Package ‘car’

March 30, 2023

Version 3.1-2
Date 2023-03-25
Title Companion to Applied Regression
Depends R (>= 3.5.0), carData (>= 3.0-0)
Imports abind, MASS, mgcv, nnet, pbkrtest (>= 0.4-4), quantreg,
grDevices, utils, stats, graphics, lme4 (>= 1.1-27.1), nlme,
scales
Suggests alr4, boot, coxme, effects, knitr, leaps, lmtest, Matrix,
MatrixModels, mvtnorm, rgl (>= 0.111.3), rio, sandwich,
SparseM, survival, survey
ByteCompile yes
LazyLoad yes
Description Functions to Accompany J. Fox and S. Weisberg,

Description

Calculates type-II or type-III analysis-of-variance tables for model objects produced by \texttt{lm}, \texttt{glm}, \texttt{multinom} (in the \texttt{nnet} package), \texttt{polr} (in the \texttt{MASS} package), \texttt{coxph} (in the \texttt{survival} package), \texttt{coxme} (in the \texttt{coxme} package), \texttt{svyglm} and \texttt{svycoxph} (in the \texttt{survey} package), \texttt{r1m} (in the \texttt{MASS} package), \texttt{lmer} in the \texttt{lme4} package, \texttt{lme} in the \texttt{nlme} package, and (by the default method) for most models with a linear predictor and asymptotically normal coefficients (see details below). For linear models, F-tests are calculated; for generalized linear models, likelihood-ratio chi-square, Wald chisquare, or F-tests are calculated; for multinomial logit and proportional-odds logit models, likelihood-ratio tests are calculated. Various test statistics are provided for multivariate linear models produced by \texttt{lm} or \texttt{manova}. Partial-likelihood-ratio tests or Wald tests are provided for Cox models. Wald chi-square tests are provided for fixed effects in linear and generalized linear mixed-effects models. Wald chi-square or F tests are provided in the default case.

Usage

\begin{verbatim}
Anova(mod, ...)          
Manova(mod, ...)         
## S3 method for class 'lm'
Anova(mod, error, type=c("II", "III", 2, 3),
      white.adjust=c(FALSE, TRUE, "hc3", "hc0", "hc1", "hc2", "hc4"),
      vcov.=NULL, singular.ok, ...)
## S3 method for class 'aov'
Anova(mod, ...)          
## S3 method for class 'glm'
Anova(mod, type=c("II", "III", 2, 3),
      test.statistic=c("LR", "Wald", "F"),
      error, error.estimate=c("pearson", "dispersion", "deviance"),
      vcov.=vcov(mod, complete=TRUE), singular.ok, ...)
## S3 method for class 'multinom'
Anova(mod, type = c("II", "III", 2, 3), ...)
## S3 method for class 'polr'
Anova(mod, type = c("II", "III", 2, 3), ...)
## S3 method for class 'mlm'
Anova(mod, type=c("II", "III", 2, 3), SSPE, error.df,
      idata, idesign, icontasts=c("contr.sum", "contr.poly"), imatrix,
      test.statistic=c("Pillai", "Wilks", "Hotelling-Lawley", "Roy"),...)
\end{verbatim}
Anova(mod, ...)

## S3 method for class 'svycoxph'
Anova(mod, type=c("II", "III", 2, 3),
      test.statistic="Wald", ...)

## S3 method for class 'rlm'
Anova(mod, ...)

## Default S3 method:
Anova(mod, type=c("II", "III", 2, 3),
      test.statistic=c("Chisq", "F"), vcov.=vcov(mod, complete=FALSE),
      singular.ok, error.df, ...)

Arguments

mod lm, aov, glm, multinom, polr mlm, coxph, coxme, lme, mer, merMod, svyglm,
     svycoxph, rlm, or other suitable model object.

error for a linear model, an lm model object from which the error sum of squares
     and degrees of freedom are to be calculated. For F-tests for a generalized
     linear model, a glm object from which the dispersion is to be estimated. If not
     specified, mod is used.

type type of test, "II", "III", 2, or 3. Roman numerals are equivalent to the corre-
     sponding Arabic numerals.

singular.ok defaults to TRUE for type-II tests, and FALSE for type-III tests where the tests
     for models with aliased coefficients will not be straightforwardly interpretable;
     if FALSE, a model with aliased coefficients produces an error. This argument is
     available only for some Anova methods.

test.statistic for a generalized linear model, whether to calculate "LR" (likelihood-ratio),
     "Wald", or "F" tests; for a Cox or Cox mixed-effects model, whether to calculate
     "LR" (partial-likelihood ratio) or "Wald" tests; in the default case or for linear
     mixed models fit by lmer, whether to calculate Wald "Chisq" or Kenward-
     Roger "F" tests with Satterthwaite degrees of freedom (warning: the KR F-tests
     can be very time-consuming). For a multivariate linear model, the multivariate
     test statistic to compute — one of "Pillai", "Wilks", "Hotelling-Lawley", or
     "Roy", with "Pillai" as the default. The summary method for Anova.mlm
     objects permits the specification of more than one multivariate test statistic, and
     the default is to report all four.

error.estimate for F-tests for a generalized linear model, base the dispersion estimate on the
     Pearson residuals ("pearson", the default); use the dispersion estimate in the
     model object ("dispersion"); or base the dispersion estimate on the residual
     deviance ("deviance"). For binomial or Poisson GLMs, where the dispersion
     is fixed to 1, setting error.estimate="dispersion" is changed to "pearson",
     with a warning.

white.adjust if not FALSE, the default, tests use a heteroscedasticity-corrected coefficient co-
     variance matrix; the various values of the argument specify different corrections.
     See the documentation for hccm for details. If white.adjust=TRUE then the
     "hc3" correction is selected.
SSPE  For Anova for a multivariate linear model, the error sum-of-squares-and-products matrix; if missing, will be computed from the residuals of the model; for the print method for the summary of an Anova of a multivariate linear model, whether or not to print the error SSP matrix (defaults to TRUE).

SSP  if TRUE (the default), print the sum-of-squares and cross-products matrix for the hypothesis and the response-transformation matrix.

error.df  The degrees of freedom for error; if error.df missing for a multivariate linear model (object of class "mlm"), the error degrees of freedom will be taken from the model.

For the default Anova method, if an F-test is requested and if error.df is missing, the error degrees of freedom will be computed by applying the df.residual function to the model; if df.residual returns NULL or NA, then a chi-square test will be substituted for the F-test (with a message to that effect).

idata  an optional data frame giving a factor or factors defining the intra-subject model for multivariate repeated-measures data. See Details for an explanation of the intra-subject design and for further explanation of the other arguments relating to intra-subject factors.

idesign  a one-sided model formula using the “data” in idata and specifying the intra-subject design.

icontrasts  names of contrast-generating functions to be applied by default to factors and ordered factors, respectively, in the within-subject “data”; the contrasts must produce an intra-subject model matrix in which different terms are orthogonal. The default is c("contr.sum", "contr.poly").

imatrix  as an alternative to specifying idata, idesign, and (optionally) icontrasts, the model matrix for the within-subject design can be given directly in the form of list of named elements. Each element gives the columns of the within-subject model matrix for a term to be tested, and must have as many rows as there are responses; the columns of the within-subject model matrix for different terms must be mutually orthogonal.

x, object  object of class "Anova.mlm" to print or summarize.

multivariate, univariate  compute and print multivariate and univariate tests for a repeated-measures ANOVA or multivariate linear model; the default is TRUE for both for repeated measures and TRUE for multivariate for a multivariate linear model.

digits  minimum number of significant digits to print.

style  for printing univariate tests if requested for a multivariate linear model; one of "wide", the default, or "long".

by  if univariate tests are printed in "long" style, they can be ordered by "response", the default, or by "term".
row.names, optional

not used.

vcov.

in the default method, an optional coefficient-covariance matrix or function to compute a covariance matrix, computed by default by applying the generic \texttt{vcov} function to the model object. A similar argument may be supplied to the \texttt{lm} method, and the default (\texttt{NULL}) is to ignore the argument; if both \texttt{vcov.} and \texttt{white.adjust} are supplied to the \texttt{lm} method, the latter is used. In the \texttt{glm} method, \texttt{vcov.} is ignored unless \texttt{test="Wald"}; in the \texttt{mer} and \texttt{merMod} methods, \texttt{vcov.} is ignored if \texttt{test="F"}.

... do not use.

Details

The designations "type-II" and "type-III" are borrowed from SAS, but the definitions used here do not correspond precisely to those employed by SAS. Type-II tests are calculated according to the principle of marginality, testing each term after all others, except ignoring the term's higher-order relatives; so-called type-III tests violate marginality, testing each term in the model after all of the others. This definition of Type-II tests corresponds to the tests produced by SAS for analysis-of-variance models, where all of the predictors are factors, but not more generally (i.e., when there are quantitative predictors). Be very careful in formulating the model for type-III tests, or the hypotheses tested will not make sense.

As implemented here, type-II Wald tests are a generalization of the linear hypotheses used to generate these tests in linear models.

For tests for linear models, multivariate linear models, and Wald tests for generalized linear models, Cox models, mixed-effects models, generalized linear models fit to survey data, and in the default case, \texttt{Anova} finds the test statistics without refitting the model. The \texttt{svyglm} method simply calls the default method and therefore can take the same arguments.

The standard R \texttt{anova} function calculates sequential ("type-I") tests. These rarely test interesting hypotheses in unbalanced designs.

A MANOVA for a multivariate linear model (i.e., an object of class "\texttt{mlm}" or "\texttt{manova}") can optionally include an intra-subject repeated-measures design. If the intra-subject design is absent (the default), the multivariate tests concern all of the response variables. To specify a repeated-measures design, a data frame is provided defining the repeated-measures factor or factors via \texttt{idata}, with default contrasts given by the \texttt{icontrasts} argument. An intra-subject model-matrix is generated from the formula specified by the \texttt{idesign} argument; columns of the model matrix corresponding to different terms in the intra-subject model must be orthogonal (as is insured by the default contrasts). Note that the contrasts given in \texttt{icontrasts} can be overridden by assigning specific contrasts to the factors in \texttt{idata}. As an alternative, the within-subjects model matrix can be specified directly via the \texttt{imatrix} argument. \texttt{Manova} is essentially a synonym for \texttt{Anova} for multivariate linear models.

If univariate tests are requested for the summary of a multivariate linear model, the object returned contains a \texttt{univaov} component of "\texttt{univaov}"; \texttt{print} and \texttt{as.data.frame} methods are provided for the "\texttt{univaov}" class.

For the default method to work, the model object must contain a standard \texttt{terms} element, and must respond to the \texttt{vcov}, \texttt{coef}, and \texttt{model.matrix} functions. If any of these requirements is missing, then it may be possible to supply it reasonably simply (e.g., by writing a missing \texttt{vcov} method for the class of the model object).
Anova

Value

An object of class "anova", or "Anova.mlm", which usually is printed. For objects of class "Anova.mlm", there is also a summary method, which provides much more detail than the print method about the MANOVA, including traditional mixed-model univariate F-tests with Greenhouse-Geisser and Huynh-Feldt corrections.

Warning

Be careful of type-III tests: For a traditional multifactor ANOVA model with interactions, for example, these tests will normally only be sensible when using contrasts that, for different terms, are orthogonal in the row-basis of the model, such as those produced by contr.sum, contr.poly, or contr.helmert, but not by the default contr.treatment. In a model that contains factors, numeric covariates, and interactions, main-effect tests for factors will be for differences over the origin. In contrast (pun intended), type-II tests are invariant with respect to (full-rank) contrast coding. If you don’t understand this issue, then you probably shouldn’t use Anova for type-III tests.

Author(s)

John Fox <jfox@mcmaster.ca>; the code for the Mauchly test and Greenhouse-Geisser and Huynh-Feldt corrections for non-spericity in repeated-measures ANOVA are adapted from the functions stats:::stats:::mauchly.test.SSD and stats:::sphericity by R Core; summary.Anova.mlm and print.summary.Anova.mlm incorporates code contributed by Gabriel Baud-Bovy.

### avPlots

**Added-Variable Plots**

**Description**

These functions construct added-variable, also called partial-regression, plots for linear and generalized linear models.

**Usage**

```r
avPlots(model, ...)
```

**Default S3 method:**

```r
avPlots(model, terms=~., intercept=FALSE,
  layout=NULL, ask, main, ...)
```

```r
avp(...)
```

```r
avPlot(model, ...)
```

**S3 method for class 'lm'

```r
avPlot(model, variable,
  id=TRUE, col = carPalette()[1], col.lines = carPalette()[2],
  xlab, ylab, pch = 1, lwd = 2, cex = par("cex"), pt.wts = FALSE,
  main=paste("Added-Variable Plot:", variable),
  grid=TRUE,
  ellipse=FALSE,
  marginal.scale=FALSE, ...)
```

**S3 method for class 'glm'

```r
avPlot(model, variable,
  id=TRUE,
  col = carPalette()[1], col.lines = carPalette()[2],
  xlab, ylab, pch = 1, lwd = 2, cex = par("cex"), pt.wts = FALSE,
  type=c("Wang", "Weisberg"),
  main=paste("Added-Variable Plot:", variable), grid=TRUE,
  ellipse=FALSE, ...)
```
avPlot3d(model, coef1, coef2, id=TRUE, ...)  

## S3 method for class 'lm'  
avPlot3d(model, coef1, coef2, id=TRUE, fit="linear", ...)  

## S3 method for class 'glm'  
avPlot3d(model, coef1, coef2, id=TRUE, type=c("Wang", "Weisberg"),  
fit="linear", ...)  

Arguments  

model  
model object produced by \texttt{lm} or \texttt{glm}.  

terms  
A one-sided formula that specifies a subset of the predictors. One added-variable plot is drawn for each term. For example, the specification \texttt{terms = \textasciitilde \textasciitilde X3} would plot against all terms except for \texttt{X3}. If this argument is a quoted name of one of the terms, the added-variable plot is drawn for that term only.  

coeff1, coeff2  
the quoted names of the two coefficients for a 3D added variable plot.  

intercept  
Include the intercept in the plots; default is \texttt{FALSE}.  

variable  
A quoted string giving the name of a regressor in the model matrix for the horizontal axis.  

layout  
If set to a value like \texttt{c(1, 1)} or \texttt{c(4, 3)}, the layout of the graph will have this many rows and columns. If not set, the program will select an appropriate layout. If the number of graphs exceed nine, you must select the layout yourself, or you will get a maximum of nine per page. If \texttt{layout=NA}, the function does not set the layout and the user can use the \texttt{par} function to control the layout, for example to have plots from two models in the same graphics window.  

main  
The title of the plot; if missing, one will be supplied.  

ask  
If \texttt{TRUE}, ask the user before drawing the next plot; if \texttt{FALSE} don't ask.  

id  
controls point identification; if \texttt{FALSE}, no points are identified; can be a list of named arguments to the \texttt{showLabels} function; \texttt{TRUE}, the default, is equivalent to \texttt{list(method=list(abs(residuals(model, type="pearson")), "x"), n=2, cex=1, col=carPalette()[1], location="lr"), which identifies the 2 points with the largest residuals and the 2 points with the most extreme horizontal values (i.e., largest partial leverage). For \texttt{avPlot3d}, point identification is through \texttt{Identify3d}.  

col  
color for points; the default is the \textit{second} entry in the current \texttt{car} palette (see \texttt{carPalette} and \texttt{par}).  

col.lines  
color for the fitted line.  

pch  
plotting character for points; default is 1 (a circle, see \texttt{par}).  

lwd  
line width; default is 2 (see \texttt{par}).  

pt.wts  
size of plotted points; default is taken from \texttt{par("cex")}.  

if \texttt{TRUE} (the default is \texttt{FALSE}), for a weighted least squares fit or a generalized linear model, the areas of plotted points are made proportional to the weights, with the average size taken from the \texttt{cex} argument.
avPlots

xlab  x-axis label. If omitted a label will be constructed.
ylab  y-axis label. If omitted a label will be constructed.
type if "Wang" use the method of Wang (1985); if "Weisberg" use the method in the Arc software associated with Cook and Weisberg (1999).
grid  If TRUE, the default, a light-gray background grid is put on the graph.
ellipse controls plotting data-concentration ellipses. If FALSE (the default), no ellipses are plotted. Can be a list of named values giving levels, a vector of one or more bivariate-normal probability-contour levels at which to plot the ellipses; and robust, a logical value determing whether to use the cov.trob function in the MASS package to calculate the center and covariance matrix for the data ellipses. TRUE is equivalent to list(levels=c(.5, .95), robust=TRUE).
marginal.scale  Consider an added-variable plot of Y versus X given Z. If this argument is FALSE then the limits on the horizontal axis are determined by the range of the residuals from the regression of X on Z and the limits on the vertical axis are determined by the range of the residuals from the regresssion of Y on Z. If the argument is TRUE, then the limits on the horizontal axis are determined by the range of X minus it mean, and on the vertical axis by the range of Y minus its means; adjustment is made if necessary to include outliers. This scaling allows visualization of the correlations between Y and Z and between X and Z. For example, if the X and Z are highly correlated, then the points will be concentrated on the middle of the plot.
fit one or both of "linear" (linear least-squares, the default) and "robust" (robust regression) surfaces to be fit to the 3D added-variable plot; see scatter3d for details.
...

avPlots passes these arguments to avPlot and avPlot passes them to plot; for avPlot3d, additional optional arguments to be passed to scatter3d.

Details

The functions intended for direct use are avPlots (for which avp is an abbreviation) and avPlot3d.

Value

These functions are used for their side effect id producing plots, but also invisibly return the coordinates of the plotted points.

    avPlot3d(lm(prestige ~ income + education + type, data=Duncan),
             "income", "education")
}
```

**bcPower**

*Box-Cox, Box-Cox with Negatives Allowed, Yeo-Johnson and Basic Power Transformations*

**Description**

Transform the elements of a vector or columns of a matrix using, the Box-Cox, Box-Cox with negatives allowed, Yeo-Johnson, or simple power transformations.

**Usage**

```r
bcPower(U, lambda, jacobian.adjusted=FALSE, gamma=NULL)
bcnPower(U, lambda, jacobian.adjusted = FALSE, gamma)
bcnPowerInverse(z, lambda, gamma)
yjPower(U, lambda, jacobian.adjusted = FALSE)
basicPower(U,lambda, gamma=NULL)
```
bcPower

Arguments

U  A vector, matrix or data.frame of values to be transformed
lambda  Power transformation parameter with one element for each column of U, usually in the range from −2 to 2.
jacobian.adjusted  If TRUE, the transformation is normalized to have Jacobian equal to one. The default FALSE is almost always appropriate.
gamma  For bcPower or basicPower, the transformation is of U + gamma, where gamma is a positive number called a start that must be large enough so that U + gamma is strictly positive. For the bcnPower, Box-cox power with negatives allowed, see the details below.
z  a numeric vector the result of a call to bcnPower with jacobian.adjusted=FALSE.

Details

The Box-Cox family of scaled power transformations equals \((x^\lambda - 1)/\lambda\) for \(\lambda \neq 0\), and \(\log(x)\) if \(\lambda = 0\). The bcPower function computes the scaled power transformation of \(x = U + \gamma\), where \(\gamma\) is set by the user so \(U + \gamma\) is strictly positive for these transformations to make sense.

The Box-Cox family with negatives allowed was proposed by Hawkins and Weisberg (2017). It is the Box-Cox power transformation of \(z = 0.5(U + \sqrt{U^2 + \gamma^2})\)

where for this family \(\gamma\) is either user selected or is estimated. gamma must be positive if \(U\) includes negative values and non-negative otherwise, ensuring that \(z\) is always positive. The bcnPower transformations behave similarly to the bcPower transformations, and introduce less bias than is introduced by setting the parameter \(\gamma\) to be non-zero in the Box-Cox family.

The function bcnPowerInverse computes the inverse of the bcnPower function, so \(U = \text{bcnPowerInverse}(\text{bcnPower}(U, \lambda=\lambda, \text{jacobian.adjusted}=\text{FALSE}, \gamma=\gamma), \lambda=\lambda, \gamma=\gamma)\) is true for any permitted value of \(\gamma\) and \(\lambda\).

If family="yeo.johnson" then the Yeo-Johnson transformations are used. This is the Box-Cox transformation of \(U + 1\) for nonnegative values, and of \(|U| + 1\) with parameter \(2 - \lambda\) for \(U\) negative.

The basic power transformation returns \(U^\lambda\) if \(\lambda\) is not 0, and \(\log(\lambda)\) otherwise for \(U\) strictly positive.

If jacobian.adjusted is TRUE, then the scaled transformations are divided by the Jacobian, which is a function of the geometric mean of \(U\) for skewPower and yjPower and of \(U + \gamma\) for bcPower. With this adjustment, the Jacobian of the transformation is always equal to 1. Jacobian adjustment facilitates computing the Box-Cox estimates of the transformation parameters.

Missing values are permitted, and return NA where ever \(U\) is equal to NA.

Value

Returns a vector or matrix of transformed values.

Examples

```r
U <- c(NA, (-3:3))
## Not run: bcPower(U, 0) # produces an error as U has negative values
bcPower(U, 0, gamma=4)
bcPower(U, .5, jacobian.adjusted=TRUE, gamma=4)
bcnPower(U, 0, gamma=2)
basicPower(U, lambda = 0, gamma=4)
yjPower(U, 0)
V <- matrix(1:10, ncol=2)
bcPower(V, c(0, 2))
basicPower(V, c(0,1))
```

Description

This function provides a simple front-end to the `boot` function in the `boot` package that is tailored to bootstrapping based on regression models. Whereas `boot` is very general and therefore has many arguments, the `Boot` function has very few arguments.

Usage

```r
Boot(object, f=coef, labels=names(f(object)), R=999,
    method=c("case", "residual"), ncores=1, ...)

## Default S3 method:
Boot(object, f=coef, labels=names(f(object)),
    R=999, method=c("case", "residual"), ncores=1,
    start = FALSE, ...)

## S3 method for class 'lm'
Boot(object, f=coef, labels=names(f(object))
```

**Bootstrapping for regression models**

This function provides a simple front-end to the `boot` function in the `boot` package that is tailored to bootstrapping based on regression models. Whereas `boot` is very general and therefore has many arguments, the `Boot` function has very few arguments.

Usage

```r
Boot(object, f=coef, labels=names(f(object)), R=999,
    method=c("case", "residual"), ncores=1, ...)

## Default S3 method:
Boot(object, f=coef, labels=names(f(object)),
    R=999, method=c("case", "residual"), ncores=1,
    start = FALSE, ...)

## S3 method for class 'lm'
Boot(object, f=coef, labels=names(f(object)),
```
R=999, method=c("case", "residual"), ncores=1, ...

## S3 method for class 'glm'
Boot(object, f=coef, labels=names(f(object)),
   R=999, method=c("case", "residual"), ncores=1, ...)

## S3 method for class 'nls'
Boot(object, f=coef, labels=names(f(object)),
   R=999, method=c("case", "residual"), ncores=1, ...)

Arguments

object A regression object of class "lm", "glm" or "nls". The function may work with other regression objects that support the update method and have a subset argument. See discussion of the default method in the details below.

f A function whose one argument is the name of a regression object that will be applied to the updated regression object to compute the statistics of interest. The default is coef, to return regression coefficient estimates. For example, \( f = \text{function(obj) coef(obj)[1]}/\text{coef(obj)[2]} \) will bootstrap the ratio of the first and second coefficient estimates.

labels Provides labels for the statistics computed by f. Default labels are obtained from a call to f, or generic labels if f does not return names.

R Number of bootstrap samples. The number of bootstrap samples actually computed may be smaller than this value if either the fitting method is iterative and fails to converge for some bootstrap samples, or if the rank of a fitted model is different in a bootstrap replication than in the original data.

method The bootstrap method, either “case” for resampling cases or “residuals” for a residual bootstrap. See the details below. The residual bootstrap is available only for lm and nls objects and will return an error for glm objects.

... Arguments passed to the boot function, see boot.

start Should the estimates returned by f be passed as starting values for each bootstrap iteration? Alternatively, start can be a numeric vector of starting values. The default is to use the estimates from the last bootstrap iteration as starting values for the next iteration.

ncores A numeric argument that specifies the number of cores for parallel processing for unix systems. If less than or equal to 1, no parallel processing will be used. Note in a Windows platform will produce a warning and set this argument to 1.

Details

Boot uses a regression object and the choice of method, and creates a function that is passed as the statistic argument to the boot function in the boot package. The argument R is also passed to boot. If ncores is greater than 1, then the parallel and ncpus arguments to boot are set appropriately to use multiple cores, if available, on your computer. All other arguments to boot are kept at their default values unless you pass values for them.
The methods available for \texttt{lm} and \texttt{nls} objects are “case” and “residual”. The case bootstrap resamples from the joint distribution of the terms in the model and the response. The residual bootstrap fixes the fitted values from the original data, and creates bootstraps by adding a bootstrap sample of the residuals to the fitted values to get a bootstrap response. It is an implementation of Algorithm 6.3, page 271, of Davison and Hinkley (1997). For \texttt{nls} objects ordinary residuals are used in the resampling rather than the standardized residuals used in the \texttt{lm} method. The residual bootstrap for generalized linear models has several competing approaches, but none are without problems. If you want to do a residual bootstrap for a \texttt{glm}, you will need to write your own call to \texttt{boot}.

For the default object to work with other types of regression models, the model must have methods for the the following generic functions: \texttt{ residuals(object, type="pearson")} must return Pearson residuals; \texttt{fitted(object)} must return fitted values; \texttt{hatvalues(object)} should return the leverages, or perhaps the value 1 which will effectively ignore setting the hatvalues. In addition, the data argument should contain no missing values among the columns actually used in fitting the model, as the resampling may incorrectly attempt to include cases with missing values. For \texttt{lm}, \texttt{glm} and \texttt{nls}, missing values cause the return of an error message.

An attempt to fit using a bootstrap sample may fail. In a \texttt{lm} or \texttt{glm} fit, the bootstrap sample could have a different rank from the original fit. In an \texttt{nls} fit, convergence may not be obtained for some bootstraps. In either case, \texttt{NA} are returned for the value of the function \texttt{f}. The summary methods handle the \texttt{NA}s appropriately.

Fox and Weisberg (2017) cited below discusses this function and provides more examples.

Value

See \texttt{boot} for the returned value of the structure returned by this function.

Warning

C=A call like \texttt{car::Boot(object, method="residual")} will fail for the residual method if not preceded by \texttt{library(car)}. If \texttt{method="case"} the \texttt{library(car)} command is not required.

Author(s)

Sanford Weisberg, <sandy@umn.edu>. Achim Zeileis added multicore support, and also fixed the default method to work for many more regression models.

Functions that work with boot objects from the boot package are boot.array, boot.ci, plot.boot and empinf. Additional functions in the car package are summary.boot, confint.boot, and hist.boot.

Examples

m1 <- lm(Fertility ~ ., swiss)
betahat.boot <- Boot(m1, R=199) # 199 bootstrap samples--too small to be useful
summary(betahat.boot) # default summary
confint(betahat.boot)
hist(betahat.boot)

# Bootstrap for the estimated residual standard deviation:
sigmahat.boot <- Boot(m1, R=199, f=sigmaHat, labels="sigmaHat")
summary(sigmahat.boot)
confint(sigmahat.boot)

### boxCox

**Graph the profile log-likelihood for Box-Cox transformations in 1D, or in 2D with the bcnPower family.**

#### Description

Computes and optionally plots profile log-likelihoods for the parameter of the Box-Cox power family, the Yeo-Johnson power family, or for either of the parameters in a bcnPower family. This is a slight generalization of the boxcox function in the MASS package that allows for families of transformations other than the Box-Cox power family. the boxCox2d function produces a contour plot of the two-dimensional likelihood profile for the bcnPower family.

#### Usage

boxCox(object, ...)

## Default S3 method:
boxCox(object,
lambda = seq(-2, 2, 1/10), plotit = TRUE,
interp = plotit, eps = 1/50,
xlab=NULL, ylab=NULL, main= "Profile Log-likelihood",
family="bcPower",
param=c("lambda", "gamma"), gamma=NULL,
grid=TRUE, ...)

## S3 method for class 'formula'
boxCox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE, family = "bcPower",
param = c("lambda", "gamma"), gamma = NULL, grid = TRUE,
...)

---

**boxCox**

Graph the profile log-likelihood for Box-Cox transformations in 1D, or in 2D with the bcnPower family.
boxCox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE, ...)

boxCox2d(x, ksd = 4, levels = c(0.5, 0.95, 0.99, 0.999),
main = "bcnPower Log-likelihood", grid=TRUE, ...)

Arguments

- **object**: a formula or fitted model object of class lm or aov.
- **lambda**: vector of values of \( \lambda \), with default (-2, 2) in steps of 0.1, where the profile log-likelihood will be evaluated.
- **plotit**: logical which controls whether the result should be plotted; default TRUE.
- **interp**: logical which controls whether spline interpolation is used. Default to TRUE if plotting with lambda of length less than 100.
- **eps**: Tolerance for lambda = 0; defaults to 0.02.
- **xlab**: defaults to "lambda" or "gamma".
- **ylab**: defaults to "log-Likelihood" or for bcnPower family to the appropriate label.
- **family**: Defaults to "bcPower" for the Box-Cox power family of transformations. If set to "yjPower" the Yeo-Johnson family, which permits negative responses, is used. If set to bcnPower the function gives the profile log-likelihood for the parameter selected via param.
- **param**: Relevant only to family="bcnPower", produces a profile log-likelihood for the parameter selected, maximizing over the remaining parameter.
- **gamma**: For use when the family="bcnPower", param="gamma". If this is a vector of positive values, then the profile log-likelihood for the location (or start) parameter in the bcnPower family is evaluated at these values of gamma. If gamma is NULL, then evaluation is done at 100 equally spaced points between min(.01, gmax - 3*sd) and gmax + 3*sd, where gmax is the maximum likelihood estimate of gamma, and sd is the sd of the response. See bcnPower for the definition of gamma.
- **grid**: If TRUE, the default, a light-gray background grid is put on the graph.
- **...**: additional arguments passed to plot, or to contour with boxCox2d.
- **x**: An object created by a call to powerTransform using family="bcnPower".
- **ksds**: Contour plotting of the log-likelihood surface will cover plus of minus ksd standard deviations on each axis.
- **levels**: Contours will be drawn at the values of levels. For example, levels=c(.5, .99) would display two contours, at the 50% level and at the 99% level.
- **main**: Title for the contour plot or the profile log-likelihood plot

Details

The boxCox function is an elaboration of the boxcox function in the MASS package. The first 7 arguments are the same as in boxcox, and if the argument family="bcPower" is used, the result is essentially identical to the function in MASS. Two additional families are the yjPower and
boxCox

bcnPower families that allow a few values of the response to be non-positive. The bcnPower family has two parameters: a power $\lambda$ and a start or location parameter $\gamma$, and the boxCox function can be used to obtain a profile log-likelihood for either parameter with $\lambda$ as the default. Alternatively, the boxCox2d function can be used to get a contour plot of the profile log-likelihood.

Value

Both functions are designed for their side effects of drawing a graph. The boxCox function returns a list of the lambda (or possibly, gamma) vector and the computed profile log-likelihood vector, invisibly if the result is plotted. If plotit=TRUE plots log-likelihood vs lambda and indicates a 95% confidence interval about the maximum observed value of lambda. If interp=TRUE, spline interpolation is used to give a smoother plot.

Examples

