Package ‘blockmodeling’

August 23, 2023

Type Package
Title Generalized and Classical Blockmodeling of Valued Networks
Version 1.1.5
Date 2023-08-23
Imports stats, methods, Matrix, parallel
Suggests sna, doRNG, doParallel, foreach
Depends R (>= 2.10)
Maintainer Aleš Žiberna <ales.ziberna@gmail.com>
License GPL (>= 2)
Encoding UTF-8
NeedsCompilation yes
Author Aleš Žiberna [aut, cre],
Marjan Cugmas [ctb]
Repository CRAN
Date/Publication 2023-08-23 15:30:02 UTC

R topics documented:

baker ................................................................. 2
blockmodeling .................................................... 3
canClu ............................................................. 5
clu ................................................................. 6
critFunC .......................................................... 7
expandMat ......................................................... 14
find.cut ........................................................... 15
This example consists of the citation data between social work journals for the 1985-86 period, collected and analyzed in Baker (1992).

Usage

\[ \text{data(baker)} \]

Format

An object of class \text{matrix} (inherits from \text{array}) with 20 rows and 20 columns.

References

Examples

```r
# data(baker)
# Transforming it to matrix format
# baker <- as.matrix(baker)
# putting zeros on the diagonal
# diag(baker) <- 0
```

blockmodeling

An R package for Generalized and classical blockmodeling of valued networks

Description

This package is primarily meant as an implementation of Generalized blockmodeling. In addition, functions for computation of (dis)similarities in terms of structural and regular equivalence, plotting and other “utility” functions are provided.

Author(s)

Aleš Žiberna

clu(res) # Hopefully we get the original partition
err(res)
plot(res)

# Adapt network for Valued blockmodeling with the same model
```
canClu

Create canonical partition and find unique canonical partitions in a list of partitions.

Description

It is used to convert any partition to a canonical partition. A canonical partition is a partition where the first unit is in cluster 1, the next unit that is not in cluster 1 in in cluster 2 and so on. So if we would take first appearances of clusters in the order they appear in the partition vector, we would get integers from 1 to the number of clusters.

Usage

canClu(clu)

canCluUnique(cluList)

Arguments

clu A partition - a vector or a list of vectors/partitions.
cluList A list of partitions(vectors).

Value

For function canClu - a canonical partition or a list of such partitions. For function canCluUnique - A list of unique canonical partitions.

See Also

clu

Examples

clu<-c(3,2,2,3,1,2)
canClu(clu)
Function for extraction of some elements for objects, returned by functions for Generalized blockmodeling

**Description**

Functions for extraction of partition (clu), all best partitions (partitions), image or blockmodel (IM)) and total error or inconsistency (err) for objects, returned by functions critFunC or optRandomParC.

**Usage**

