](#), [bitwhich](#)

**Examples**

```
is.ri(TRUE)
is.ri(ri(1,4,12))
is.bit(TRUE)
is.bitwhich(TRUE)
is.bit(as.bit(TRUE))
is.bitwhich(as.bitwhich(TRUE))
```

---

is.sorted

*Generics related to cache access*

---

**Description**

These generics are packaged here for methods in packages `bit64` and `ff`.

**Usage**

```
is.sorted(x, ...)
is.sorted(x, ...) <- value
na.count(x, ...)
na.count(x, ...) <- value
nvalid(x, ...)
nunique(x, ...)
nunique(x, ...) <- value
nties(x, ...)
nties(x, ...) <- value
```

**Arguments**

<code>x</code>	some object
<code>value</code>	value assigned on responsibility of the user
<code>...</code>	ignored

**Details**

see help of the available methods

**Value**

see help of the available methods

**Author(s)**

Jens Oehlschlägel <Jens.Oehlschlaegel@truecluster.com>

**See Also**

[is.sorted.integer64](#), [na.count.integer64](#), [nvalid.integer64](#), [nunique.integer64](#), [nties.integer64](#)

**Examples**

```
methods("na.count")
```

---

length.bit

*Getting and setting length of bit, bitwhich and ri objects*

---

**Description**

Query the number of bits in a [bit](#) vector or change the number of bits in a bit vector.

Query the number of bits in a [bitwhich](#) vector or change the number of bits in a bit vector.

**Usage**

```
## S3 method for class 'ri'
length(x)
## S3 method for class 'bit'
length(x)
## S3 method for class 'bitwhich'
length(x)
## S3 replacement method for class 'bit'
length(x) <- value
## S3 replacement method for class 'bitwhich'
length(x) <- value
```

**Arguments**

x                    a [bit](#), [bitwhich](#) or [ri](#) object  
value                the new number of bits

**Details**

NOTE that the length does NOT reflect the number of selected (TRUE) bits, it reflects the sum of both, TRUE and FALSE bits. Increasing the length of a [bit](#) object will set new bits to FALSE. The behaviour of increasing the length of a [bitwhich](#) object is different and depends on the content of the object:

- TRUEall included, new bits are set to TRUE
- positive integerssome included, new bits are set to FALSE
- negative integerssome excluded, new bits are set to TRUE
- FALSEall excluded:, new bits are set to FALSE

Decreasing the length of bit or bitwhich removes any previous information about the status bits above the new length.

**Value**

the length A bit vector with the new length

**Author(s)**

Jens Oehlschlägel

**See Also**

[length](#), [sum](#), [poslength](#), [maxindex](#)

**Examples**

```
stopifnot(length(ri(1, 1, 32))==32)
```

```
x <- as.bit(ri(32, 32, 32))
stopifnot(length(x)==32)
stopifnot(sum(x)==1)
length(x) <- 16
stopifnot(length(x)==16)
stopifnot(sum(x)==0)
length(x) <- 32
stopifnot(length(x)==32)
stopifnot(sum(x)==0)
```

```
x <- as.bit(ri(1, 1, 32))
stopifnot(length(x)==32)
stopifnot(sum(x)==1)
length(x) <- 16
stopifnot(length(x)==16)
stopifnot(sum(x)==1)
length(x) <- 32
stopifnot(length(x)==32)
stopifnot(sum(x)==1)
```

```
x <- as.bitwhich(bit(32))
stopifnot(length(x)==32)
stopifnot(sum(x)==0)
length(x) <- 16
stopifnot(length(x)==16)
stopifnot(sum(x)==0)
length(x) <- 32
stopifnot(length(x)==32)
stopifnot(sum(x)==0)
```

```
x <- as.bitwhich(!bit(32))
stopifnot(length(x)==32)
stopifnot(sum(x)==32)
length(x) <- 16
stopifnot(length(x)==16)
stopifnot(sum(x)==16)
length(x) <- 32
```

```
stopifnot(length(x)==32)
stopifnot(sum(x)==32)

x <- as.bitwhich(ri(32, 32, 32))
stopifnot(length(x)==32)
stopifnot(sum(x)==1)
length(x) <- 16
stopifnot(length(x)==16)
stopifnot(sum(x)==0)
length(x) <- 32
stopifnot(length(x)==32)
stopifnot(sum(x)==0)

x <- as.bitwhich(ri(2, 32, 32))
stopifnot(length(x)==32)
stopifnot(sum(x)==31)
length(x) <- 16
stopifnot(length(x)==16)
stopifnot(sum(x)==15)
length(x) <- 32
stopifnot(length(x)==32)
stopifnot(sum(x)==31)

x <- as.bitwhich(ri(1, 1, 32))
stopifnot(length(x)==32)
stopifnot(sum(x)==1)
length(x) <- 16
stopifnot(length(x)==16)
stopifnot(sum(x)==1)
length(x) <- 32
stopifnot(length(x)==32)
stopifnot(sum(x)==1)

x <- as.bitwhich(ri(1, 31, 32))
stopifnot(length(x)==32)
stopifnot(sum(x)==31)
message("NOTE the change from 'some excluded' to 'all excluded' here")
length(x) <- 16
stopifnot(length(x)==16)
stopifnot(sum(x)==16)
length(x) <- 32
stopifnot(length(x)==32)
stopifnot(sum(x)==32)
```