```r
with(trees, boxCox(Volume ~ log(Height) + log(Girth), data = trees,
                  lambda = seq(-0.25, 0.25, length = 10)))

data("quine", package = "MASS")
with(quine, boxCox(Days ~ Eth*Sex*Age*Lrn,
                  lambda = seq(-0.05, 0.45, len = 20), family="yjPower"))
```
boxCoxVariable

**Description**

Computes a constructed variable for the Box-Cox transformation of the response variable in a linear model.

**Usage**

`boxCoxVariable(y)`

**Arguments**

- `y` response variable.

**Details**

The constructed variable is defined as $y[\log(y/\bar{y}) - 1]$, where $\bar{y}$ is the geometric mean of $y$.

The constructed variable is meant to be added to the right-hand-side of the linear model. The t-test for the coefficient of the constructed variable is an approximate score test for whether a transformation is required.

If $b$ is the coefficient of the constructed variable, then an estimate of the normalizing power transformation based on the score statistic is $1 - b$. An added-variable plot for the constructed variable shows leverage and influence on the decision to transform $y$.

**Value**

a numeric vector of the same length as $y$.

Boxplot

Boxplots With Point Identification

Description

Boxplot is a wrapper for the standard R `boxplot` function, providing point identification, axis labels, and a formula interface for boxplots without a grouping variable.

Usage

```r
Boxplot(y, ...)
```

## Default S3 method:
```r
Boxplot(y, g, id=TRUE, xlab, ylab, ...)
```

## S3 method for class 'formula'
```r
Boxplot(formula, data=NULL, subset, na.action=NULL,
        id=TRUE, xlab, ylab, ...)
```

## S3 method for class 'list'
```r
Boxplot(y, xlab="", ylab="", ...)
```

## S3 method for class 'data.frame'
```r
Boxplot(y, id=TRUE, ...)
```

## S3 method for class 'matrix'
```r
Boxplot(y, ...)
```

Arguments

- `y` a numeric variable for which the boxplot is to be constructed; a list of numeric variables, each element of which will be treated as a group; a numeric data frame or a numeric matrix, each of whose columns will be treated as a group.

- `g` a grouping variable, usually a factor, for constructing parallel boxplots.

- `id` a list of named elements giving one or more specifications for labels of individual points ("outliers"): `n`, the maximum number of points to label (default 10); `location`, "lr" (left or right) of points or "avoid" to try to avoid overplotting; `method`, one of "y" (automatic, the default), "identify" (interactive), or "none"; `col` for labels (default is the first color in `carPalette()`); and `cex` size of labels (default is 1). Can be `FALSE` to suppress point identification or

---

Boxplot
TRUE (the default) to use all defaults. This is similar to how showLabels handles point labels for other functions in the car package, except that the usual default is id=FALSE.

xlab, ylab  text labels for the horizontal and vertical axes; if missing, Boxplot will use the variable names, or, in the case of a list, data frame, or matrix, empty labels.

formula a `model` formula, of the form ~ y to produce a boxplot for the variable y, or of the form y ~ g, y ~ g1*g2*... or y ~ g1 + g2 + ... to produce parallel boxplots for y within levels of the grouping variable(s) g, etc., usually factors.

data, subset, na.action
as for statistical modeling functions (see, e.g., lm).

... further arguments, such as at, to be passed to boxplot.

Author(s)
John Fox <jfox@mcmaster.ca>, with a contribution from Steve Ellison to handle at argument (see boxplot).

Examples
Boxplot(~income, data=Prestige, id=list(n=Inf)) # identify all outliers
Boxplot(income ~ type, data=Prestige)
Boxplot(income ~ type, data=Prestige, at=c(1, 3, 2))
Boxplot(k5 + k618 ~ lfp*wc, data=Mroz)
with(Prestige, Boxplot(income, id=list(labels=rownames(Prestige))))
with(Prestige, Boxplot(income, type, id=list(labels=rownames(Prestige))))
Boxplot(scale(Prestige[, 1:4]))

boxTidwell  Box-Tidwell Transformations

Description
Computes the Box-Tidwell power transformations of the predictors in a linear model.
### boxTidwell

#### Usage

```r
boxTidwell(y, ...)  
```

```r
## S3 method for class 'formula'
boxTidwell(formula, other.x=NULL, data=NULL, subset,
            na.action=getOption("na.action"), verbose=FALSE, tol=0.001,
            max.iter=25, ...)
```

```r
## Default S3 method:
boxTidwell(y, x1, x2=NULL, max.iter=25, tol=0.001,
           verbose=FALSE, ...)
```

```r
## S3 method for class 'boxTidwell'
print(x, digits=getOption("digits") - 2, ...)
```

#### Arguments

- `formula` two-sided formula, the right-hand-side of which gives the predictors to be transformed.
- `other.x` one-sided formula giving the predictors that are not candidates for transformation, including (e.g.) factors.
- `data` an optional data frame containing the variables in the model. By default the variables are taken from the environment from which `boxTidwell` is called.
- `subset` an optional vector specifying a subset of observations to be used.
- `na.action` a function that indicates what should happen when the data contain NAs. The default is set by the `na.action` setting of `options`.
- `verbose` if `TRUE` a record of iterations is printed; default is `FALSE`.
- `tol` if the maximum relative change in coefficients is less than `tol` then convergence is declared.
- `max.iter` maximum number of iterations.
- `y` response variable.
- `x1` matrix of predictors to transform.
- `x2` matrix of predictors that are not candidates for transformation.
- `...` not for the user.
- `x` `boxTidwell` object.
- `digits` number of digits for rounding.

#### Details

The maximum-likelihood estimates of the transformation parameters are computed by Box and Tidwell’s (1962) method, which is usually more efficient than using a general nonlinear least-squares routine for this problem. Score tests for the transformations are also reported.

#### Value

An object of class `boxTidwell`, which is normally just printed.

## S3 method for class 'glm'
brief(object, terms = ~ ., 
        intercept=missing(terms), pvalues=FALSE, 
        digits=3, horizontal=TRUE, vcov., dispersion, exponentiate, ...)

## S3 method for class 'multinom'
brief(object, terms = ~ ., 
        intercept=missing(terms), pvalues=FALSE, 
        digits=3, horizontal=TRUE, exponentiate=TRUE, ...)

## S3 method for class 'polr'
brief(object, terms = ~ ., 
        intercept, pvalues=FALSE, 
        digits=3, horizontal=TRUE, exponentiate=TRUE, ...)

## Default S3 method:
brief(object, terms = ~ ., 
        intercept=missing(terms), pvalues=FALSE, 
        digits=3, horizontal=TRUE, ...)

### Arguments

- **object**
  - a data or model object to abbreviate.

- **rows**
  - for a matrix or data frame, a 2-element integer vector with the number of rows to print at the beginning and end of the display; for a vector or factor, the number of lines of output to show at the beginning and end; for a list, the number of elements to show at the beginning and end; for a function, the number of lines to show at the beginning and end.

- **cols**
  - for a matrix or data frame, a 2-element integer vector with the number of columns to print at the beginning (i.e., left) and end (right) of the display.

- **head, tail**
  - alternatives to the rows argument; if TRUE, print the first or last 6 rows; can also be the number of the first or last few rows to print; only one of heads and tails should be specified; ignored if FALSE (the default).

- **elided**
  - controls whether to report the number of elided elements, rows, or columns; default is TRUE.

- **classes**
  - show the class of each column of a data frame at the top of the column; the classes are shown in single-character abbreviated form—e.g., [f] for a factor, [i] for an integer variable, [n] for a numeric variable, [c] for a character variable.
**brief**

**terms**  
a one-sided formula giving the terms to summarize; the default is \( \sim \) — i.e., to summarize all terms in the model.

**intercept**  
whether or not to include the intercept; the default is TRUE unless the terms argument is given, in which case the default is FALSE; ignored for polr models.

**pvalues**  
include the p-value for each coefficient in the table; default is FALSE.

**exponentiate**  
for a "glm" or "glmerMod" model using the log or logit link, or a "polr" or "multinom" model, show exponentiated coefficient estimates and confidence bounds.

**digits**  
significant digits for printing.

**horizontal**  
if TRUE (the default), orient the summary produced by brief horizontally, which typically saves space.

**dispersion**  
use an estimated covariance matrix computed as the dispersion times the unscaled covariance matrix; see `summary.glm`.

**vcov.**  
either a matrix giving the estimated covariance matrix of the estimates, or a function that when called with object as an argument returns an estimated covariance matrix of the estimates. If not set, `vcov(object, complete=FALSE)` is called to use the usual estimated covariance matrix with aliased regressors removed. Other choices include the functions documented at `hccm`, and a bootstrap estimate `vcov.=vcov(Boot(object))`; see the documentation for `Boot`.  
**NOTES:**  
(1) The dispersion and vcov. arguments may not both be specified.  
(2) Setting `vcov.=vcov` returns an error if the model includes aliased terms; use `vcov.=vcov(object, complete=FALSE)`.  
(3) The hccm method will generally return a matrix of full rank even if the model has aliased terms. Similarly `vcov.=vcov(Boot(object))` may return a full rank matrix.  

...  
arguments to pass down.

**Value**

Invisibly returns object for a data object, or summary for a model object.

**Note**

The method `brief.matrix` calls `brief.data.frame`, and `brief.tbl` (for tibbles) calls `print`.

spread.level.plot(...)  
```
Arguments

... pass arguments down.

Details

av.plot and av.plots are replaced by avPlot and avPlots functions.
box.cox and bc are now replaced by bcPower.
box.cox.powers is replaced by powerTransform.
box.cox.var is replaced by boxCoxVariable.
box.tidwell is replaced by boxTidwell.
cookd is replaced by cooks.distance in the stats package.
confidence.ellipse is replaced by confidenceEllipse.
ceres.plot and ceres.plots are now replaced by the ceresPlot and ceresPlots functions.
cr.plot and cr.plots are now replaced by the crPlot and crPlots functions.
data.ellipse is replaced by dataEllipse.
durbin.watson is replaced by durbinWatsonTest.
levene.test is replaced by leveneTest function.
leverage.plot and leverage.plots are now replaced by the leveragePlot and leveragePlots functions.
linear.hypothesis is replaced by the linearHypothesis function.
cncv.test is replaced by ncvTest.
outlier.test is replaced by outlierTest.
qq.plot is replaced by qqPlot.
 skewPower is replaced by bcnPower.
spread.level.plot is replaced by spreadLevelPlot.
Arguments

... arguments to pass to methods.

Details

These functions are replaced by Boot.

car-internal.Rd

Internal Objects for the car package

Description

These objects (currently only the .carEnv environment) are exported for technical reasons and are not for direct use.

Author(s)

John Fox <jfox@mcmaster.ca>

carHexsticker

View the Official Hex Sticker for the car Package

Description

Open the official hex sticker for the car package in your browser

Usage

carHexsticker()

Value

Used for its side effect of opening the hex sticker for the car package in your browser.

Author(s)

John Fox <jfox@mcmaster.ca>

Examples

```r
## Not run: # intended for interactive use
carHexsticker()
```

```r
## End(Not run)
```
carPalette  

Set or Retrieve car Package Color Palette

Description

This function is used to set or retrieve colors to be used in car package graphics functions.

Usage

carPalette(palette)

Arguments

palette

If missing, returns the colors that will be used in car graphics; if present, the colors to be used in graphics will be set. The palette argument may also be one of "car" or "default" to use the default car palette (defined below), "R" to use the default R palette, or "colorblind" to use a colorblind-friendly palette (from https://jfly.uni-koeln.de/color/).

Details

This function sets or returns the value of options(carPalette=pallete) that will be use in car graphics functions to determine colors. The default is c("black", "blue", "magenta", "cyan", "orange", "gray", "green3", "red")), which is nearly a permutation of the colors returned by the standard palette function that minimizes the use of red and green in the same graph, and that substitutes orange for the often hard to see yellow.

Value

Invisibly returns the previous value of the car palette.

Author(s)

Sanford Weisberg and John Fox

See Also

palette, colors
Examples

```r
# Standard color palette
palette()
# car standard color palette
carPalette()
# set colors to all black
carPalette(rep("black", 8))
# Use a custom color palette with 12 distinct colors
carPalette(sample(colors(distinct=TRUE), 12))
# restore default
carPalette("default")
```

---

carWeb

**Access to the R Companion to Applied Regression Website**

Description

This function will access the website for *An R Companion to Applied Regression*, or setup files or data.

Usage

```r
carWeb(page = c("webpage", "errata", "taskviews"), script, data, setup)
```

Arguments

- `page` A character string indicating what page to open. The default "webpage" will open the main web page, "errata" displays the errata sheet for the book, "taskviews" fetches and displays a list of available task views from CRAN.
- `script` The quoted name of a chapter in *An R Companion to Applied Regression*, like "chap-1", "chap-2", up to "chap-10". All the R commands used in that chapter will be displayed in your browser, where you can save them as a text file.
- `data` The quoted name of a data file in *An R Companion to Applied Regression*, like "Duncan.txt" or "Prestige.txt". The file will be opened in your web browser. You do not need to specify the extension .txt
- `setup` If TRUE this command will download a number of files to your computer that are discussed in Fox and Weisberg (2019), beginning in Chapter 1.

Value

Either displays a web page or a PDF document or downloads files to your working directory.

Author(s)

Sanford Weisberg, based on the function UsingR in the *UsingR* package by John Verzani
ceresPlots

References

Examples

```r
## Not run: # meant for interactive use
carWeb()
carWeb(setup=TRUE)
## End(Not run)
```

ceresPlots

*Ceres Plots*

Description

These functions draw Ceres plots for linear and generalized linear models.

Usage

```r
ceresPlots(model, ...)

# Default S3 method:
ceresPlots(model, terms = ~., layout = NULL, ask, main, ...)

ceresPlot(model, ...)

# S3 method for class 'lm'
ceresPlot(model, variable, id=FALSE, line=TRUE, smooth=TRUE, col=carPalette()[1], col.lines=carPalette()[-1], xlab, ylab, pch=1, lwd=2, grid=TRUE, ...)

# S3 method for class 'glm'
ceresPlot(model, ...)
```

Arguments

- `model`: model object produced by `lm` or `glm`.
- `terms`: A one-sided formula that specifies a subset of the regressors. One component-plus-residual plot is drawn for each term. The default `~.` is to plot against all numeric predictors. For example, the specification `terms = ~. - X3` would plot against all predictors except for `X3`. Factors and nonstandard predictors such as B-splines are skipped. If this argument is a quoted name of one of the regressors, the component-plus-residual plot is drawn for that predictor only.
layout If set to a value like c(1, 1) or c(4, 3), the layout of the graph will have this many rows and columns. If not set, the program will select an appropriate layout. If the number of graphs exceed nine, you must select the layout yourself, or you will get a maximum of nine per page. If layout=NA, the function does not set the layout and the user can use the par function to control the layout, for example to have plots from two models in the same graphics window.

ask If TRUE, ask the user before drawing the next plot; if FALSE, the default, don’t ask. This is relevant only if not all the graphs can be drawn in one window.

main Overall title for any array of ceres plots; if missing a default is provided.

... ... ceresPlots passes these arguments to ceresPlot. ceresPlot passes them to plot.

variable A quoted string giving the name of a variable for the horizontal axis

id controls point identification; if FALSE (the default), no points are identified; can be a list of named arguments to the showLabels function; TRUE is equivalent to list(method=list(abs(residuals(model, type="pearson")),"x"), n=2, cex=1, col=carPalette()[1], location="lr"), which identifies the 2 points with the largest residuals and the 2 points with the most extreme horizontal (X) values.

line TRUE to plot least-squares line.

smooth specifies the smoother to be used along with its arguments; if FALSE, no smoother is shown; can be a list giving the smoother function and its named arguments; TRUE, the default, is equivalent to list(smoother=loessLine). See ScatterplotSmoothers for the smoothers supplied by the car package and their arguments. Ceres plots do not support variance smooths.

col color for points; the default is the first entry in the current car palette (see carPalette and par).

col.lines a list of at least two colors. The first color is used for the ls line and the second color is used for the fitted lowess line. To use the same color for both, use, for example, col.lines=c("red", "red")

xlab,ylab labels for the x and y axes, respectively. If not set appropriate labels are created by the function.

pch plotting character for points; default is 1 (a circle, see par).

lwd line width; default is 2 (see par).

grid If TRUE, the default, a light-gray background grid is put on the graph

Details

Ceres plots are a generalization of component+residual (partial residual) plots that are less prone to leakage of nonlinearity among the predictors.

The function intended for direct use is ceresPlots.

The model cannot contain interactions, but can contain factors. Factors may be present in the model, but Ceres plots cannot be drawn for them.
Value
NULL. These functions are used for their side effect: producing plots.

Examples

ceresPlots(lm(prestige~income+education+type, data=Prestige), terms= ~ . - type)

```r
compareCoefs(..., se = TRUE, zvals = FALSE, pvals = FALSE, vcov.,
             print = TRUE, digits = 3)
```

**Description**
This function extracts estimates of regression parameters and their standard errors from one or more models and prints them in a table.

**Usage**
```
compareCoefs(..., se = TRUE, zvals = FALSE, pvals = FALSE, vcov.,
             print = TRUE, digits = 3)
```

**Arguments**

... One or more regression-model objects. These may be of class `lm`, `glm`, `nls`, or any other regression method for which the functions `coef` and `vcov` return appropriate values, or if the object inherits from the `mer` class created by the `lme4` package or `lme` in the `nlme` package.

se If TRUE, the default, show standard errors as well as estimates.

zvals If TRUE (the default is FALSE), print Wald statistics, the ratio of each coefficient to its standard error.
Contrasts

pvals

If code TRUE (the default is FALSE), print two-sided p-values from the standard normal distribution corresponding to the Wald statistics.

vcov.

an optional argument, specifying a function to be applied to all of the models, returning a coefficient covariance matrix for each, or a list with one element for each model, with each element either containing a function to be applied to the corresponding model or a coefficient covariance matrix for that model. If omitted, vcov is applied to each model. This argument can also be a list of estimated covariance matrices of the coefficient estimates.

print

If TRUE, the default, the results are printed in a nice format using printCoefmat. If FALSE, the results are returned as a matrix

digits

Passed to the printCoefmat function for printing the result.

Value

This function is mainly used for its side-effect of printing the result. It also invisibly returns a matrix of estimates, standard errors, Wald statistics, and p-values.

compareCoefs(mod1, mod1, vcov.=list(vcov, hccm))

Contrasts

Functions to Construct Contrasts

Description

These are substitutes for similarly named functions in the stats package (note the uppercase letter starting the second word in each function name). The only difference is that the contrast functions from the car package produce easier-to-read names for the contrasts when they are used in statistical models.

The functions and this documentation are adapted from the stats package.
Usage

contr.Treatment(n, base = 1, contrasts = TRUE)
contr.Sum(n, contrasts = TRUE)
contr.Helmert(n, contrasts = TRUE)

Arguments

n a vector of levels for a factor, or the number of levels.
base an integer specifying which level is considered the baseline level. Ignored if
contrasts is FALSE.
contrasts a logical indicating whether contrasts should be computed.

Details

These functions are used for creating contrast matrices for use in fitting analysis of variance
and regression models. The columns of the resulting matrices contain contrasts which can be used for
coding a factor with \( n \) levels. The returned value contains the computed contrasts. If the argument
contrasts is FALSE then a square matrix is returned.

Several aspects of these contrast functions are controlled by options set via the \texttt{options}
command:

decorate.contrasts This option should be set to a 2-element character vector containing the pre-
fix and suffix characters to surround contrast names. If the option is not set, then \texttt{c(”[”, ”]”)}
is used. For example, setting \texttt{options(decorate.contrasts=c(”.”, ””))} produces con-
trast names that are separated from factor names by a period. Setting \texttt{options( decorate.contrasts=c(””, ””))} reproduces the behaviour of the R base contrast functions.

decorate.contr.Treatment A character string to be appended to contrast names to signify treat-
ment contrasts; if the option is unset, then ”T.” is used.

decorate.contr.Sum Similar to the above, with default ”S.”.

decorate.contr.Helmert Similar to the above, with default ”H.”.

contr.Sum.show.levels Logical value: if TRUE (the default if unset), then level names are used
for contrasts; if FALSE, then numbers are used, as in \texttt{contr.sum} in the base package.

Note that there is no replacement for \texttt{contr.poly} in the base package (which produces orthogonal-
polynomial contrasts) since this function already constructs easy-to-read contrast names.

Value

A matrix with \( n \) rows and \( k \) columns, with \( k = n - 1 \) if contrasts is TRUE and \( k = n \) if contrasts
is FALSE.

**crPlots**

**Component+Residual (Partial Residual) Plots**

**Description**

These functions construct component+residual plots, also called partial-residual plots, for linear and generalized linear models.
Usage

crPlots(model, ...)  

## Default S3 method:  
crPlots(model, terms = ~., layout = NULL, ask, main, ...)  

crp(...)  

crPlot(model, ...)  

## S3 method for class 'lm'  
crPlot(model, variable, id=FALSE,  
   order=1, line=TRUE, smooth=TRUE,  
   col=carPalette()[1], col.lines=carPalette()[-1],  
   xlab, ylab, pch=1, lwd=2, grid=TRUE, ...)  

crPlot3d(model, var1, var2, ...)  

## S3 method for class 'lm'  
crPlot3d(model, var1, var2,  
   xlab = var1,  
   ylab = paste0("C+R(" , eff$response , ")") , zlab = var2,  
   axis.scales = TRUE, axis.ticks = FALSE, revolutions = 0,  
   bg.col = c("white", "black"),  
   axis.col = if (bg.col == "white") c("darkmagenta", "black", "darkcyan")  
     else c("darkmagenta", "white", "darkcyan"),  
   surface.col = carPalette()[2:3], surface.alpha = 0.5,  
   point.col = "yellow", text.col = axis.col,  
   grid.col = if (bg.col == "white") "black" else "gray",  
   fogtype = c("exp2", "linear", "exp", "none"),  
   fill = TRUE, grid = TRUE, grid.lines = 26,  
   smoother = c("loess", "mgcv", "none"), df.mgcv = NULL, loess.args = NULL,  
   sphere.size = 1, radius = 1, threshold = 0.01, speed = 1, fov = 60,  
   ellipsoid = FALSE, level = 0.5, ellipsoid.alpha = 0.1,  
   id = FALSE,  
   mouseMode=c(none="none", left="polar", right="zoom", middle="fov",  
   wheel="pull"),  
   ...)  

Arguments

model model object produced by lm or glm.

terms A one-sided formula that specifies a subset of the regressors. One component-plus-residual plot is drawn for each regressor. The default ~ . is to plot against all numeric regressors. For example, the specification terms = ~ . - X3 would plot against all regressors except for X3, while terms = ~ log(X4) would give the plot for the predictor X4 that is represented in the model by log(X4). If this
argument is a quoted name of one of the predictors, the component-plus-residual plot is drawn for that predictor only.

**var1, var2**
The quoted names of the two predictors in the model to use for a 3D C+R plot.

**layout**
If set to a value like c(1, 1) or c(4, 3), the layout of the graph will have this many rows and columns. If not set, the program will select an appropriate layout. If the number of graphs exceed nine, you must select the layout yourself, or you will get a maximum of nine per page. If layout=NA, the function does not set the layout and the user can use the par function to control the layout, for example to have plots from two models in the same graphics window.

**ask**
If TRUE, ask the user before drawing the next plot; if FALSE, the default, don’t ask. This is relevant only if not all the graphs can be drawn in one window.

**main**
The title of the plot; if missing, one will be supplied.

**...**
crPlots passes these arguments to crPlot. crPlot passes them to plot.

**variable**
A quoted string giving the name of a variable for the horizontal axis.

**id**
controls point identification; if FALSE (the default), no points are identified; can be a list of named arguments to the showLabels function; TRUE is equivalent to list(method=list(abs(residuals(model, type="pearson")), "x"), n=2, cex=1, col=carPalette()[1], location="lr"), which identifies the 2 points with the largest residuals and the 2 points with the most extreme horizontal (X) values. For 3D C+R plots, see Identify3d.

**order**
order of polynomial regression performed for predictor to be plotted; default 1.

**line**
TRUE to plot least-squares line.

**smooth**
specifies the smoother to be used along with its arguments; if FALSE, no smoother is shown; can be a list giving the smoother function and its named arguments; TRUE, the default, is equivalent to list(smooother=loessLine). See ScatterplotSmoothers for the smoothers supplied by the car package and their arguments.

**smoother**, **df.mgcv**, **loess.args**
smoother specifies quoted name of the surface smoother to use for the partial residuals, either loess, the default, or mgcv. df.mgcv gives the degrees of freedom for the mgcv smoother; NULL, the default, causes the df to be computed by mgcv. loess.args is an optional list with named elements span, family and degree, with default span = 2/3; family = "gaussian" for a binomial or Poisson GLM and family = "symmetric" otherwise; and degree = 1 (see loess).

**col**
color for points; the default is the first entry in the current car palette (see carPalette and par).

**col.lines**
a list of at least two colors. The first color is used for the ls line and the second color is used for the fitted lowess line. To use the same color for both, use, for example, col.lines=c("red", "red")

**xlab, ylab, zlab**
labels for the x and y axes, and for the z axis of a 3D plot. If not set appropriate labels are created by the function. for the 3D C+R plot, the predictors are on the x and z axes and the response on the y (vertical) axis.

**pch**
plotting character for points; default is 1 (a circle, see par).

**lwd**
line width; default is 2 (see par).
grid       If TRUE, the default, a light-gray background grid is put on the graph. For a 3D C+R plot, see the grid argument for `scatter3d`.

grid.lines number of horizontal and vertical lines to be drawn on regression surfaces for 2D C+R plots (26 by default); the square of grid.lines corresponds to the number of points at which the fitted partial regression surface is evaluated and so this argument should not be set too small.

axis.scales, axis.ticks, revolutions, bg.col, axis.col, surface.col, surface.alpha, point.col, text.col see `scatter3d`.

Details

The functions intended for direct use are `crPlots`, for which `crp` is an abbreviation, and, for 3D C+R plots, `crPlot3d`.

For 2D plots, the model cannot contain interactions, but can contain factors. Parallel boxplots of the partial residuals are drawn for the levels of a factor. `crPlot3d` can handle models with two-way interactions.