```r
clu(res, which = 1, ...)
partitions(res)
err(res, ...)
IM(res, which = 1, drop = TRUE, ...)
EM(res, which = 1, drop = TRUE, ...)
```

**Arguments**

- `res` Result of function critFunC or optRandomParC.
- `which` From which (if there are more than one) "best" solution should the element be extracted. Warning! which greater than the number of "best" partitions produces an error.
- `drop` If TRUE (default), dimensions that have only one level are dropped (drop function is applied to the final result).

**Value**

The desired element.

**Author(s)**

Aleš Žiberna

Examples

n <- 8 # If larger, the number of partitions increases dramatically,
# as does if we increase the number of clusters
net <- matrix(NA, ncol = n, nrow = n)
clu <- rep(1:2, times = c(3, 5))
tclu <- table(clu)
net[clu == 1, clu == 1] <- rnorm(n = tclu[1] * tclu[1], mean = 0, sd = 1)
net[clu == 1, clu == 2] <- rnorm(n = tclu[1] * tclu[2], mean = 4, sd = 1)
net[clu == 2, clu == 1] <- rnorm(n = tclu[2] * tclu[1], mean = 0, sd = 1)
net[clu == 2, clu == 2] <- rnorm(n = tclu[2] * tclu[2], mean = 0, sd = 1)

# We select a random partition and then optimize it
all.par <- nkpartitions(n = n, k = length(tclu))
# Forming the partitions
all.par <- lapply(apply(all.par, 1, list), function(x) x[[1]])
# to make a list out of the matrix
res <- optParC(M = net,
               clu = all.par[[sample(1:length(all.par), size = 1)]],
               approaches = "hom", homFun = "ss", blocks = "com")
plot(res) # Hopefully we get the original partition
clu(res) # Hopefully we get the original partition
err(res) # Error
IM(res) # Image matrix/array.
EM(res) # Error matrix/array.

---

critFunC

Functions for Generalized blockmodeling for valued networks

Description

Functions for implementation of Generalized blockmodeling for valued networks where the values
of the ties are assumed to be measured on at least interval scale. critFunC calculates the criterion
function, based on the network, partition and blockmodel/equivalece. optParC optimizes a partition
based on the criterion function based on a local search algorithm.

Usage

critFunC(
    M,
    clu,
    approaches,
    blocks,
    isTwoMode = NULL,
)
isSym = NULL,
diag = 1,
IM = NULL,
EM = NULL,
Earr = NULL,
justChange = FALSE,
rowCluChange = c(0, 0),
colCluChange = c(0, 0),
sameIM = FALSE,
regFun = "max",
homFun = "ss",
usePreSpecM = NULL,
preSpecM = NULL,
save.initial.param = TRUE,
relWeights = 1,
posWeights = 1,
blockTypeWeights = 1,
combWeights = NULL,
returnEnv = FALSE,
mulReg = TRUE,
addGroupLlErr = TRUE
)

optParC(
M,
clu,
approaches,
blocks,
nMode = NULL,
isSym = NULL,
diag = 1,
useMulti = FALSE,
maxPar = 50,
IM = NULL,
EM = NULL,
Earr = NULL,
justChange = TRUE,
sameIM = FALSE,
regFun = "max",
homFun = "ss",
usePreSpecM = NULL,
preSpecM = NULL,
minUnitsRowCluster = 1,
minUnitsColCluster = 1,
maxUnitsRowCluster = 9999,
maxUnitsColCluster = 9999,
relWeights = 1,
posWeights = 1,
blockTypeWeights = 1,
combWeights = NULL,
exchageClusters = "all",
fixClusters = NULL,
save.initial.param = TRUE,
mulReg = TRUE,
addGroupLlErr = TRUE
)

Arguments

M A matrix representing the (usually valued) network. For multi-relational networks, this should be an array with the third dimension representing the relation. The network can have one or more modes (different kinds of units with no ties among themselves). If the network is not two-mode, the matrix must be square.

clu A partition. Each unique value represents one cluster. If the network is one-mode, than this should be a vector, else a list of vectors, one for each mode. Similarly, if units are comprised of several sets, clu should be the list containing one vector for each set.

approaches One of the approaches (for each relation in multi-relational networks in a vector) described in Žiberna (2007). Possible values are:
"bin" - binary blockmodeling,
"val" - valued blockmodeling,
"hom" - homogeneity blockmodeling,
"ss" - sum of squares homogeneity blockmodeling, and
"ad" - absolute deviations homogeneity blockmodeling.

The last two options are "shorthand" for specifying approaches="hom" and homFun to either "ss" or "ad".

blocks A vector, a list of vectors or an array with names of allowed block types.

Only listing of allowed block types (blockmodel is not pre-specified).
A vector with names of allowed block types. For multi-relational networks, it can be a list of such vectors. For approaches = "bin" or approaches = "val", at least two should be selected. Possible values are:
"nul" - null or empty block
"com" - complete block
"rdo", "cdo" - row and column-dominant blocks (binary and valued approach only)
"reg" - (f-)regular block
"rre", "cre" - row and column-(f-)regular blocks
"rfn", "cfn" - row and column-dominant blocks (binary, valued only)
"den" - density block (binary approach only)
"avg" - average block (valued approach only)
"dnc" - do not care block - the error is always zero
The ordering is important, since if several block types have identical error, the first on the list is selected.
A pre-specified blockmodel.
An array with four dimensions (see example below). The third and the fourth represent the clusters (for rows and columns). The first is as long as the maximum number of allows block types for a given block. If some block has less possible block types, the empty slots should have values NA. The second dimension is the number of relations (1 for single-relational networks). The values in the array should be the ones from above. The array can have only three dimensions in case of one-relational networks or if the same pre-specified blockmodel is assumed for all relations. Further, it can have only two dimensions, if in addition only one block type is allowed per block.

**isTwoMode**
1 for one-mode networks and 2 for two-mode networks. The default value is set to NULL.

**isSym**
Specifying if the matrix (for each relation) is symmetric.

**diag**
Should the special status of diagonal be acknowledged. A single number or a vector equal to the number of relation. The default value is set to 1. Codes:
0 - diagonal is treated in the same way as other values
1 - diagonal is treated separately, or
2 - diagonal values are ignored.

**IM**
The obtained image for objects. For debugging purposes only.

**EM**
Block errors by blocks. For debugging purposes only.

**Earr**
The array of errors for all allowed block types by next dimensions: allowed block types, relations, row clusters and column clusters. The dimensions should match the dimensions of the block argument if specified as an array. For debugging purposes only.

**justChange**
Value specifying if only the errors for changed clusters should be computed. Used only for debugging purposes by developers.

**rowCluChange**
An array holding the two row clusters where the change occurred. Used only for debugging purposes by developers.

**colCluChange**
An array holding the col row clusters where the change occurred. Used only for debugging purposes by developers.

**sameIM**
Should we demand the same blockmodel image for all relations. The default value is set to FALSE.

**regFun**
Function f used in row-f-regular, column-f-regular, and f-regular blocks. Not used in binary approach. For multi-relational networks, it can be a vector of such character strings. The default value is set to "max".

**homFun**
In case of homogeneity blockmodeling two variability criteria can be used: "ss" - sum of squares (set by default), "ad" - absolute deviations and "bll" - -(minus) binary log-likelihood.

**usePreSpecM**
Specifying weather a pre-specified value should be used when computing inconsistency.

**preSpecM**
Sufficient value for individual cells for valued approach. Can be a number or a character string giving the name of a function. Set to "max" for implicit approach. For multi-relational networks, it can be a vector of such values. In case
ob binary blockmodeling this argument is a threshold used for binerizing the network. Therefore all values with values lower than \texttt{preSpecM} are recoded into 0s, all other into 1s. For multi-relational networks, it can be a vector of such values. In case of pre-specified blockmodeling, it can have the same dimensions as \texttt{blocks}.

\texttt{save.initial.param}  
Should the initial parameters (approaches, ...) be saved. The default value is \texttt{TRUE}.

\texttt{relWeights}  
Weights for all type of relations in a blockmodel. The default value is set to 1.

\texttt{posWeights}  
Weights for positions in the blockmodel (the dimensions must be the same as the error matrix (rows, columns)). For now this is a matrix (two-dimensional) even for multi-relational networks.

\texttt{blockTypeWeights}  
Weights for each type of block used, if they are to be different across block types (see \texttt{blocks} above). It must be supplied in form of a named vector, where the names are one or all allowed block types from \texttt{blocks}. If only some block types are specified, the other have a default weight of 1. The default value is set to 1.

\texttt{combWeights}  
Weights for all type of block used, The default value is set to \texttt{NULL}. The dimension must be the same as \texttt{blocks}, if \texttt{blocks} would be specified in array format (which is usual in pre-specified case).

\texttt{returnEnv}  
Should the function also return the environment after its completion.

\texttt{mulReg}  
Should the errors that apply to rows/columns (and not to cells) should be multiplied by number of rows/columns. Defaults to \texttt{TRUE}.

\texttt{addGroupLLErr}  
Used only when stochastic generalized blockmodeling is used. Should the total error included the part based on sizes of groups. Defaults to \texttt{TRUE}. Will return wrong results for two-mode networks if \texttt{critFunC} is called directly (should be fine if called via \texttt{optParC} function).

\texttt{nMode}  
Number of nodes. If \texttt{NULL}, then determined from \texttt{clu}.

\texttt{useMulti}  
Which version of local search should be used. The default value is set to \texttt{FALSE}. If \texttt{FALSE}, first possible all moves in random order and then all possible exchanges in random order are tired. When a move with lower value of criterion function is found, the algorithm moves to this new partition. If \texttt{TRUE} the version of local search where all possible moves and exchanges are tired first and then the one with the lowest error is selected and used. In this case, several optimal partitions are found. \texttt{maxPar} best partitions are returned.

\texttt{maxPar}  
The number of partitions with optimal criterion function to be returned. Only used if \texttt{useMulti} is \texttt{TRUE}.

\texttt{minUnitsRowCluster}  
Minimum number of units in row cluster.

\texttt{minUnitsColCluster}  
Minimum number of units in col cluster.

\texttt{maxUnitsRowCluster}  
Maximum number of units in row cluster.

\texttt{maxUnitsColCluster}  
Maximum number of units in col cluster.
exchangeClusters
A matrix of dimensions "number of clusters" x "number of clusters" indicating
to which clusters can units from a specific cluster be moved. Useful for multi-
level blockmodeling or in some other cases where some units cannot mix.

fixClusters
Clusters to be fixed. Used only if exchangeClusters = "all". A vector of inte-
gers that specify clusters to be fixed, where clusters are numbered from 1 to the
total (in all modes or sets) number of clusters.

Value

critFunC returns a list containing:

M
The matrix of the network analyzed.

err
The error or inconsistency empirical network with the ideal network for a given
blockmodel (model, approach,...) and partition.

clu
The analyzed partition.

EM
Block errors by blocks.

IM
The obtained image for objects.

BM
Block means by block - only for Homogeneity blockmodeling.

Earr
The array of errors for all allowed block types by next dimensions: allowed
block types, relations, row clusters and column clusters. The dimensions should
match the dimensions of the block argument if specified as an array.

optParC returns a list containing:

M
The matrix of the network analyzed.

err
The error or inconsistency empirical network with the ideal network for a given
blockmodel (model, approach,...) and partition.

clu
The analyzed partition.

EM
Block errors by blocks.

IM
The obtained image for objects.

BM
Block means by block - only for Homogeneity blockmodeling.

Earr
The array of errors for all allowed block types by next dimensions: allowed
block types, relations, row clusters and column clusters. The dimensions should
match the dimensions of the block argument if specified as an array.

useMulti
The value of the input parameter useMulti.

bestRowParMatrix
(If useMulti = TRUE) Matrix, where there are different solutions for columns,
where rows represent units.

sameErr
The number of partitions with the minimum value of the criterion function.

---

**expandMat**

Expands a square matrix by repeating each row/column the specified number of times.

---

**Description**

Expands a square matrix by repeating each row/column the specified number of times.

**Usage**

`expandMat(mat, nn)`
find.cut

Arguments

- mat: A square matrix to be expanded
- nn: A vector of number of times each row/column must be repeated. Its length must match the number of rows/columns

Value

Sum of squared deviations from the mean using only valid (non NA) values.

Author(s)

Aleš Žiberna

Description

The functions compute the maximum value of \( m/cut \) where a certain block is still classified as alt.blocks and not "null". The difference between find.m and find.m2 is that find.m uses an optimization approach and is faster and more precise than find.m2. However, find.m only supports regular ("reg") and complete ("com") as alt.blocks, while find.m2 supports all block types. Also, find.m does not always work, especially if cormet is not "none".

Usage

find.cut(M, clu, alt.blocks = "reg", cuts = "all", ...)

find.m(
  M,
  clu,
  alt.blocks = "reg",
  diag = !is.list(clu),
  cormet = "none",
  half = TRUE,
  FUN = "max"
)

find.m2(M, clu, alt.blocks = "reg", neval = 100, half = TRUE, ms = NULL, ...)

Arguments

- M: A matrix representing the (usually valued) network. For now, only one-relational networks are supported. The network can have one or more modes (different kinds of units with no ties among themselves. If the network is not two-mode, the matrix must be square.
clu A partition. Each unique value represents one cluster. If the network is one-
mode, then this should be a vector, else a list of vectors, one for each mode.

alt.blocks Only one of allowed blocktypes, as alternative to the null block:
"com" - complete block
"rdo", "cdo" - row and column-dominant blocks (binary, valued, and implicit
approach only)
"reg" - (f-)regular block
"rre", "cre" - row and column-(f-)regular blocks
"rfn", "cfn" - row and column-dominant blocks (binary, valued, and implicit
approach only)
"den" - density block (binary approach only)
"avg" - average block (valued approach only).

cuts The cuts, which should be evaluated. If cuts="all" (default), all unique values
are evaluated.

... Other parameters to critFunC.

diag (default = TRUE) Should the special status of diagonal be acknowledged.
cormet Which method should be used to correct for different maximum error contribu-
tions
"none" - no correction
"censor" - censor values larger than M
"correct" - so that the maximum possible error contribution of the cell is the
same regardless of a condition (either that something must be 0 or at least M).
half Should the returned value of m be one half of the value where the inconsistencies
are the same.

FUN (default = "max") Function f used in row-f-regular, column-f-regular, and f-
regular blocks.

neval A number of different m values to be evaluated.

ms The values of m where the function should be evaluated.

Value
A matrix of maximal m/cut values.

critFunC and maybe also optParC, plotMat

formatA  
A formatting function for numbers

Description

Formats a vector or matrix of numbers so that all have equal length (digits). This is especially suitable for printing tables.

Usage

formatA(x, digits = 2, FUN = round, ...)

Arguments

x  
A numerical vector or matrix.
digits  
The number of desired digits.
FUN  
Function used for "shortening" the numbers.
...  
Additional arguments to format.

Value

A character vector or matrix.

Examples

A <- matrix(c(1, 1.02002, 0.2, 10.3), ncol = 2)
formatA(A)
funByBlocks.default  Computation of function values by blocks

Description
Computes a value of a function over blocks of a matrix, defined by a partition.

Usage
---
## Default S3 method:
funByBlocks(
  x = M,
  clu,
  M = x,
  ignore.diag = "default",
  sortNames = TRUE,
  FUN = "mean",
  ...
)
## S3 method for class 'optMorePar'
funByBlocks(x, which = 1, orderClu = FALSE, sortNames = NULL, ...)
## S3 method for class 'opt.more.par'
funByBlocks(x, which = 1, orderClu = FALSE, sortNames = NULL, ...)
funByBlocks(x, ...)
fun.by.blocks(x, ...)

Arguments
---
x  An object of suitable class or a matrix/array representing the (usually valued) network. For multi-relational networks, this should be an array with the third dimension representing the relation. The network can have one or more modes (different kinds of units with no ties among themselves. If the network is not two-mode, the matrix must be square.
clu  A partition. Each unique value represents one cluster. If the network is one-mode, then this should be a vector, else a list of vectors, one for each mode.
M  A matrix representing the (usually valued) network. For multi-relational networks, this should be an array with the third dimension representing the relation. The network can have one or more modes (different kinds of units with no ties among themselves. If the network is not two-mode, the matrix must be square.
ignore.diag  Should the diagonal be ignored.
sortNames  Should the rows and columns of the matrix be sorted based on their names.
funByBlocks.default

FUN
The function to be computed over the blocks.
...
Further arguments to funByBlocks.default.
which
Which (if several) of the "best" solutions should be used.
orderClu
Should the partition be ordered before computing. FALSE by default. If TRUE, orderClu is used (using default arguments) to order the clusters in a partition in "decreasing" (see orderClu for interpretation) order. If TRUE, sortNames is set to FALSE.

Value
A numerical matrix of FUN values by blocks, induced by a partition clu.

funByBlocks(res)
# Computing mean by blocks, ignoring the diagonal (default)
**Description**

Computes a generalized matrix multiplication, where sum and product functions (element-wise and summary functions) can be replaced by arbitrary functions.

**Usage**

\[
\text{genMatrixMult}(A, B, \text{FUNelement} = \ast, \text{FUNsummary} = \text{sum})
\]

**Arguments**

- **A**: The first matrix.
- **B**: The second matrix.
- **FUNelement**: Element-wise operator.
- **FUNsummary**: Summary function.

**Value**

A character vector or matrix.

**Author(s)**

Aleš Žiberna

**See Also**

matmult

**Examples**

# Operations can be anything
x <- matrix(letters[1:8], ncol = 2)
y <- matrix(1:10, nrow = 2)
genMatrixMult(x, y, FUNelement = paste,
FUNsummary = function(x) paste(x, collapse = "|"))

# Binary logic
set.seed(1)
x <- matrix(rbinom(8, size = 1, prob = 0.5) == 1, ncol = 2)
y <- matrix(rbinom(10, size = 1, prob = 0.5) == 1, nrow = 2)
genMatrixMult(x, y, FUNelement = \ast, FUNsummary = \text{any})
The function for generating random partitions

Description

The function generates random partitions. The function is meant to be called by the function `optRandomParC`.

Usage