**Description**

Boolean 'negation', 'and', 'or' and 'exclusive or'.

**Usage**

```

## S3 method for class 'bit'
!x
## S3 method for class 'bitwhich'
!x
## S3 method for class 'bit'
e1 & e2
## S3 method for class 'bitwhich'
e1 & e2
## S3 method for class 'bit'
e1 | e2
## S3 method for class 'bitwhich'
e1 | e2
## S3 method for class 'bit'
e1 == e2
## S3 method for class 'bitwhich'
e1 == e2
## S3 method for class 'bit'
e1 != e2
## S3 method for class 'bitwhich'
e1 != e2
xor(x, y)
## Default S3 method:
xor(x, y)
## S3 method for class 'bit'
xor(x, y)
## S3 method for class 'bitwhich'
xor(x, y)

```

**Arguments**

x	a bit vector (or one logical vector in binary operators)
y	a bit vector or an logical vector
e1	a bit vector or an logical vector
e2	a bit vector or an logical vector

**Details**

Binary operators and function `xor` can combine 'bit' objects and 'logical' vectors. They do not recycle, thus the lengths of objects must match. Boolean operations on bit vectors are extremely fast because they are implemented using C's bitwise operators. If one argument is 'logical' it is converted to 'bit'.

Binary operators and function `xor` can combine 'bitwhich' objects and other vectors. They do not recycle, thus the lengths of objects must match. Boolean operations on bitwhich vectors are fast if the distribution of TRUE and FALSE is very asymmetric. If one argument is not 'bitwhich' it is

converted to 'bitwhich'.

The xor function has been made generic and xor.default has been implemented much faster than R's standard xor. This was possible because actually boolean function xor and comparison operator != do the same (even with NAs), and != is much faster than the multiple calls in (x | y) & !(x & y)

### Value

An object of class 'bit' (or 'bitwhich')

### Author(s)

Jens Oehlschlägel

### See Also

[bit](#), [Logic](#)

### Examples

```
x <- as.bit(c(FALSE, FALSE, FALSE, NA, NA, NA, TRUE, TRUE, TRUE))
y1 <- c(FALSE, NA, TRUE, FALSE, NA, TRUE, FALSE, NA, TRUE)
y <- as.bit(y1)
!x
x & y
x | y
xor(x, y)
x != y
x == y
x & y1
x | y1
xor(x, y1)
x != y1
x == y1

x <- as.bitwhich(c(FALSE, FALSE, FALSE, NA, NA, NA, TRUE, TRUE, TRUE))
y1 <- c(FALSE, NA, TRUE, FALSE, NA, TRUE, FALSE, NA, TRUE)
y <- as.bitwhich(y1)
!x
x & y
x | y
xor(x, y)
x != y
x == y
x & y1
x | y1
xor(x, y1)
x != y1
x == y1
```

---

physical

*Physical and virtual attributes*

---

## Description

Compatibility functions (to package ff) for getting and setting physical and virtual attributes.

## Usage

```
physical(x)
virtual(x)
physical(x) <- value
virtual(x) <- value
## Default S3 method:
physical(x)
## Default S3 method:
virtual(x)
## Default S3 replacement method:
physical(x) <- value
## Default S3 replacement method:
virtual(x) <- value
## S3 method for class 'physical'
print(x, ...)
## S3 method for class 'virtual'
print(x, ...)
```

## Arguments

x	a ff or ram object
value	a list with named elements
...	further arguments

## Details

ff objects have physical and virtual attributes, which have different copying semantics: physical attributes are shared between copies of ff objects while virtual attributes might differ between copies. [as.ram](#) will retain some physical and virtual attributes in the ram clone, such that [as.ff](#) can restore an ff object with the same attributes.