For 2D C+R plots, the fit is represented by a broken blue line and a smooth of the partial residuals by a solid magenta line. For 3D C+R plots, the fit is represented by a blue surface and a smooth of the partial residuals by a magenta surface.

Value

NULL. These functions are used for their side effect of producing plots.

### deltaMethod

Estimate and Standard Error of a Nonlinear Function of Estimated Regression Coefficients

#### Description

deltaMethod is a generic function that uses the delta method to get a first-order approximate standard error for a nonlinear function of a vector of random variables with known or estimated covariance matrix.

#### Usage

deltaMethod(object, ...)  
  
## Default S3 method:  
  deltaMethod(object, g., vcov., constants, level=0.95,  
  rhs, ..., envir=parent.frame())  
  
## S3 method for class 'lm'  
  deltaMethod(object, g., vcov.=vcov(object, complete=FALSE),  
  parameterNames=names(coef(object)), ..., envir=parent.frame())  
  
## S3 method for class 'nls'  
  deltaMethod(object, g., vcov.=vcov(object, complete=FALSE), ..., envir=parent.frame())  
  
## S3 method for class 'multinom'  
  deltaMethod(object, g., vcov. = vcov(object, complete=FALSE),  
  parameterNames = if (is.matrix(coef(object)))  
  colnames(coef(object)) else names(coef(object)), ..., envir=parent.frame())  
  
## S3 method for class 'polr'  
  deltaMethod(object, g., vcov.=vcov(object, complete=FALSE), ..., envir=parent.frame())  
  
## S3 method for class 'survreg'  
  deltaMethod(object, g., vcov. = vcov(object, complete=FALSE),  
  parameterNames = names(coef(object)), ..., envir=parent.frame())  
  
## S3 method for class 'coxph'  
  deltaMethod(object, g., vcov. = vcov(object, complete=FALSE),  
  parameterNames = names(coef(object)), ..., envir=parent.frame())  
  
## S3 method for class 'mer'  
  deltaMethod(object, g., vcov. = vcov(object, complete=FALSE),  
  parameterNames = names(fixef(object)), ..., envir=parent.frame())  
  
## S3 method for class 'merMod'  
  deltaMethod(object, g., vcov. = vcov(object, complete=FALSE),  
  parameterNames = names(fixef(object)), ..., envir=parent.frame())
## S3 method for class 'lm'
deltaMethod(object, g., vcov. = vcov(object, complete=FALSE),
    parameterNames = names(fixef(object)), ..., envir=parent.frame())
## S3 method for class 'lmList'
deltaMethod(object, g., ..., envir=parent.frame())

### Arguments

- **object**
  For the default method, object is either (1) a vector of \( p \) named elements, so `names(object)` returns a list of \( p \) character strings that are the names of the elements of object; or (2) a model object for which there are `coef` and `vcov` methods, and for which the named coefficient vector returned by `coef` is asymptotically normally distributed with asymptotic covariance matrix returned by `vcov`. For the other methods, `object` is a regression object for which `coef(object)` or `fixef(object)` returns a vector of parameter estimates.

- **g.**
  A quoted string that is the function of the parameter estimates to be evaluated; see the details below.

- **vcov.**
  The (estimated) covariance matrix of the coefficient estimates. For the default method, this argument is required. For all other methods, this argument must either provide the estimated covariance matrix or a function that when applied to `object` returns a covariance matrix. The default is to use the function `vcov`.

- **func**
  A quoted string used to annotate output. The default of `func = g.` is usually appropriate.

- **parameterNames**
  A character vector of length \( p \) that gives the names of the parameters in the same order as they appear in the vector of estimates. This argument will be useful if some of the names in the vector of estimates include special characters, like \( I(x^2) \), or \( x_1:x_2 \) that will confuse the numerical differentiation function. See details below.

- **constants**
  This argument is a named vector whose elements are constants that are used in the `f` argument. It isn’t generally necessary to specify this argument but it may be convenient to do so.

- **level**
  Level for confidence interval, default 0.95.

- **rhs**
  Hypothesized value for the specified function of parameters; if absent no hypothesis test is performed.

- **...**
  Used to pass arguments to the generic method.

- **envir**
  Environment in which `g.` is evaluated; not normally specified by the user.

### Details

Suppose \( x \) is a random vector of length \( p \) that is at least approximately normally distributed with mean \( \beta \) and estimated covariance matrix \( C \). Then any function \( g(\beta) \) of \( \beta \), is estimated by \( g(x) \), which is in large samples normally distributed with mean \( g(\beta) \) and estimated variance \( h'Ch \), where \( h \) is the first derivative of \( g(\beta) \) with respect to \( \beta \) evaluated at \( x \). This function returns both \( g(x) \) and its standard error, the square root of the estimated variance.
The default method requires that you provide \( x \) in the argument \( \text{object} \), \( C \) in the argument \( \text{vcov} \), and a text expression in argument \( g \) that when evaluated gives the function \( g \). The call \( \text{names(object)} \) must return the names of the elements of \( x \) that are used in the expression \( g \).

Since the delta method is often applied to functions of regression parameter estimates, the argument \( \text{object} \) may be the name of a regression object from which the estimates and their estimated variance matrix can be extracted. In most regression models, estimates are returned by the \( \text{coef(object)} \) and the variance matrix from \( \text{vcov(object)} \). You can provide an alternative function for computing the sample variance matrix, for example to use a sandwich estimator.

For mixed models using \texttt{lm} or \texttt{nlm}, the coefficient estimates are returned by the \texttt{fixef} function, while for \texttt{multinom}, \texttt{lmList} and \texttt{nlsList} coefficient estimates are returned by \( \text{coef} \) as a matrix. Methods for these models are provided to get the correct estimates and variance matrix.

The argument \( g \) must be a quoted character string that gives the function of interest. For example, if you set \( m2 \leftarrow \texttt{lm(Y \sim X1 + X2 + X1:X2)} \), then \( \text{deltaMethod(m2,"X1/X2"}) \) applies the delta method to the ratio of the coefficient estimates for \( X1 \) and \( X2 \). The argument \( g \) can consist of constants and names associated with the elements of the vector of coefficient estimates.

In some cases the names may include characters such as the colon : used in interactions, or mathematical symbols like + or - signs that would confuse the function that computes numerical derivatives, and for this case you can replace the names of the estimates with the \texttt{parameterNames} argument. For example, the ratio of the \( X2 \) main effect to the interaction term could be computed using \( \text{deltaMethod(m2, \"b1/b3\", parameterNames=c("b0", "b1", "b2", "b3"))} \). The name \"(Intercept)\" used for the intercept in linear and generalized linear models is an exception, and it will be correctly interpreted by \text{deltaMethod}. Another option is to use back-ticks to quote non-standard R names, as in \texttt{deltaMethod(m2,"X1/\text{``X1:X2``}").}

For \texttt{multinom} objects, the \texttt{coef} function returns a matrix of coefficients, with each row giving the estimates for comparisons of one category to the baseline. The \texttt{deltaMethod} function applies the delta method to each row of this matrix. Similarly, for \texttt{lmList} and \texttt{nlsList} objects, the delta method is computed for each element of the list of models fit.

For nonlinear regression objects produced by the \texttt{nls} function, the call \( \text{coef(object)} \) returns the estimated coefficient vectors with names corresponding to parameter names. For example, \( m2 \leftarrow \texttt{nls(y \sim \theta/(1 + \gamma * x), start = \text{list(theta=2, gamma=3)})} \) will have parameters named \( \text{c("\theta", "\gamma")}. \) In many other familiar regression models, such as those produced by \texttt{lm} and \texttt{glm}, the names of the coefficient estimates are the corresponding regressor names, not parameter names.

For mixed-effects models fit with \texttt{lmer} and \texttt{glmer} from the \texttt{lme4} package or \texttt{lme} and \texttt{nlme} from the \texttt{nlme} package, only fixed-effect coefficients are considered.

For regression models for which methods are not provided, you can extract the named vector of coefficient estimates and estimate of its covariance matrix and then apply the default \texttt{deltaMethod} function.

Note: Earlier versions of \texttt{deltaMethod} included an argument \texttt{parameterPrefix} that implemented the same functionality as the \texttt{parameterNames} argument, but which caused several problems that were not easily fixed without the change in syntax.

Value

An object of class "\texttt{deltaMethod}" inheriting from "\texttt{data.frame}" for which a print method is provided. The object contains columns named \texttt{Estimate} for the estimate, \texttt{SE} for its standard error,
and columns for confidence limits and possibly a hypothesis test. The value of \( g \) is given as a row label.

**Author(s)**

Sanford Weisberg, <sandy@umn.edu>, John Fox <jfox@mcmaster.ca>, and Pavel Krivitsky.

**References**

**See Also**

First derivatives of \( g \) are computed using symbolic differentiation by the function \( D \).

**Examples**

```r
m1 <- lm(time ~ t1 + t2, data = Transact)
deltaMethod(m1, "b1/b2", parameterNames= paste("b", 0:2, sep=""))
deltaMethod(m1, "t1/t2", rhs=1) # use names of preds. rather than coefs.
deltaMethod(m1, "t1/t2", vcov=hccm) # use hccm function to est. vars.
deltaMethod(m1, "1/(Intercept)"
# The next example invokes the default method by extracting the
# vector of estimates and covariance matrix explicitly
deltaMethod(coef(m1), "t1/t2", vcov.=vcov(m1))
```

**densityPlot**

Nonparametric Density Estimates

**Description**

densityPlot constructs and graphs nonparametric density estimates, possibly conditioned on a factor, using the standard \( R \) `density` function or by default `adaptiveKernel`, which computes an adaptive kernel density estimate. `depan` provides the Epanechnikov kernel and `dbiwt` provides the biweight kernel.

**Usage**

densityPlot(x, ...)

## Default S3 method:
densityPlot(x, g, method=c("adaptive", "kernel"),
  bw=if (method == "adaptive") bw.nrd0 else "SJ", adjust=1,
  kernel, xlim, ylim,
  normalize=FALSE, xlab=deparse(substitute(x)), ylab="Density", main="",
  col=carPalette(), lty=seq_along(col), lwd=2, grid=TRUE,
Arguments

- **x**
  a numeric variable, the density of which is estimated; for depan and dbiwt, the argument of the kernel function.

- **g**
  an optional factor to divide the data.

- **formula**
  an R model formula, of the form `~ variable` to estimate the unconditional density of `variable`, or `variable ~ factor` to estimate the density of `variable` within each level of `factor`.

- **data**
  an optional data frame containing the data.

- **subset**
  an optional vector defining a subset of the data.

- **na.action**
  a function to handle missing values; defaults to the value of the R `na.action` option, initially set to `na.omit`.

- **method**
  either "adaptive" (the default) for an adaptive-kernel estimate or "kernel" for a fixed-bandwidth kernel estimate.

- **bw**
  the geometric mean bandwidth for the adaptive-kernel or bandwidth of the kernel density estimate(s). Must be a numerical value or a function to compute the bandwidth (default `bw.nrd0`) for the adaptive kernel estimate; for the kernel estimate, may either the quoted name of a rule to compute the bandwidth, or a numeric value. If plotting by groups, `bw` may be a vector of values, one for each group. See `density` and `bw.SJ` for details of the kernel estimator.

- **adjust**
  a multiplicative adjustment factor for the bandwidth; the default, 1, indicates no adjustment; if plotting by groups, `adjust` may be a vector of adjustment factors, one for each group. The default bandwidth-selection rule tends to give a value that's too large if the distribution is asymmetric or has multiple modes; try setting `adjust < 1`, particularly for the adaptive-kernel estimator.

- **kernel**
  for `densityPlot` this is the name of the kernel function for the kernel estimator (the default is "gaussian", see `density`); or a kernel function for the adaptive-kernel estimator (the default is `dnorm`, producing the Gaussian kernel). For `adaptiveKernel` this is a kernel function, defaulting to `dnorm`, which is the Gaussian kernel (standard-normal density).

- **xlim, ylim**
  axis limits; if missing, determined from the range of x-values at which the densities are estimated and the estimated densities.
normalize if TRUE (the default is FALSE), the estimated densities are rescaled to integrate approximately to 1; particularly useful if the density is estimated over a restricted domain, as when from or to are specified.
xlab label for the horizontal-axis; defaults to the name of the variable x.
ylab label for the vertical axis; defaults to "Density".
main plot title; default is empty.
col vector of colors for the density estimate(s); defaults to the color carPalette.
lty vector of line types for the density estimate(s); defaults to the successive integers, starting at 1.
lwd line width for the density estimate(s); defaults to 2.
grid if TRUE (the default), grid lines are drawn on the plot.
legend a list of up to two named elements: location, for the legend when densities are plotted for several groups, defaults to "upperright" (see legend); and title of the legend, which defaults to the name of the grouping factor. If TRUE, the default, the default values are used; if FALSE, the legend is suppressed.
n number of equally spaced points at which the adaptive-kernel estimator is evaluated; the default is 500.
from, to, cut the range over which the density estimate is computed; the default, if missing, is min(x) - cut*bw, max(x) + cut*bw.
na.rm remove missing values from x in computing the adaptive-kernel estimate? The default is TRUE.
show.bw if TRUE, show the bandwidth(s) in the horizontal-axis label or (for multiple groups) the legend; the default is FALSE.
rug if TRUE (the default), draw a rug plot (one-dimensional scatterplot) at the bottom of the density estimate.
... arguments to be passed down to graphics functions.

Details
If you use a different kernel function than the default dnorm that has a standard deviation different from 1 along with an automatic rule like the default function bw.nrd0, you can attach an attribute to the kernel function named "scale" that gives its standard deviation. This is true for the two supplied kernels, depan and dbiwt

Value
densityPlot invisibly returns the "density" object computed (or list of "density" objects) and draws a graph. adaptiveKernel returns an object of class "density" (see density).

John Fox <jfox@mcmaster.ca>
dfbetaPlots

dfbeta and dfbetas Index Plots

Description

These functions display index plots of dfbeta (effect on coefficients of deleting each observation in turn) and dfbetas (effect on coefficients of deleting each observation in turn, standardized by a deleted estimate of the coefficient standard error). In the plot of dfbeta, horizontal lines are drawn at 0 and +/- one standard error; in the plot of dfbetas, horizontal lines are drawn at 0 and +/- 1.
Usage

dfbetaPlots(model, ...)

dfbetasPlots(model, ...)

## S3 method for class 'lm'
dfbetaPlots(model, terms=~., intercept=FALSE, layout=NULL, ask,
            main, xlab, ylab, labels=rownames(dfbeta),
            id.method="y",
            id.n=if(id.method[1]=="identify") Inf else 0, id.cex=1,
            id.col=carPalette()[1], id.location="lr", col=carPalette()[1], grid=TRUE, ...)

## S3 method for class 'glm'
dfbetasPlots(model, terms=~., intercept=FALSE, layout=NULL, ask,
             main, xlab, ylab,
             labels=rownames(dfbetas), id.method="y",
             id.n=if(id.method[1]=="identify") Inf else 0, id.cex=1,
             id.col=carPalette()[1], id.location="lr", col=carPalette()[1], grid=TRUE, ...)

Arguments

model: model object produced by \texttt{lm} or \texttt{glm}.

terms: A one-sided formula that specifies a subset of the terms in the model. One dfbeta or dfbetas plot is drawn for each regressor. The default ~ . is to plot against all terms in the model with the exception of an intercept. For example, the specification terms = ~ .-X3 would plot against all terms except for X3. If this argument is a quoted name of one of the terms, the index plot is drawn for that term only.

intercept: Include the intercept in the plots; default is \texttt{FALSE}.

layout: If set to a value like \texttt{c(1, 1)} or \texttt{c(4, 3)}, the layout of the graph will have this many rows and columns. If not set, the program will select an appropriate layout. If the number of graphs exceed nine, you must select the layout yourself, or you will get a maximum of nine per page. If \texttt{layout=NA}, the function does not set the layout and the user can use the \texttt{par} function to control the layout, for example to have plots from two models in the same graphics window.

main: The title of the graph; if missing, one will be supplied.

xlab: Horizontal axis label; defaults to "Index".

ylab: Vertical axis label; defaults to coefficient name.

ask: If \texttt{TRUE}, ask the user before drawing the next plot; if \texttt{FALSE}, the default, don’t ask.

...: optional additional arguments to be passed to \texttt{plot}, \texttt{points}, and \texttt{showLabels}.

id.method, labels, id.n, id.cex, id.col, id.location: Arguments for the labelling of points. The default is \texttt{id.n=0} for labeling no points. See \texttt{showLabels} for details of these arguments.

col: color for points; defaults to the first entry in the color \texttt{carPalette}.

grid: If \texttt{TRUE}, the default, a light-gray background grid is put on the graph.
Value

NULL. These functions are used for their side effect: producing plots.

durbinWatsonTest  Durbin-Watson Test for Autocorrelated Errors

Description

Computes residual autocorrelations and generalized Durbin-Watson statistics and their bootstrapped p-values. dwt is an abbreviation for durbinWatsonTest.

Usage

durbinWatsonTest(model, ...)

dwt(...)

## S3 method for class 'lm'
durbinWatsonTest(model, max.lag=1, simulate=TRUE, reps=1000,
                  method=c("resample","normal"),
                  alternative=c("two.sided", "positive", "negative"), ...)

## Default S3 method:
durbinWatsonTest(model, max.lag=1, ...)

## S3 method for class 'durbinWatsonTest'
print(x, ...)
Arguments

- **model**: a linear-model object, or a vector of residuals from a linear model.
- **max.lag**: maximum lag to which to compute residual autocorrelations and Durbin-Watson statistics.
- **simulate**: if TRUE p-values will be estimated by bootstrapping.
- **reps**: number of bootstrap replications.
- **method**: bootstrap method: "resample" to resample from the observed residuals; "normal" to sample normally distributed errors with 0 mean and standard deviation equal to the standard error of the regression.
- **alternative**: sign of autocorrelation in alternative hypothesis; specify only if max.lag = 1; if max.lag > 1, then alternative is taken to be "two.sided".
- **...**: arguments to be passed down.
- **x**: `durbinWatsonTest` object.

Value

Returns an object of type "durbinWatsonTest".

Note

p-values are available only from the `lm` method.

Examples

```
durbinWatsonTest(lm(fconvict ~ tfr + partic + degrees + mconvict, data=Hartnagel))
```

Ellipses, Data Ellipses, and Confidence Ellipses

Description

These functions draw ellipses, including data ellipses, and confidence ellipses for linear, generalized linear, and possibly other models.
Ellipses 

Usage

ellipsoe(center, shape, radius, log="", center.pch=19, center.cex=1.5, 
    segments=51, draw=TRUE, add=draw, xlab="", ylab="", 
    col=carPalette()[2], lwd=2, fill=FALSE, fill.alpha=0.3, grid=TRUE, ...)

dataEllipse(x, y, groups, group.labels=group.levels, ellipse.label, 
    weights, log="", levels=c(0.5, 0.95), center.pch=19, 
    center.cex=1.5, draw=TRUE, plot.points=draw, add=!plot.points, segments=51, 
    robust=FALSE, xlab=deparse(substitute(x)), ylab=deparse(substitute(y)), 
    col=if (missing(groups)) carPalette()[1:2] else carPalette()[1:length(group.levels)], 
    pch=if (missing(groups)) 1 else seq(group.levels), 
    lwd=2, fill=FALSE, fill.alpha=0.3, grid=TRUE, id=FALSE, ...)

confidenceEllipse(model, ...)

## S3 method for class 'lm'
confidenceEllipse(model, which.coef, vcov.=vcov,
    L, levels=0.95, Scheffe=FALSE, dfn, 
    center.pch=19, center.cex=1.5, segments=51, xlab, ylab, 
    col=carPalette()[2], lwd=2, fill=FALSE, fill.alpha=0.3, draw=TRUE, add=!draw, 
    grid=TRUE, ...)

## S3 method for class 'glm'
confidenceEllipse(model, chisq, ...)

## S3 method for class 'mlm'
confidenceEllipse(model, xlab, ylab, which.coef=1:2, ...)

## Default S3 method:
confidenceEllipses(model, ...)

 confidenceEllipses(model, coefnames, main, grid=TRUE, ...)

 Arguments

center 2-element vector with coordinates of center of ellipse.
shape 2 × 2 shape (or covariance) matrix.
radius radius of circle generating the ellipse.
when an ellipse is to be added to an existing plot, indicates whether computations were on logged values and to be plotted on logged axes; "x" if the x-axis is logged, "y" if the y-axis is logged, and "xy" or "yx" if both axes are logged. The default is "", indicating that neither axis is logged.

- **center.pch**: character for plotting ellipse center; if FALSE or NULL the center point isn’t plotted.
- **center.cex**: relative size of character for plotting ellipse center.
- **segments**: number of line-segments used to draw ellipse.
- **draw**: if TRUE produce graphical output; if FALSE, only invisibly return coordinates of ellipse(s).
- **add**: if TRUE add ellipse(s) to current plot.
- **xlab**: label for horizontal axis.
- **ylab**: label for vertical axis.
- **x**: a numeric vector, or (if y is missing) a 2-column numeric matrix.
- **y**: a numeric vector, of the same length as x.
- **groups**: optional: a factor to divide the data into groups; a separate ellipse will be plotted for each group (level of the factor).
- **group.labels**: labels to be plotted for the groups; by default, the levels of the groups factor.
- **ellipse.label**: a label for the ellipse(s) or a vector of labels; if several ellipses are drawn and just one label is given, then that label will be repeated. The default is not to label the ellipses.
- **weights**: a numeric vector of weights, of the same length as x and y to be used by cov.wt or cov.trob in computing a weighted covariance matrix; if absent, weights of 1 are used.
- **plot.points**: if FALSE data ellipses are drawn, but points are not plotted.
- **levels**: draw elliptical contours at these (normal) probability or confidence levels.
- **robust**: if TRUE use the cov.trob function in the MASS package to calculate the center and covariance matrix for the data ellipse.
- **model**: a model object produced by lm or glm.
- **which.coef**: 2-element vector giving indices of coefficients to plot; if missing, the first two coefficients (disregarding the regression constant) will be selected.
- **vcov.**: a coefficient-covariance matrix or a function (such as hccm) to compute the coefficient-covariance matrix from model; the default is the vcov function.
- **L**: As an alternative to selecting coefficients to plot, a transformation matrix can be specified to compute two linear combinations of the coefficients; if the L matrix is given, it takes precedence over the which.coef argument. L should have two rows and as many columns as there are coefficients. It can be given directly as a numeric matrix, or specified by a pair of character-valued expressions, in the same manner as for the link{linearHypothesis} function, but with no right-hand side.
- **Scheffe**: if TRUE scale the ellipse so that its projections onto the axes give Scheffe confidence intervals for the coefficients.
**Ellipses**

- dfn: “numerator” degrees of freedom (or just degrees of freedom for a GLM) for drawing the confidence ellipse. Defaults to the number of coefficients in the model (disregarding the constant) if Scheffe is TRUE, or to 2 otherwise; selecting dfn = 1 will draw the “confidence-interval generating” ellipse, with projections on the axes corresponding to individual confidence intervals with the stated level of coverage.

- chisq: if TRUE, the confidence ellipse for the coefficients in a generalized linear model are based on the chisquare statistic, if FALSE on the $F$-statistic. This corresponds to using the default and linear-model methods respectively.

- col: color for lines and ellipse center; the default is the second entry in the current car palette (see carPalette and par). For dataEllipse, two colors can be given, in which case the first is for plotted points and the second for lines and the ellipse center; if ellipses are plotted for groups, then this is a vector of colors for the groups.

- pch: for dataEllipse this is the plotting character (default, symbol 1, a hollow circle) to use for the points; if ellipses are plotted by groups, then this a vector of plotting characters, with consecutive symbols starting with 1 as the default.

- lwd: line width; default is 2 (see par).

- fill: fill the ellipse with translucent color col (default, FALSE)?

- fill.alpha: transparency of fill (default = 0.3).

- ...: other plotting parameters to be passed to plot and line.

- id: controls point identification; if FALSE (the default), no points are identified; can be a list of named arguments to the showLabels function; TRUE is equivalent to list(method="mahal", n=2, cex=1, col=carPalette()[1], location="lr") (with the default col actually dependent on the number of groups), which identifies the 2 points with the largest Mahalanobis distances from the center of the data.

- grid: If TRUE, the default, a light-gray background grid is put on the graph.

- coefnames: character vector of coefficient names to use to label the diagonal of the pairwise confidence ellipse matrix plotted by confidenceEllipses; defaults to the names of the coefficients in the model.

- main: title for matrix of pairwise confidence ellipses.

**Details**

The ellipse is computed by suitably transforming a unit circle.

dataEllipse superimposes the normal-probability contours over a scatterplot of the data.

confidenceEllipses plots a matrix of all pairwise confidence ellipses; each panel of the matrix is created by confidenceEllipse.

**Value**

These functions are mainly used for their side effect of producing plots. For greater flexibility (e.g., adding plot annotations), however, ellipse returns invisibly the (x, y) coordinates of the calculated ellipse. dataEllipse and confidenceEllipse return invisibly the coordinates of one or more ellipses, in the latter instance a list named by levels; confidenceEllipses invisibly returns NULL.

Description

Uses the `export` function in the `rio` package to export a file to disk. This function adds an argument for converting row.names to a column in the resulting file.

Usage

```r
Export(x, file, format, ..., keep.row.names)
```

Arguments

- `x`: A data frame or matrix to be written to a file.
- `file`: A character string naming a file. If the file name has an extension, such as `.xlsx`, the extension is used to infer the type of file to be exported. See `export` for the file types supported.
- `format`: see `export`.
- `...`: Additional arguments; see `export`.
- `keep.row.names`: If set to `TRUE`, then the data frame’s row.names are appended to the left of the data frame with the name "id". If set to quoted character string, the row.names are added using the character string as its name. If set to `FALSE` row.names are lost.

Details

This is a convenience function in the `car` package for exporting (writing) a data frame to a file in a wide variety of formats including csv, Microsoft Excel. It optionally allows converting the row.names for the data frame to a column before writing. It then calls `export` in the `rio` package. That function in turn uses many other packages and functions for writing the function to a file.

Value

The name of the output file as a character string (invisibly).

Author(s)

Sanford Weisberg <sandy@umn.edu>

  Export(Duncan, "Duncan.csv", keep.row.names="occupation")
  Duncan2 <- Import("Duncan.csv") # Automatically restores row.names
  identical(Duncan, Duncan2)
  # cleanup
  unlink("Duncan.csv")
}
```

hccm

### Heteroscedasticity-Corrected Covariance Matrices

Description

Calculates heteroscedasticity-corrected covariance matrices linear models fit by least squares or weighted least squares. These are also called “White-corrected” or “White-Huber” covariance matrices.

Usage

```r
hccm(model, ...)
```

## S3 method for class 'lm'
```r
hccm(model, type=c("hc3", "hc0", "hc1", "hc2", "hc4"),
     singular.ok=TRUE, ...)
```

## Default S3 method:
```r
hccm(model, ...)
```

Arguments

- `model`: a unweighted or weighted linear model, produced by `lm`.
- `type`: one of "hc0", "hc1", "hc2", "hc3", or "hc4"; the first of these gives the classic White correction. The "hc1", "hc2", and "hc3" corrections are described in Long and Ervin (2000); "hc4" is described in Cribari-Neto (2004).
- `singular.ok`: if FALSE (the default is TRUE), a model with aliased coefficients produces an error; otherwise, the aliased coefficients are ignored in the coefficient covariance matrix that’s returned.
- `...`: arguments to pass to `hccm.lm`. 
Details

The original White-corrected coefficient covariance matrix ("hc0") for an unweighted model is

\[ V(b) = (X'X)^{-1}X'diag(e_i^2)X(X'X)^{-1} \]

where \( e_i^2 \) are the squared residuals, and \( X \) is the model matrix. The other methods represent adjustments to this formula. If there are weights, these are incorporated in the corrected covariance matrix.

The function \texttt{hccm.default} simply catches non-\texttt{lm} objects.

See Freedman (2006) and Fox and Weisberg (2019, Sec. 5.1.2) for discussion of the use of these methods in generalized linear models or models with nonconstant variance.

Value

The heteroscedasticity-corrected covariance matrix for the model.

The function will return an error, rather than a matrix, under two circumstances. First, if any of the cases have hatvalue (leverage) equal to one, then the corresponding fitted value will always equal the observed value. For types hc2, hc3 and hc4 the hccm matrix is undefined. For hc0 and hc1 it is defined but it can be shown to be singular, and therefore not a consistent estimate of the covariance matrix of the coefficient estimates. A singular estimate of the covariance matrix may also be obtained if the matrix \( X \) is ill-conditioned. In this latter case rescaling the model matrix may give a full-rank estimate.

**Description**

The `Boot` function in the car package uses the `boot` function from the boot package to do a straightforward case or residual bootstrap for many regression objects. These are method functions for standard generics to summarize the results of the bootstrap. Other tools for this purpose are available in the boot package.

**Usage**

```r
## S3 method for class 'boot'
hist(x, parm, layout = NULL, ask, main = "", freq = FALSE,
estPoint = TRUE, point.col = carPalette()[1], point.lty = 2, point.lwd = 2,
estDensity = !freq, den.col = carPalette()[2], den.lty = 1, den.lwd = 2,
estNormal = !freq, nor.col = carPalette()[3], nor.lty = 2, nor.lwd = 2,
ci = c("bca", "none", "perc", "norm"), level = 0.95,
legend = c("top", "none", "separate"), box = TRUE, ...)