```r
genRandomPar(
  k,
  n,
  seed = NULL,
  mingr = 1,
  maxgr = Inf,
  addParam = list(genPajekPar = TRUE, probGenMech = NULL)
)
```

Arguments

- **k**: Number of clusters (by modes).
- **n**: Number of units (by modes).
- **seed**: Seed for generating random numbers (partitions).
- **mingr**: Minimal allowed group size.
- **maxgr**: Maximal allowed group size.
- **addParam**: This has to be a list with the following parameters (any or all can be missing, then the default values (see usage) are used):
  - "genPajekPar" - Should the partitions be generated as in Pajek (Batagelj & Mrvar, 2006). If FALSE, all partitions are selected completely at random while making sure that the partitions have the required number of clusters.
  - `probGenMech` - Here the probabilities for 4 different generating mechanisms can be specified. If this is not specified, the value is set to `c(1/3, 1/3, 1/3, 0)` if `genPajekPar` is TRUE and to `c(0, 0, 0, 1)` if `genPajekPar` is FALSE. The first 3 mechanisms are the same as implemented in Pajek (the second one has almost all units in only one cluster) and the fourth is completely random (from uniform distribution).

Value

A random partition in the format required by `optRandomParC`. If a network has several modes, then a list of partitions, one for each mode.

gplot1

**A wrapper for function gplot - Two-Dimensional Visualization of Graphs**

---

**Description**
The function calls function `gplot` from the library `sna` with different defaults. Use `fun` for plotting image graphs.

**Usage**

```r
gplot1(
  M,
  diag = TRUE,
  displaylabels = TRUE,
  boxed.labels = FALSE,
  loop.cex = 4,
  edge.lwd = 1,
  edge.col = "default",
  rel.thresh = 0.05,
  ...
)