## Value

physical and virtual returns a list with named elements

## Author(s)

Jens Oehlschlägel

**See Also**

[physical.ff](#), [physical.ffdf](#)

**Examples**

```
physical(bit(12))
virtual(bit(12))
```

---

ramsort

*Generics for in-RAM sorting and ordering*

---

**Description**

These are generic stubs for low-level sorting and ordering methods implemented in packages `'bit64'` and `'ff'`. The `..sortorder` methods do sorting and ordering at once, which requires more RAM than ordering but is (almost) as fast as sorting.

**Usage**

```
ramsort(x, ...)
ramorder(x, i, ...)
ramsortorder(x, i, ...)
mergesort(x, ...)
mergeorder(x, i, ...)
mergesortorder(x, i, ...)
quicksort(x, ...)
quickorder(x, i, ...)
quicksortorder(x, i, ...)
shellsort(x, ...)
shellorder(x, i, ...)
shellsortorder(x, i, ...)
radixsort(x, ...)
radixorder(x, i, ...)
radixsortorder(x, i, ...)
keysort(x, ...)
keyorder(x, i, ...)
keysortorder(x, i, ...)
```

**Arguments**

<code>x</code>	a vector to be sorted by <a href="#">ramsort</a> and <a href="#">ramsortorder</a> , i.e. the output of <a href="#">sort</a>
<code>i</code>	integer positions to be modified by <a href="#">ramorder</a> and <a href="#">ramsortorder</a> , default is <code>1:n</code> , in this case the output is similar to <a href="#">order</a>
<code>...</code>	further arguments to the sorting methods

## Details

The sort generics do sort their argument 'x', some methods need temporary RAM of the same size as 'x'. The order generics do order their argument 'i' leaving 'x' as it was, some methods need temporary RAM of the same size as 'i'. The sortorder generics do sort their argument 'x' and order their argument 'i', this way of ordering is much faster at the price of requiring temporary RAM for both, 'x' and 'i', if the method requires temporary RAM. The ram generics are high-level functions containing an optimizer that chooses the 'best' algorithms given some context.

## Value

These functions return the number of NAs found or assumed during sorting

## Index of implemented methods

<b>generic</b>		<b>ff</b>	<b>bit64</b>
ramsort	<a href="#">ramsort.default</a>		<a href="#">ramsort.integer64</a>
shellsort	<a href="#">shellsort.default</a>		<a href="#">shellsort.integer64</a>
quicksort			<a href="#">quicksort.integer64</a>
mergesort	<a href="#">mergesort.default</a>		<a href="#">mergesort.integer64</a>
radixsort	<a href="#">radixsort.default</a>		<a href="#">radixsort.integer64</a>
keysort	<a href="#">keysort.default</a>		
<b>generic</b>		<b>ff</b>	<b>bit64</b>
ramorder	<a href="#">ramorder.default</a>		<a href="#">ramorder.integer64</a>
shellorder	<a href="#">shellorder.default</a>		<a href="#">shellorder.integer64</a>
quickorder			<a href="#">quickorder.integer64</a>
mergeorder	<a href="#">mergeorder.default</a>		<a href="#">mergeorder.integer64</a>
radixorder	<a href="#">radixorder.default</a>		<a href="#">radixorder.integer64</a>
keyorder	<a href="#">keyorder.default</a>		
<b>generic</b>		<b>ff</b>	<b>bit64</b>
ramsortorder			<a href="#">ramsortorder.integer64</a>
shellsortorder			<a href="#">shellsortorder.integer64</a>
quicksortorder			<a href="#">quicksortorder.integer64</a>
mergesortorder			<a href="#">mergesortorder.integer64</a>
radixsortorder			<a href="#">radixsortorder.integer64</a>
keysortorder			

## Note

Note that these methods purposely violate the functional programming paradigm: they are called for the side-effect of changing some of their arguments. The rationale behind this is that sorting is very RAM-intensive and in certain situations we might not want to allocate additional memory if not necessary to do so. The sort-methods change x, the order-methods change i, and the sortorder-methods change both x and i. You as the user are responsible to create copies of the input data 'x'

and 'i' if you need non-modified versions.