## S3 method for class 'boot'
summary(object, parm, high.moments = FALSE, extremes = FALSE, ...)

## S3 method for class 'boot'
confint(object, parm, level = 0.95, type = c("bca", "norm",
       "basic", "perc"), ...)

## S3 method for class 'boot'
Confint(object, parm, level = 0.95, type = c("bca", "norm",
       "basic", "perc"), ...)

## S3 method for class 'boot'
vcov(object, use="complete.obs", ...)
```
Arguments

x, object  An object created by a call to boot in the boot package, or to Boot in the car package of class "boot".

parm  A vector of numbers or coefficient names giving the coefficients for which a histogram or confidence interval is desired. If numbers are used, 1 corresponds to the intercept, if any. The default is all coefficients.

layout  If set to a value like c(1, 1) or c(4, 3), the layout of the graph will have this many rows and columns. If not set, the program will select an appropriate layout. If the number of graphs exceed nine, you must select the layout yourself, or you will get a maximum of nine per page. If layout=NA, the function does not set the layout and the user can use the par function to control the layout, for example to have plots from two models in the same graphics window.

ask  If TRUE, ask the user before drawing the next plot; if FALSE, don’t ask.

main  Main title for the graphs. The default is main="" for no title.

freq  The default for the generic hist function is freq=TRUE to give a frequency histogram. The default for hist.boot is freq=FALSE to give a density histogram. A density estimate and/or a fitted normal density can be added to the graph if freq=FALSE but not if freq=TRUE.

estPoint, point.col, point.lty, point.lwd  If estPoint=TRUE, the default, a vertical line is drawn on the histogram at the value of the point estimate computed from the complete data. The remaining three optional arguments set the color, line type and line width of the line that is drawn.

estDensity, den.col, den.lty, den.lwd  If estDensity=TRUE and freq=FALSE, the default, a kernel density estimate is drawn on the plot with a call to the density function with no additional arguments. The remaining three optional arguments set the color, line type and line width of the lines that are drawn.

estNormal, nor.col, nor.lty, nor.lwd  If estNormal=TRUE and freq=FALSE, the default, a normal density with mean and sd computed from the data is drawn on the plot. The remaining three optional arguments set the color, line type and line width of the lines that are drawn.

ci  A confidence interval based on the bootstrap will be added to the histogram using the BCa method if ci="bca" the percentile method if ci="perc", or the normal method if ci="norm". No interval is drawn if ci="none". The default is "bca". The interval is indicated by a thick horizontal line at y=0. For some bootstraps the BCa method is unavailable, in which case a warning is issued and ci="perc" is substituted. If you wish to see all the options at once, see boot.ci. The normal method is computed as the (estimate from the original data) minus the bootstrap bias plus or minus the standard deviation of the bootstrap replicates times the appropriate quantile of the standard normal distribution.

legend  A legend can be added to the (array of) histograms. The value “top” puts at the top-left of the plots. The value “separate” puts the legend in its own graph following all the histograms. The value “none” suppresses the legend.

box  Add a box around each histogram.
Additional arguments passed to `hist`; for other methods this is included for compatibility with the generic method. For example, the argument `border=par()$bg` in `hist` will draw the histogram transparently, leaving only the density estimates. With the `vcov` function, the additional arguments are passed to `cov`. See the Value section, below.

**high.moments** Should the skewness and kurtosis be included in the summary? Default is `FALSE`.

**extremes** Should the minimum, maximum and range be included in the summary? Default is `FALSE`.

**level** Confidence level, a number between 0 and 1. In `confint`, `level` can be a vector; for example `level=c(.50, .90, .95)` will return the following estimated quantiles: `c(.025, .05, .25, .75, .95, .975)`.

**type** Selects the confidence interval type. The types implemented are the "percentile" method, which uses the function `quantile` to return the appropriate quantiles for the confidence limit specified, the default `bca` which uses the bias-corrected and accelerated method presented by Efron and Tibshirani (1993, Chapter 14). For the other types, see the documentation for `boot`.

**use** The default `use="complete.obs"` for `vcov` computes a bootstrap covariance matrix by deleting bootstraps that returned NAs. Setting `use` to anything else will result in a matrix of NAs.

### Value

`hist` is used for the side-effect of drawing an array of histograms of each column of the first argument. `summary` returns a matrix of summary statistics for each of the columns in the bootstrap object. The `confint` method returns confidence intervals. `Confint` appends the estimates based on the original fitted model to the left of the confidence intervals.

The function `vcov` returns the sample covariance of the bootstrap sample estimates, by default skipping any bootstrap samples that returned NA.

Examples

```r
m1 <- lm(Fertility ~ ., swiss)
betahat.boot <- Boot(m1, R=99) # 99 bootstrap samples--too small to be useful
summary(betahat.boot) # default summary
confint(betahat.boot)
hist(betahat.boot)
```

Import

Import data from many file formats

Description

Uses the `import` function from the `rio` package to read a data.frame from a variety of file types. The `Import` function includes 2 additional arguments adding row names and for converting character and logical variables to factors for some file types.

Usage

```r
Import(file, format, ..., row.names=TRUE,
      stringsAsFactors = FALSE)
```

Arguments

- `file` A character string naming a file, URL, or .zip or .tar archive. See the details below. If the file name has an extension like .xlsx or .csv then the type of file is inferred from the extension.
- `format` If an extension is not present in the file name or it is wrong, the file format can be set with this argument; see `import`.
- `...` Additional arguments passed to `import`.
- `row.names` If TRUE, the default, the left-most character variable that has all unique elements is removed from the data frame and set to be `row.names`. To match `import`, set `row.names=FALSE`.
- `stringsAsFactors` If TRUE, then character variables that do not have all unique elements are converted to factors. The default is FALSE. Prior to May 2020 the default was determined by `getOption("stringsAsFactors")`, which then defaulted to TRUE. This option is FALSE in R 4.0.0 and has been deprecated.

Details

This function calls the `import` function to read a data frame from a file. Many file types are supported. For files of type "txt", "csv", "xlsx", "xls" or "ods" the arguments `row.names` and `stringsAsFactors` can be used to add row names and convert character variables to factors, respectively. Many more details are given on the man page for `import`. 
infIndexPlot

Influence Index Plot

Description

Provides index plots of influence and related diagnostics for a regression model.

Usage

infIndexPlot(model, ...)

influenceIndexPlot(model, ...)

## S3 method for class 'lm'
infIndexPlot(model, vars=c("Cook", "Studentized", "Bonf", "hat"),
             id=TRUE, grid=TRUE, main="Diagnostic Plots", ...)

## S3 method for class 'influence.merMod'
inIndexPlot(model,
             vars = c("dfbeta", "dfbetas", "var.cov.comps", ...)

Value

A data frame. See import for more details

Author(s)

Sanford Weisberg <sandy@umn.edu>

import, Export, strings2factors

Examples

if(require("rio")) {

  head(Duncan, 3) # first three rows
  Export(Duncan, "Duncan.csv", keep.row.names="occupation")
  Duncan2 <- Import("Duncan.csv") # Automatically restores row.names and factors
  brief(Duncan2)
  identical(Duncan, Duncan2) # FALSE because type is of a different class
  Duncan3 <- Import("Duncan.csv", stringsAsFactors=TRUE)
  brief(Duncan3)
  identical(Duncan, Duncan3) # TRUE type is of same class
  # cleanup
  unlink("Duncan.csv")
}

infIndexPlot

Influence Index Plot

infIndexPlot
infIndexPlot

```
infIndexPlot(model, 
  vars = c("dfbeta", "dfbetas", "var.cov.comps", 
    "cookd"), id = TRUE, grid = TRUE, main = "Diagnostic Plots", ...)
```

## S3 method for class 'influence.lme'

```
influence.lme
```

### Arguments

**model**
A regression object of class `lm`, `glm`, or `lmerMod`, or an influence object for a `lmer`, `glmer`, or `lme` object (see `influence.mixed.models`). The "lmerMod" method calls the "lm" method and can take the same arguments.

**vars**
All the quantities listed in this argument are plotted. Use "Cook" for Cook's distances, "Studentized" for Studentized residuals, "Bonf" for Bonferroni p-values for an outlier test, and and "hat" for hat-values (or leverages) for a linear or generalized linear model, or "dfbeta", "dfbetas", "var.cov.comps", and "cookd" for an influence object derived from a mixed model. Capitalization is optional. All but "dfbeta" and "dfbetas" may be abbreviated by the first one or more letters.

**main**
main title for graph

**id**
a list of named values controlling point labelling. The default, TRUE, is equivalent to `id=list(method="y", n=2, cex=1, col=carPalette()[1], location="lr")`; FALSE suppresses point labelling. See `showLabels` for details.

**grid**
If TRUE, the default, a light-gray background grid is put on the graph.

### Value

Used for its side effect of producing a graph. Produces index plots of diagnostic quantities.

```
## Not run: # a little slow
if (require(lme4)){
  print(fm1 <- lmer(Reaction ~ Days + (Days | Subject),
                   sleepstudy)) # from ?lmer
  infIndexPlot(influence(fm1, "Subject"))
  infIndexPlot(influence(fm1))
}

if (require(lme4)){
  gml <- glmer(cbind(incidence, size - incidence) ~ period + (1 | herd),
                data = cbpp, family = binomial) # from ?glmer
  infIndexPlot(influence(gml, "herd", maxfun=100))
  infIndexPlot(influence(gml, maxfun=100))
  gml.11 <- update(gml, subset = herd != 11) # check deleting herd 11
  compareCoefs(gml, gml.11)
}
```

## End(Not run)

---

**influence.mixed.models**

*Influence Diagnostics for Mixed-Effects Models*

**Description**

These functions compute deletion influence diagnostics for linear mixed-effects models fit by `lme` in the *nlme* package. The main function is a method for the `influence` generic function. Other functions are provided for computing `dfbeta`, `dfbetas`, `cooks.distance`, and influence on variance-covariance components based on the object computed by `influence.lme`.

**Usage**

```
## S3 method for class 'lme'
influence(model, groups, data, ncores=1, ...)

## S3 method for class 'influence.lme'
cooks.distance(model, ...)

## S3 method for class 'influence.lme'
dfbeta(model, which = c("fixed", "var.cov"), ...)

## S3 method for class 'influence.lme'
dfbetas(model, ...)
```
Arguments

- **model**: in the case `influence`, a model of class "lme"; in the case of `cooks.distance`, `dfbeta`, or `dfbetas`, an object returned by `influence.lme`.
- **groups**: a character vector containing the name of a grouping factor or names of grouping factors; if more than one name is supplied, then groups are defined by all combinations of levels of the grouping factors that appear in the data. If omitted, then each individual row of the data matrix is treated as a "group" to be deleted in turn.
- **data**: an optional data frame with the data to which `model` was fit; `influence.lme` can access the data unless `data=FALSE` was specified in the call to `lme`, so it's usually unnecessary to supply the `data` argument.
- **ncores**: number of cores for parallel computation of diagnostics; if 1 (the default), the computation isn't parallelized; if `Inf`, all of the available physical cores (not necessarily logical cores — see `detectCores`) on the computer will be used.
- **which**: if "fixed.effects" (the default), return influence on the fixed effects; if "var.cov", return influence on the variance-covariance components.
- **...**: ignored.

Details

`influence.lme` starts with the estimated variance-covariance components from `model` and then refits the model omitting each group in turn.

The other functions are methods for the `dfbeta`, `dfbetas`, and `cooks.distance` generics, to be applied to the "influence.lme" object produced by the `influence` function; the `dfbeta` methods can also return influence on the variance-covariance components.

Value

`influence.lme` returns an object of class "influence.lme", which contains the following elements:

- "fixed.effects" the estimated fixed effects for the model.
- "fixed.effects[-groups]" a matrix with columns corresponding to the fixed-effects coefficients and rows corresponding to groups, giving the estimated fixed effects with each group deleted in turn; `groups` is formed from the name(s) of the grouping factor(s).
- "var.cov.comps" the estimated variance-covariance parameters for the model.
- "var.cov.comps[-groups]" a matrix with the estimated covariance parameters (in columns) with each group deleted in turn.
- "vcov" The estimated covariance matrix of the fixed-effects coefficients.
- "vcov[-groups]" a list each of whose elements is the estimated covariance matrix of the fixed-effects coefficients with one group deleted.
- "groups" a character vector giving the names of the grouping factors.
- "deleted" the possibly composite grouping factor, each of whose elements is deleted in turn.

For plotting "influence.lme" objects, see `infIndexPlot`. 
influencePlot

Regression Influence Plot

Description
This function creates a “bubble” plot of Studentized residuals versus hat values, with the areas of the circles representing the observations proportional to the value Cook’s distance. Vertical reference lines are drawn at twice and three times the average hat value, horizontal reference lines at -2, 0, and 2 on the Studentized-residual scale.

Usage
influencePlot(model, ...)

## S3 method for class 'lm'
influencePlot(model, scale=10,
  xlab="Hat-Values", ylab="Studentized Residuals", id=TRUE,
  fill=TRUE, fill.col=carPalette()[2], fill.alpha=0.5, ...)

## S3 method for class 'lmerMod'
influencePlot(model, ...)

Arguments

- **model**: a linear, generalized-linear, or linear mixed model; the "lmerMod" method calls the "lm" method and can take the same arguments.
- **scale**: a factor to adjust the size of the circles.

Examples

```r
if (require(nlme)){
  print(fm1 <- lme(distance ~ age, data = Orthodont))
inIndexPlot(influence(fm1, "Subject"))
inIndexPlot(influence(fm1))
}
```
influencePlot

xlab, ylab  axis labels.

id           settings for labelling points; see link{showLabels} for details. To omit point
             labelling, set id=FALSE; the default, id=TRUE is equivalent to id=list(method="noteworthy",
             n=2, cex=1, col=carPalette()[1], location="lr"). The default method="noteworthy"
             is used only in this function and indicates setting labels for points with large
             Studentized residuals, hat-values or Cook’s distances. Set id=list(method="identify")
             for interactive point identification.

fill         if TRUE (the default) fill the circles, with the opacity of the filled color propor-
             tional to Cook’s D, using the alpha function in the scales package to compute
             the opacity of the fill.

fill.col     color to use for the filled points, taken by default from the second element of the
             carPalette color palette.

fill.alpha   the maximum alpha (opacity) of the points.
...           arguments to pass to the plot and points functions.

Value

If points are identified, returns a data frame with the hat values, Studentized residuals and Cook’s
distance of the identified points. If no points are identified, nothing is returned. This function is
primarily used for its side-effect of drawing a plot.

             id=list(method="identify"))

## End(Not run)
invResPlot  

Inverse Response Plots to Transform the Response

Description

For a lm model, draws an inverse.response plot with the response $Y$ on the vertical axis and the fitted values $\hat{Y}$ on the horizontal axis. Uses nls to estimate $\lambda$ in the function $\hat{Y} = b_0 + b_1 Y^\lambda$. Adds the fitted curve to the plot. invResPlot is an alias for inverseResponsePlot.

Usage

inverseResponsePlot(model, lambda=c(-1, 0, 1), robust=FALSE, xlab=NULL, ...)  

## S3 method for class 'lm'
inverseResponsePlot(model, lambda=c(-1,0,1),
    robust=FALSE, xlab=NULL, id=FALSE, ...)

invResPlot(model, ...)

Arguments

model  
A "lm" regression object.

lambda  
A vector of values for lambda. A plot will be produced with curves corresponding to these lambdas and to the nonlinear least squares estimate of lambda.

robust  
If TRUE, then estimation uses Huber M-estimates with the median absolute deviation to estimate scale and $k = 1.345$. The default is FALSE.

xlab  
The horizontal axis label. If NULL, it is constructed by the function.

id  
controls point identification; if FALSE (the default), no points are identified; can be a list of named arguments to the showLabels function; TRUE is equivalent to list(method=list(method="x", n=2, cex=1, col=carPalette()[1], location="lr"), which identifies the 2 points with the most extreme horizontal (X) values.

...  
Other arguments passed to invTranPlot and then to plot.

Value

As a side effect, a plot is produced with the response on the horizontal axis and fitted values on the vertical axis. Several lines are added to be plot as the ols estimates of the regression of $\hat{Y}$ on $Y^\lambda$, interpreting $\lambda = 0$ to be natural logarithms.

Numeric output is a list with elements

lambda  
Estimate of transformation parameter for the response

RSS  
The residual sum of squares at the minimum if robust=FALSE. If robust = TRUE, the value of Huber objective function is returned.
invTranPlot

Author(s)
Sanford Weisberg, sandy@umn.edu

References

See Also
invTranPlot, powerTransform, showLabels

Examples
m2 <- lm(rate ~ log(len) + log(adt) + slim + shld + log(sigs1), Highway1)
invResPlot(m2)

invTranPlot

Choose a Predictor Transformation Visually or Numerically

Description
invTranPlot draws a two-dimensional scatterplot of \(Y\) versus \(X\), along with the OLS fit from the regression of \(Y\) on \((X^\lambda - 1)/\lambda\). invTranEstimate finds the nonlinear least squares estimate of \(\lambda\) and its standard error.

Usage

invTranPlot(x, ...)

## S3 method for class 'formula'
invTranPlot(x, data, subset, na.action, id=FALSE, ...)

## Default S3 method:
invTranPlot(x, y, lambda=c(-1, 0, 1), robust=FALSE,
lty.lines=rep(c("solid", "dashed", "dotdash", "longdash", "twodash"),
length=1 + length(lambda)), lwd.lines=2,
col=carPalette()[1], col.lines=carPalette(),
xlab=deparse(substitute(x)), ylab=deparse(substitute(y)),
family="bcPower", optimal=TRUE, key="auto", id=FALSE,
grid=TRUE, ...)

invTranEstimate(x, y, family="bcPower", confidence=0.95, robust=FALSE)
Arguments

- **x**: The predictor variable, or a formula with a single response and a single predictor.
- **y**: The response variable.
- **data**: An optional data frame to get the data for the formula.
- **subset**: Optional, as in `lm`, select a subset of the cases.
- **na.action**: Optional, as in `lm`, the action for missing data.
- **lambda**: The powers used in the plot. The optimal power than minimizes the residual sum of squares is always added unless optimal is `FALSE`.
- **robust**: If `TRUE`, then the estimated transformation is computed using Huber M-estimation with the MAD used to estimate scale and $k=1.345$. The default is `FALSE`.
- **family**: The transformation family to use, "bcPower", "yjPower", or a user-defined family.
- **confidence**: returns a profile likelihood confidence interval for the optimal transformation with this confidence level. If `FALSE`, or if robust=TRUE, no interval is returned.
- **optimal**: Include the optimal value of lambda?
- **lty.lines**: line types corresponding to the powers.
- **lwd.lines**: the width of the plotted lines, defaults to 2 times the standard.
- **col**: color(s) of the points in the plot. If you wish to distinguish points according to the levels of a factor, we recommend using symbols, specified with the pch argument, rather than colors.
- **col.lines**: color of the fitted lines corresponding to the powers. The default is to use the colors returned by `carPalette`.
- **key**: The default is "auto", in which case a legend is added to the plot, either above the top marign or in the bottom right or top right corner. Set to NULL to suppress the legend.
- **xlab**: Label for the horizontal axis.
- **ylab**: Label for the vertical axis.
- **id**: controls point identification; if FALSE (the default), no points are identified; can be a list of named arguments to the `showLabels` function; TRUE is equivalent to `list(method=list(method="x", n=2, cex=1, col=carPalette()[1], location="lr"))`, which identifies the 2 points with the most extreme horizontal values — i.e., the response variable in the model.
- **...**: Additional arguments passed to the plot method, such as pch.
- **grid**: If TRUE, the default, a light-gray background grid is put on the graph.

Value

`invTranPlot` plots a graph and returns a data frame with $\lambda$ in the first column, and the residual sum of squares from the regression for that $\lambda$ in the second column.

`invTranEstimate` returns a list with elements `lambda` for the estimate, `se` for its standard error, and `RSS`, the minimum value of the residual sum of squares.

Examples
with(UN, invTranPlot(ppgdp, infantMortality))
with(UN, invTranEstimate(ppgdp, infantMortality))

leveneTest
Levene’s Test

Description
Computes Levene’s test for homogeneity of variance across groups.

Usage
leveneTest(y, ...)
## S3 method for class 'formula'
leveneTest(y, data, ...)
## S3 method for class 'lm'
leveneTest(y, ...)
## Default S3 method:
leveneTest(y, group, center=median, ...)

Arguments
y
response variable for the default method, or a lm or formula object. If y is a linear-model object or a formula, the variables on the right-hand-side of the model must all be factors and must be completely crossed.
group
factor defining groups.
center
The name of a function to compute the center of each group; mean gives the original Levene’s test; the default, median, provides a more robust test.
data
a data frame for evaluating the formula.
... arguments to be passed down, e.g., data for the formula and lm methods; can also be used to pass arguments to the function given by center (e.g., center=mean and trim=0.1 specify the 10% trimmed mean).
leveragePlots

Value
returns an object meant to be printed showing the results of the test.

Note
adapted from a response posted by Brian Ripley to the r-help email list.

leveragePlots

Regression Leverage Plots

Description
These functions display a generalization, due to Sall (1990) and Cook and Weisberg (1991), of added-variable plots to multiple-df terms in a linear model. When a term has just 1 df, the leverage plot is a rescaled version of the usual added-variable (partial-regression) plot.

Usage
```r
leveragePlots(model, terms = ~., layout = NULL, ask,
              main, ...)