gplot2(
  M,
  uselen = TRUE,
  usecurve = TRUE,
  edge.len = 0.001,
  diag = TRUE,
  displaylabels = TRUE,
  boxed.labels = FALSE,
  loop.cex = 4,
  arrowhead.cex = 2.5,
  edge.lwd = 1,
  edge.col = "default",
  rel.thresh = 0.05,
  ...
)
```

**Arguments**

- **M**
  A matrix (array) of a graph or set thereof. This data may be valued.

- **diag**
  Boolean indicating whether or not the diagonal should be treated as valid data. Set this TRUE if and only if the data can contain loops. diag is FALSE by default.
ircNorm

**displaylabels**  Boolean; should vertex labels be displayed.

**boxed.labels**  Boolean; place vertex labels within boxes.

**loop.cex**  An expansion factor for loops; may be given as a vector, if loops are to be of different sizes.

**edge.lwd**  Line width scale for edges; if set greater than 0, edge widths are scaled by `edge.lwd*dat`. May be given as a vector or adjacency matrix, if edges are to have different line widths.

**edge.col**  Color for edges; may be given as a vector or adjacency matrix, if edges are to be of different colors.

**rel.thresh**  Real number indicating the lower relative (compared to the highest value) threshold for tie values. Only ties of value `thresh` are displayed. By default, `thresh = 0`.

...  Additional arguments to `plot` or `link(sna::gplot)`:

  **mode**  the vertex placement algorithm; this must correspond to a `gplot.layout` function from package `sna`.
  **uselen**  Boolean; should we use `edge.len` to rescale edge lengths.
  **usecurve**  Boolean; should we use `edge.curve`.
  **edge.len**  If `uselen == TRUE`, curved edge lengths are scaled by `edge.len`.
  **arrowhead.cex**  An expansion factor for edge arrowheads.

**Value**

Plots a graph.

`link(sna::gplot)`

---

**ircNorm**

*Function for iterated row and column normalization of valued matrices*

**Description**

The aim is to obtain a matrix with row and column sums equal to 1. This is achieved by iterating row and column normalization. This is usually not possible if any row or column has only 1 non-zero cell.
Usage

ircNorm(M, eps = 10^-12, maxiter = 1000)

Arguments

M  A non-negative valued matrix to be normalized.
eps  The maximum allows squared deviation of a row or column’s maximum from 1 (if not exactly 0). Also, if the all deviations in two consecutive iterations are smaller, the process is terminated.
maxiter  Maximum number of iterations. If reached, the process is terminated and the current solution returned.

Value

Normalized matrix.

Author(s)

Aleš Žiberna

Examples

A <- matrix(runif(100), ncol = 10)
A # A non-normalized matrix with different row and column sums.
apply(A, 1, sum)
apply(A, 2, sum)
A.norm <- ircNorm(A)
A.norm # Normalized matrix with all row and column sums approximately 1.
apply(A.norm, 1, sum)
apply(A.norm, 2, sum)

loadmatrix

Functions for loading and writing Pajek files

Description

loadmatrix - Loads a Pajek ".mat" filename as a matrix.
Functions for reading/loading and writing Pajek files:
loadnetwork - Loads a Pajek ".net" filename as a matrix. For now, only simple one and two-mode networks are supported (eg. only single relations, no time information).
loadnetwork2 - The same as above, but adapted to be called within loadpajek.
loadnetwork3 - Another version for reading networks.
loadnetwork4 - Another version for reading networks.
loadpajek - Loads a Pajek project file name (".paj") as a list with the following components: Networks, Partitions, Vectors and Clusters. Clusters and hierarchies are dismissed.
loadmatrix

loadvector - Loads a Pajek ".clu" filename as a vector.
loadvector2 - The same as above, but adapted to be called within loadpajek - as a consequence not suited for reading clusters.
savematrix - Saves a matrix into a Pajek ".mat" filename.
savenetwork - Saves a matrix into a Pajek ".net" filename.
savevector - Saves a vector into a Pajek ".clu" filename.

Usage

loadmatrix(filename)

loadnetwork(filename, useSparseMatrix = NULL, minN = 50)

loadnetwork2(
    filename,
    useSparseMatrix = NULL,
    minN = 50,
    safe = TRUE,
    closeFile = TRUE
)

loadnetwork3(filename, useSparseMatrix = NULL, minN = 50)

loadnetwork4(filename, useSparseMatrix = NULL, minN = 50, fill = FALSE)

loadpajek(filename)

loadvector(filename)

loadvector2(filename)

savematrix(n, filename, twomode = 1)

savenetwork(n, filename, twomode = "default", symmetric = NULL)

savevector(v, filename)

Arguments

filename The name of the file to be loaded or saved to or an open file object.
useSparseMatrix Should a sparse matrix be use instead of the ordinary one? Sparse matrices can only be used if package Matrix is installed. The default NULL uses sparse matrices for networks with more that minN vertices.
minN The minimal number of units in the network to use sparse matrices.
safe If FALSE error will occur if not all vertices have labels. If TRUE reading works faster.
nanRep

Replaces NaN values by the specified values (0 by default)

Description

Replaces NaN values by the specified values (0 by default)

Usage

nanRep(x, rep = 0)

Arguments

x A vector or similar where the NaNs are to be replaced.
rep A value that should replace the NaNs (0 by default).

Value

NULL, a matrix or a vector.

Author(s)

Vladimir Batagelj & Andrej Mrvar (most functions), Aleš Žiberna (loadnetwork, loadpajek and modification of others)

References

See Also

plot.mat, critFunC, optRandomParC

nanRep

Should the connection be closed at the end. Should be always TRUE if function is used directly.
fill If TRUE, then in case the rows have unequal length, blank fields are added.
n A matrix representing the network.
twomode 1 for one-mode networks and 2 for two-mode networks. Default sets the argument to 1 for square matrices and to 2 for others.
symmetric If TRUE, only the lower part of the matrix is used and the values are interpreted as "Edges", not "Arcs".
v A vector.
nkpar

Value

x with NaNs replaced by rep.

Author(s)

Aleš Žiberna

nkpar  Functions for listing all possible partitions or just counting the number of them

Description

The function nkpartitions lists all possible partitions of n objects into k clusters.

Usage

nkpar(n, k)

nkpartitions(n, k, exact = TRUE, print = FALSE)

Arguments

n  Number of units/objects.

k  Number of clusters/groups.

exact  Search for partitions with exactly k or at most k clusters.

print  Print results as they are found.

Value

The matrix or number of possible partitions.

Author(s)

Chris Andrews

Examples

n <- 8  # If larger, the number of partitions increases dramatically,
# as does if we increase the number of clusters
net <- matrix(NA, ncol = n, nrow = n)
clu <- rep(1:2, times = c(3, 5))
tclu <- table(clu)
net[clu == 1, clu == 1] <- rnorm(n = tclu[1] * tclu[1], mean = 0, sd = 1)
net[clu == 1, clu == 2] <- rnorm(n = tclu[1] * tclu[2], mean = 4, sd = 1)
net[clu == 2, clu == 1] <- rnorm(n = tclu[2] * tclu[1], mean = 0, sd = 1)
net[clu == 2, clu == 2] <- rnorm(n = tclu[2] * tclu[2], mean = 0, sd = 1)
The notes borrowing network between social-informatics students

Description

The data come from a survey conducted in May 1993 on 13 social-informatics students (Hlebec, 1996). The network was constructed from answers to the question, "How often did you borrow notes from this person?" for each of the fellow students. The respondents indicated the frequency of borrowing by choosing (on a computer) a line of length 1-20, where 1 meant no borrowing. 1 was deducted from all answers, so that 0 now means no borrowing. The data was first used for blockmodeling in Žiberna (2007).

Usage

data("notesBorrowing")

Format

The data set is a valued matrix with 13 rows and columns.

References

Examples

data(notesBorrowing)

# Plot the network.
# (The function plotMat is from blockmodeling package.)
# plotMat(nyt)
Two-mode network conversions

Description

Converting two mode networks from two to one mode matrix representation and vice versa. If a
two-mode matrix is converted into a one-mode matrix, the original two-mode matrix lies in the
upper right corner of the one-mode matrix.

Usage

one2two(M, clu = NULL)
two2one(M, clu = NULL)

Arguments

- **M**: A matrix representing the (usually valued) network.
- **clu**: A partition. Each unique value represents one cluster. This should be a list of
two vectors, one for each mode.

Value

Function returns list with the elements: a two mode matrix of the two mode network in its upper
left corner.

- **M**: The matrix.
- **clu**: The partition, in form appropriate for the mode of the matrix.

# Converting one to two mode matrix and plotting
plot.mat(one2two(M1, clu = clu)$M, clu = clu)
```

---

**optRandomParC**

*Optimizing a set of partitions based on the value of a criterion function*

**Description**

The function optimizes a set of partitions based on the value of a criterion function (see `critFunC` for details on the criterion function) for a given network and blockmodel for Generalized blockmodeling (Žiberna, 2007) based on other parameters (see below). The optimization is done through local optimization, where the neighborhood of a partition includes all partitions that can be obtained by moving one unit from one cluster to another or by exchanging two units (from different clusters). The number of clusters and a number of partitions to generate can be specified (optParC).