regtest.bit

*Regressiontests for bit*

---

**Description**

Test package bit for correctness

**Usage**

```
regtest.bit(N = 100)
```

**Arguments**

N                    number of random test runs

**Details**

random data of random length are generated and correctness of package functions tested on these

**Value**

a vector of class 'logical' or 'integer'

**Author(s)**

Jens Oehlschlägel

**See Also**

[bit](#), [as.bit](#), [as.logical](#), [as.integer](#), [which](#)

**Examples**

```

if (regtest.bit()){
  message("regtest.bit is OK")
}else{
  message("regtest.bit failed")
}

## Not run:
regtest.bit(10000)

## End(Not run)

```

---

repeat.time

*Adaptive timer*

---

**Description**

Repeats timing expr until minSec is reached

**Usage**

```
repeat.time(expr, gcFirst = TRUE, minSec = 0.5, envir=parent.frame())
```

**Arguments**

expr	Valid R expression to be timed.
gcFirst	Logical - should a garbage collection be performed immediately before the timing? Default is TRUE.
minSec	number of seconds to repeat at least
envir	the environment in which to evaluate expr (by default the calling frame)

**Value**

A object of class "proc\_time": see [proc.time](#) for details.

**Author(s)**

Jens Oehlschlägel <Jens.Oehlschlaegel@truecluster.com>

**See Also**

[system.time](#)

**Examples**

repeat.time(1+1)
system.time(sort(runif(1e6)))
repeat.time(sort(runif(1e6)))

```

---

repsfromto	<i>Virtual recycling</i>
------------	--------------------------

---

### Description

repsfromto virtually recycles object `x` and cuts out positions from `from` to `to`

### Usage

```
repsfromto(x, from, to)
repsfromto(x, from, to) <- value
```

### Arguments

<code>x</code>	an object from which to recycle
<code>from</code>	first position to return
<code>to</code>	last position to return
<code>value</code>	value to assign

### Details

repsfromto is a generalization of [rep](#), where `rep(x, n) == repsfromto(x, 1, n)`. You can see this as an R-side (vector) solution of the `mod_iterate` macro in `arithmetic.c`

### Value

a vector of length `from - to + 1`

### Author(s)

Jens Oehlschlägel

### See Also

[rep](#), [ffvecapply](#)

### Examples

```
message("a simple example")
repsfromto(0:9, 11, 20)
```

---

ri	<i>Range index</i>
----	--------------------

---

### Description

A range index can be used to extract or replace a continuous ascending part of the data

### Usage

```
ri(from, to = NULL, maxindex=NA)
## S3 method for class 'ri'
print(x, ...)
```

### Arguments

from	first position
to	last position
x	an object of class 'ri'
maxindex	the maximal length of the object-to-be-subscripted (if known)
...	further arguments

### Value

A two element integer vector with class 'ri'

### Author(s)

Jens Oehlschlägel

### See Also

[as.hi.ri](#)

### Examples

```
bit(12)[ri(1,6)]
```

---

rlepack

*Hybrid Index, rle-pack utilities*

---

## Description

Basic utilities for rle packing and unpacking and appropriate methods for [rev](#) and [unique](#).

## Usage

```
rlepack(x, ...)
## S3 method for class 'integer'
rlepack(x, pack = TRUE, ...)
rleunpack(x)
## S3 method for class 'rlepack'
rleunpack(x)
## S3 method for class 'rlepack'
rev(x)
## S3 method for class 'rlepack'
unique(x, incomparables = FALSE, ...)
## S3 method for class 'rlepack'
anyDuplicated(x, incomparables = FALSE, ...)
```

## Arguments

x	in 'rlepack' an integer vector, in the other functions an object of class 'rlepack'
pack	FALSE to suppress packing
incomparables	just to keep R CMD CHECK quiet (not used)
...	just to keep R CMD CHECK quiet (not used)

## Value

A list with components

first	the first element of the packed sequence
dat	either an object of class <a href="#">rle</a> or the complete input vector x if rle-packing is not efficient
last	the last element of the packed sequence

## Author(s)

Jens Oehlschlägel

## See Also

**Examples**