leveragePlot(model, ...)
```

## S3 method for class 'lm'
```r
leveragePlot(model, term.name,
id=TRUE, col=carPalette()[1], col.lines=carPalette()[2], lwd=2,
xlab, ylab, main="Leverage Plot", grid=TRUE, ...)
```

## S3 method for class 'glm'
```r
leveragePlot(model, ...)
```
Arguments

model  model object produced by lm

terms  A one-sided formula that specifies a subset of the numeric regressors, factors and interactions. One added-variable plot is drawn for each term, either a main effect or an interactions. The default ~. is to plot against all terms in the model. For example, the specification terms = ~ . - X3 would plot against all predictors except for X3. If this argument is a quoted name of one of the predictors, the added-variable plot is drawn for that predictor only. The plots for main effects with interactions present violate the marginality principle and may not be easily interpreted.

layout  If set to a value like c(1, 1) or c(4, 3), the layout of the graph will have this many rows and columns. If not set, the program will select an appropriate layout. If the number of graphs exceed nine, you must select the layout yourself, or you will get a maximum of nine per page. If layout=NA, the function does not set the layout and the user can use the par function to control the layout, for example to have plots from two models in the same graphics window.

ask  if TRUE, a menu is provided in the R Console for the user to select the term(s) to plot.

xlab, ylab  axis labels; if missing, labels will be supplied.

main  title for plot; if missing, a title will be supplied.

...  arguments passed down to method functions.

term.name  Quoted name of term in the model to be plotted; this argument is omitted for leveragePlots.

id  controls point identification; if FALSE, no points are identified; can be a list of named arguments to the showLabels function; TRUE, the default, is equivalent to list(method=list(abs(residuals(model, type="pearson")), "x"), n=2, cex=1, col=carPalette()[1], location="lr"), which identifies the 2 points with the largest residuals and the 2 points with the greatest partial leverage.

col  color(s) of points

col.lines  color of the fitted line

lwd  line width; default is 2 (see par).

grid  If TRUE, the default, a light-gray background grid is put on the graph

Details

The function intended for direct use is leveragePlots.

The model can contain factors and interactions. A leverage plot can be drawn for each term in the model, including the constant.

leveragePlot.glm is a dummy function, which generates an error message.

Value

NULL. These functions are used for their side effect: producing plots.

linearHypothesis Test Linear Hypothesis

Description
Generic function for testing a linear hypothesis, and methods for linear models, generalized linear models, multivariate linear models, linear and generalized linear mixed-effects models, generalized linear models fit with svyglm in the survey package, robust linear models fit with rlm in the MASS package, and other models that have methods for coef and vcov. For mixed-effects models, the tests are Wald chi-square tests for the fixed effects.

Usage
linearHypothesis(model, ...)
lht(model, ...)

## Default S3 method:
linearHypothesis(model, hypothesis.matrix, rhs=NULL, test=c("Chisq", "F"), vcov.=NULL, singular.ok=FALSE, verbose=FALSE, coef. = coef(model), suppress.vcov.msg=FALSE, error.df, ...)

## S3 method for class 'lm'
linearHypothesis(model, hypothesis.matrix, rhs=NULL, test=c("F", "Chisq"), vcov.=NULL, white.adjust=c(FALSE, TRUE, "hc3", "hc0", "hc1", "hc2", "hc4"), singular.ok=FALSE, ...)
linearHypothesis

## S3 method for class 'glm'
linearHypothesis(model, ...)

## S3 method for class 'lmList'
linearHypothesis(model, ..., vcov.=vcov, coef.=coef)

## S3 method for class 'nlsList'
linearHypothesis(model, ..., vcov.=vcov, coef.=coef)

## S3 method for class 'mlm'
linearHypothesis(model, hypothesis.matrix, rhs=NULL, V,
    test, idata, icontasts=c("contr.sum", "contr.poly"), idesign, iterms,
    check.imatrix=TRUE, P=NULL, title="", singular.ok=FALSE, verbose=FALSE, ...)

## S3 method for class 'polr'
linearHypothesis(model, hypothesis.matrix, rhs=NULL, vcov.,
    verbose=FALSE, ...)

## S3 method for class 'linearHypothesis.mlm'
print(x, SSP=TRUE, SSPE=SSP,
    digits=getOption("digits"), ...)

## S3 method for class 'lme'
linearHypothesis(model, hypothesis.matrix, rhs=NULL,
    vcov.=NULL, singular.ok=FALSE, verbose=FALSE, ...)

## S3 method for class 'mer'
linearHypothesis(model, hypothesis.matrix, rhs=NULL,
    vcov.=NULL, test=c("Chisq", "F"), singular.ok=FALSE, verbose=FALSE, ...)

## S3 method for class 'merMod'
linearHypothesis(model, hypothesis.matrix, rhs=NULL,
    vcov.=NULL, test=c("Chisq", "F"), singular.ok=FALSE, verbose=FALSE, ...)

## S3 method for class 'svyglm'
linearHypothesis(model, ...)

## S3 method for class 'rlm'
linearHypothesis(model, ...)

## S3 method for class 'survreg'
linearHypothesis(model, hypothesis.matrix, rhs=NULL,
    test=c("Chisq", "F"), vcov., verbose=FALSE, ...)

matchCoefs(model, pattern, ...)

## Default S3 method:
linearHypothesis

matchCoefs(model, pattern, coef.=coef, ...)

## S3 method for class 'lme'
matchCoefs(model, pattern, ...)

## S3 method for class 'mer'
matchCoefs(model, pattern, ...)

## S3 method for class 'merMod'
matchCoefs(model, pattern, ...)

## S3 method for class 'mlm'
matchCoefs(model, pattern, ...)

## S3 method for class 'lmList'
matchCoefs(model, pattern, ...)

Arguments

model fitted model object. The default method of linearHypothesis works for models for which the estimated parameters can be retrieved by coef and the corresponding estimated covariance matrix by vcov. See the Details for more information.

hypothesis.matrix matrix (or vector) giving linear combinations of coefficients by rows, or a character vector giving the hypothesis in symbolic form (see Details).

rhs right-hand-side vector for hypothesis, with as many entries as rows in the hypothesis matrix; can be omitted, in which case it defaults to a vector of zeroes. For a multivariate linear model, rhs is a matrix, defaulting to 0. This argument isn’t available for F-tests for linear mixed models.

singular.ok if FALSE (the default), a model with aliased coefficients produces an error; if TRUE, the aliased coefficients are ignored, and the hypothesis matrix should not have columns for them. For a multivariate linear model, will return the hypothesis and error SSP matrices even if the latter is singular; useful for computing univariate repeated-measures ANOVAs where there are fewer subjects than df for within-subject effects.

error.df For the default linearHypothesis method, if an F-test is requested and if error.df is missing, the error degrees of freedom will be computed by applying the df.residual function to the model; if df.residual returns NULL or NA, then a chi-square test will be substituted for the F-test (with a message to that effect.

idata an optional data frame giving a factor or factors defining the intra-subject model for multivariate repeated-measures data. See Details for an explanation of the intra-subject design and for further explanation of the other arguments relating to intra-subject factors.

icontrasts names of contrast-generating functions to be applied by default to factors and ordered factors, respectively, in the within-subject “data”; the contrasts must produce an intra-subject model matrix in which different terms are orthogonal.
idesign a one-sided model formula using the “data” in idata and specifying the intra-subject design.

items the quoted name of a term, or a vector of quoted names of terms, in the intra-subject design to be tested.

check.imatrix check that columns of the intra-subject model matrix for different terms are mutually orthogonal (default, TRUE). Set to FALSE only if you have already checked that the intra-subject model matrix is block-orthogonal.

P transformation matrix to be applied to the repeated measures in multivariate repeated-measures data; if NULL and no intra-subject model is specified, no response-transformation is applied; if an intra-subject model is specified via the idata, idesign, and (optionally) icontrasts arguments, then P is generated automatically from the items argument.

SSPE in linearHypothesis method for mlm objects: optional error sum-of-squares-and-products matrix; if missing, it is computed from the model. In print method for linearHypothesis.mlm objects: if TRUE, print the sum-of-squares and cross-products matrix for error.

test character string, "F" or "Chisq", specifying whether to compute the finite-sample F statistic (with approximate F distribution) or the large-sample Chi-squared statistic (with asymptotic Chi-squared distribution). For a multivariate linear model, the multivariate test statistic to report — one or more of "Pillai", "Wilks", "Hotelling-Lawley", or "Roy", with "Pillai" as the default.

title an optional character string to label the output.

V inverse of sum of squares and products of the model matrix; if missing it is computed from the model.

vcov. a function for estimating the covariance matrix of the regression coefficients, e.g., hccm, or an estimated covariance matrix for model. See also white.adjust. For the "lmList" and "nlsList" methods, vcov. must be a function (defaulting to vcov) to be applied to each model in the list.

coef. a vector of coefficient estimates. The default is to get the coefficient estimates from the model argument, but the user can input any vector of the correct length. For the "lmList" and "nlsList" methods, coef. must be a function (defaulting to coef) to be applied to each model in the list.

white.adjust logical or character. Convenience interface to hccm (instead of using the argument vcov.). Can be set either to a character value specifying the type argument of hccm or TRUE, in which case "hc3" is used implicitly. The default is FALSE.

verbose If TRUE, the hypothesis matrix, right-hand-side vector (or matrix), and estimated value of the hypothesis are printed to standard output; if FALSE (the default), the hypothesis is only printed in symbolic form and the value of the hypothesis is not printed.

x an object produced by linearHypothesis.mlmc.

SSP if TRUE (the default), print the sum-of-squares and cross-products matrix for the hypothesis and the response-transformation matrix.

digits minimum number of significant digits to print.

pattern a regular expression to be matched against coefficient names.
linearHypothesis

linearHypothesis computes either a finite-sample F statistic or asymptotic Chi-squared statistic for carrying out a Wald-test-based comparison between a model and a linearly restricted model. The default method will work with any model object for which the coefficient vector can be retrieved by `coef` and the coefficient-covariance matrix by `vcov` (otherwise the argument `vcov.` has to be set explicitly). For computing the F statistic (but not the Chi-squared statistic) a `df.residual` method needs to be available. If a formula method exists, it is used for pretty printing.

The method for "lm" objects calls the default method, but it changes the default test to "F", supports the convenience argument `white.adjust` (for backwards compatibility), and enhances the output by the residual sums of squares. For "glm" objects just the default method is called (bypassing the "lm" method). The "svyglm" method also calls the default method.

Multinomial logit models fit by the `multinom` function in the `nnet` package invoke the default method, and the coefficient names are composed from the response-level names and conventional coefficient names, separated by a period ("."): see one of the examples below.

The function `lht` also dispatches to `linearHypothesis`.

The hypothesis matrix can be supplied as a numeric matrix (or vector), the rows of which specify linear combinations of the model coefficients, which are tested equal to the corresponding entries in the right-hand-side vector, which defaults to a vector of zeroes.

Alternatively, the hypothesis can be specified symbolically as a character vector with one or more elements, each of which gives either a linear combination of coefficients, or a linear equation in the coefficients (i.e., with both a left and right side separated by an equals sign). Components of a linear expression or linear equation can consist of numeric constants, or numeric constants multiplying coefficient names (in which case the number precedes the coefficient, and may be separated from it by spaces or an asterisk); constants of 1 or -1 may be omitted. Spaces are always optional. Components are separated by plus or minus signs. Newlines or tabs in hypotheses will be treated as spaces. See the examples below.

If the user sets the arguments `coef.` and `vcov.`, then the computations are done without reference to the `model` argument. This is like assuming that `coef.` is normally distributed with estimated variance `vcov.`, and the `linearHypothesis` will compute tests on the mean vector for `coef.`., without actually using the `model` argument.

A linear hypothesis for a multivariate linear model (i.e., an object of class "mlm") can optionally include an intra-subject transformation matrix for a repeated-measures design. If the intra-subject transformation is absent (the default), the multivariate test concerns all of the corresponding coefficients for the response variables. There are two ways to specify the transformation matrix for the repeated measures:

1. The transformation matrix can be specified directly via the `P` argument.
2. A data frame can be provided defining the repeated-measures factor or factors via `idata`, with default contrasts given by the `icontrasts` argument. An intra-subject model-matrix is generated from the one-sided formula specified by the `idesign` argument; columns of the model matrix corresponding to different terms in the intra-subject model must be orthogonal (as is insured by the default contrasts). Note that the contrasts given in `icontrasts` can
be overridden by assigning specific contrasts to the factors in idata. The repeated-measures transformation matrix consists of the columns of the intra-subject model matrix corresponding to the term or terms in iters. In most instances, this will be the simpler approach, and indeed, most tests of interests can be generated automatically via the Anova function.

matchCoefs is a convenience function that can sometimes help in formulating hypotheses; for example matchCoefs(mod, ":") will return the names of all interaction coefficients in the model mod.

Value

For a univariate model, an object of class "anova" which contains the residual degrees of freedom in the model, the difference in degrees of freedom, Wald statistic (either "F" or "Chisq"), and corresponding p value. The value of the linear hypothesis and its covariance matrix are returned respectively as "value" and "vcov" attributes of the object (but not printed).

For a multivariate linear model, an object of class "linearHypothesis.mlm", which contains sums-of-squares-and-product matrices for the hypothesis and for error, degrees of freedom for the hypothesis and error, and some other information.

The returned object normally would be printed.

logit

Logit Transformation

Description

Compute the logit transformation of proportions or percentages.

Usage

logit(p, percents, adjust)

Arguments

p numeric vector or array of proportions or percentages.
percents TRUE for percentages, FALSE for proportions. If the argument is missing and the
largest value of p > 1, percents is set to TRUE, otherwise to FALSE.
adjust adjustment factor to avoid proportions of 0 or 1; defaults to 0 if there are no such
proportions in the data, and to .025 if there are.
Details

Computes the logit transformation \( \text{logit} = \log \left( \frac{p}{1 - p} \right) \) for the proportion \( p \).

If \( p = 0 \) or \( 1 \), then the logit is undefined. \texttt{logit} can remap the proportions to the interval \((\text{adjust}, 1 - \text{adjust})\) prior to the transformation. If it adjusts the data automatically, \texttt{logit} will print a warning message.

Value

A numeric vector or array of the same shape and size as \( p \).

mcPlots

\texttt{mcPlots} \hspace{1cm} *Draw Linear Model Marginal and Conditional Plots in Parallel or Overlaid*

Description

The \texttt{mcPlots} function draws two graphs or overlays the two graphs. For a response \( Y \) and a regressor \( X \), the first plot is the marginal plot of \( Y \) versus \( X \) with both variables centered, visualizing the conditional distribution of \( Y \) given \( X \) ignoring all other regressors. The second plot is an added-variable for \( X \) after all other regressors, visualizing the conditional distribution of \( Y \) given \( X \) after adjusting for all other predictors. The added variable plot by default is drawn using the same \texttt{xlim} and \texttt{ylim} as the centered marginal plot to emphasize that conditioning removes variation in both the regressor and the response. The plot is primarily intended as a pedagogical tool for understanding coefficients in first-order models.
Usage
mcPlots(model, ...)

## Default S3 method:
mcPlots(model, terms=~., layout=NULL, ask, overlaid=TRUE, ...)

mcPlot(model, ...)

## S3 method for class \texttt{lm}
mcPlot(model, variable, id=FALSE,
       col.marginal=carPalette()[2], col.conditional=carPalette()[3],
       col.arrows="gray", pch = c(16,1), cex=par("cex"), pt.wts=FALSE,
       lwd = 2, grid=TRUE, ellipse=FALSE, overlaid=TRUE, new=TRUE,
       title=TRUE, ...)

## S3 method for class \texttt{glm}
mcPlot(model, ...)

Arguments
model model object produced by \texttt{lm}; the "glm" method just reports an error.
terms A one-sided formula that specifies a subset of the predictors. One added-variable plot is drawn for each regressor and for each basis vector used to define a factor. For example, the specification \texttt{terms = \sim . \ - X3} would plot against all terms except for \texttt{X3}. If this argument is a quoted name of one of the regressors or factors, the added-variable plot is drawn for that regressor or factor only. Unlike other \texttt{car} functions, the formula should include the names of regressors, not predictors. That is, if \texttt{log(X4)} is used to represent a predictor \texttt{X4}, the formula should specify \texttt{terms = \sim \log(X4)}.

variable A quoted string giving the name of a numeric predictor in the model matrix for the horizontal axis. To plot against a factor, you need to specify the full name of one of the indicator variables that define the factor. For example, for a factor called \texttt{type} with levels \texttt{A}, \texttt{B} and \texttt{C}, using the usual drop-first level parameterization of the factor, the regressors for \texttt{type} would be \texttt{typeB} or \texttt{typeC}. Similarly, to plot against the regressor \texttt{log(X4)}, you must specify \texttt{"log((X4)"}, not \texttt{"X4"}.

layout If set to a value like \texttt{c(1, 2)} or \texttt{c(6, 2)}, the layout of the graph will have this many rows and columns. If not set, behavior depends on the value of the \texttt{overlaid} argument; see the details

ask If \texttt{TRUE}, ask the user before drawing the next plot; if \texttt{FALSE} don’t ask.

\dotfill

\texttt{...} mcPlots passes these arguments to \texttt{mcPlot}. \texttt{mcPlot} passes arguments to \texttt{plot}.

id controls point identification: if \texttt{FALSE} (the default), no points are identified; can be a list of named arguments to the \texttt{showLabels} function; \texttt{TRUE} is equivalent to \texttt{list(method=list(abs(residuals(model, type="pearson")), "x"), n=2, cex=1, col=carPalette()[1], location="lr"), which identifies the 2 points with the largest residuals and the 2 points with the most extreme horizontal (X) values.
overlaid If TRUE, the default, overlay the marginal and conditional plots on the same graph; otherwise plot them side-by-side. See the details below.

col.marginal, col.conditional
  colors for points, lines, ellipses in the marginal and conditional plots, respectively. The defaults are determined by the \texttt{carPalette} function.

col.arrows color for the arrows with overlaid=TRUE

pch Plotting character for marginal and conditional plots, respectively.

cex size of plotted points; default is taken from \texttt{par("cex")}.

pt.wts if TRUE (the default is FALSE), the areas of plotted points for a weighted least squares fit are made proportional to the weights, with the average size taken from the cex argument.

lwd line width; default is 2 (see \texttt{par}).

grid If TRUE, the default, a light-gray background grid is put on the graph.

ellipse Arguments to pass to the \texttt{dataEllipse} function, in the form of a list with named elements; e.g., \texttt{ellipse.args=list(robust=TRUE))} will cause the ellipse to be plotted using a robust covariance-matrix. if FALSE, the default, no ellipse is plotted. TRUE is equivalent to \texttt{ellipse=list(levels=0.5)}, which plots a bivariate-normal 50 percent concentration ellipse.

new if TRUE, the default, the plot window is reset when overlaid=FALSE using \texttt{par(mfrow=c(1, 2))}. If FALSE, the layout of the plot window is not reset. Users will ordinarily ignore this argument.

title If TRUE, the default, the standard main argument in plot is used to add a standard title to each plot. If FALSE no title is used.

Details

With an \texttt{lm} object, suppose the response is \( Y \), \( X \) is a numeric regressor of interest, and \( Z \) is all the remaining predictors, possibly including interactions and factors. This function produces two graphs. The first graph is the marginal plot of \( Y \) versus \( X \), with each variable centered around its mean. The second conditional plot is the added-variable plot of \( e(Y|Z) \) versus \( e(X|Z) \) where \( e(ab) \) means the Pearson residuals from the regression of \( a \) on \( b \). If overlaid=TRUE, these two plots are overlaid in one graph, with the points in different colors. In addition, each point in the marginal plot is joined to its value in the conditional plot by an arrow. Least squares regression lines fit to the marginal and conditional graphs are also shown; data ellipsoids can also be added. If overlaid=FALSE, then the two graphs are shown in side-by-side plots as long as the second argument to \texttt{layout} is equal to 2, or \texttt{layout} is set by the function. The arrows are omitted if the graphs are not overlaid.

These graphs are primarily for teaching, as the marginal plot shows the relationship between \( Y \) and \( X \) ignoring \( Z \), while the conditional is the relationship between \( Y \) and \( X \) given \( X \). By keeping the scales the same in both graphs the effect of conditioning on both \( X \) and \( Y \) can be visualized.

This function is intended for first-order models with numeric predictors only. For a factor, one (pair) of mcPlots will be produced for each of the dummy variables in the basis for the factor, and the resulting plots are not generally meaningful because they depend on parameterization. If the mean function includes interactions, then mcPlots for main effects may violate the hierarchy principle, and may also be of little interest. mcPlots for interactions of numerical predictors, however, can be useful.
These graphs are closely related to the ARES plots proposed by Cook and Weisberg (1989). This plot would benefit from animation.

Value

These functions are used for their side effect of producing plots.

### mmps

**Marginal Model Plotting**

**Description**

For a regression object, draw a plot of the response on the vertical axis versus a linear combination \( u \) of regressors in the mean function on the horizontal axis. Added to the plot are a smooth for the graph, along with a smooth from the plot of the fitted values on \( u \). `mmps` is an alias for `marginalModelPlots`, and `mmp` is an alias for `marginalModelPlot`.

**Usage**

```r
marginalModelPlots(...)```

```r
mmps(model, terms= ~ ., fitted=TRUE, layout=NULL, ask, main, groups, key=TRUE, ...)```

```r
marginalModelPlot(...)```

---
mmp(model, ...) 

## S3 method for class 'lm'

mmp(model, variable, sd = FALSE,  
xlab = deparse(substitute(variable)),  
smooth=TRUE, key=TRUE, pch, groups=NULL, ...)

## Default S3 method:

mmp(model, variable, sd = FALSE,  
xlab = deparse(substitute(variable)), ylab, smooth=TRUE,  
key=TRUE, pch, groups=NULL,  
col.line = carPalette()[c(2, 8)], col=carPalette()[1],  
id=FALSE, grid=TRUE, ...)

## S3 method for class 'glm'

mmp(model, variable, sd = FALSE,  
xlab = deparse(substitute(variable)), ylab,  
smooth=TRUE, key=TRUE, pch, groups=NULL,  
col.line = carPalette()[c(2, 8)], col=carPalette()[1],  
id=FALSE, grid=TRUE, ...)

### Arguments

- **model**: A regression object, usually of class either `lm` or `glm`, for which there is a `predict` method defined.
- **terms**: A one-sided formula. A marginal model plot will be drawn for each term on the right-side of this formula that is not a factor. The default is `~ .`, which specifies that all the terms in `formula(object)` will be used. If a conditioning argument is given, eg `terms = ~ . | a`, then separate colors and smoothers are used for each unique non-missing value of `a`. See examples below.
- **fitted**: If `TRUE`, the default, then a marginal model plot in the direction of the fitted values for a linear model or the linear predictor of a generalized linear model will be drawn.
- **layout**: If set to a value like `c(1, 1)` or `c(4, 3)`, the layout of the graph will have this many rows and columns. If not set, the program will select an appropriate layout. If the number of graphs exceed nine, you must select the layout yourself, or you will get a maximum of nine per page. If `layout=NA`, the function does not set the layout and the user can use the `par` function to control the layout, for example to have plots from two models in the same graphics window.
- **ask**: If `TRUE`, ask before clearing the graph window to draw more plots.
- **main**: Main title for the array of plots. Use `main=""` to suppress the title; if missing, a title will be supplied.
- **...**: Additional arguments passed from `mmps` to `mmp` and then to `plot`. Users should generally use `mmps`, or equivalently `marginalModelPlots`.
- **variable**: The quantity to be plotted on the horizontal axis. If this argument is missing, the horizontal variable is the linear predictor, returned by `predict(object)`.
mmp

for models of class lm, with default label "Fitted values", or returned by predict(object, type="link") for models of class glm, with default label "Linear predictor". It can be any other vector of length equal to the number of observations in the object. Thus the mmp function can be used to get a marginal model plot versus any regressor or predictor while the mmps function can be used only to get marginal model plots for the first-order regressors in the formula. In particular, terms defined by a spline basis are skipped by mmps, but you can use mmp to get the plot for the variable used to define the splines.

sd

If TRUE, display sd smooths. For a binomial regression with all sample sizes equal to one, this argument is ignored as the SD bounds don’t make any sense.

xlab

label for horizontal axis.

ylab

label for vertical axis, defaults to name of response.

smooth

specifies the smoother to be used along with its arguments; if FALSE, no smoother is shown; can be a list giving the smoother function and its named arguments; TRUE, the default, is equivalent to list(smoother=loessLine, span=2/3) for linear models and list(smoother=gamLine, k=3) for generalized linear models. See ScatterplotSmoothers for the smoothers supplied by the car package and their arguments; the spread argument is not supported for marginal model plots.

groups

The name of a vector that specifies a grouping variable for separate colors/smoothers. This can also be specified as a conditioning argument on the terms argument.

key

If TRUE, include a key at the top of the plot, if FALSE omit the key. If grouping is present, the key is only printed for the upper-left plot.

id

controls point identification; if FALSE (the default), no points are identified; can be a list of named arguments to the showLabels function; TRUE is equivalent to list(method="y", n=2, cex=1, col=carPalette()[1], location="lr"), which identifies the 2 points with the most unusual response (Y) values.

pch

plotting character to use if no grouping is present.

col.line

colors for data and model smooth, respectively. The default is to use carPalette, carPalette()[c(2, 8)], blue and red.

col

color(s) for the plotted points.

grid

If TRUE, the default, a light-gray background grid is put on the graph:

Details

mmp and marginalModelPlot draw one marginal model plot against whatever is specified as the horizontal axis. mmps and marginalModelPlots draws marginal model plots versus each of the terms in the terms argument and versus fitted values. mmps skips factors and interactions if they are specified in the terms argument. Terms based on polynomials or on splines (or potentially any term that is represented by a matrix of regressors) will be used to form a marginal model plot by returning a linear combination of the terms. For example, if you specify terms = ~ X1 + poly(X2, 3) and poly(X2, 3) was part of the original model formula, the horizontal axis of the marginal model plot for X2 will be the value of predict(model, type="terms")[, "poly(X2, 3)"]. If the predict method for the model you are using doesn’t support type="terms", then the polynomial/spline term is skipped. Adding a conditioning variable, e.g., terms = ~ a + b | c, will produce marginal model plots for a and b with different colors and smoothers for each unique non-missing value of c.
For linear models, the default smoother is loess. For generalized linear models, the default smoother uses \texttt{gamLine}, fitting a generalized additive model with the same family, link and weights as the fit of the model. SD smooths are not computed for for generalized linear models.

For generalized linear models the default number of elements in the spline basis is \( k=3 \); this is done to allow fitting for predictors with just a few support points. If you have many support points you may wish to set \( k \) to a higher number, or \( k=-1 \) for the default used by \texttt{gam}.

\textbf{Value}

Used for its side effect of producing plots.

\textbf{Examples}

```r
  c1 <- lm(infantMortality ~ ppgdp, UN)
  mmps(c1)
  c2 <- update(c1, ~ log(ppgdp))
  mmps(c2)
  # include SD lines
  p1 <- lm(prestige ~ income + education, Prestige)
  mmps(p1, sd=TRUE)
  # condition on type:
  mmps(p1, ~. | type)
  # logistic regression example
  # smoothers return warning messages.
  # fit a separate smoother and color for each type of occupation.
  m1 <- glm(lfp ~ ., family=binomial, data=Mroz)
  mmps(m1)
```
ncvTest

Score Test for Non-Constant Error Variance

Description
Computes a score test of the hypothesis of constant error variance against the alternative that the error variance changes with the level of the response (fitted values), or with a linear combination of predictors.

Usage
ncvTest(model, ...)

## S3 method for class 'lm'
ncvTest(model, var.formula, ...)

## S3 method for class 'glm'
ncvTest(model, ...) # to report an error

Arguments
- **model**: a weighted or unweighted linear model, produced by \texttt{lm}.
- **var.formula**: a one-sided formula for the error variance; if omitted, the error variance depends on the fitted values.
- **...**: arguments passed down to methods functions; not currently used.

Details
This test is often called the Breusch-Pagan test; it was independently suggested with some extension by Cook and Weisberg (1983).

ncvTest.glm is a dummy function to generate an error when a \texttt{glm} model is used.

Value
The function returns a \texttt{chisqTest} object, which is usually just printed.

Author(s)
John Fox <jfox@mcmaster.ca>, Sandy Weisberg <sandy@umn.edu>

References
outlierTest

Description

Reports the Bonferroni p-values for testing each observation in turn to be a mean-shift outlier, based
Studentized residuals in linear (t-tests), generalized linear models (normal tests), and linear mixed
models.

Usage

outlierTest(model, ...)

## S3 method for class 'lm'
outlierTest(model, cutoff=0.05, n.max=10, order=TRUE,
labels=names(rstudent), ...)

## S3 method for class 'lmerMod'
outlierTest(model, ...)

## S3 method for class 'outlierTest'
print(x, digits=5, ...)

Arguments

model an lm, glm, or lmerMod model object; the "lmerMod" method calls the "lm"
method and can take the same arguments.
cutoff observations with Bonferroni p-values exceeding cutoff are not reported, un-
less no observations are nominated, in which case the one with the largest Stu-
dentized residual is reported.
n.max maximum number of observations to report (default, 10).
order report Studenized residuals in descending order of magnitude? (default, TRUE).
labels an optional vector of observation names.
... arguments passed down to methods functions.
x outlierTest object.
digits number of digits for reported p-values.

Details
For a linear model, p-values reported use the t distribution with degrees of freedom one less than the residual df for the model. For a generalized linear model, p-values are based on the standard-normal distribution. The Bonferroni adjustment multiplies the usual two-sided p-value by the number of observations. The lm method works for glm objects. To show all of the observations set cutoff=Inf and n.max=Inf.

Value
an object of class outlierTest, which is normally just printed.

Examples
outlierTest(lm(prestige ~ income + education, data=Duncan))

panel.car

Panel Function for Coplots

Description
a panel function for use with coplot that plots points, a lowess line, and a regression line.

Usage

panel.car(x, y, col, pch, cex=1, span=0.5, lwd=2,
         reg.line=lm, lowess.line=TRUE, ...)
Arguments

- **x**: vector giving horizontal coordinates.
- **y**: vector giving vertical coordinates.
- **col**: point color.
- **pch**: plotting character for points.
- **cex**: character expansion factor for points.
- **span**: span for lowess smoother.
- **lwd**: line width, default is 2.
- **reg.line**: function to compute coefficients of regression line, or FALSE for no line.
- **lowess.line**: if TRUE plot lowess smooth.
- **...**: other arguments to pass to functions `lines` and `regLine`.

Value

NULL. This function is used for its side effect: producing a panel in a coplot.

Author(s)

John Fox <jfox@mcmaster.ca>

See Also

coplot, regLine

Examples

coplot(prestige ~ income|education, panel=panel.car, col="red", data=Prestige)

pointLabel

Label placement for points to avoid overlaps

Description

Use optimization routines to find good locations for point labels without overlaps.

Usage

```r
pointLabel(x, y = NULL, labels = seq(along = x), cex = 1, 
method = c("SANN", "GA"), 
allowSmallOverlap = FALSE, 
trace = FALSE, 
doPlot = TRUE, 
...)
```
Arguments

x, y
as with `plot.default`, these provide the x and y coordinates for the point labels. Any reasonable way of defining the coordinates is acceptable. See the function `xy.coords` for details.

labels
as with `text`, a character vector or expression specifying the text to be written. An attempt is made to coerce other language objects (names and calls) to expressions, and vectors and other classed objects to character vectors by `as.character`.

cex
numeric character expansion factor as with `text`.

method
the optimization method, either “SANN” for simulated annealing (the default) or “GA” for a genetic algorithm.

allowSmallOverlap
logical; if TRUE, labels are allowed a small overlap. The overlap allowed is 2% of the diagonal distance of the plot area.

trace
logical; if TRUE, status updates are given as the optimization algorithms progress.

doPlot
logical; if TRUE, the labels are plotted on the existing graph with `text`.

... arguments passed along to `text` to specify labeling parameters such as `col`.

Details

Eight positions are candidates for label placement, either horizontally, vertically, or diagonally offset from the points. The default position for labels is the top right diagonal relative to the point (considered the preferred label position).

With the default settings, simulating annealing solves faster than the genetic algorithm. It is an open question as to which settles into a global optimum the best (both algorithms have parameters that may be tweaked).

The label positioning problem is NP-hard (nondeterministic polynomial-time hard). Placement becomes difficult and slows considerably with large numbers of points. This function places all labels, whether overlaps occur or not. Some placement algorithms remove labels that overlap.

Note that only cex is used to calculate string width and height (using `strwidth` and `strheight`), so passing a different font may corrupt the label dimensions. You could get around this by adjusting the font parameters with `par` prior to running this function.

Value

An `xy` list giving the x and y positions of the label as would be placed by `text(xy, labels)`.

Note

This function was moved from the `maptools` package in anticipation of the retirement of that package, and with the permission of the function author.

pointLabel(x, y, expression(over(alpha, beta[123])), offset = 0, cex = .8)

poTest

Test for Proportional Odds in the Proportional-Odds Logistic-Regression Model

Description

The poTest function implements tests proposed by Brant (1990) for proportional odds for logistic
models fit by the polr function in the MASS package.

Usage

poTest(model, ...)
## S3 method for class 'polr'
poTest(model, ...)
## S3 method for class 'poTest'
print(x, digits=3, ...)
powerTransform

Arguments

model  a proportional-odds logit model fit by \texttt{polr}.
x      an object produced by \texttt{poTest}.
digits number of significant digits to print.
...    ignored.

Value

\texttt{poTest} returns an object meant to be printed showing the results of the tests.

}\end{verbatim}

Finding Univariate or Multivariate Power Transformations

Description

\texttt{powerTransform} uses the maximum likelihood-like approach of Box and Cox (1964) to select a transformation of a univariate or multivariate response for normality, linearity and/or constant variance. Available families of transformations are the default Box-Cox power family and two additional families that are modifications of the Box-Cox family that allow for (a few) negative responses. The summary method automatically computes two or three likelihood ratio type tests concerning the transformation powers.

Usage

\begin{verbatim}
\texttt{powerTransform(object, \ldots)}
\end{verbatim}

## Default S3 method:
\begin{verbatim}
\texttt{powerTransform(object, family="bcPower", \ldots)}
\end{verbatim}

## S3 method for class 'lm'
\begin{verbatim}
\end{verbatim}
powerTransform(object, family="bcPower", ...)

## S3 method for class 'formula'
powerTransform(object, data, subset, weights, na.action,
    family="bcPower", ...)

## S3 method for class 'lmerMod'
powerTransform(object, family="bcPower", ...)

Arguments

- **object**: This can either be an object of class `lm` or `lmerMod`, a formula, or a matrix or vector; see below.
- **family**: The quoted name of a family of transformations. The available options are "bcPower" for the default for the Box-Cox power family; "bcnPower" for a two-parameter modification of the Box-Cox family that allows negative responses (Hawkins and Weisberg (2017)), and the "yjPower" family (Yeo and Johnson(2000)), another modification of the Box-Cox family that allows a few negative values. All three families are documented at `bcPower`.
- **data**: A data frame or environment, as in `lm`.
- **subset**: Case indices to be used, as in `lm`.
- **weights**: Weights as in `lm`.
- **na.action**: Missing value action, as in `lm`.
- **...**: Additional arguments that used in the iterative algorithm; defaults are generally adequate. For use with the `bcnPower` family, a convergence criterion can be set with `conv=.0001` the default, and a minimum positive value of the location parameter can be set, with default `gamma.min=.1`.