**Usage**

```r
optRandomParC(
  M,
  k,
  approaches,
  blocks,
  rep,
  save.initial.param = TRUE,
  save.initial.param.opt = FALSE,
  deleteMs = TRUE,
  max.iden = 10,
  switch.names = NULL,
  return.all = FALSE,
  return.err = TRUE,
  seed = NULL,
  RandomSeed = NULL,
  parGenFun = genRandomPar,
  mingr = NULL,
  maxgr = NULL,
)```

- `M`: Network matrix.
- `k`: Number of clusters.
- `approaches`: Approaches for optimizing partitions.
- `blocks`: Blocks for the blockmodel.
- `rep`: Replications.
- `save.initial.param`: Whether to save initial parameter values.
- `save.initial.param.opt`: Whether to save initial parameter values for the optimization.
- `deleteMs`: Whether to delete MS matrices.
- `max.iden`: Maximum number of iterations.
- `switch.names`: Switch names for clusters.
- `return.all`: Whether to return all results.
- `return.err`: Whether to return error information.
- `seed`: Random seed.
- `RandomSeed`: Random seed for optimization.
- `parGenFun`: Function for generating partitions.
- `mingr`: Minimum number of generations.
- `maxgr`: Maximum number of generations.
```r
addParam = list(genPajekPar = TRUE, probGenMech = NULL),
maxTriesToFindNewPar = rep * 10,
skip.par = NULL,
useOptParMultiC = FALSE,
useMulti = useOptParMultiC,
printRep = ifelse(rep <= 10, 1, round(rep/10)),
n = NULL,
nCores = 1,
useParLapply = FALSE,
useLB = NULL,
chunk.size = 1,
cl = NULL,
stopcl = is.null(cl),
useRegParrallaBackend = FALSE,
...
)
```

```r
## S3 method for class 'optMorePar'
print(x, ...)
```

### Arguments

**M**
A matrix representing the (usually valued) network. For multi-relational networks, this should be an array with the third dimension representing the relation. The network can have one or more modes (different kinds of units with no ties among themselves). If the network is not two-mode, the matrix must be square.

**k**
The number of clusters used in the generation of partitions.

**approaches**
One of the approaches (for each relation in multi-relational networks in a vector) described in Žiberna (2007). Possible values are:
- "bin" - binary blockmodeling,
- "val" - valued blockmodeling,
- "hom" - homogeneity blockmodeling,
- "ss" - sum of squares homogeneity blockmodeling, and
- "ad" - absolute deviations homogeneity blockmodeling.

The last two options are "shorthand" for specifying approaches="hom" and homFun to either "ss" or "ad".

**blocks**
A vector, a list of vectors or an array with names of allowed block types.

Only listing of allowed block types (blockmodel is not pre-specified).
A vector with names of allowed block types. For multi-relational networks, it can be a list of such vectors. For approaches = "bin" or approaches = "val", at least two should be selected. Possible values are:
- "nul" - null or empty block
- "com" - complete block
- "rdo", "cdo" - row and column-dominant blocks (binary and valued approach only)
- "reg" - (f-)regular block
"rre", "cre" - row and column-(f)-regular blocks
"rfn", "cfn" - row and column-dominant blocks (binary, valued only)
"den" - density block (binary approach only)
"avg" - average block (valued approach only)
"dnc" - do not care block - the error is always zero

The ordering is important, since if several block types have identical error, the first on the list is selected.

A pre-specified blockmodel.
An array with four dimensions (see example below). The third and the fourth represent the clusters (for rows and columns). The first is as long as the maximum number of allows block types for a given block. If some block has less possible block types, the empty slots should have values NA. The second dimension is the number of relations (1 for single-relational networks). The values in the array should be the ones from above. The array can have only three dimensions in case of one-relational networks or if the same pre-specified blockmodel is assumed for all relations. Further, it can have only two dimensions, if in addition only one block type is allowed per block.

rep The number of repetitions/different starting partitions to check.
save.initial.param Should the initial parameters (approaches, ...) be saved. The default value is TRUE.
save.initial.param.opt Should the initial parameters (approaches, ...) of using optParC be saved. The default value is FALSE.
deleteMs Delete networks/matrices from the results of to save space.
max.iden Maximum number of results that should be saved (in case there are more than max.iden results with minimal error, only the first max.iden will be saved).
switch.names Should partitions that only differ in group names be considered equal. By default it is set to TRUE if blocks is either a vector or a list of vectors and to FALSE otherwise.
return.all If FALSE, solution for only the best (one or more) partition/s is/are returned.
return.err Should the error for each optimized partition be returned.
seed Optional. The seed for random generation of partitions.
RandomSeed Optional. Integer vector, containing the random number generator. It is only looked for in the user’s workspace.
parGenFun The function (object) that will generate random partitions. The default function is genRandomPar. The function has to accept the following parameters: k (number of partitions by modes, n (number of units by modes), seed (seed value for random generation of partition), addParam (a list of additional parameters).
mingr Minimal allowed group size.
maxgr Maximal allowed group size.
addParam A list of additional parameters for function specified above. In the usage section they are specified for the default function genRandomPar.
optRandomParC

maxTriesToFindNewPar
The maximum number of partition try when trying to find a new partition to optimize that was not yet checked before - the default value is rep * 1000.

skip.par
The partitions that are not allowed or were already checked and should therefore be skipped.

useOptParMultiC
For backward compatibility. May be removed soon. See next argument.

useMulti
Which version of local search should be used. Default is currently FALSE. If FALSE, first possible all moves in random order and then all possible exchanges in random order are tried. When a move with lower value of criterion function is found, the algorithm moves to this new partition. If TRUE the version of local search where all possible moves and exchanges are tried first and then the one with the lowest error is selected and used. In this case, several optimal partitions are found. maxPar best partitions are returned.

printRep
Should some information about each optimization be printed.

n
The number of units by "modes". It is used only for generating random partitions. It has to be set only if there are more than two modes or if there are two modes, but the matrix representing the network is one mode (both modes are in rows and columns).

nCores
Number of cores to be used. Value 0 means all available cores. It can also be a cluster object.

useParLapply
Should parLapplyLB or parLapply (see useLB) be used for parallel execution (on multiple cores). Otherwise mforeach is used. Defaults to FALSE. If useParLapply = TRUE and useLB = TRUE, results are not reproducible.

useLB
Should be logical if set. Only used if useParLapply = TRUE. Should load balancing be used (parLapplyLB instead of parLapply). Using load balancing usually means faster execution, but results are with not reproducible. Defaults to NULL, which is changed to TRUE, but a warning.

chunk.size
chunk.size used in parLapplyLB if it is used, otherwise ignored. Defaults to 1.

c1
The cluster to use (if formed beforehand). Defaults to NULL. Ignored if useParLapply = FALSE (default) and foreach::getDoParRegistered is true

stopcl
Should the cluster be stoped after the function finishes. Defaults to is.null(c1).

useRegParallBackend
Should the function use already registered parallel backend. Defaults to FALSE. If TRUE, you must make sure that an appropriate backend is correctly set up and registered. Use only if useParLapply = FALSE (default) and nCore is not 1.

...
Arguments passed to other functions, see critFunC.

x
The result of optRandomParC.

genPajekPar
Should the partitions be generated as in Pajek.

probGenMech
Should the probabilities for different mechanisms for specifying the partitions be set. If probGenMech is not set, it is determined based on the parameter genPajekPar.
Value

- **M** The matrix of the network analyzed.
- **res** If `return.all = TRUE` - A list of results the same as `best` - one best for each partition optimized.
- **best** A list of results from `optParC`, only without `M`.
- **err** If `return.err = TRUE` - The vector of errors or inconsistencies of the empirical network with the ideal network for a given blockmodel (model, approach,...) and partitions.
- **nIter** The vector of the number of iterations used - one value for each starting partition that was optimized. It can show that `maxiter` is too low if a lot of these values have the value of `maxiter`.
- **checked.par** If selected - A list of checked partitions. If `merge.save.skip.par` is `TRUE`, this list also includes the partitions in `skip.par`.
- **call** The call used to call the function.
- **initial.param** If selected - The initial parameters are used.

Warning

It should be noted that the time complexity of package blockmodeling is increasing with the number of units and the number of clusters (due to its algorithm). Therefore the analysis of network with more than 100 units can take a lot of time (from a few hours to a few days).

net[clu == 2, clu == 1] <- rnorm(n = tclu[2] * tclu[1], mean = 0, sd = 1)
net[clu == 2, clu == 2] <- rnorm(n = tclu[2] * tclu[2], mean = 0, sd = 1)

# Optimizing 10 random chosen partitions with optRandomParC
res <- optRandomParC(M = net, k = 2, rep = 10,
                        approaches = "hom", homFun = "ss", blocks = "com")
pplot(res)  # Hopefully we get the original partition

orderClu

Order the partition so that mean values of fun applied to columns (if
funWay=2, default), rows (if funWay=1) or both (if funWay=c(1,2))
is decreasing by clusters.

Description

Orders the partition so that mean values of fun applied to columns (if funWay=2, default), rows (if funWay=1) or both (if funWay=c(1,2)) is decreasing by clusters. The function can be used on the results of critFunC, optRandomParC or similar, or matrix and a partition can be supplied. It should also work on multirelational and lined networks.

Usage

orderClu(
    x,  
    clu = NULL,
    fun = sum,
    funWay = 2,
    nn = NULL,
    returnList = TRUE,
    scale = TRUE
)

Arguments

x A result of critFunC, optRandomParC or similar (something containing M (matrix) and clu (partition)) or a matrix (or array for multirelational networks).

clu A partition - a vector or a list of vectors/partitions. It must be supplied only if x is a matrix or array.
funWay

In which "way" should fun be applied - to columns (if funWay=2, default), rows (if funWay=1) or both (if funWay=c(1,2))

nn

The numbers of units by sets of units. In principle, the function should determine this automatically.

returnList

Logical. Should the partition be returned in form of a list (for lined networks only). TRUE by default.

scale

Only used in case of multirelational networks. Should relations be scaled (TRUE by default) before summation. It can also be a vector of weights by relations.

Value

An ordered partition. In an attribute ("reorder"), the information on how things were reordered.

See Also

clu

Description

The main function plot.mat or plotMat plots a (optionally partitioned) matrix. If the matrix is partitioned, the rows and columns of the matrix are rearranged according to the partitions. Other functions are only wrappers for plot.mat or plotMat for convenience when plotting the results of the corresponding functions. The plotMatNm plots two matrices based on M, normalized by rows and columns, next to each other. The plotArray plots an array. plot.mat.nm has been replaced by plotMatNm.

Usage