```
x <- rlepack(rep(0L, 10))
```

---

setattributes	<i>Attribute setting by reference</i>
---------------	---------------------------------------

---

**Description**

Function `setattr` sets a single attribute and function `setattributes` sets a list of attributes.

**Usage**

```
setattr(x, which, value)
setattributes(x, attributes)
```

**Arguments**

<code>x</code>	
<code>which</code>	name of the attribute
<code>value</code>	value of the attribute, use <code>NULL</code> to remove this attribute
<code>attributes</code>	a named list of attribute values

**Details**

The attributes of `'x'` are changed in place without copying `x`. function `setattributes` does only change the named attributes, it does not delete the non-names attributes like `attributes` does.

**Value**

`invisible()`, we do not return the changed object to remind you of the fact that this function is called for its side-effect of changing its input object.

```

### Arguments

x	an object of class bit or bitwhich
object	an object of class bit
range	a <a href="#">ri</a> or an integer vector of length==2 giving a range restriction for chunked processing
...	formally required but not used

### Details

Bit summaries are quite fast because we use a double loop that fixes each word in a processor register. Furthermore we break out of looping as soon as possible.

**Value**

as expected

**Author(s)**

Jens Oehlschlägel

**See Also**

[bit](#), [all](#), [any](#), [min](#), [max](#), [range](#), [sum](#), [summary](#)

**Examples**

```
x <- as.bit(c(TRUE, TRUE))
all(x)
any(x)
min(x)
max(x)
range(x)
sum(x)
summary(x)

x <- as.bitwhich(c(TRUE, TRUE))
all(x)
any(x)
min(x)
max(x)
range(x)
sum(x)
summary(x)

## Not run:
n <- .Machine$integer.max
x <- !bit(n)
N <- 1000000L # batchsize
B <- n %% N # number of batches
R <- n %% N # rest

message("Batched sum (52.5 sec on Centrino duo)")
system.time({
  s <- 0L
  for (b in 1:B){
    s <- s + sum(x[((b-1L)*N+1L):(b*N)])
  }
  if (R)
    s <- s + sum(x[(n-R+1L):n])
})

message("Batched sum saving repeated memory allocation for the return vector
(44.4 sec on Centrino duo)")

system.time(sum(x))

## End(Not run)
```

---

unattr

*Attribute removal*

---

### Description

Returns object with attributes removed

### Usage

```
unattr(x)
```

### Arguments

x                    any R object

### Details

attribute removal copies the object as usual

### Value

a similar object with attributes removed

### Author(s)

Jens Oehlschlägel

### See Also

[attributes](#), [setattributes](#), [unclass](#)

### Examples

```
bit(2)[]
unattr(bit(2)[])
```

---

vecseq	<i>Vectorized Sequences</i>
--------	-----------------------------

---

**Description**

vecseq returns concatenated multiple sequences

**Usage**

```
vecseq(x, y=NULL, concat=TRUE, eval=TRUE)
```

**Arguments**

x	vector of sequence start points
y	vector of sequence end points (if <code>is.null(y)</code> then x are taken as endpoints, all starting at 1)
concat	vector of sequence end points (if <code>is.null(y)</code> then x are taken as endpoints, all starting at 1)
eval	vector of sequence end points (if <code>is.null(y)</code> then x are taken as endpoints, all starting at 1)

**Details**

This is a generalization of [sequence](#) in that you can choose sequence starts other than 1 and also have options to no concat and/or return a call instead of the evaluated sequence.

**Value**

if `concat==FALSE` and `eval==FALSE` a list with n calls that generate sequences  
if `concat==FALSE` and `eval==TRUE` a list with n sequences  
if `concat==TRUE` and `eval==FALSE` a single call generating the concatenated sequences  
if `concat==TRUE` and `eval==TRUE` an integer vector of concatenated sequences

**Author(s)**

Angelo Canty, Jens Oehlschlägel

**See Also**

[:](#), [seq](#), [sequence](#)

**Examples**

```
sequence(c(3,4))  
vecseq(c(3,4))  
vecseq(c(1,11), c(5, 15))  
vecseq(c(1,11), c(5, 15), concat=FALSE, eval=FALSE)  
vecseq(c(1,11), c(5, 15), concat=FALSE, eval=TRUE)  
vecseq(c(1,11), c(5, 15), concat=TRUE, eval=FALSE)  
vecseq(c(1,11), c(5, 15), concat=TRUE, eval=TRUE)
```