Details

This function implements the Box and Cox (1964) method of selecting a power transformation of a variable toward normality, and its generalization by Velilla (1993) to a multivariate response. Cook and Weisberg (1999) and Weisberg (2014) suggest the usefulness of transforming a set of predictors $z_1, z_2, z_3$ for multivariate normality. It also includes two additional families that allow for negative values.

If the object argument is of class `lm` or `lmerMod`, the Box-Cox procedure is applied to the conditional distribution of the response given the predictors. For `lm` objects, the response may be multivariate, and each column will have its own transformation. With `lmerMod` the response must be univariate.

The object argument may also be a formula. For example, $z \sim x_1 + x_2 + x_3$ will estimate a transformation for the response $z$ from a family after fitting a linear model with the given formula. $\text{cbind}(y_1, y_2, y_3) \sim 1$ specifies transformations to multivariate normality with no predictors. A vector value for object, for example `powerTransform(ais$LBM)`, is equivalent to `powerTransform(LBM ~ 1, ais)`. Similarly, `powerTransform(\text{cbind}(ais$LBM, ais$SSF))`, where the first argument is a matrix rather than a formula is equivalent to specification of a multivariate linear model `powerTransform(\text{cbind}(LBM, SSF) ~ 1, ais)`.
Three families of power transformations are available. The default Box-Cox power family (family="bcPower") of power transformations effectively replaces a vector by that vector raised to a power, generally in the range from -3 to 3. For powers close to zero, the log-transformation is suggested. In practical situations, after estimating a power using the powerTransform function, a variable would be replaced by a simple power transformation of it, for example, if $\lambda \approx 0.5$, then the corresponding variable would be replaced by its square root; if $\lambda$ is close enough to zero, the variable would be replaced by its natural logarithm. The Box-Cox family requires the responses to be strictly positive.

The family="bcnPower", or Box-Cox with negatives, family proposed by Hawkins and Weisberg (2017) allows for (a few) non-positive values, while allowing for the transformed data to be interpreted similarly to the interpretation of Box-Cox transformed values. This family is the Box-Cox transformation of $z = 0.5 \times (y + (y^2 + \gamma^2)^{1/2})$ that depends on a location parameter $\gamma$. The quantity $z$ is positive for all values of $y$. If $\gamma = 0$ and $y$ is strictly positive, then the Box-Cox and the bcnPower transformations are identical. When fitting the Box-Cox with negatives family, $\lambda$ is restricted to the range [-3, 3], and $\gamma$ is restricted to the range from $\gamma_{\min}=.1$ to the largest positive value of the variable, since values outside these ranges are unreasonable in practice. The value of $\gamma_{\min}$ can be changed with an argument to powerTransform.

The final family family="yjPower" uses the Yeo-Johnson transformation, which is the Box-Cox transformation of $U + 1$ for nonnegative values, and of $|U| + 1$ with parameter $2 - \lambda$ for $U$ negative and thus it provides a family for fitting when (a few) observations are negative. Because of the unusual constraints on the powers for positive and negative data, this transformation is not used very often, as results are difficult to interpret. In practical problems, a variable would be replaced by its Yeo-Johnson transformation computed using the yjPower function.

The function testTransform is used to obtain likelihood ratio tests for any specified value for the transformation parameter(s).

Computations maximize the likelihood-like functions described by Box and Cox (1964) and by Velilla (1993). For univariate responses, the computations are very stable and problems are unlikely, although for ‘lmer’ models computations may be very slow because the model is refit many times. For multivariate responses with the bcnPower family, the computing algorithm may fail. In this case we recommend adding the argument itmax = 1 to the call to powerTransform. This will return the starting value estimates of the transformation parameters, fitting a d-dimensional response as if all the d responses were independent.

Value

An object of class powerTransform or class bcnPowerTransform if family="bcnPower" that inherits from powerTransform is returned, including the components listed below.

A summary method presents estimated values for the transformation power $\lambda$ and for the ‘bcnPower’ family the location parameter $\gamma$ as well. Standard errors and Wald 95% confidence intervals based on the standard errors are computed from the inverse of the sample Hessian matrix evaluated at the estimates. The interval estimates for the $\gamma$ parameters will generally be very wide, reflecting little information available about the location parameter. Likelihood ratio type tests are also provided. For the ‘bcnPower’ family these are based on the profile loglikelihood for $\lambda$ alone; that is, we treat $\gamma$ as a nuisance parameter and average over it.

The components of the returned object includes

$\lambda$ Estimated transformation parameter
The `powerTransform` function performs power transformations on the data. It estimates the value of `lambda` that maximizes the likelihood and provides a 95 percent Wald normal theory confidence interval for `lambda` computed as the estimate plus or minus 1.96 times the standard error. The function returns an array with columns labeled "Est Power" for the value of `lambda` that maximizes the likelihood, "Rounded Pwr" for `roundlam`, and columns "Wald Lwr Bnd" and "Wald Ur Bnd" for the confidence interval.

## End(Not run)

### Description

**Predict** is a generic function with, at present, a single method for "lm" objects, **Predict.lm**, which is a modification of the standard **predict.lm** method in the **stats** package, but with an additional **vcov**. argument for a user-specified covariance matrix for interval estimation.

### Usage

```
Predict(object, ...)  ```
# S3 method for class 'lm'
Predict(object, newdata, se.fit = FALSE,
    scale = NULL, df = Inf,
    interval = c("none", "confidence", "prediction"),
    level = 0.95, type = c("response", "terms"),
    terms = NULL, na.action = na.pass,
    pred.var = res.var/weights, weights = 1, vcov., ...)

Arguments

  * object a model object for which predictions are desired.
  * newdata, se.fit, scale, df, interval, level, type, terms, na.action, pred.var, weights
    see predict.lm.
  * vcov. optional, either a function to compute the coefficient covariance matrix of object
    (e.g., hccm) or a coefficient covariance matrix (as returned, e.g., by hccm). To use
    a bootstrap to estimate the covariance matrix, set vcov. = vcov(Boot(object)).
  * ... arguments to pass down to Predict or predict methods.

Details

If there is no appropriate method for Predict, then a predict method is invoked. If there is a specific predict method for the primary class of object but only an inherited Predict method, then the predict method is invoked. Thus an object of class c("glm", "lm") will invoke method predict.glm rather than Predict.lm, but an object of class c("aov", "lm") will invoke Predict.lm rather than predict.lm.

Value

See predict and predict.lm.

all.equal(p3, p4) # the same

---

### Description

Plots empirical quantiles of a variable, or of studentized residuals from a linear model, against theoretical quantiles of a comparison distribution. Includes options not available in the `qqnorm` function.

### Usage

`qqPlot(x, ...)`

`qqp(...)`

```r
## Default S3 method:
qqPlot(x, distribution="norm", groups, layout,
ylim=range(x, na.rm=TRUE), ylab=deparse(substitute(x)),
xlab=paste(distribution, "quantiles"), glab=deparse(substitute(groups)),
main=NULL, las=par("las"),
envelope=TRUE, col=carPalette()[1], col.lines=carPalette()[2],
lwd=2, pch=1, cex=par("cex"),
line=c("quartiles", "robust", "none"), id=TRUE, grid=TRUE, ...)
```

```r
## S3 method for class 'formula'
qqPlot(formula, data, subset, id=TRUE, ylab, glab, ...)
```

```r
## S3 method for class 'lm'
qqPlot(x, xlab=paste(distribution, "Quantiles"),
ylab=paste("Studentized Residuals(",
deparse(substitute(x)), ",")", sep=""),
main=NULL, distribution=c("t", "norm"),
line=c("robust", "quartiles", "none"), las=par("las"),
simulate=TRUE, envelope=TRUE, reps=100,
col=carPalette()[1], col.lines=carPalette()[2], lwd=2, pch=1, cex=par("cex"),
id=TRUE, grid=TRUE, ...)
```

### Arguments

- **x**: vector of numeric values or `lm` object.
- **distribution**: root name of comparison distribution – e.g., "norm" for the normal distribution; `t` for the t-distribution.
groups

an optional factor; if specified, a QQ plot will be drawn for \( x \) within each level of groups.

layout

a 2-vector with the number of rows and columns for plotting by groups – for example \( c(1, 3) \) for 1 row and 3 columns; if omitted, the number of rows and columns will be selected automatically; the specified number of rows and columns must be sufficient to accommodate the number of groups; ignored if there is no grouping factor.

formula

one-sided formula specifying a single variable to be plotted or a two-sided formula of the form variable ~ factor, where a QQ plot will be drawn for variable within each level of factor.

data

optional data frame within which to evaluate the formula.

subset

optional subset expression to select cases to plot.

ylim

limits for vertical axis; defaults to the range of \( x \). If plotting by groups, a common y-axis is used for all groups.

ylab

label for vertical (empirical quantiles) axis.

xlab

label for horizontal (comparison quantiles) axis.

glab

label for the grouping variable.

main

label for plot.

envelope

TRUE (the default), FALSE, a confidence level such as 0.95, or a list specifying how to plot a point-wise confidence envelope (see Details).

las

if 0, ticks labels are drawn parallel to the axis; set to 1 for horizontal labels (see par).

col

color for points; the default is the first entry in the current car palette (see carPalette and par).

col.lines

color for lines; the default is the second entry in the current car palette.

pch

plotting character for points; default is 1 (a circle, see par).

cex

factor for expanding the size of plotted symbols; the default is 1.

id

controls point identification; if FALSE, no points are identified; can be a list of named arguments to the showLabels function; TRUE is equivalent to list(method="y", n=2, cex=1, col=carPalette()[1], location="lr"), which identifies the 2 points with the 2 points with the most extreme verical values — studentized residuals for the "lm" method. Points labels are by default taken from the names of the variable being plotted is any, else case indices are used. Unlike most graphical functions in car, the default is id=TRUE to include point identification.

lwd

line width; default is 2 (see par).

line

"quartiles" to pass a line through the quartile-pairs, or "robust" for a robust-regression line; the latter uses the rlm function in the MASS package. Specifying line = "none" suppresses the line.

simulate

if TRUE calculate confidence envelope by parametric bootstrap; for lm object only. The method is due to Atkinson (1985).

reps

integer; number of bootstrap replications for confidence envelope.

...

arguments such as df to be passed to the appropriate quantile function.

grid

If TRUE, the default, a light-gray background grid is put on the graph.
**Details**

Draws theoretical quantile-comparison plots for variables and for studentized residuals from a linear model. A comparison line is drawn on the plot either through the quartiles of the two distributions, or by robust regression.

Any distribution for which quantile and density functions exist in R (with prefixes `q` and `d`, respectively) may be used. When plotting a vector, the confidence envelope is based on the SEs of the order statistics of an independent random sample from the comparison distribution (see Fox, 2016). Studentized residuals from linear models are plotted against the appropriate t-distribution with a point-wise confidence envelope computed by default by a parametric bootstrap, as described by Atkinson (1985). The function `qpp` is an abbreviation for `qqPlot`.

The envelope argument can take a list with the following named elements; if an element is missing, then the default value is used:

- `level` confidence level (default 0.95).
- `style` one of "filled" (the default), "lines", or "none".
- `col` color (default is the value of `col.lines`).
- `alpha` transparency/opacity of a filled confidence envelope, a number between 0 and 1 (default 0.15).
- `border` controls whether a border is drawn around a filled confidence envelope (default TRUE).

**Value**

These functions return the labels of identified points, unless a grouping factor is employed, in which case `NULL` is returned invisibly.

```r
x <- rchisq(100, df=2)
qqPlot(x)
qqPlot(x, dist="chisq", df=2, envelope=list(style="lines"))

qqPlot(~ income, data=Prestige, subset = type == "prof")
qqPlot(income ~ type, data=Prestige, layout=c(1, 3))
```
qqPlot(lm(prestige ~ income + education + type, data=Duncan),
envelope=.99)

---

**recode**  
*Recode a Variable*

**Description**

Recodes a numeric vector, character vector, or factor according to simple recode specifications. Recode is an alias for `recode` that avoids name clashes with packages, such as **Hmisc**, that have a `recode` function.

**Usage**

```r
recode(var, recodes, as.factor, as.numeric=TRUE, levels,
   to.value="=", interval=":", separator=";")
```

`Recode(...)`

**Arguments**

- `var`  
  numeric vector, character vector, or factor.

- `recodes`  
  character string of recode specifications: see below.

- `as.factor`  
  return a factor; default is TRUE if `var` is a factor, FALSE otherwise.

- `as.numeric`  
  if TRUE (the default), and `as.factor` is FALSE, then the result will be coerced to numeric if all values in the result can represent numbers (contain only numerals, minus signs, etc.).

- `levels`  
  an optional argument specifying the order of the levels in the returned factor; the default is to use the sort order of the level names.

- `to.value`  
  The operator to separate old from new values, "=" by default; some other possibilities: "->", "~", "~>". Cannot include the interval operator (by default ":") or the separator string (by default ;), so, e.g., by default ":=>" is not allowed. The discussion in Details assumes the default "=". Use a non-default `to.value` if factor levels contain =.

- `interval`  
  the operator used to denote numeric intervals, by default ":". The discussion in Details assumes the default ":". Use a non-default `interval` if factor levels contain :

- `separator`  
  the character string used to separate recode specifications, by default ";". The discussion in Details assumes the default ";". Use a non-default `separator` if factor levels contain ;

- `...`  
  arguments to be passed to `recode`. 

Details

Recode specifications appear in a character string, separated by default by semicolons (see the examples below), each of the form input=output (where = may be replaced by a non-default value of the to.value argument, e.g., input -> output). Spaces may be used for clarity. If an input value satisfies more than one specification, then the first (from left to right) applies. If no specification is satisfied, then the input value is carried over to the result. NA is allowed on input and output. Several recode specifications are supported:

**single value**  For example, 0=NA.

**vector of values**  For example, c(7, 8, 9) = 'high'.

**range of values**  For example, 7:9 = 'C'. The special values lo and hi may appear in a range. For example, lo:10=1. Note: : is not the R sequence operator. In addition, you may not use : with the c function within a recode specification, so for example c(1, 3, 5:7) will cause an error. The : is the default value of the recode interval operator; a non-default value may be specified.

else  everything that does not fit a previous specification. For example, else = NA. Note that else matches all otherwise unspecified values on input, including NA, and if present should appear last among the recode specifications.

Character data and factor levels on the left-hand side of a recode specification must be quoted. Thus, e.g., c(a, b, c) = 'low' is not allowed, and should be c('a', 'b', 'c') = 'low'. Similarly, the colon is reserved for numeric data, and, e.g., c('a':'c') = 'low' is not allowed. If the var argument is a character variable with (some) values that are character representations of numbers, or a factor with (some) levels that are numbers (e.g., '12' or '-2'), then these too must be quoted and cannot be used with colons (e.g., '15':'19' = '15 to 19' is not allowed, and could be specified as c('15', '16', '17', '18', '19') = '15 to 19', assuming that all values are the character representation of whole numbers).

If all of the output values are numeric, and if as.factor is FALSE, then a numeric result is returned; if var is a factor, then by default so is the result.

Value

a recoded vector of the same length as var.

Warning

The factor levels may not contain the character strings in to.value (by default "=") or separator (by default ";").

   cut, factor

Examples

   x <- rep(1:3, 3)
   x
   recode(x, "c(1, 2) = 'A';
      else = 'B'")
   Recode(x, "1-2 -> ':=1' // 3 -> ':=2'", to.value="->",
      interval="-", separator="/"")

regLine

Description

Plots a regression line on a scatterplot; the line is plotted between the minimum and maximum x-values.

Usage

   regLine(mod, col=carPalette()[2], lwd=2, lty=1,...)

Arguments

   mod     a model, such as produced by lm, that responds to the coef function by returning
      a 2-element vector, whose elements are interpreted respectively as the intercept
      and slope of a regression line.
   col     color for points and lines; the default is the second entry in the current car
      palette (see carPalette and par).
   lwd     line width; default is 2 (see par).
   lty     line type; default is 1, a solid line (see par).
   ...    optional arguments to be passed to the lines plotting function.

Details

In contrast to abline, this function plots only over the range of the observed x-values. The x-values
are extracted from mod as the second column of the model matrix.

Value

   NULL. This function is used for its side effect: adding a line to the plot.

regLine(lm(repwt~weight, subset=sex=="F", data=Davis), lty=2)

residualPlots Residual Plots for Linear and Generalized Linear Models

Description

Draws a plot or plots of residuals versus one or more term in a mean function and/or versus fitted values. For linear models curvature tests are computed for each of the plots by adding a quadratic term to the regression function and testing the quadratic to be zero. This is Tukey’s test for nonadditivity when plotting against fitted values.

Usage

### This is a generic function with only one required argument:
residualPlots (model, ...)

### Default S3 method:
residualPlots(model, terms= ~ . ,
               layout=NULL, ask, main="",
               fitted=TRUE, AsIs=TRUE, plot=TRUE, tests=TRUE, groups, ...)

### S3 method for class 'lm'
residualPlots(model, ...)

### S3 method for class 'glm'
residualPlots(model, ...)

### residualPlots calls residualPlot, so these arguments can be
### used with either function
residualPlot(model, ...)

### Default S3 method:
residualPlot(model, variable = "fitted", type = "pearson",
             groups, plot = TRUE, linear = TRUE,
             quadratic = if(missing(groups)) TRUE else FALSE,
             smooth=FALSE, id=FALSE,
             col = carPalette()[1], col.quad = carPalette()[2], pch=1,
xlab, ylab, lwd=1, grid=TRUE, key=!missing(groups), ...)

## S3 method for class 'lm'
residualPlot(model, ...)

## S3 method for class 'glm'
residualPlot(model, variable = "fitted", type = "pearson",
            plot = TRUE, quadratic = FALSE, smooth=TRUE, ...)

Arguments

model A regression object.
terms A one-sided formula that specifies a subset of the terms that appear in the formula that defined the model. The default ~. is to plot against all first-order terms. Interactions are skipped. For example, the specification terms = ~ . X3 would plot against all terms except for X3. To get a plot against fitted values only, use the arguments terms = ~ 1. If a term like log(X1) is in the formula, then the corresponding plot is obtained using terms = ~ log(X1). For polynomial terms generated using the poly function, the plot is against the first-order variable, which may be centered and scaled depending on how the arguments to the poly function. Plots against factors are boxplots. Plots against splines use the result of predict(model), type="terms"[, variable]) as the horizontal axis. A grouping variable can also be specified, so, for example terms= ~ .|type would use the factor type to set a different color and symbol for each level of type. Any fits in the plots will also be done separately for each level of group. This can be useful of finding interactions between the grouping variable and the term on the horizontal axis. The grouping variable can also be set using the argument groups="type".

layout If set to a value like c(1, 1) or c(4, 3), the layout of the graph will have this many rows and columns per "page" with a prompt given the in console to change to the next page. If not set, the program will select an appropriate layout. If the number of graphs exceed nine, you must select the layout yourself, or you will get a maximum of nine per page. If layout=NA, the function does not set the layout and the user can use the par function to control the layout, for example to have plots from two models in the same graphics window.

ask If TRUE, ask the user before drawing the next plot; if FALSE, don’t ask.

main Main title for the graphs. The default is main="" for no title.
fitted If TRUE, the default, include the plot against fitted values.
AsIs Some terms in a model formula use the as-is or identity function, for example a term like I(X^2) to include a quadratic. These terms will be skipped in plotting if AsIs is FALSE. The default is TRUE.

plot If TRUE, draw the plot(s).
tests If TRUE, display the curvature tests.
... Additional arguments passed to residualPlot and then to plot.
variable Quoted variable name for the factor or regressor to be put on the horizontal axis, or the default "fitted" to plot versus fitted values.
residualPlots

type  Specifies the type of residual to be plotted. Any of c("working", "response", "deviance", "pearson", "partial", "rstudent", "rstandard") may be specified. The default type = "pearson" is usually appropriate, since it is equal to ordinary residuals observed minus fit with ols, and correctly weighted residuals with wls or for a glm. The last two options use the rstudent and rstandard functions and use studentized or standardized residuals.

groups  A grouping indicator, provided as the quoted name of a grouping variable in the model, such as "type", or "ageGroup". Points in different groups will be plotted with different colors and symbols. If missing, no grouping is used. In residualPlots, the grouping variable can also be set in the terms argument, as described above. The default is no grouping.

linear  If TRUE, adds a horizontal line at zero if no groups. With groups, within level of groups display the ols regression of the residuals as response and the horizontal axis as the regressor.

quadratic  if TRUE, fits the quadratic regression of the vertical axis on the horizontal axis and displays a lack of fit test. Default is TRUE for lm and FALSE for glm or if groups not missing.

smooth  specifies the smoother to be used along with its arguments; if FALSE, which is the default except for generalized linear models, no smoother is shown; can be a list giving the smoother function and its named arguments; TRUE is equivalent to list(smoother=loessLine, span=2/3, col=carPalette()[3]), which is the default for a GLM. See ScatterplotSmoothers for the smoothers supplied by the car package and their arguments.

id  controls point identification; if FALSE (the default), no points are identified; can be a list of named arguments to the showLabels function; TRUE is equivalent to list(method="r", n=2, cex=1, col=carPalette()[1], location="lr"), which identifies the 2 points with the largest absolute residuals.

col  default color for points. If groups is set, col can be a list at least as long as the number of levels for groups giving the colors for each groups.

col.quad  default color for quadratic fit if groups is missing. Ignored if groups are used.
pch  plotting character. The default is pch=1. If groups are used, pch can be set to a vector at least as long as the number of groups.

xlab  X-axis label. If not specified, a useful label is constructed by the function.

ylab  Y-axis label. If not specified, a useful label is constructed by the function.

lwd  line width for the quadratic fit, if any.

grid  If TRUE, the default, a light-gray background grid is put on the graph

key  Should a key be added to the plot? Default is !is.null(groups).

Details  residualPlots draws one or more residuals plots depending on the value of the terms and fitted arguments. If terms = ~ ., the default, then a plot is produced of residuals versus each first-order term in the formula used to create the model. A plot of residuals versus fitted values is also included unless fitted=FALSE. Setting terms = ~1 will provide only the plot against fitted values.
A table of curvature tests is displayed for linear models. For plots against a term in the model formula, say $X_1$, the test displayed is the t-test for for $I(X_1^2)$ in the fit of update, model, $\sim + I(X_1^2)$. Econometricians call this a specification test. For factors, the displayed plot is a boxplot, no curvature test is computed, and grouping is ignored. For fitted values in a linear model, the test is Tukey’s one-degree-of-freedom test for nonadditivity. You can suppress the tests with the argument tests=FALSE. If grouping is used curvature tests are not displayed.

residualPlot, which is called by residualPlots, should be viewed as an internal function, and is included here to display its arguments, which can be used with residualPlots as well. The residualPlot function returns the curvature test as an invisible result.

residCurvTest computes the curvature test only. For any factors a boxplot will be drawn. For any polynomials, plots are against the linear term. Other non-standard predictors like B-splines are skipped.

Value

For lm objects, returns a data.frame with one row for each plot drawn, one column for the curvature test statistic, and a second column for the corresponding p-value. This function is used primarily for its side effect of drawing residual plots.

Examples

```r
m1 <- lm(prestige ~ income + type, data=Prestige)
residualPlots(m1)
residualPlots(m1, terms= ~ 1 | type) # plot vs. yhat grouping by type
```
Description

The **car** package replaces the `summary` and `confint` functions for `lm`, `glm`, `multinom`, and `polr` objects, with additional arguments but the same defaults as the original functions. The Confint method for “polr” objects profiles the likelihood to get confidence intervals for the regression parameters but uses Wald intervals for the thresholds. Default methods that call the standard R `summary` and `confint` functions are provided for the `S` and `Confint` generics, so the **car** functions should be safe to use in general. The default method for `Confint` also assumes that there is an appropriate `coef` method. For briefer model summaries, see `brief`.

Usage

```r
S(object, brief, ...)  
```
## S3 method for class 'S.lm'
print(x, digits = max(3, getOption("digits") - 3),
     symbolic.cor = x$symbolic.cor, signif.stars = getOption("show.signif.stars"), ...)

## S3 method for class 'S.glm'
print(x, digits = max(3L, getOption("digits") - 3L),
     symbolic.cor = x$symbolic.cor, signif.stars = getOption("show.signif.stars"), ...)

## S3 method for class 'S.multinom'
print(x, digits = max(3, getOption("digits") - 3),
     signif.stars = getOption("show.signif.stars"), ...)

## S3 method for class 'S.polr'
print(x, digits = max(3, getOption("digits") - 3),
     signif.stars = getOption("show.signif.stars"), ...)

## S3 method for class 'S.lme'
print(x, digits = max(3, getOption("digits") - 3),
     signif.stars = getOption("show.signif.stars"), ...)

## S3 method for class 'S.lmerMod'
print(x, digits = max(3, getOption("digits") - 3),
     signif.stars = getOption("show.signif.stars"), ...)

## S3 method for class 'S.glmerMod'
print(x, digits = max(3, getOption("digits") - 3),
     signif.stars = getOption("show.signif.stars"), ...)

Confint(object, ...)

## S3 method for class 'lm'
Confint(object, estimate=TRUE,
         parm, level=0.95, vcov.=vcov(object, complete=FALSE), ...)

## S3 method for class 'glm'
Confint(object, estimate=TRUE, exponentiate=FALSE,
         vcov., dispersion, type=c("LR", "Wald"), ...)

## S3 method for class 'polr'
Confint(object, estimate=TRUE, exponentiate=FALSE,
         thresholds=!exponentiate, ...)

## S3 method for class 'multinom'
Confint(object, estimate=TRUE, exponentiate=FALSE, ...)

## S3 method for class 'lme'
Confint(object, estimate=TRUE, level=0.95, ...)
### S3 method for class 'lmerMod'
Confint(object, estimate=TRUE, level=0.95, ...)

### S3 method for class 'glmerMod'
Confint(object, estimate=TRUE, level=0.95,
exponentiate=FALSE, ...)

### Default S3 method:
Confint(object, estimate=TRUE, level=0.95, vcov., ...)

#### Arguments

- **object**
  - a model or other object, e.g., of class "lm" as produced by a call to `lm`.

- **exponentiate**
  - for a "glm" or "glmerMod" model using the log or logit link, or a "polr" or "multinom" model, show exponentiated coefficient estimates and confidence bounds.

- **correlation, symbolic.cor**
  - see `summary.lm`

- **x, digits, signif.stars**
  - see `summary.lm`

- **dispersion**
  - see `summary.glm`

- **vcov.**
  - either a matrix giving the estimated covariance matrix of the estimates, or a function that when called with `object` as an argument returns an estimated covariance matrix of the estimates. The default of `vcov. = vcov` uses the usual estimated covariance matrix. Other choices include the functions documented at `hccm`. See example below for using a bootstrap to estimate the covariance matrix. For the `glm` methods of `Confint` and `S`, if the `vcov.` or `dispersion` argument is specified, then Wald-based confidence limits are computed; otherwise the reported confidence limits are computed by profiling the likelihood. NOTE: The dispersion and `vcov.` arguments may not both be specified.

- **header**
  - if TRUE, print the header for the summary output, default is TRUE

- **resid.summary**
  - if TRUE, print the five-number summary of the residuals in the summary, defaults to FALSE

- **adj.r2**
  - if TRUE, print the adjusted r-squared in the summary, default is FALSE

- **brief**
  - if TRUE, set header, resid.summary and adj.r.squared to FALSE, and suppress exponentiated coefficients for GLMs with log or logit link. For a data frame, equivalent to use of `brief`.

- **KR**
  - if TRUE (default is FALSE), compute Kenward-Roger standard errors and Satterthwaite degrees of freedom for t-tests. **Warning:** This computation can be very time-consuming.

- **parm, level**
  - see `confint`

- **estimate**
  - show the estimated coefficients in the confidence-interval table; default is TRUE.

- **thresholds**
  - show confidence intervals for the estimated thresholds in the "polr" model.

- **type**
  - if "LR" (the default) compute confidence intervals based on the LR statistics by profiling the likelihood; if "Wald" base confidence intervals on the Wald statistic using the coefficient standard error and the normal distribution.
... additional arguments to be passed down, for consistency with summary and confint methods

Details

All these functions mimic functions in the stats and other standard R packages for summarizing aspects of linear, generalized linear, and some other statistical models. The S function also provides an alternative to summary for data frames, treating character variables as if they were factors.

The S and Confint functions add support for the vcov. argument for linear models, which allows specifying a covariance matrix for the regression coefficients other than the usual covariance matrix returned by the function vcov. This argument may be either the name of a function, so that the call to vcov.(object) returns a covariance matrix, or else vcov. is set equal to a covariance matrix. For example, setting vcov. = hccm uses 'proposal 3' described by Long and Ervin (2000) for a sandwich coefficient-variance estimator that may be robust against nonconstant variance (see hccm). Setting vcov. = hccm(object, type = "hc2") would use the matrix returned by the hccm function using proposal 2. For use with a bootstrap, see the examples below. The overall F-test in the S.lm output uses the supplied covariance matrix in a call to the linearHypothesis function.

The supplied print method for S.lm (and for other S methods) has additional arguments to customize the standard summary.lm output. Standard output is obtained by setting resid.summary=TRUE, adj.r2=TRUE.

Using a heteroscedasticity-corrected covariance matrix computed using hccm with GLMs other than Gaussian is not justified; see the article by Freedman (2006).

The Summary.glm method for models fit with the log or logit link by default prints a table of exponentiated coefficients and their confidence limits; Summary.multinom and Summary.polr optionally print tables of exponentiated coefficients.

Value

The S.lm and S.glm functions return a list with all the elements shown at summary.lm and summary.glm.

The S.multinom and S.polr functions return a list with all the elements shown at summary.multinom and summary.polr plus potentially a table of exponentiated coefficients and confidence bounds.

The Confint.lm function returns either the output from confint.lm if vcov. = vcov or Wald-type confidence intervals using the supplied covariance matrix for any other choice of vcov..

Finally, Confint applied to any object that does not inherit from "lm", "multinom", or "polr" simply calls confint, along with, by default, using coef to add a column of estimates to the confidence limits.

**scatter3d**

*Three-Dimensional Scatterplots and Point Identification*

**Description**

The *scatter3d* function uses the *rgl* package to draw 3D scatterplots with various regression surfaces. The function `Identify3d` allows you to label points interactively with the mouse: Press the right mouse button (on a two-button mouse) or the centre button (on a three-button mouse), drag a rectangle around the points to be identified, and release the button. Repeat this procedure for each point or set of “nearby” points to be identified. To exit from point-identification mode, click the right (or centre) button in an empty region of the plot.

**Usage**