```r
## S3 method for class 'critFun'
plot(x, main = NULL, ...)

## S3 method for class 'crit.fun'
plot(x, main = NULL, ...)

plotMatNm(
  M = x,
  x = M,
  ...,
  main.title = NULL,
  title.row = "Row normalized",
  title.col = "Column normalized",

Arguments

x A result from a corresponding function or a matrix or similar object representing a network.
main Main title.
... Additional arguments to plot.default for plotMat and also to plotMat for other functions.
M A matrix or similar object representing a network - either x or M must be supplied - both are here to make the code compatible with generic and with older functions.
main.title Main title in plotArray version.
title.row Title for the row-normalized matrix in nm version
title.col Title for the column-normalized matrix in nm version
main.title.line The line in which main title is printed in plotArray version.
par.set A list of possible plotting parameters (to par) to be used in nm version

print.axes.val

print.x.axis.val

print.y.axis.val

Which (if there are more than one) of optimal solutions to plot.

A partition. Each unique value represents one cluster. If the network is one-
mode, then this should be a vector, else a list of vectors, one for each mode/set.

Should the partition be ordered before plotting. FALSE by default. If TRUE, 
orderClu is used (using default arguments) to order the clusters in a partition in
"decreasing" (see orderClu for interpretation) order.

Label for y axis.

Label for x axis.

Should the values be printed in the matrix.

Should the legend for shades be plotted.

Should the values be printed in the legend.

The number of digits that should appear in the legend.

The number of digits that should appear in the cells (of the matrix and/or legend).

If not NULL, the above argument is ignored, the cell values are printed as the cell
are multiplied by this factor and rounded.

Should the title be printed on the 'inner' or 'outer' margin of the plot, default is
'inner' margin.

The line (from the top) where the title should be printed. The suitable values
depend heavily on the displayed type.

A numerical vector of the form c(bottom, left, top, right) which gives the
lines of margin to be specified on the four sides of the plot. The R default for
ordinary plots is c(5, 4, 4, 2) + 0.1, while this function default is c(0.5, 7,
8.5, 0) + 0.1.

The size of the values printed. The default is 10 / 'number of units'.

Correction for centering the values in the squares in y direction.

Correction for centering the values in the squares in x direction.

Size of the text in the legend.

The title of the legend.

Size of the characters in axes. Default makes the cex so small that all categories
can be printed.

Should the axes values be printed. Default prints each axis if rownames or
colnames is not NULL.

Should the x axis values be printed. Default prints each axis if rownames or
colnames is not NULL.

Should the y axis values be printed. Default prints each axis if rownames or
colnames is not NULL.
x.axis.val.pos  The x coordinate of the y axis values.
y.axis.val.pos  The y coordinate of the x axis values.
cex.main      Size of the text in the main title.
cex.lab       Size of the text in matrix.
yaxis.line    The position of the y axis (the argument 'line').
xaxis.line    The position of the x axis (the argument 'line').
legend.left   How much left should the legend be from the matrix.
legend.up     How much up should the legend be from the matrix.
legend.size   Relative legend size.
legend.text.hor.pos
               Horizontal position of the legend text (bottom) - 0 = bottom, 0.5 = middle, ...
par.line.width The width of the line that separates the partitions.
par.line.width.newSet
               The width of the line that separates that separates the sets/modes - only used when clu is a list and par.line.width has length 1.
par.line.col   The color of the line that separates the partitions.
par.line.col.newSet
               The color of the line that separates that separates the sets/modes - only used when clu is a list and par.line.col has length 1.
IM.dens       The density of shading lines in each block.
IM            The image (as obtained with critFunC) of the blockmodel. dens.leg is used to translate this image into IM.dens.
wnet          Specifies which matrix (if more) should be plotted - used if M is an array.
wIM           Specifies which IM (if more) should be used for plotting. The default value is set to wnet) - used if IM is an array.
use.IM        Specifies if IM should be used for plotting.
dens.leg      It is used to translate the IM into IM.dens.
blackdens     At which density should the values on dark colors of lines be printed in white.
plotLines     Should the lines in the matrix be printed. The default value is set to FALSE, best set to TRUE for very small networks.
frameMatrix   Should the matrix be framed (if plotLines is FALSE). The default value is set to TRUE.
x0ParLine     Coordinates for lines separating clusters.
x1ParLine     Coordinates for lines separating clusters.
y0ParLine     Coordinates for lines separating clusters.
y1ParLine     Coordinates for lines separating clusters.
colByUnits    Coloring units. It should be a vector of unit length.
colByRow      Coloring units by rows. It should be a vector of unit length.
colByCol      Coloring units by columns. It should be a vector of unit length.
mulCol  Multiply color when joining with row, column. Only used when when colByUnits is not NULL.

joinColOperator  Function to join colByRow and colByCol. The default value is set to "+".

colTies  If TRUE, ties are colored, if FALSE, 0-ties are colored.

maxValPlot  The value to use as a maximum when computing colors (ties with maximal positive value are plotted as black).

printMultipliedMessage  Should the message '* all values in cells were multiplied by' be printed on the plot. The default value is set to TRUE.

replaceNAdiagWith0  If replaceNAdiagWith0 = TRUE Should the NA values on the diagonal of a matrix be replaced with 0s.

colLabels  Should the labels of units be colored. If FALSE, these are not colored, if TRUE, they are colored with colors of clusters as defined by palette. This can be also a vector of colors (or integers) for one-mode networks or a list of two such vectors for two-mode networks.