```r
scatter3d(x, ...)
```

## S3 method for class 'formula'
scatter3d(formula, data, subset, radius, xlab, ylab, zlab, id=FALSE, ...)

## Default S3 method:
scatter3d(x, y, z,
xlab=deparse(substitute(x)), ylab=deparse(substitute(y)),
zlab=deparse(substitute(z)), axis.scales=TRUE, axis.ticks=FALSE,
revolutions=0,
bg.col=c("white", "black"),
axis.col=if (bg.col == "white") c("darkmagenta", "black", "darkcyan")
else c("darkmagenta", "white", "darkcyan"),
surface.col=carPalette()[-1], surface.alpha=0.5,
neg.res.col="magenta", pos.res.col="cyan",
point.col="yellow", text.col=axis.col,
grid.col=if (bg.col == "white") "black" else "gray",
foptype=c("exp2", "linear", "exp", "none"),
residuals=(length(fit) == 1),
surface=TRUE, fill=TRUE,
grid=TRUE, grid.lines=26, df.smooth=NULL, df.additive=NULL,
sphere.size=1, radius=1, speed=1, fov=60,
fit="linear", groups=NULL, parallel=TRUE,
ellipsoid=FALSE, level=0.5, ellipsoid.alpha=0.1, id=FALSE,
model.summary=FALSE,
reg.function, reg.function.col=surface.col[length(surface.col)],
mouseMode=c(\text{none}="none", \text{left}="polar", \text{right}="zoom", \text{middle}="fov",
wheel="pull"),
...)

Identify3d(x, y, z, axis.scales=TRUE, groups = NULL, labels = 1:length(x),
col = c("blue", "green", "orange", "magenta", "cyan", "red", "yellow", "gray"),
offset = (((100/length(x))^(1/3)) * 0.02)

Arguments

\begin{itemize}
  \item \textbf{formula} \text{"model" formula, of the form $y \sim x + z$ or to plot by groups $y \sim x + z \mid g$, where $g$ evaluates to a factor or other variable dividing the data into groups.}
  \item \textbf{data} \text{data frame within which to evaluate the formula.}
  \item \textbf{subset} \text{expression defining a subset of observations.}
  \item \textbf{x} \text{variable for horizontal axis.}
  \item \textbf{y} \text{variable for vertical axis (response).}
  \item \textbf{z} \text{variable for out-of-screen axis.}
  \item \textbf{xlab}, \textbf{ylab}, \textbf{zlab} \text{axis labels.}
  \item \textbf{axis.scales} \text{if TRUE, label the values of the ends of the axes. \textit{Note}: For Identify3d to work properly, the value of this argument must be the same as in scatter3d.}
  \item \textbf{axis.ticks} \text{if TRUE, print interior axis-"tick" labels; the default is FALSE. (The code for this option was provided by David Winsemius.)}
\end{itemize}

<td>fill the plotted surface(s) with colour (TRUE or FALSE).</td>
</tr>
<tr>
<td>grid</td>
<td>plot grid lines on the regression surface(s) (TRUE or FALSE).</td>
</tr>
<tr>
<td>grid.lines</td>
<td>number of lines (default, 26) forming the grid, in each of the x and z directions.</td>
</tr>
<tr>
<td>df.smooth</td>
<td>degrees of freedom for the two-dimensional smooth regression surface; if NULL (the default), the gam function will select the degrees of freedom for a smoothing spline by generalized cross-validation; if a positive number, a fixed regression spline will be fit with the specified degrees of freedom.</td>
</tr>
<tr>
<td>df.additive</td>
<td>degrees of freedom for each explanatory variable in an additive regression; if NULL (the default), the gam function will select degrees of freedom for the smoothing splines by generalized cross-validation; if a positive number or a vector of two positive numbers, fixed regression splines will be fit with the specified degrees of freedom for each term.</td>
</tr>
<tr>
<td>sphere.size</td>
<td>general size of spheres representing points; the actual size is dependent on the number of observations.</td>
</tr>
<tr>
<td>radius</td>
<td>relative radii of the spheres representing the points. This is normally a vector of the same length as the variables giving the coordinates of the points, and for the formula method, that must be the case or the argument may be omitted, in which case spheres are the same size; for the default method, the default for the argument, 1, produces spheres all of the same size. The radii are scaled so that their median is 1.</td>
</tr>
<tr>
<td>threshold</td>
<td>if the actual size of the spheres is less than the threshold, points are plotted instead.</td>
</tr>
</tbody>
</table>
speed  
relative speed of revolution of the plot.

fov  
field of view (in degrees); controls degree of perspective.

fit  
one or more of "linear" (linear least squares regression), "quadratic" (quadratic least squares regression), "smooth" (nonparametric regression), "additive" (nonparametric additive regression), "robust" (robust linear regression); to display fitted surface(s); partial matching is supported – e.g., c("lin", "quad").

groups  
if NULL (the default), no groups are defined; if a factor, a different surface or set of surfaces is plotted for each level of the factor; in this event, the colours in surface.col are used successively for the points, surfaces, and residuals corresponding to each level of the factor.

parallel  
when plotting surfaces by groups, should the surfaces be constrained to be parallel? A logical value, with default TRUE.

ellipsoid  
plot concentration ellipsoid(s) (TRUE or FALSE).

level  
expected proportion of bivariate-normal observations included in the concentration ellipsoid(s); default is 0.5.

ellipsoid.alpha  
transparency of ellipsoids, from 0.0 (fully transparent) to 1.0 (opaque); default is 0.1.

id  
FALSE, TRUE, or a list controlling point identification, similar to showLabels for 2D plots (see Details).

model.summary  
print summary or summaries of the model(s) fit (TRUE or FALSE). scatter3d rescales the three variables internally to fit in the unit cube; this rescaling will affect regression coefficients.

labels  
text labels for the points, one for each point; defaults to the observation indices.

col  
colours for the point labels, given by group. There must be at least as many colours as groups; if there are no groups, the first colour is used. Normally, the colours would correspond to the surface.col argument to scatter3d.

offset  
vertical displacement for point labels (to avoid overplotting the points).

reg.function  
an arithmetic expression that is a function of x and z (respectively, the horizontal and out-of-screen explanatory variables), representing an arbitrary regression function to plot.

reg.function.col  
color to use for the surface produced by reg.function; defaults to the last color in surface.col.

mouseMode  
defines what the mouse buttons, etc., do; passed to par3d in the rgl package; the default in scatter3d is the same as in the rgl package, except for the left mouse button.

...  
arguments to be passed down.

Details

The id argument to scatter3d can be FALSE, TRUE (in which case 2 points will be identified according to their Mahalanobis distances from the center of the data), or a list containing any or all of the following elements:
method if "mahal" (the default), relatively extreme points are identified automatically according to their Mahalanobis distances from the centroid (point of means); if "identify", points are identified interactively by right-clicking and dragging a box around them; right-click in an empty area to exit from interactive-point-identification mode; if "xz", identify extreme points in the predictor plane; if "y", identify unusual values of the response; if "xyz" identify unusual values of a variable; if "none", no point identification. See showLabels for more information.

n Number of relatively extreme points to identify automatically (default, 2, unless method="identify", in which case identification continues until the user exits).

labels text labels for the points, one for each point; in the default method defaults to the observation indices, in the formula method to the row names of the data.

offset vertical displacement for point labels (to avoid overplotting the points).

Value

scatter3d does not return a useful value; it is used for its side-effect of creating a 3D scatterplot. Identify3d returns the labels of the identified points.

Note

You have to install the rgl package to produce 3D plots. On a Macintosh (but not on Windows or Linux), you may also need to install the X11 windowing system. Go to https://www.xquartz.org/ and click on the link for XQuartz. Double-click on the downloaded disk-image file, and then double-click on XQuartz.pkg to start the installer. You may take all of the defaults in the installation. After XQuartz is installed, you should restart your Macintosh.

**Description**

This function uses basic R graphics to draw a two-dimensional scatterplot, with options to allow for plot enhancements that are often helpful with regression problems. Enhancements include adding marginal boxplots, estimated mean and variance functions using either parametric or nonparametric methods, point identification, jittering, setting characteristics of points and lines like color, size and symbol, marking points and fitting lines conditional on a grouping variable, and other enhancements. *sp* is an abbreviation for *scatterplot*.

**Usage**

```r
scatterplot(x, ...)
```

## S3 method for class 'formula'

---
scatterplot(formula, data, subset, xlab, ylab, id=FALSE, legend=TRUE, ...)  

## Default S3 method:
scatterplot(x, y, boxplots=if (by.groups) "" else "xy",  
  regLine=TRUE, legend=TRUE, id=FALSE, ellipse=FALSE, grid=TRUE,  
  smooth=TRUE,  
  groups, by.groups=!missing(groups),  
  xlab=deparse(substitute(x)), ylab=deparse(substitute(y)),  
  log="", jitter=list(), cex=par("cex"),  
  col=carPalette()[-1], pch=1:n.groups,  
  reset.par=TRUE, ...)  

sp(x, ...)  

Arguments  

x  
vector of horizontal coordinates (or first argument of generic function).  

y  
vector of vertical coordinates.  

formula  
a model formula, of the form \( y \sim x \) or, if plotting by groups, \( y \sim x \mid z \), where \( z \) evaluates to a factor or other variable dividing the data into groups. If \( x \) is a factor, then parallel boxplots are produced using the \texttt{Boxplot} function.  

data  
data frame within which to evaluate the formula.  

subset  
expression defining a subset of observations.  

boxplots  
if "x" a marginal boxplot for the horizontal \( x \)-axis is drawn below the plot; if "y" a marginal boxplot for vertical \( y \)-axis is drawn to the left of the plot; if "xy" both marginal boxplots are drawn; set to "" or FALSE to suppress both boxplots.  

regLine  
controls adding a fitted regression line to the plot. if \texttt{regLine}=FALSE, no line is drawn. If TRUE, the default, an OLS line is fit. This argument can also be a list. The default of TRUE is equivalent to \texttt{regLine=list(method=lm, lty=1, lwd=2, col=col)}, which specifies using the \texttt{lm} function to estimate the fitted line, to draw a solid line (\texttt{lty}=1) of width 2 times the nominal width (\texttt{lwd}=2) in the color given by the first element of the \texttt{col} argument described below.  

legend  
when the plot is drawn by groups and \texttt{legend}=TRUE, controls placement and properties of the legend; if FALSE, the legend is suppressed. Can be a list of named arguments, as follows: title for the legend; inset, giving space as a proportion of the axes to offset the legend from the axes; coords specifying the position of the legend in any form acceptable to the \texttt{legend} function or, if not given, the legend is placed above the plot in the upper margin; columns for the legend, determined automatically to prefer a horizontal layout if not given explicitly; cex giving the relative size of the legend symbols and text. TRUE (the default) is equivalent to \texttt{list(title=deparse(substitute(groups)), inset=0.02, cex=1)}.  

id  
controls point identification; if FALSE (the default), no points are identified; can be a list of named arguments to the \texttt{showLabels} function; TRUE is equivalent to \texttt{list(method="mahal", n=2, cex=1, col=carPalette()[-1], location="lr"),}
which identifies the 2 points (in each group) with the largest Mahalanobis
distances from the center of the data. See showLabels for a description of the other
arguments. The default behavior of id is not the same in all graphics functions
in car, as the method used depends on the type of plot.

**ellipse**  
controls plotting data-concentration ellipses. If FALSE (the default), no ellipses
are plotted. Can be a list of named values giving levels, a vector of one or
more bivariate-normal probability-contour levels at which to plot the ellipses;
robust, a logical value determining whether to use the cov.trob function in the
MASS package to calculate the center and covariance matrix for the data ellipses; and fill and fill.alpha, which control whether the ellipse is filled and
the transparency of the fill. TRUE is equivalent to list(levels=c(.5, .95),
robust=TRUE, fill=TRUE, fill.alpha=0.2).

**grid**  
If TRUE, the default, a light-gray background grid is put on the graph

**smooth**  
specifies a nonparametric estimate of the mean or median function of the vertical
axis variable given the horizontal axis variable and optionally a nonparametric
estimate of the conditional variance. If smooth=FALSE neither function is drawn.
If smooth=TRUE, then both the mean function and variance functions are drawn
for ungrouped data, and the mean function only is drawn for grouped data. The
default smoother is loessLine, which uses the loess function from the stats
package. This smoother is fast and reliable. See the details below for changing
the smoother, line type, width and color, of the added lines, and adding arguments
for the smoother.

**groups**  
a factor or other variable dividing the data into groups; groups are plotted with
different colors, plotting characters, fits, and smooths. Using this argument is
equivalent to specifying the grouping variable in the formula.

**by.groups**  
if TRUE (the default when there are groups), regression lines are fit by groups.

**xlab**  
label for horizontal axis.

**ylab**  
label for vertical axis.

**log**  
same as the log argument to plot, to produce log axes.

**jitter**  
a list with elements x or y or both, specifying jitter factors for the horizontal and
vertical coordinates of the points in the scatterplot. The jitter function is used
to randomly perturb the points; specifying a factor of 1 produces the default
jitter. Fitted lines are unaffected by the jitter.

**col**  
with no grouping, this specifies a color for plotted points; with grouping, this
argument should be a vector of colors of length at least equal to the number of
groups. The default is value returned by carPalette[-1].

**pch**  
plotting characters for points; default is the plotting characters in order (see par).

**cex**  
sets the size of plotting characters, with cex=1 the standard size. You can also set
the sizes of other elements with the arguments cex.axis, cex.lab, cex.main, and cex.sub. See par.

**reset.par**  
if TRUE (the default) then plotting parameters are reset to their previous values
when scatterplot exits; if FALSE then the mar and mfcol parameters are altered for the current plotting device. Set to FALSE if you want to add graphical elements (such as lines) to the plot.
other arguments passed down and to plot. For example, the argument las sets
the style of the axis labels, and xlim and ylim set the limits on the horizontal
and vertical axes, respectively; see par.

Details

Many arguments to scatterplot were changed in version 3 of car to simplify use of this function.
The smooth argument is used to control adding smooth curves to the plot to estimate the conditional
center of the vertical axis variable given the horizontal axis variable, and also the conditional
variability. Setting smooth=FALSE omits all smoothers, while smooth=TRUE, the default, includes
default smoothers. Alternatively smooth can be set to a list of subarguments that provide finer
control over the smoothing.

The default behavior of smooth=TRUE is equivalent to smooth=list(smother=loessLine, var=!by.groups,
lty.var=2, lty.var=4, style="filled", alpha=0.15, border=TRUE, vertical=TRUE), specifying the default loessLine smoother for the conditional mean smooth and variance smooth. The
color of the smoothes is the same of the color of the points, but this can be changed with the arguments col.smooth and col.var.

Additional available smoothers are gamLine which uses the gam function and quantregLine which
uses quantile regression to estimate the median and quartile functions using rqss. All of these
smoothers have one or more arguments described on their help pages, and these arguments can
be added to the smooth argument; for example, smooth = list(span=1/2) would use the default loessLine smoother, include the variance smooth, and change the value of the smoothing parameter to 1/2.

For loessLine and gamLine the variance smooth is estimated by separately smoothing the squared
positive and negative residuals from the mean smooth, using the same type of smoother. The displayed curves are equal to the mean smooth plus the square root of the fit to the positive squared residuals, and the mean fit minus the square root of the smooth of the negative squared residuals. The lines therefore represent the conditional variability at each value on the horizontal axis. Because smoothing is done separately for positive and negative residuals, the variation shown will generally not be symmetric about the fitted mean function. For the quantregLine method, the center estimates the conditional median, and the variability estimates the lower and upper quartiles of the estimated conditional distribution.

The default depiction of the variance functions is via a shaded envelope between the upper and
lower estimate of variability, setting the subargument style="lines" will display only the boundaries of this region, and style="none" suppresses variance smoothing.

For style="filled" several subarguments modify the appearance of the region: codealpha is a number between 0 and 1 that specifies opacity with default 0.15, border, TRUE or FALSE specifies a border for the envelope, and vertical either TRUE or FALSE, modifies the behavior of the envelope at the edges of the graph.

The sub-arguments spread, lty.spread and col.spread of the smooth argument are equivalent
to the newer var, col.var and lty.var, respectively, recognizing that the spread is a measure of conditional variability.

Value

If points are identified, their labels are returned; otherwise NULL is returned invisibly.
scatterplotMatrix

Scatterplot Matrices

Description

This function provides a convenient interface to the pairs function to produce enhanced scatterplot matrices, including univariate displays on the diagonal and a variety of fitted lines, smoothers, variance functions, and concentration ellipsoids. spm is an abbreviation for scatterplotMatrix.
scatterplotMatrix

Usage

scatterplotMatrix(x, ...)

## S3 method for class 'formula'
scatterplotMatrix(formula, data=NULL, subset, ...)

## Default S3 method:
scatterplotMatrix(x, smooth = TRUE,
    id = FALSE, legend = TRUE, regLine = TRUE,
    ellipse = FALSE, var.labels = colnames(x), diagonal = TRUE,
    plot.points = TRUE, groups = NULL, by.groups = TRUE,
    use = c("complete.obs", "pairwise.complete.obs"), col =
    carPalette()[-1], pch = 1:n.groups, cex = par("cex"),
    cex.axis = par("cex.axis"), cex.labels = NULL,
    cex.main = par("cex.main"), row1attop = TRUE, ...)

spm(x, ...)

Arguments

x a data matrix or a numeric data frame.

formula a one-sided “model” formula, of the form ~ x1 + x2 + ... + xk or ~ x1 + x2 + ... + xk | z where z evaluates to a factor or other variable to divide the data into groups.

data for scatterplotMatrix.formula, a data frame within which to evaluate the formula.

subset expression defining a subset of observations.

smooth specifies a nonparametric estimate of the mean or median function of the vertical axis variable given the horizontal axis variable and optionally a nonparametric estimate of the spread or variance function. If smooth=FALSE neither function is drawn. If smooth=TRUE, then both the mean function and variance functions are drawn for ungrouped data, and the mean function only is drawn for grouped data. The default smoother is loessLine, which uses the loess function from the stats package. This smoother is fast and reliable. See the details below for changing the smoother, line type, width and color, of the added lines, and adding arguments for the smoother.

id controls point identification; if FALSE (the default), no points are identified; can be a list of named arguments to the showLabels function; TRUE is equivalent to list(method="mahal", n=2, cex=1, location="lr"), which identifies the 2 points (in each group, if by.groups=TRUE) with the largest Mahalanobis distances from the center of the data; list(method="identify") for interactive point identification is not allowed.

legend controls placement, point size, and text size of a legend if the plot is drawn by groups; if FALSE, the legend is suppressed. Can be a list with the named element coords specifying the position of the legend in any form acceptable to
the legend function, and elements pt.cex and cex corresponding respectively to the pt.cex and cex arguments of the legend function; TRUE (the default) is equivalent to list(coords=NULL, pt.cex=pt.cex, cex=cex), for which placement will vary by the the value of the diagonal argument—e.g., “topright" for diagonal=TRUE.

regLine controls adding a fitted regression line to each plot, or to each group of points if by.groups=TRUE. If regLine=FALSE, no line is drawn. This argument can also be a list with named list, with default regLine=TRUE equivalent to regLine = list(method=lm, lty=1, lwd=2, col=col[1]) specifying the name of the function that computes the line, with line type 1 (solid) of relative line width 2 and the color equal to the first value in the argument col. Setting method=MASS::rlm would fit using a robust regression.

ellipse controls plotting data-concentration ellipses. If FALSE (the default), no ellipses are plotted. Can be a list of named values giving levels, a vector of one or more bivariate-normal probability-contour levels at which to plot the ellipses; robust, a logical value determining whether to use the cov.trob function in the MASS package to calculate the center and covariance matrix for the data ellipses; and fill and fill.alpha, which control whether the ellipse is filled and the transparency of the fill. TRUE is equivalent to list(levels=c(.5, .95), robust=TRUE, fill=TRUE, fill.alpha=0.2).

var.labels variable labels (for the diagonal of the plot).

diagonal contents of the diagonal panels of the plot. If diagonal=TRUE adaptive kernel density estimates are plotted, separately for each group if grouping is present. diagonal=FALSE suppresses the diagonal entries. See details below for other choices for the diagonal.

plot.points if TRUE the points are plotted in each off-diagonal panel.

groups a factor or other variable dividing the data into groups; groups are plotted with different colors and plotting characters.

by.groups if TRUE, the default, regression lines and smooths are fit by groups.

use if "complete.obs" (the default), cases with missing data are omitted; if "pairwise.complete.obs"), all valid cases are used in each panel of the plot.

pch plotting characters for points; default is the plotting characters in order (see par).

col colors for points; the default is carPalette starting at the second color. The color of the regLine and smooth are the same as for points but can be changed using the the regLine and smooth arguments.

cex relative size of plotted points

cex.axis relative size of axis labels

cex.labels relative size of labels on the diagonal

cex.main relative size of the main title, if any

row1attop If TRUE (the default) the first row is at the top, as in a matrix, as opposed to at the bottom, as in graph (argument suggested by Richard Heiberger).

... arguments to pass down.
Details

Many arguments to `scatterplotMatrix` were changed in version 3 of `car`, to simplify use of this function.

The `smooth` argument is usually either set to `TRUE` or `FALSE` to draw, or omit, the smoother. Alternatively, `smooth` can be set to a list of arguments. The default behavior of `smooth=TRUE` is equivalent to `smooth=list(smoother=loessLine, spread=TRUE, lty.smooth=1, lwd.smooth=1.5, lty.spread=3, lwd.spread=1)`, specifying the smoother to be used, including the spread or variance smooth, and the line widths and types for the curves. You can also specify the colors you want to use for the mean and variance smooths with the arguments `col.smooth` and `col.spread`. Alternative smoothers are `gamLine` which uses the `gam` function from the `mgcv` package, and `quantregLine` which uses quantile regression to estimate the median and quartile functions using `rqss` from the `quantreg` package. All of these smoothers have one or more arguments described on their help pages, and these arguments can be added to the `smooth` argument; for example, `smooth=list(span=1/2)` would use the default `loessLine` smoother, include the variance smooth, and change the value of the smoothing parameter to `1/2`. For `loessLine` and `gamLine` the variance smooth is estimated by separately smoothing the squared positive and negative residuals from the mean smooth, using the same type of smoother. The displayed curves are equal to the mean smooth plus the square root of the fit to the positive squared residuals, and the mean fit minus the square root of the smooth of the negative squared residuals. The lines therefore represent the conditional variability at each value on the horizontal axis. Because smoothing is done separately for positive and negative residuals, the variation shown will generally not be symmetric about the fitted mean function. For the `quantregLine` method, the center estimates the median for each value on the horizontal axis, and the spread estimates the lower and upper quartiles of the estimated conditional distribution for each value of the horizontal axis.

The sub-arguments `spread`, `lty.spread` and `col.spread` of the `smooth` argument are equivalent to the newer `var`, `col.var` and `lty.var`, respectively, recognizing that the spread is a measure of conditional variability.

By default, the diagonal argument is used to draw kernel density estimates of the variables by setting `diagonal=TRUE`, which is equivalent to setting `diagonal=list(method="adaptiveDensity", bw=bw.nrd0, adjust=1, kernel=dnorm, na.rm=TRUE)`. The additional arguments shown are described at `adaptiveKernel`. The other methods available, with their default arguments, are `diagonal=list(method="density", bw="nrd0", adjust=1, kernel="gaussian", na.rm=TRUE)` which uses `density` for nonadaptive kernel density estimation; `diagonal=list(method="histogram", breaks="FD")` which uses `hist` for drawing a histogram that ignores grouping, if present; `diagonal=list(method="boxplot")` with no additional arguments which draws (parallel) boxplots; `diagonal=list(method="qqplot")` with no additional arguments which draws a normal QQ plot; and `diagonal=list(method="oned")` with no additional arguments which draws a rug plot tilted to the diagonal, as suggested by Richard Heiberger.

Earlier versions of `scatterplotMatrix` included arguments `transform` and `family` to estimate power transformations using the `powerTransform` function before drawing the plot. The same functionality can be achieved by calling `powerTransform` directly to estimate a transformation, saving the transformed variables, and then plotting.

Value

`NULL`, returned invisibly. This function is used for its side effect: producing a plot. If point identification is used, a vector of identified points is returned.

ScatterplotSmoothers  Smoothers to Draw Lines on Scatterplots

Description

These smoothers are used to draw nonparametric-regression lines on scatterplots produced by the `scatterplot`, `scatterplotMatrix`, and several other `car` functions. The functions are not meant to be called directly by the user, although the user can supply options via the `smoother.args` argument, the contents of which vary by the smoother (see Details below). The `gamLine` smoother uses the `gam` function in the `mgcv` package, the `loessLine` smoother uses the `loess` function in the `stats` package, and the `quantregLine` smoother uses the `rqss` function in the `quantreg` package.

Usage

```r
gamLine(x, y, col=carPalette()[1], log.x=FALSE, log.y=FALSE, var=FALSE, spread=var, 
        smoother.args=NULL, draw=TRUE, offset=0)

loessLine(x, y, col=carPalette()[1], log.x=FALSE, log.y=FALSE, var=FALSE, spread=var, 
          smoother.args=NULL, draw=TRUE, offset=0)

quantregLine(x, y, col=carPalette()[1], log.x=FALSE, log.y=FALSE, var=FALSE, spread=var, 
             smoother.args=NULL, draw=TRUE, offset=0)
```
Arguments

- **x**: horizontal coordinates of points.
- **y**: vertical coordinates of points.
- **col**: line color.
- **log.x**: should be set to TRUE (default is FALSE) if the horizontal axis is logged.
- **log.y**: should be set to TRUE (default is FALSE) if the vertical axis is logged.
- **spread, var**: the default is to plot only an estimated mean or median function. If either of these arguments is TRUE, then a measure of variability is also plotted.
- **smoother.args**: additional options accepted by the smoother, in the form of a list of named values (see Details below).
- **draw**: if TRUE, the default, draw the smoother on the currently active graph. If FALSE, return a list with coordinates x and y for the points that make up the smooth and if requested x.pos, y.pos, x.neg, y.neg for the spread smooths.
- **offset**: For use when spread=TRUE, the vertical axis is sqrt(offset^2 + variance smooth).

Details

The `loessLine` function is a re-implementation of the `loess` smoother that was used in car prior to September 2012. The main enhancement is the ability to set more options through the smoother.args argument.

The `gamLine` function is more general than `loessLine` because it supports fitting a generalized spline regression model, with user-specified error distribution and link function.

The `quantregLine` function fits a model using splines with estimation based on L1 regression for the median and quantile regression the (optional) spread. It is likely to be more robust than the other smoothers.

The smoother.args argument is a list of named elements (or sub-arguments) used to pass additional arguments to the smoother. As of November, 2016, the smoother is evaluated by default at an equally spaced grid of 50 points in the range of the horizontal variable. With any of the smoothers, you can change to, say, 100 evaluation points via the argument smoother.args=list(evaluation=100).

As of version 3.0-1, the smoother.args elements col.var, lty.var, and lwd.var are equivalent to col.spread, lty.spread, and lwd.spread, respectively. The style sub-argument controls how spread/variance envelopes are displayed, with choices "filled" (the default), "lines", and "none" (which is equivalent to var=FALSE). The alpha subargument controls the transparency/opacity of filled spread envelopes with allowable values between 0 and 1 (default 0.15). The border subargument controls whether a border line is drawn around the filled region (the default is TRUE). The vertical subargument controls whether the left and right ends of the filled region are forced to be vertical (the default is TRUE).

For `loessLine`, the default is smoother.args=list(lty.smooth=1, lwd.smooth=2, lty.spread=4, lwd.spread=2, style="filled", alpha=0.15, span=2/3, degree=1, family="symmetric", iterations=4). (Prior to November 2016, the default span was 1/2.) The elements lty.smooth, lwd.smooth, and col.spread are the line type, line width, and line color, respectively of the mean or median smooth; lty.spread, lwd.spread, and col.spread are the line type, width, and color of the spread smooths, if requested. The elements span, degree, and family are passed as arguments to the `loess` function, along with iterations robustness iterations.
ScatterplotSmoothers

For `gamLine`, the default is `smoother.args=list(lty.smooth=1, lwd.smooth=2, lty.spread=4, lwd.spread=2, style="filled", alpha=0.15, k=-1, bs="tp", family="gaussian", link=NULL, weights=NULL)`.

The first six elements are as for `loessLine`. The next two elements are passed to the `gam` function to control smoothing: `k=-1` allows `gam` to choose the number of splines in the basis function; `bs="tp"` provides the type of spline basis to be used, with "tp" for the default thin-plate splines. The last three arguments specify a distributional family, link function, and weights as in generalized linear models. See the examples below. The spread element is ignored unless family="gaussian" and link=NULL.

For `quantregLine`, the default is `smoother.args=list(lty.smooth=1, lwd.smooth=2, lty.spread=4, lwd.spread=2, style="filled", alpha=0.15, lambda=IQR(x))`.

The first six elements are as for `loessLine`. The last element is passed to the `qss` function in `quantreg`. It is a smoothing parameter, by default a robust estimate of the scale of the horizontal axis variable. This is an arbitrary choice, and may not work well in all circumstances.

---

showLabels

Functions to Identify and Mark Extreme Points in a 2D Plot.

Description

This function is called by several graphical functions in the car package to mark extreme points in a 2D plot. Although the user is unlikely to call this function directly, the documentation below applies to all these other functions.

Usage

showLabels(x, y, labels=NULL, method="identify",
 n = length(x), cex=1, col=carPalette()[1], location=c("lr", "ab", "avoid"), ...)

Arguments

x
Plotted horizontal coordinates.

y
Plotted vertical coordinates.

labels
Plotting labels. When called from within a car plotting function, the labels are automatically obtained from the row names in the data frame used to create the modeling object. If labels=NULL, case numbers will be used. If labels are long, the substr or abbreviate functions can be used to shorten them. Users may supply their own labels as a character vector of length equal to the number of plotted points. For use with car plotting functions, the number of plotted points is equal to the number of rows of data that have neither missing values nor are excluded using the ‘subset’ argument. When called directly, the length of labels shoud equal the length of x.

method
How points are to be identified. See Details below.

n
Number of points to be identified. If set to 0, no points are identified.

cex
Controls the size of the plotted labels. The default is 1.

col
Controls the color of the plotted labels. The default is the first element returned by carPalette().
showLabels

location Where should the label be drawn? The default is "lr" to draw the label to the left of the point for points in the right-half of the graph and to the right for points in the left-half. The other option is "ab" for above the point for points below the middle of the graph and above the point below the middle. Finally, "avoid" tries to avoid over-plotting labels.

... not used.

Details

The argument method determine how the points to be identified are selected. For the default value of method="identify", the identify function is used to identify points interactively using the mouse. Up to n points can be identified, so if n=0, which is the default in many functions in the car package, then no point identification is done.

Automatic point identification can be done depending on the value of the argument method.

- method = "x" select points according to their value of abs(x - mean(x))
- method = "y" select points according to their value of abs(y - mean(y))
- method = "r" select points according to their value of abs(y), as may be appropriate in residual plots, or others with a meaningful origin at 0
- method = "mahal" Treat (x, y) as if it were a bivariate sample, and select cases according to their Mahalanobis distance from (mean(x), mean(y))
- method can be a vector of the same length as x consisting of values to determine the points to be labeled. For example, for a linear model m, setting method=cooks.distance(m) will label the points corresponding to the largest values of Cook's distance, or method = which(abs(residuals(m, type="pearson")) > 2 would label all observations with Pearson residuals greater than 2 in absolute value. Warning: If missing data are present, points may be incorrectly labelled.
- method can be a vector of case numbers or case-labels, in which case those cases will be labeled. Warning: If missing data are present, a list of case numbers may identify the wrong points. A list of case labels, however, will work correctly with missing values.
- method = "none" causes no point labels to be shown.

With showLabels, the method argument can be a list, so, for example method=list("x", "y") would label according to the horizontal and vertical axes variables.

Finally, if the axes in the graph are logged, the function uses logged-variables where appropriate.

Value

A function primarily used for its side-effect of drawing point labels on a plot. Returns invisibly the labels of the selected points, or NULL if no points are selected. Although intended for use with other functions in the car package, this function can be used directly.

    labels=rownames(Prestige), method=abs(residuals(m)), n=4))
```

---

**sigmaHat**

_Return the scale estimate for a regression model_

**Description**

This function provides a consistent method to return the estimated scale from a linear, generalized linear, nonlinear, or other model.

**Usage**

`sigmaHat(object)`

**Arguments**

- `object` A regression object of type lm, glm or nls

**Details**

For an lm or nls object, the returned quantity is the square root of the estimate of $\sigma^2$. For a glm object, the returned quantity is the square root of the estimated dispersion parameter.

**Value**

A nonnegative number

**Author(s)**

Sanford Weisberg, <sandy@umn.edu>

**Examples**

```r
m1 <- lm(prestige ~ income + education, data=Duncan)
sigmaHat(m1)
```
Sample a Few Elements of an Object

Description

Randomly select a few elements of an object, typically a data frame, matrix, vector, or list. If the object is a data frame or a matrix, then rows are sampled.

Usage

some(x, ...)

## S3 method for class 'data.frame'
some(x, n=10, cols=NULL, ...)

## S3 method for class 'matrix'
some(x, n=10, cols=NULL, ...)

## Default S3 method:
some(x, n=10, ...)

Arguments

x the object to be sampled.
n number of elements to sample.
cols if NULL, use all columns, if a vector of column names or numbers, use only the columns indicated
... arguments passed down.

Value

Sampled elements or rows.

Note

These functions are adapted from head and tail in the utils package.

spreadLevelPlot

Examples

some(Duncan)
some(Duncan, cols=names(Duncan)[1:3])

Description

Creates plots for examining the possible dependence of spread on level, or an extension of these plots to the studentized residuals from linear models.

Usage

spreadLevelPlot(x, ...)  

slp(...)

## S3 method for class 'formula'
spreadLevelPlot(x, data=NULL, subset, na.action,  
                 main=paste("Spread-Level Plot for", varnames[response],  
                      "by", varnames[-response]), ...)

## Default S3 method:
spreadLevelPlot(x, by, robust.line=TRUE,  
                 start=0, xlab="Median", ylab="Hinge-Spread",  
                 point.labels=TRUE, las=par("las"),  
                 main=paste("Spread-Level Plot for", deparse(substitute(x)),  
                      "by", deparse(substitute(by))),  
                 col=carPalette()[1], col.lines=carPalette()[2],  
                 pch=1, lwd=2, grid=TRUE, ...)

## S3 method for class 'lm'
spreadLevelPlot(x, robust.line=TRUE,  
                 xlab="Fitted Values", ylab="Absolute Studentized Residuals", las=par("las"),  
                 main=paste("Spread-Level Plot for\n", deparse(substitute(x))),  
                 pch=1, col=carPalette()[1], col.lines=carPalette()[2:3], lwd=2, grid=TRUE,  
                 id=FALSE, smooth=TRUE, ...)

## S3 method for class 'spreadLevelPlot'
print(x, ...)

Arguments

x a formula of the form y ~ x, where y is a numeric vector and x is a factor, or an  
   lm object to be plotted; alternatively a numeric vector.
spreadLevelPlot

- data: an optional data frame containing the variables to be plotted. By default the variables are taken from the environment from which spreadLevelPlot is called.
- subset: an optional vector specifying a subset of observations to be used.
- na.action: a function that indicates what should happen when the data contain NAs. The default is set by the na.action setting of options.
- by: a factor, numeric vector, or character vector defining groups.
- robust.line: if TRUE a robust line is fit using the rlm function in the MASS package; if FALSE a line is fit using lm.
- start: add the constant start to each data value.
- main: title for the plot.
- xlab: label for horizontal axis.
- ylab: label for vertical axis.
- point.labels: if TRUE label the points in the plot with group names.
- las: if 0, ticks labels are drawn parallel to the axis; set to 1 for horizontal labels (see par).
- col: color for points; the default is the first entry in the current car palette (see carPalette and par).
- col.lines: for the default method, the line color, defaulting to the second entry in the car color palette; for the "lm" method, a vector of two colors for, respectively, the fitted straight line and a nonparametric regression smooth line, default to the second and third entries in the car color palette.
- pch: plotting character for points; default is 1 (a circle, see par).
- lwd: line width; default is 2 (see par).
- grid: If TRUE, the default, a light-gray background grid is put on the graph.
- id: controls point identification; if FALSE (the default), no points are identified; can be a list of named arguments to the showLabels function; TRUE is equivalent to list(method=list("x", "y"), n=2, cex=1, col=carPalette() [1], location="lr"), which identifies the 2 points the most extreme horizontal ("X", absolute studentized residual) values and the 2 points with the most extreme horizontal ("Y", fitted values) values.
- smooth: specifies the smoother to be used along with its arguments; if FALSE, no smoother is shown; can be a list giving the smoother function and its named arguments; TRUE, the default, is equivalent to list(smooother=loessLine). See ScatterplotSmoothers for the smoothers supplied by the car package and their arguments.
- ... arguments passed to plotting functions.

Details

Except for linear models, computes the statistics for, and plots, a Tukey spread-level plot of log(hinge-spread) vs. log(median) for the groups; fits a line to the plot; and calculates a spread-stabilizing transformation from the slope of the line.

For linear models, plots log(abs(studentized residuals)) vs. log(fitted values). Point labeling was added in November, 2016.

The function slp is an abbreviation for spreadLevelPlot.
Value

An object of class `spreadLevelPlot` containing:

Statistics  a matrix with the lower-hinge, median, upper-hinge, and hinge-spread for each group. (Not for an `lm` object.)

PowerTransformation  spread-stabilizing power transformation, calculated as \(1 - \text{slope}\) of the line fit to the plot.

**strings2factors**  *Convert Character-String Variables in a Data Frame to Factors*

**Description**

Converts the character variables (or a subset of these variables) in a data frame to factors, with optional control of the order of the resulting factor levels.

**Usage**

```r
strings2factors(object, which, not, exclude.unique, levels, verbose, ...)
## S3 method for class 'data.frame'
strings2factors(object, which, not, exclude.unique=TRUE, levels=list(), verbose=TRUE, ...)
```
Arguments

object  a data frame or an object inheriting from the "data.frame" class.
which  an optional character vector of names or column numbers of the character variables to be converted to factors; if absent, all character variables will be converted, except as excluded by the not and exclude.unique arguments (see below).
not  an optional character vector of names or column numbers of character variables not to be converted to factors.
exclude.unique  if TRUE (the default), character variables all of whose values are unique (i.e., all different from each other) are not converted to factors. Such variables, which would have as many levels as there are cases, are typically case identifiers and not categorical variables. If FALSE, character variables all of whose values are unique are converted to factors with a warning.
levels  an optional named list, each element of which is a character vector of levels of the corresponding factor. This argument allows you to control the order of levels of the factor; if omitted, or if a particular factor is omitted from the list, the levels will be in the default alphabetic order.
verbose  if TRUE (the default), the names of the character variables that were converted to factors are printed on the console.
...
not used.

Value

a data frame with (some) character variables replaced by corresponding factors.

M$names <- rownames(M) # values are unique
str(M)
str(strings2factors(M))
str(strings2factors(M, levels=list(partner=c("low", "high"), fcat=c("low", "medium", "high"))))
str(strings2factors(M, which="partner", levels=list(partner=c("low", "high"))))
str(strings2factors(M, not="partner", exclude.unique=FALSE))
Description

The `regsubsets` function in the `leaps` package finds optimal subsets of predictors based on some criterion statistic. This function plots a measure of fit against subset size.

Usage

```r
subsets(object, ...)  
## S3 method for class 'regsubsets'
subsets(object,  
  names=abbreviate(object$xnames, minlength = abbrev),  
  abbrev=1, min.size=1, max.size=length(names),  
  legend="interactive",  
  statistic=c("bic", "cp", "adjr2", "rsq", "rss"),  
  las=par('las'), cex.subsets=1, ...)  
```

Arguments

- `object` a `regsubsets` object produced by the `regsubsets` function in the `leaps` package.
- `names` a vector of (short) names for the predictors, excluding the regression intercept, if one is present; if missing, these are derived from the predictor names in `object`.
- `abbrev` minimum number of characters to use in abbreviating predictor names.
- `min.size` minimum size subset to plot; default is 1.
- `max.size` maximum size subset to plot; default is number of predictors.
- `legend` If not `FALSE`, in which case the legend is suppressed, the coordinates at which to place a legend of the abbreviated predictor names on the plot, in a form recognized by the `legend` function. If "interactive", the legend is placed on the plot interactively with the mouse. By expanding the left or right plot margin, you can place the legend in the margin, if you wish (see `par`).
- `statistic` statistic to plot for each predictor subset; one of: "bic", Bayes Information Criterion; "cp", Mallows's \( C_p \); "adjr2", \( R^2 \) adjusted for degrees of freedom; "rsq", unadjusted \( R^2 \); "rss", residual sum of squares.
- `las` if 0, ticks labels are drawn parallel to the axis; set to 1 for horizontal labels (see `par`).
- `cex.subsets` can be used to change the relative size of the characters used to plot the regression subsets; default is 1.
- `...` arguments to be passed down to `subsets.regsubsets` and `plot`.
Value

NULL if the legend is TRUE; otherwise a data frame with the legend.

Author(s)

John Fox

References

See Also

`regsubsets`

Examples

```r
if (require(leaps)){
  subsets(regsubsets(undercount ~ ., data=Ericksen),
         legend=c(3.5, -37))
}
```

Description

`symbox` first transforms `x` to each of a series of selected powers, with each transformation standardized to mean 0 and standard deviation 1. The results are then displayed side-by-side in boxplots, permitting a visual assessment of which power makes the distribution reasonably symmetric. For the "lm" method, the response variable in the model is successively transformed.

Usage

```r
symbox(x, ...)
## S3 method for class 'formula'
symbox(formula, data=NULL, subset, na.action=NULL, ylab, ...)
## Default S3 method:
symbox(x, powers = c(-1, -0.5, 0, 0.5, 1), start,
       trans=bcPower, xlab="Powers", ylab, ...)
## S3 method for class 'lm'
symbox(x, powers = c(-1, -0.5, 0, 0.5, 1), start, trans=bcPower,
       xlab, ylab="Studentized residuals", ...)
```
Arguments

- **x**: a numeric vector.
- **formula**: a one-sided formula specifying a single numeric variable.
- **data, subset, na.action**: as for statistical modeling functions (see, e.g., `lm`).
- **xlab, ylab**: axis labels; if `ylab` is missing, a label will be supplied. For the "lm" method, if `xlab` is missing, a label will also be supplied.
- **powers**: a vector of selected powers to which `x` is to be raised. For meaningful comparison of powers, `1` should be included in the vector of powers.
- **start**: a constant to be added to `x`. If `start` is missing and `trans` is `bcPower` (the default) or `bcnPower`, then a start will be automatically generated if there are zero or negative values in `x`, and a warning will be printed; the auto-generated `start` is the absolute value of the minimum `x` plus 1 percent of the range of `x`.
- **trans**: a transformation function whose first argument is a numeric vector and whose second argument is a transformation parameter, given by the `powers` argument; the default is `bcPower`, and another possibility is `yjPower`. `bcnPower` may also be used, in which case the `gamma` parameter is set to the value of `start`.
- ...: arguments to be passed down.

Value

as returned by `boxplot`.

symbox(lm(wages ~ education + poly(age, 2) + sex, data=SLID))
Tapply

Apply a Function to a Variable Within Factor Levels

Description

Applies a function, typically to compute a single statistic, like a mean, median, or standard deviation, within levels of a factor or within combinations of levels of two or more factors to produce a table of statistics. This function provides a formula interface to the standard R `tapply` function.

Usage

Tapply(formula, fun, data, na.action = na.pass, ..., targs = list())

Arguments

- **formula**: a two-sided formula of the form `variable ~ factor.1 + factor.2 + ... + factor.n` or, equivalently, `variable ~ factor.1*factor.2* ... *factor.n`. The variables on the right-hand side of the formula are normally factors or are otherwise coerced to factors.
- **fun**: a function, like `mean`, `median`, or `sd`, that takes a vector first argument and typically returns a single number as its value.
- **data**: an optional data frame within which to find the variable and factor(s).
- **na.action**: a function to handle missing values, as in statistical modeling functions like `lm`; the default is `na.pass`.
- **...**: arguments to pass to the function given in the `fun` argument, such as (commonly) `na.rm=TRUE`.
- **targs**: a list of optional arguments to pass to `tapply`.

Details

The function given by `fun` is applied to the values of the left-hand-side variable in `formula` within (combination of) levels of the factor(s) given in the right-hand side of `formula`, producing a table of statistics.

Value

The object returned by `tapply`, typically simply printed.

Tapply(conformity ~ partner.status + fcategory, mean, data=Moore, na.rm=TRUE)
Tapply(conformity ~ partner.status + fcategory, mean, data=Moore, na.action=na.omit) # equivalent
remove("Moore")

Description

testTransform computes likelihood ratio tests for particular values of the power parameter based on powerTransform objects.

Usage

testTransform(object, lambda)

## S3 method for class 'powerTransform'
testTransform(object, lambda=rep(1, dim(object$y)[2]))

## S3 method for class 'lmerModpowerTransform'
testTransform(object, lambda=1)

## S3 method for class 'bcnPowerTransformlmer'
testTransform(object, lambda=1)

Arguments

object An object created by a call to powerTransform.
lambda A vector of powers of length equal to the number of variables transformed.
Details

The function `powerTransform` is used to estimate a power transformation for a univariate or multivariate sample or multiple linear regression problem, using the method of Box and Cox (1964). It is usual to round the estimates to nearby convenient values, and this function is used to compute a likelihood ratio test for values of the transformation parameter other than the ml-type estimate.

For one-parameter families of transformations, namely the Box-Cox power family `bcPower` and the Yeo-Johnson power family `yjPower`, this function computes a test based on twice the difference in the log-likelihood between the maximum likelihood-like estimate and the log-likelihood evaluated at the value of lambda specified.

For the `bcnPower` Box-Cox power with negatives allowed, the test is based on the profile log-likelihood maximizing over the location (or gamma) parameter(s). Thus, gamma is treated as a nuisance parameter.

Value

A data frame with one row giving the value of the test statistic, its degrees of freedom, and a p-value. The test is the likelihood ratio test, comparing the value of the log-likelihood at the hypothesized value to the value of the log-likelihood at the maximum likelihood estimate.

testTransform(q1, c(.3, .8))
```
TransformationAxes

Axe$\text{s for Transformed Variables}$

**Description**

These functions produce axes for the original scale of transformed variables. Typically these would appear as additional axes to the right or at the top of the plot, but if the plot is produced with `axes=FALSE`, then these functions could be used for axes below or to the left of the plot as well.

**Usage**

```r
basicPowerAxis(power, base=exp(1),  
    side=c("right", "above", "left", "below"),  
    at, start=0, lead.digits=1, n.ticks, grid=FALSE, grid.col=gray(0.50),  
    grid.lty=2,  
    axis.title="Untransformed Data", cex=1, las=par("las"))
```

```r
bcPowerAxis(power, side=c("right", "above", "left", "below"),  
    at, start=0, lead.digits=1, n.ticks, grid=FALSE, grid.col=gray(0.50),  
    grid.lty=2,  
    axis.title="Untransformed Data", cex=1, las=par("las"))
```

```r
bcnPowerAxis(power, shift, side=c("right", "above", "left", "below"),  
    at, start=0, lead.digits=1, n.ticks, grid=FALSE, grid.col=gray(0.50),  
    grid.lty=2,  
    axis.title="Untransformed Data", cex=1, las=par("las"))
```

```r
yjPowerAxis(power, side=c("right", "above", "left", "below"),  
    at, lead.digits=1, n.ticks, grid=FALSE, grid.col=gray(0.50),  
    grid.lty=2,  
    axis.title="Untransformed Data", cex=1, las=par("las"))
```

```r
probabilityAxis(scale=c("logit", "probit"),  
    side=c("right", "above", "left", "below"),  
    at, lead.digits=1, grid=FALSE, grid.lty=2, grid.col=gray(0.50),  
    axis.title = "Probability", interval = 0.1, cex = 1, las=par("las"))
```

**Arguments**

- `power`: power for Box-Cox, Box-Cox with negatives, Yeo-Johnson, or simple power transformation.
- `shift`: the shift (gamma) parameter for the Box-Cox with negatives family.
- `scale`: transformation used for probabilities, "logit" (the default) or "probit".
- `side`: side at which the axis is to be drawn; numeric codes are also permitted: side = 1 for the bottom of the plot, side=2 for the left side, side = 3 for the top, side = 4 for the right side.
TransformationAxes

at numeric vector giving location of tick marks on original scale; if missing, the
function will try to pick nice locations for the ticks.

start if a start was added to a variable (e.g., to make all data values positive), it can
now be subtracted from the tick labels.

lead.digits number of leading digits for determining 'nice' numbers for tick labels (default
is 1).

n.ticks number of tick marks; if missing, same as corresponding transformed axis.

grid if TRUE grid lines for the axis will be drawn.

grid.col color of grid lines.

grid.lty line type for grid lines.

axis.title title for axis.

cex relative character expansion for axis label.

las if 0, ticks labels are drawn parallel to the axis; set to 1 for horizontal labels (see
par).

base base of log transformation for power.axis when power = 0.

interval desired interval between tick marks on the probability scale.

Details

The transformations corresponding to the three functions are as follows:

basicPowerAxis: Simple power transformation, \( x' = x^p \) for \( p \neq 0 \) and \( x' = \log x \) for \( p = 0 \).

bcPowerAxis: Box-Cox power transformation, \( x' = (x^\lambda - 1)/\lambda \) for \( \lambda \neq 0 \) and \( x' = \log x \) for \( \lambda = 0 \).

bcnPowerAxis: Box-Cox with negatives power transformation, the Box-Cox power transformation
of \( z = .5 \ast (y + (y^2 + \gamma^2)^{1/2}) \), where \( \gamma \) is strictly positive if \( y \) includes negative values and
non-negative otherwise. The value of \( z \) is always positive.

yjPowerAxis: Yeo-Johnson power transformation, for non-negative \( x \), the Box-Cox transformation
of \( x + 1 \); for negative \( x \), the Box-Cox transformation of \( |x| + 1 \) with power \( 2 - p \).

probabilityAxis: logit or probit transformation, \( \logit = \log[p/(1 - p)] \), or \( \text{probit} = \Phi^{-1}(p) \),
where \( \Phi^{-1} \) is the standard-normal quantile function.

These functions will try to place tick marks at reasonable locations, but producing a good-looking
graph sometimes requires some fiddling with the at argument.

Value

These functions are used for their side effects: to draw axes.

John Fox <jfox@mcmaster.ca>

References

**vif**

**Variance Inflation Factors**

**Description**

Calculates variance-inflation and generalized variance-inflation factors (VIFs and GVIFs) for linear, generalized linear, and other regression models.

**Usage**

vif(mod, ...)

## Default S3 method:

vif(mod, ...)

## S3 method for class 'lm'

vif(mod, type=c("terms", "predictor"), ...)
## S3 method for class 'merMod'
\texttt{vif(mod, \ldots)}

## S3 method for class 'polr'
\texttt{vif(mod, \ldots)}

## S3 method for class 'svyolr'
\texttt{vif(mod, \ldots)}

### Arguments

- **mod**: for the default method, an object that responds to \texttt{coef}, \texttt{vcov}, and \texttt{model.matrix}, such as a \texttt{glm} object.
- **type**: for unweighted \texttt{lm} objects only, how to handle models that contain interactions: see Details below.
- ...: not used.

### Details

If all terms in an unweighted linear model have 1 df, then the usual variance-inflation factors are calculated.

If any terms in an unweighted linear model have more than 1 df, then generalized variance-inflation factors (Fox and Monette, 1992) are calculated. These are interpretable as the inflation in size of the confidence ellipse or ellipsoid for the coefficients of the term in comparison with what would be obtained for orthogonal data.

The generalized VIFs are invariant with respect to the coding of the terms in the model (as long as the subspace of the columns of the model matrix pertaining to each term is invariant). To adjust for the dimension of the confidence ellipsoid, the function also prints $GVIF^{1/(2 \times df)}$ where \texttt{df} is the degrees of freedom associated with the term.

Through a further generalization, the implementation here is applicable as well to other sorts of models, in particular weighted linear models, generalized linear models, and mixed-effects models.

Two methods of computing GVIFs are provided for unweighted linear models:

- Setting \texttt{type="terms"} (the default) behaves like the default method, and computes the GVIF for each term in the model, ignoring relations of marginality among the terms in models with interactions. GVIFs computed in this manner aren’t generally sensible.
- Setting \texttt{type="predictor"} focuses in turn on each predictor in the model, combining the main effect for that predictor with the main effects of the predictors with which the focal predictor interacts and the interactions; e.g., in the model with formula $y \sim a \times b + b \times c$, the GVIF for the predictor $a$ also includes the $b$ main effect and the $a:b$ interaction regressors; the GVIF for the predictor $c$ includes the $b$ main effect and the $b:c$ interaction; and the GVIF for the predictor $b$ includes the $a$ and $c$ main effects and the $a:b$ and $a:c$ interactions (i.e., the whole model), and is thus necessarily 1. These predictor GVIFs should be regarded as experimental.

Specific methods are provided for ordinal regression model objects produced by \texttt{polr} in the \texttt{MASS} package and \texttt{svyolr} in the \texttt{survey} package, which are "intercept-less"; VIFs or GVIFs for linear and similar regression models without intercepts are generally not sensible.
Value
A vector of VIFs, or a matrix containing one row for each term, and columns for the GVIF, df, and $GVIF^{1/(2 \times df)}$, the last of which is intended to be comparable across terms of different dimension.

wcrossprod

<table>
<thead>
<tr>
<th>wcrossprod</th>
<th>Weighted Matrix Crossproduct</th>
</tr>
</thead>
</table>

Description
Given matrices x and y as arguments and an optional matrix or vector of weights, w, return a weighted matrix cross-product, $t(x) w y$. If no weights are supplied, or the weights are constant, the function uses `crossprod` for speed.

Usage
wcrossprod(x, y, w)

Arguments
x, y x, y numeric matrices; missing(y) is taken to be the same matrix as x. Vectors are promoted to single-column or single-row matrices, depending on the context.
w A numeric vector or matrix of weights, conformable with x and y.

Value
A numeric matrix, with appropriate dimnames taken from x and y.

drop <- 4
sex <- sample(c("M", "F"), n, replace=TRUE)
x1 <- 1:n
x2 <- sample(1:n)
extra <- c(rep(0, n - drop), floor(15 + 10 * rnorm(drop)) )
y1 <- x1 + 3*x2 + 6*(sex=="M") + floor(10 * rnorm(n)) + extra
y2 <- x1 - 2*x2 - 8*(sex=="M") + floor(10 * rnorm(n)) + extra
# assign non-zero weights to ‘dropped’ obs
wt <- c(rep(1, n-drop), rep(.2,drop))
X <- cbind(x1, x2)
Y <- cbind(y1, y2)
wcrossprod(X)
wcrossprod(X, w=wt)
wcrossprod(X, Y)
wcrossprod(X, Y, w=wt)
wcrossprod(x1, y1)
wcrossprod(x1, y1, w=wt)

whichNames Position of Row Names

Description

These functions return the indices of the supplied row names of a data frame or names of another object, such as a vector or list. whichNames is just an alias for which.names.

Usage

whichNames(names, object, ...)

which.names(names, object, ...)

## S3 method for class 'data.frame'
whichNames(names, object, ...)

whichNames
whichNames

## Default S3 method:
whichNames(names, object, ...)

**Arguments**
- **names**: a name or character vector of names.
- **object**: a data frame or an object with a names attribute.
- **...**: not used.

**Value**
Returns the index or indices of names in row names of the data frame or names of an object of another class.

**Author(s)**
John Fox <jfox@mcmaster.ca>