MplotValues  A matrix to strings to plot in cells. Only to be used if other values than those in the original matrix (x or M arguments) should be used. Defaults to NULL, in which case the valued from original matrix are plotted (if this is not prevented by some other arguments). Overrides all other arguments that deal with cell values (e.g. print.digits.cells). Sets print.val to TRUE and plot.legend to FALSE.

mfrow  mfrow Argument to par - number of row and column plots to be plotted on one figure.

Value

The functions are used for their side effect - plotting.

printBlocks

Nice printing of the blocks parameter as used in optRandomParC and critFunC.

Description

Nice printing of the blocks parameter as used in optRandomParC and critFunC.

Usage

printBlocks(blocks)

Arguments

blocks blocks parameter as used in optRandomParC and critFunC.

Value

Used for side effects (printing)

Author(s)

Aleš, Žiberna

optRandomParC, critFunC
Comparing partitions on one or multiple sets of units

Description

Rand Index and Rand Index corrected/adjusted for chance for comparing partitions (Hubert & Arabie, 1985). The functions also support computing these indices on partitions on multiple sets (where a "combined" partition is a list of multiple partitions). The names of the clusters do not matter.

Usage

```r
rand(clu1, clu2, tab)

crand(
  clu1, clu2, tab,
  multiSets = c("weights", "unlist"),
  weights = c("size", "equal"),
  returnIndividual = "attr"
)

rand2(clu1, clu2)

crand2(clu1, clu2)
```

Arguments

- `clu1` The first of the two partitions to be compared, given in the form of vectors, where for each unit a cluster membership is given. Alternatively, this can be a contingency table obtained as a `table(clu1, clu2)`. If a partition, `clu2` must also be provided. In case of multiple sets, this should be a list of partitions.
- `clu2` If `clu1` is partition or a list of partitions, this must be a compatible the second partition or list of partitions.
- `tab` A contingency table obtained as a `table(clu1, clu2)`. This is included for back-compatibility reasons. If this is present, all other arguments are ignored.
- `multiSets` How should we compute the index in case of multiple sets of units (if `clu1` and `clu2` are lists of partitions)? Possible values are "unlist" and "weight" (the default).
- `weights` Weights to be used if `multiSets` is "weight". It can be "equal", "size" (default) or a numeric (non-negative) vector of the same length as the number of sets (the number of partitions in the list of partitions).
- `returnIndividual` If `multiSets` is "weight", should the indices for individual sets be also returned. If `TRUE`, the function returns a list instead of a single value. If the values is "attr" (the default), the indices by sets are given as an attribute "bySets"
Value

The value of Rand Index (corrected/adjusted for chance) unless multiSets="weight" and returnIndividual=FALSE. In this case, a list with two items is return. The "global" index is in global, while the the indices by sets are in bySets.

recode | Recode
--- | ---

Description

Recodes values in a vector.

Usage

recode(x, oldcode = sort(unique(x)), newcode)

Arguments

x | A vector.
oldcode | A vector of old codes.
newcode | A vector of new codes.

Value

A recoded vector.

Author(s)

Aleš Žiberna

Examples

x <- rep(1:3, times = 1:3)
newx <- recode(x, oldcode = 1:3, newcode = c("a", "b", "c"))
Description

REGE - Algorithms for computing (dis)similarities in terms of regular equivalence (White & Reitz, 1983). REGE, REGE.for - Classical REGE or REGGE, as also implemented in Ucinet. Similarities in terms of regular equivalence are computed. The REGE.for is a wrapper for calling the FORTRAN subroutine written by White (1985a), modified to be called by R. The REGE does the same, however it is written in R. The functions with and without ".for" differ only in whether they are implemented in R of FORTRAN. Needless to say, the functions implemented in FORTRAN are much faster. REGE.ow, REGE.ow.for - The above function, modified so that a best match is searched for each arc separately (and not for both arcs, if they exist, together). REGE.nm, REGE.nm.for - REGE or REGGE, modified to use row and column normalized matrices instead of the original matrix. REGE.ownm, REGE.ownm.for - The above function, modified so that a best match for an outgoing ties is searched on row-normalized network and for incoming ties on column-normalized network. REGD.for - REGD or REGDI, a dissimilarity version of the classical REGE or REGGE. Dissimilarities in terms of regular equivalence are computed. The REGD.for is a wrapper for calling the FORTRAN subroutine written by White (1985b), modified to be called by R. REGE.FC - Actually an earlier version of REGE. The difference is in the denominator. See Žiberna (2007) for details. REGE.FC.ow - The above function, modified so that a best match is searched for each arc separately (and not for both arcs, if they exist, together). other - still in testing stage.

Usage

```r
REGE.FC(
  M,
  E = 1,
  iter = 3,
  until.change = TRUE,
  use.diag = TRUE,
  normE = FALSE
)

REGE.FC.ow(
  M,
  E = 1,
  iter = 3,
  until.change = TRUE,
  use.diag = TRUE,
  normE = FALSE
)

REGE(M, E = 1, iter = 3, until.change = TRUE, use.diag = TRUE)

REGE.ow(M, E = 1, iter = 3, until.change = TRUE, use.diag = TRUE)
```
REGE.for(M, iter = 3, E = 1)
REGD.for(M, iter = 3, E = 0)
REGE.ow.for(M, iter = 3, E = 1)
REGD.ow.for(M, iter = 3, E = 0)
REGE.ownm.for(M, iter = 3, E = 1)
REGE.ownm.diag.for(M, iter = 3, E = 1)
REGE.nm.for(M, iter = 3, E = 1)
REGE.nm.diag.for(M, iter = 3, E = 1)
REGE.ne.for(M, iter = 3, E = 1)
REGE.ow.ne.for(M, iter = 3, E = 1)
REGE.ownm.ne.for(M, iter = 3, E = 1)
REGE.nm.ne.for(M, iter = 3, E = 1)
REGD.ne.for(M, iter = 3, E = 0)
REGD.ow.ne.for(M, iter = 3, E = 0)

Arguments

M Matrix or a 3 dimensional array representing the network. The third dimension allows for several relations to be analyzed.
E Initial (dis)similarity in terms of regular equivalence.
iter The desired number of iterations.
until.change Should the iterations be stopped when no change occurs.
use.diag Should the diagonal be used. If FALSE, all diagonal elements are set to 0.
normE Should the equivalence matrix be normalized after each iteration.

Value

E A matrix of (dis)similarities in terms of regular equivalence.
Eall An array of (dis)similarity matrices in terms of regular equivalence, each third dimension represents one iteration. For "for" functions, only the initial and the final (dis)similarities are returned.
M Matrix or a 3 dimensional array representing the network used in the call.
iter The desired number of iterations.
use.diag Should the diagonal be used - for functions implemented in R only.

plot.mat(net, clu = cutree(hclust(d = as.dist(1 - D), method = "ward.D"), k = 2))
# REGE returns similarities, which have to be converted to
# disimilarities

res <- optRandomParC(M = net, k = 2, rep = 10, approaches = "hom", homFun = "ss", blocks = "reg")
plot(res) # Hopefully we get the original partition
```
functions for computing "relative inverse" ($x[1]/x$).

**Description**

For a vector $x$, it computes $x[1]/x$. For `relInv2`, if certain elements of the result are not finite (e.g. if certain elements of $x$ are 0), these elements are replaced with 0s.

**Usage**

relInv(x)

relInv2(x)

**Arguments**

- **x**
  
  A numeric vector. For `relInv` it should not contain 0s (while for `relInv2` it can).

**Value**

A vector computed as $x[1]/x$. For `relInv2`, if the non-finite elements are replaced with 0s.

---

reorderImage

Reordering an image matrix of the blockmodel (or an error matrix based on new and old partition)

**Description**

Reorders an image matrix of the blockmodel (or an error matrix based on new and old partition. The partitions should be the same, except that classes can have different labels. It is useful when we want to have a different order of classes in figures and then also in image matrices. Currently it is only suitable for one-mode blockmodels.

**Usage**

reorderImage(IM, oldClu, newClu)

**Arguments**

- **IM**
  
  An image or error matrix.

- **oldClu**
  
  Old partition.

- **newClu**
  
  New partition, the same as the old one except for class labels.
Value

Reorder matrix (rows and columns are reordered).

**RF**

*Calculate the value of the Relative Fit function*

Description

The function calculates the value of the Relative Fit function. Currently implemented only for one-relational one-mode or two-mode networks.

Usage

`RF(res, m = 10, loops = NULL)`

Arguments

- `res` An object returned by the function `optRandomParC`.
- `m` The number of randomized networks for the estimation of the expected value of a criterion function. It has to be as high as possible. Defaults to 10.
- `loops` Whether loops are treated the same as any other values or not.

Details

The function randomizes an empirical network to compute the value of the Relative Fit function. The networks are randomized in such a way that the values on the links are randomly relocated. Other approaches to randomization also exist and might be more appropriate in some cases, see Cugmas et al. (2021).
Value

- **RF** - The value of the Relative Fit function.
- **err** - The value of a criterion function that is used for blockmodeling (for empirical network).
- **rand.err** - A vector with the values of the criterion function that is used for blockmodeling (for randomized networks).

Examples

```r
n <- 8  # If larger, the number of partitions increases
# dramatically as does if we increase the number of clusters
net <- matrix(NA, ncol = n, nrow = n)
clu <- rep(1:2, times = c(3, 5))
tclu <- table(clu)
net[clu == 1, clu == 1] <- rnorm(n = tclu[1] * tclu[1], mean = 0, sd = 1)
net[clu == 1, clu == 2] <- rnorm(n = tclu[1] * tclu[2], mean = 4, sd = 1)
net[clu == 2, clu == 1] <- rnorm(n = tclu[2] * tclu[1], mean = 0, sd = 1)
net[clu == 2, clu == 2] <- rnorm(n = tclu[2] * tclu[2], mean = 0, sd = 1)
res <- optRandomParC(M = net, k = 2, rep = 10, approaches = "hom", homFun = "ss", blocks = "com")
RF(res = res, m = 100, loops = TRUE)
```

---

**sedist**

*Computes distances in terms of Structural equivalence (Lorrain & White, 1971)*

Description

The functions compute the distances in terms of Structural equivalence (Lorrain and White, 1971) between the units of a one-mode network. Several options for treating the diagonal values are supported.
sedist

Usage

```r
sedist(
  M,
  method = "default",
  fun = "default",
  fun.on.rows = "default",
  handle.interaction = "switch",
  use = "pairwise.complete.obs",
  ...
)
```

Arguments

- **M**: A matrix representing the (usually valued) network. For now, only one-relational networks are supported. The network must be one-mode.
- **method**: The method used to compute distances - any of the methods allowed by functions `dist`, "cor" or "cov" (all `package::stats`) or just "cor" or "cov" (given as a character).
- **fun**: Which function should be used to compute distances (given as a character).
- **fun.on.rows**: For non-standard function - does the function compute measure on rows (such as "cor", "cov",...) of the data matrix (as opposed to computing measure on columns (such as `dist`).
- **handle.interaction**: How should the interaction between the vertices analysed be handled:
  - "switch" (the default) - assumes that when comparing units i and j, M[i,i] should be compared with M[j,j] and M[i,j] with M[j,i]. These two comparisons are weighted by 2. This should be used with Euclidean distance to get the corrected Euclidean distance with \( p = 2 \).
  - "switch2" - the same (alias)
  - "switch1" - the same as above, only that the two comparisons are weighted by 1. This should be used with Euclidean distance to get the corrected Wuclidean distance with \( p = 1 \).
  - "ignore" (diagonal) - Diagonal is ignored. This should be used with Euclidean distance to get the corrected Euclidean distance with \( p = 0 \).
  - "none" - the matrix is used "as is"
- **use**: For use with methods "cor" and "cov", for other methods (the default option should be used if `handle.interaction == "ignore"`), "pairwise.complete.obs" are always used, if `stats.dist.cor.cov = TRUE`.
- **...**: Additional arguments to `fun`

Details

If both method and `fun` are "default", the Euclidean distances are computed. The "default" method for `fun = "dist"` is 'euclidean' and for `fun = "cor" "pearson".

Value

A matrix (usually of class `dist`) is returned.

splitClu

Functions creating a list of partitions based on a single partition and information on the number of units in each set.

Description
Function splitClu creates a list of partitions based on a single partition (clu) and information on the number of units in each set (n).

Function splitCluRes does the same but extracts the information from the result of (old versions of) functions critFunC, optParC, optRandomParC or similar (newer versions should already return a list of partitions in case they are used on networks with more sets of units.)
Usage

splitClu(clu, n, renumber = FALSE)

splitCluRes(res, renumber = FALSE)

Arguments

clu    A vector representing a partition of units from different sets. Result of some legacy code for optRandomParC or optParC or similar functions.

n      A vector with number of units per set. The assumption is that the first n[1] elements of clu are for the first set, the second n[2] elements of clu are for the second set and so on. sum(n) must be equal to length(clu).

renumber If TRUE, elements of each partition (for each set) in the list are renumbered to be from 1:"number of clusters" in that partition). Defaults to FALSE.

res    Result of (old versions of) functions critFunC, optParC, optRandomParC or similar.

Value

A list of partitions if clu, one for each set of units. A single vector if only one set of units is present.

Examples

n <- c(8,8)
clu <- c(rep(1:2, times = c(3, 5)), rep(3:4, times = c(3, 5)))
splitClu(clu = clu, n = n)
splitClu(clu = clu, n = n, renumber = TRUE)

ss        Sum of Squared deviations from the mean and sum of Absolute Deviations from the median

Description

Functions to compute Sum of Squared deviations from the mean and sum of Absolute Deviations from the median. ssNa removes missing values (NAs) before calling the ss function.
Usage

```
ss(x)
ssNa(x)
ad(x)
```

Arguments

- `x`: A numeric vector.

Value

Sum of Squared deviations from the mean or sum of Absolute Deviations from the median.

### `unlistClu`

*Function for "unlisting" a partition.*

#### Description

Essentially, if the argument is a list (otherwise function just returns its argument), the function calls `unlist` on it. Before it, it however makes sure that names from different elements of the list do not repeat. The opposite of `splitClu`. The `n` argument of the `splitClu` is returned as an attribute. If `renumber=TRUE` (default), it is practically identical to `unlistCluInt`.

#### Usage

```
unlistClu(clu, renumber = FALSE)
```

Arguments

- `clu`: A list representing a partition of units from different sets. Each element should be a partition for one set.
- `renumber`: If `TRUE` (default), are renumbered so that they are 1:”total number of clusters”. If any cluster "ID" is present in more than one set of units (one partition, one element of the list), this is done even if `renumber = FALSE`.

Value

A vector representing a partition. It also has an attribute `n` with the number of units that were in each set.
unlistCluInt

Author(s)
Aleš Žiberna

See Also
clu, splitClu, unlistCluInt

Examples
n <- c(8,8)
cluList <- c(rep(1:2, times = c(3, 5)), rep(5:6, times = c(3, 5)))
unlistClu(clu = clu)
unlistClu(clu = clu, renumber = FALSE)

Description
It is used to convert a partition by sets into a single "simple" partition. Simple partition is a partition
of only one set, that is a vector where units with the same value are considered to belong to the
same cluster. The partitions by sets is a list, where each element of a list is a "simple" partition that
corresponds to one set. The function first converts all elements of the lists to integers, that makes
sure that each set uses different integers and on the end uses unlist function on such list.

Usage
unlistCluInt(clu)

Arguments
clu A partition by sets, that is a list of "simple" partitions.

Value
The unlisted partition - one vector containing only integers.
